Proceedings of the International Conference on Applied Innovations in IT

Volume 13 | Issue 5

Koethen, Germany
22 December 2025

EDITORIAL BOARD

Editor-in-Chief

Prof. Dr. Eduard Siemens (Anhalt University of Applied Sciences), Germany

Topical Editors

Prof. Dr. Marija Kalendar (Ss. Cyrill and Methodius University in Scopje), North Macedonia

Prof. Dr. Halina Falfushynska (ENERTRAG SE), Germany

Prof. Dr. Hassan Bevrani (University of Kurdistan), Iran

Prof. Dr. Ralph Gottschalg (Fraunhofer IMWS), Germany

Prof. Dr. Iryna Stankevych (Odessa State Academy of Civil Engineering and Architecture), Ukraine

Prof. Dr. Douglas Hall (St. Mary's University), USA

Technical Editor

Kateryna Shulakova (State University of Intelligent Technologies and Telecommunications, HSA)

The Proceedings of the International Conference on Applied Innovations in IT, Volume 13(5), contains selected papers accepted for publication from those presented at several international scientific events. This issue features contributions from the International Conference for Pure Science and Information Technologies (ICPSIT 2025), organized by the College of Education for Pure Science, Wasit University, Iraq, as well as from the International Scientific Practical Conference on "The Role of Renewable Energy on a Global Scale within the Framework of the 'Green Economy' and the Fourth Industrial Revolution: Innovations, Technologies and Ensuring Sustainable Development," organized by the Tashkent University of Applied Sciences and the Tashkent State Technical University named after Islam Karimov, Uzbekistan. Additional contributions are included from the International Conference on Advances in Engineering and Technology Toward Future Sustainability (ICETFS 2025), held in Manila, Philippines. This volume also includes selected articles prepared specifically for the ICAIIT 2026 Special Issue, covering recent advances and applied research results contributed by international authors.

ISBN: 978-3-96057-193-3 (Online)
ISSN: 2199-8876

All papers published in this jornal are full-open access:
immediately freely available to read and download.

ABOUT THIS SPECIAL ISSUE

The Proceedings of the International Conference on Applied Innovations in IT (ICAIIT), Volume 13(5), represents a special issue that consolidates high-quality, peer-reviewed research papers from multiple international scientific events, along with contributions submitted directly by international authors. This volume reflects a multidisciplinary approach, integrating advances in engineering, information technologies, renewable energy, and sustainable development.

All papers included in this issue were selected through a rigorous peer-review process and subsequently organized into a unified thematic framework. The contributions were grouped into the following research areas:

1. Communication Technologies and Hardware
2. Data Transport Technologies
3. Control and Automation
4. Data Analysis and Processing
5. Statistical Modelling and Analysis and their Applications in Life Sciences
6. Information Technology in Economics
7. Power Engineering

By combining research outcomes from several international conferences into a single publication, this special issue provides a comprehensive overview of current scientific trends and fosters interdisciplinary collaboration among researchers and practitioners worldwide.

About International Conference for Pure Sciences and Information Technology (ICPSIT 2025)

The International Conference for Pure Sciences and Information Technology (ICPSIT 2025) was held on October 29–30, 2025, at the College of Education for Pure Science, Wasit University, Iraq. The conference was organized to bridge the gap between fundamental scientific research and modern technological applications.

ICPSIT 2025 brought together researchers, academicians, and industry professionals to exchange knowledge and present recent advancements in pure sciences and information technologies. The conference covered key areas including mathematics, information theory, computer science, physics, communication technologies, and information technology in economics.

The event featured keynote lectures, technical sessions, and workshops focusing on emerging topics such as artificial intelligence, cybersecurity, Internet of Things (IoT), data analytics, and computational modeling. By integrating theoretical and applied research, ICPSIT 2025 contributed to the development of innovative solutions and strengthened international scientific collaboration.

Selected high-quality papers from the conference were included in this special issue of ICAIIT, highlighting interdisciplinary research and practical applications in science and technology.

About International Scientific and Practical Conference on Renewable Energy and Green Economy (Tashkent, 2025)

The International Scientific and Practical Conference on "The Role of Renewable Energy on a Global Scale within the Framework of the Green Economy and the Fourth Industrial Revolution: Innovations, Technologies and Ensuring Sustainable Development" was held on October 3–4, 2025, in Tashkent, Uzbekistan.

The conference was organized by the Ministry of Higher Education, Science and Innovation of the Republic of Uzbekistan, the Ministry of Energy of the Republic of Uzbekistan, and the Tashkent State Technical University named after Islam Karimov. It served as a platform for discussing global challenges related to renewable energy, environmental sustainability, and digital transformation.

The conference brought together researchers, educators, doctoral students, and industry specialists to share scientific findings and practical solutions. Key topics included renewable energy systems, the transition to a green economy, climate change mitigation, integration of artificial intelligence in environmental protection, and technological challenges in modern energy systems.

The event emphasized the importance of reducing carbon emissions, improving energy efficiency, and ensuring environmental security through innovative technologies. Selected papers from this conference were incorporated into the ICAIIT special issue, contributing to the advancement of sustainable energy research.

About International Conference on Advances in Engineering and Technology Toward Sustainable Development (AETSD 2025)

The International Conference on Advances in Engineering and Technology Toward Sustainable Development (AETSD 2025) was held on November 27–29, 2025, at De La Salle University, Manila, Philippines.

AETSD 2025 aimed to address contemporary challenges in engineering and technology within the framework of sustainable development. The conference brought together leading researchers, industry experts, and policymakers to exchange knowledge and present innovative solutions aligned with the United Nations Sustainable Development Goals (SDGs).

The conference program included keynote presentations, technical sessions, and research discussions covering a wide range of topics such as renewable energy, sustainable infrastructure, environmental engineering, smart systems, and digital transformation. Distinguished speakers from international institutions contributed insights into cutting-edge technological developments.

All submitted papers underwent a double-blind peer-review process, ensuring high academic quality. Accepted papers were presented both physically and virtually, enabling broad international participation. Selected contributions were included in this ICAIIT special issue, reflecting global perspectives on sustainable engineering and technological innovation.

About Integration of Contributions

The integration of papers from these conferences into a single special issue allowed for the consolidation of diverse research directions into a coherent scientific framework. Despite the variety of topics and geographical representation, all contributions were aligned with common themes of technological innovation, sustainability, and applied research.

This unified approach enhances the scientific value of the volume and provides readers with a comprehensive understanding of current developments across multiple disciplines, supporting future research and international cooperation.

Content

Section 1 Communication Technologies and Hardware

Oleksandr Lemeshko, Oleksandra Yeremenko and Roman Savchenko
Modeling of Traffic Engineering Queues with QoS Differentiation..... 1

Victor Tikhonov, Valery Sitnikov and Serhii Tikhonov
An Improved AI-Driven Algorithm of Data Flow Optimization on the Normalized Bipolar Planar Free-Oriented Network Graph 7

Zhaniya Zhapparbekova, Simeon Trendov and Dmitry Kachan
Voice-Enabled Emergency Communication for Maritime Workers Using Low-Power LoRaWAN Technology..... 15

Huda Abdulateef Ali
Leveraging Elliptic Modern Techniques in Secure Communication..... 23

Esraa Saleh Alomari, Manar Bashar Mortatha Alkorani and Kamal Alieyan
Securing the Post-Quantum Internet: A Comparative Study of Quantum-Resistant Protocols and Migration Strategies..... 29

Abduljabbar J. Ajeel and Jamal Kh-Madhloom
AI-Based Intrusion Detection for Smart Grid Security..... 41

Olha Dienichieva, Svitlana Lukianchuk, Serhii Topachevskyi, Tetiana Verhun and Bohdan Muskyi
The Impact of Intelligent Communication Technologies on Language Education..... 49

Nilufar Tukhboeva, Sanjar Anvarov, Saidislom Mannonov, Takhir Mamatmusaev, Shukhrat Reyimbaev and Maktuba Abdujabbarova
Digital Reconstruction of Architectural Heritage through Virtual Reality: The Samarkand Aksaray Monument Case Study..... 57

Section 2 Data Transport Technologies

Kirill Karpov, Dmitry Kachan, Veronika Kirova, Ali Ghermezian, Daria Koshutina and Eduard Siemens
Tunable Multi-Objective Tree Synthesis for Application-Layer Multicast..... 69

Makism Gering, Yevhen Medianyk, Anastasiia Sapeha, Simeon Trendov, Kirill Karpov, Hanna Skaskiv, Dmitry Kachan and Eduard Siemens
Botnet Simulation and Observation Framework for AI-Driven Virtual Personas..... 75

Mustafa Abduljabbar
Simulation-Based Construction of an M/M/1 Queue Model..... 83

Esraa Abd Alhasn Alkafajy and M. AL-Jenabi
A New Suggested Algorithm for SSM to Solve TP..... 89

Nilo T. Bugtai, Renann G. Baldovino, Francisco Emmanuel T. Munsayac Jr. III, Edison Anit and Charmine Sheena Saflor
Eye Tracking: A Comprehensive Review of Methods and Applications..... 95

Enrico P. Chavez, Porfirio R. Catolico Jr. and Janine M. Dela Cruz
A Mixed-Methods Study on Google Classroom Use: Thematic Perspectives and Quantitative Insights on Student Engagement and Connectivity at the City of Malabon University..... 101

Anesa P. Mangindra
Workshop Assisted by Interactive Touch Screen Television and Its Effect on Students' Skills in Crafting a Research Proposal..... 109

Section 3 Data Analysis and Processing

Yaseen Abbas and Ahmed Al-Azawei
Emotions and Textual Feature Analysis for Motion Picture Association of America (MPAA) Rating Classification..... 117

Kyrylo Vadurin, Olena Kortsova, Kateryna Vasiutynska andrii Perekrest and Volodymyr Bakharev
A Big Data Framework for Automated Environmental Risk Stratification Using a Composite Hazard Index and Unsupervised Clustering..... 127

Anastasija Kostovska and Hristijan Gjoreski
Predicting Trial-to-Paid User Conversion in Video Streaming Platforms Using Session-Based Behavioral Data..... 135

Isariev Vladyslav, Iryna Hurklis, Kateryna Shulakova and Oksana Vasylenko
Hybrid Cascade Model for Personalized Recommendations..... 143

Andrii Liashenko and Larysa Globa
Comparative Analysis of Consumer Strategies for Real-Time Traffic Graph Updates in IoT Systems..... 151

Janna Mae G. Boitizon, Babylyn P. Barte, Joseph P. Layco, Althea Nicole J. Zoleta and Irene L. Balmes
The Influence of AI Code Assistants on Programming Learning: A Descriptive Study of Student Dependence..... 161

Viktoriia Khaustova, Mykola Kyzym, Iryna Hubarieva, Nataliia Trushkina and Yevhen Yudenko
Methodical Approach to Assessing Economic Security under the Conditions of Ukraine's Economic Restructuring..... 175

Bojana Velichkovska, Jasmina Angelevska Kostadinoska, Dushko Stavrov and Goran Jakimovski
A Survey of Large and Small Language Models..... 187

Anastasiia Sapeha, Eduard Sariiev, Mykyta Sapeha, Ibrahim Kovan, Subashkumar Rajanayagam, Kirill Karpov, Maksim Gering, Dmitry Kachan and Eduard Siemens
GTA-NarrativeTraj: Language-Aware Trajectory Prediction from GPS and Dialogue in an Open-World Simulator..... 193

Dhyaa-Al Rahman Lateef and Ahmed J. Obaid
News Recommendation System Based on Deep Learning on Large and Small MIND Datasets..... 201

Azhen Omar Jabbar and Asim Majeed Murshid
Automatic Skin Lesion Segmentation Using an Enhanced U-Net Framework..... 211

Saif Hameed Abbood, Ahmed Fadhil Qutaif, Zainab Mohanad Issa and Haza Nuzly Abdull Hamed
Interventional Deep Generative Models for Scalable Causal Discovery and Counterfactual Analysis..... 219

Rana H. Saloom, Hussein K. Khafaji, Nabaa Ali Abd Alradha Al-saeedi, Saif Ali Abd Alradha Alsaidi and Furat Al Daamee
Efficient DNA Mutation Classification Using Deep Active Learning Techniques..... 233

Hussein A. Mutar, Abdul Hadi M.Alaidi, Ammar A.Kazm, Saif Ali Abd Alradha Alsaidi, Haider TH. Salim Alrikabi, Ali Khalaf Hussein, Ibtihal R. N. Alrubeei and Nabaa Ali Abd Alradha Alsaeedi
AI-Based Arabic Sign Language to Voice Translation System……..... 243

Elaf Baha, Munaf Yousif Hmood, Al-Duais Fuad S. and Ali Khalaf Hussein
Soft Nonlinear Quantile-Based AI Regression Under Uncertainty..... 255

Alaa H. Jalob and Lekaa Ali Mohamed
Dimensionality Reduction of Multivariate Functional Data Using FPCA..... 265

Raissan A. Zalan
Hybrid ARMAX-ANN Model for Temperature Forecasting..... 273

Zahraa Kadhim Alitbi and Seyed Amin Hosseini Seno
Fog Computing Integration for Real-Time Iot Data Processing..... 283

Shahab A. Hassan, Noor H. Abdullah and Waleed A. Saeed
Existence and Stability Analysis of Nonlinear Volterra-Fredholm Integral Equations..... 291

Nada S. AL-Fartosi and Ahmed K. Al-Jaberi
Digital Image Inpainting Analysis Based on the Cahn-Hilliard Model..... 297

Muhanad Jabar Yaser, Konstantin A. Polshchykov and Ilya K. Polshchikov
Fuzzy Logic-Based Evaluation of IoT Training Simulators..... 309

Asmaa H. Mujalli and Najwa J. Jubier
The Role of Silver Nanoparticles in Enhancing the Structural and Antibacterial Properties of Chitosan/PEO Blend Films..... 319

Salih Nasser Rahmah and Mahdi A. Mohammed
An IT-Guided Design of Smart Bio-Nanocomposite Films for Next-Generation Antimicrobial Wound..... 329

Mutasim Ibrahim Malik
Remote Sensing-Based Numerical Methods for Water Surface Area Estimation..... 337

Sayyora Asanova, Azamat Shukurov, Akbar Halimov and Jasurjon Akhatov
Multi-Objective Optimization of Design nZEBs in Uzbekistan 345

Yusupaliev Risbek, Kuchkarov Abdullo, Xodjalimova Matluba, Azimova Munira and Kurbanova Nargiza
Radiation Grafted Copolymerization of Vinylidene Fluoride to Cotton Cellulose and
Hydrated Cellulose Fibers..... 351

Jowie Espaldon, Lord Edgardian Tavu, Catherine Lagadia, Steven Jocson, Erika Joy Lagos,
Rosemarie Arcilla and Maria Aileen Candelaza
Retrospective Analysis of Student Evaluation of Faculty Using Main Management Information System..... 359

Ahmed Saleh and Hardik Joshi
Survey of Sensor-Based Arabic Sign Language Datasets……..... 369

Nurullo Zikrillayev, Elyor Saitov, Otabek Begmullaev, Zulumkan Teshebaeva, Dilbar Ruzmetova,
Lale Hamlet İsmayılova, Ramatov Jumaniyaz, Nurgazy Erkinbay Uulu and Gulchehra Abdukarimova
Innovation-Driven Analysis of Social Project Mechanisms for Renewable Energy Transition..... 377

Anna Pearl B. Iglesia, Klint Allen Mariñas and Michael G. Calamba
Balancing Career and Academic Pursuits of Young Professionals for Sustainable Career and
Education Development..... 393

Giyosjon Jumaev, Dadanur Shukurov, Kamoljon Khudoyqulov and Xayotjon Kurbanov
AI in Education: Revolutionizing Learning and Personalized Instruction..... 401

Section 4 Control and Automation

Nataliia Zaiets, Nataliia Lutska, Lidiia Vlasenko and Stefan Junge
Efficient Production Management System with a Packaging Quality Control Module..... 411

Martin Obert, Subashkumar Rajanayagam and Stefan Twieg
Robust Indoor Mapping on a Smart Walking Aid via Visual SLAM..... 417

Yuhao Cheng, Haifeng Duan, Rani Schilling, Maryna Popova and Stefan Twieg
Intelligent Goose Nest: Review, Development and Evaluation of Initial Results for Design Concepts..... 425

Rasheed Al-Salih, Watheq Laith, Fadhil Mahan and Osamah Abbas
A Hybrid GA-MOORA Approach for Objective Criteria Weighting in Multi-Criteria Decision Making..... 437

Oleksii Cherkashyn
Application Test Automation in Headless Android Emulator……..... 445

Mohamad Wael Kheshfeh, Sebastian Linke, Markus Muller, Tobias Tute and Rudiger Mecke
Leveraging Semantic Knowledge Graphs for Smart Manufacturing Integration via Asset Administration Shells..... 453

Giorgi Tsivtsivadze, Giorgi Burjanadze, Giorgi Kekelidze and Lali Akhalbedashvili
An Effective Method of Using Ozone Generator in Viticulture Instead of Pesticides..... 461

Jamaica Arielle Tan, Armyn Sy, Franciso Emmanuel Munsayac III, Nilo Bugtai and Edison Anit
Development of a Wearable Exoskeleton for Active-Assist Knee Flexion-Extension..... 467

Rebekah C. Gempero and James M. Dumaguit
Development of a Low-Cost Device to Monitor and Alert Prolonged Sitting Posture..... 475

Svitlana Sulima, Larysa Globa and Nikita Tkachenko
Edge-Based Control Framework with Semantic Command Interpretation for Residential Automation..... 481

Asanbek Akmataliev, Arslon Jalilov, Samat Abdumomun Uulu, Aikokul Orozalieva, Sona Rauf Muradova, Tashtemir Tashkenbayev, Zhyldyz Irmatova and Ilyos Valixanov
Innovations in Hydropower Development and Their Impact on the Environmental Safety of Aquatic Systems..... 493

Bolotbek Zhorobekov, Nasiba Jumaniyazova, Sonunbu Artykbaeva, Mehriniso Kurbanova, Samira Kamil Akimova, Daulet Gulomov, Kanybek Isakov and Guldora Mustaeva
Challenges in Implementing Innovative Solutions for the Efficient Utilization of Geothermal Energy..... 507

Zhanbolot Tursunbaev, Ortikjon Mamasaliev, Kyzzhibek Mamytova, Farogat Shakirova, Bektur Omurzakov, Gulnora Shadiyeva, Akima Amir Ahmadova and Abror Xaydarov
Digital and Smart Technologies as Key Drivers of Energy Efficiency..... 519

Azam Mamahonov, Ismoilkhon Khikmatillaev and Eldor Eshbobo Dustmurodov
Smart Automation and Digital Modelling for the Development of an Efficient Hairy Seed Sieving Machine..... 535

Bobby D. Buendia, Dr. Noelah Mae D. Borbon, Maria Penny A. Lumbera, Lorena Manimtim, Ian S. Pasahol, Josierene V. Abel and Jay U. Sargento
Impact of Technology Integration on Students' Knowledge, Attitudes and Practices (KAP) Towards the Sustainable Development Goals (SDGs): A Structural Equation Modeling (SEM) Approach..... 547

Ilyas Khudhair, Hasimi Sallehudin, Azana Hafizah Mohd Aman and Muntadher Saadoon
IPFS-Enabled Blockchain Framework for Fair Payment Systems..... 559

Jenan Jader Msad, Anvar Khamdamov and Alaa Majeed Shnain
Intrusion Detection in Smart Grids by Collective Learning Algorithm and Particle Swarm Optimization Algorithm..... 569

Olga Filina, Olimjon Toirov, Azat Khusnutdinov, Valerei Butakov, Olga Salnikova and Elena Kugergina
Mathematical Foundations for Modeling and Scaling of Dynamic Systems..... 575

Rowee M. Marfil, Rogelio T. Mamaradlo and Jesus S. Paguigan
Evaluation of GMA Civil Registrar Online Transaction System..... 583

Christian Cabungcal, Klint Allen Mariñas and Michael G. Calamba
AI-Driven FinTech: Accelerating Sustainable Development Goals and Economic Growth in the Philippines……..……... 591

Wydian Razaq Al-Dulaimi and Suha Shihab
A Computational Framework for Optimal Control Using Polynomial-Based Approximation Methods with Applications in Intelligent Systems..... 597

Section 5 Statistical Modelling and Analysis and their Applications in Life Sciences

Ahmed Khudhair Abbas, Ihsan Salman Jasim and Adil Ibrahim Khalil
Lung Disease Detection by Processing X-ray Image Database Using Deep Learning Techniques..... 605

Svitlana Sokulieva, Ibrahim Kovan and Stefan Twieg
Towards Intelligent Care: Human Behavior Analysis Using Energy Consumption and Door Operation Patterns in the Internet of Care Things..... 613

Lola Anančevska and Hristijan Gjoreski
A Cross-Dataset Evaluation of Machine Learning Approaches for Autism Spectrum Disorder Across Age Groups..... 621

Maria Zheleva, Boyan Jekov, Tamara Riskova and Mariana Filipova
AI-Driven Medical Education for Personalized Health..... 629

Anastasija Stefanovska and Hristijan Gjoreski
Brain Tumor Classifications Using MRI Scans with Deep Learning..... 637

Fahad Hussein Enad and Asmaa Ghalib Jaber
Brain Tumor Mri Segmentation Using A Hybrid Otsu–Fcm Model..... 643

Ammar A. Kazm, Zamen Abood Ramadhan, Jaafar Sadiq Alrubaye, Iman Kadhim Ajlan, Jamal Kh-Madhloom, Eshaq Aziz Awadh AL Mandhari, Fahad Taha AL-Dhief, Nurhizam Safie and Ali Hashim Abbas
Hybrid AdaBoost-PSO Model for Thyroid Disease Diagnosis..... 659

Keywords: Quality of Service, Traffic Engineering, Queue, Classification, Optimization, Bandwidth Allocation, Utilization.

Abstract: The paper analyzes the Class-Based Traffic Engineering Queue (CB-TEQ) model, which provides organization and management of class queues on the router interface, supporting differentiated and balanced packet service. It is demonstrated that the advantage of CB-TEQ lies in the implementation of an optimal interface bandwidth allocation between class queues based on a linear programming problem. At the same time, a shortcoming of the model has been identified, related to the need for heuristic selection of the normalization coefficient. To address this issue, an Enhanced Class-Based Traffic Engineering Queue (ECB-TEQ) model is proposed, in which the normalization coefficient is considered as a control variable. This enabled the calculation of the optimal value of the normalization coefficient by solving a nonlinear optimization problem with a modified criterion and a system of constraints. The results of experimental studies confirmed the efficiency of ECB-TEQ, in particular its ability to provide the maximum level of differentiation when servicing packets in different class queues.

1 INTRODUCTION

Quality of service (QoS) is a primary concern in modern communication networks [1], [2]. Complexity of QoS provision is due to several factors, including geographical distribution, environmental heterogeneity, network state dynamics, growth in the number of users and services, limited resources, and the need to support various QoS models [3]-[5]. Ensuring QoS requires the coordinated operation of all OSI layers protocols, particularly at the network layer, where scheduling and resource allocation mechanisms play a crucial role [4]-[7]. They determine the bandwidth allocation between packet queues on the network equipment (routers and switches) and form the basis of the IntServ and DiffServ models [8], [9]. These mechanisms must support multiple queues, provide service guarantees, ensure consistent packet processing, and be easy to implement. In practice, routers use several mechanisms simultaneously, and their effectiveness is determined by the mathematical models and methods used.

Modern queue management mechanisms are in demand in various network environments, as confirmed by studies [10]-[18]. The tasks of optimal resource allocation and QoS assurance are relevant in general-purpose networks [10], [19]-[21], industrial IoT solutions [11], specific environments [12], [13], [15], [17], and hierarchical solutions [16], [19], [20]. This highlights the importance of adaptive queue management methods for a wide range of scenarios. The purpose of this work is to optimize the queue management process to ensure differentiated packet servicing at the router interface. To this end, the existing solution will be considered, and its enhancement will be proposed, followed by proving its effectiveness on a set of computational examples.

2 BASIC CLASS-BASED TRAFFIC ENGINEERING QUEUE MODEL

Let the Class-Based Traffic Engineering Queue (CB-TEQ) model, introduced in [21], serve as the basis for further enhancement. Within the CB-TEQ model, the resource allocation problem is considered. Pre-aggregated packet flows are directed into class queues based on the proximity of their class values [21]. The following notations are used:

- B – router interface bandwidth (bits per second);
- N – number of class queues on the interface;
- b_i – interface bandwidth allocated for the ith class queue;
- r_i – average intensity of the aggregated packet flow arriving at the ith queue (bits per second), $i = \overline{1,N}$.

The variables b_i are subject to constraint:

$$b_i \geq 0, \quad (1)$$

$$\sum_{i=1}^{N} b_i = B. \quad (2)$$

Additionally, nonlinear overload prevention conditions must be met related to the optimal resource allocation and balanced bandwidth utilization among queues under the Traffic Engineering Queues [21]:

$$h_i^{\alpha} r_i \leq \alpha b_i \ \ (i = \overline{1,N}), \quad (3)$$

where α is the control variable for the upper dynamically regulated bound on queue utilization, following the condition:

$$0 < \alpha \leq 1. \quad (4)$$

The h_i^{α} is the class coefficient for balanced interface bandwidth allocation for the ith queue:

$$h_i^{\alpha} = 1 + i/(N \cdot D) \ \ (i = \overline{1,N}). \quad (5)$$

In addition, D is the normalization coefficient that determines both the influence of the queue class on h_i^{α} and the degree of bandwidth balancing across queues. As shown in [19], [20], the minimum allowable value D_{min} ensures the highest level of service differentiation among packets in different class queues. A higher queue class corresponds to a larger h_i^{α}, which in turn leads to lower utilization ρ_i for the same boundary value α. Within the framework of model (1)-(5), the utilization coefficient is given by:

$$\rho_i = \frac{r_i}{b_i} \ \ (i = \overline{1,N}). \quad (6)$$

An increase in the normalization coefficient D reduces the influence of the queue class on allocated bandwidth. Using expressions (3)-(6), the model provides differentiated allocation of router interface bandwidth among class queues. Maximum differentiation is achieved when D is set to its minimum permissible value [19], [20]. Condition (3) is nonlinear because of the product of the control variables b_i and α, and bandwidth balancing is ensured by α. As shown in [21], (3) can be transformed into a linear form:

$$\beta h_i^{\alpha} r_i \leq b_i \ \ (i = \overline{1,N}), \quad (7)$$

where β is the control variable, inversely proportional to the upper bound of queue utilization α, i.e.,

$$\beta = \frac{1}{\alpha}. \quad (8)$$

The variable β is subject to the constraints:

$$\beta > 1. \quad (9)$$

The queue management optimality criterion is given by:

$$\beta \rightarrow max. \quad (10)$$

Criterion (10) minimizes the upper bound of queue utilization, with weights determined by the class values in (3) and (5). Thus, the CB-TEQ solution (1)-(10) is a linear programming problem with criterion (10) and constraints (1), (2), (7), and (9).

3 ENHANCED CLASS-BASED TRAFFIC ENGINEERING QUEUE MODEL

A limitation of the CB-TEQ model is that it requires prior configuration, namely the heuristic selection of the normalization coefficient D. This coefficient must be set so that, first, the minimization problem (10), subject to constraints (1), (2), (7), and (9), admits a solution, and second, that a sufficient degree of differentiation is achieved in the service of packets across different queues. To address this, the present work proposes an enhancement of the CB-TEQ model in which the optimal (minimum) value of D (5) is computed jointly with the control variables β and b_i. This approach guarantees differentiation in packet servicing across queues. Then, considering (5), condition (7) is reformulated as follows:

$$\beta r_i (1 + i/(N \cdot D)) \leq b_i \ \ \left(i = \overline{1,N}\right). \quad (11)$$

Analysis of expression (11) and the results obtained in works [19]-[21] show that, with an increase in the coefficient D, there will be no differentiation in the servicing of packets across different queues, since their utilization coefficients (6) will be equal. To increase service differentiation, the normalization coefficient must be reduced to a specific, but previously unknown, value. Thus, with a very small D, it will be impossible to satisfy the requirements of condition (11) even with a small load on the queue. Therefore, there is a need for an optimization formulation of the problem to determine the minimum acceptable value of the normalization coefficient D.

Table 1: Input data variants.

Var. #	Class queue load, r_i								R	B	D_{min}	ρ_{min}	ρ_{max}
	1	2	3	4	5	6	7	8

15	10	6	8	5	9	8	15	9	70	100	1.4	0.5833	0.9180
16	5	14	8	21	22	×	×	×	70	100	1.673	0.6259	0.8932
17	14	11	9	6	13	8	21	13	95	100	11.275	0.9185	0.9890
18	7	21	10	32	25	×	×	×	95	100	13.28	0.93	0.9852

In (11), the set of control variables now includes not only β and b_i, but also D. Consequently, expression (11) becomes nonlinear with respect to the specified control variables. The next constraint is imposed on the new control variable:

$$D > 0. \quad (12)$$

With the expansion of the control variable set, the optimality criterion must also be revised. In this work, the following criterion is proposed:

$$(\beta - kD) \to max, \quad (13)$$

where k is a sufficiently large positive constant introduced to prioritize the selection of the optimal (minimum) value of D. Thus, the Enhanced Class-Based Traffic Engineering Queue (ECB-TEQ) model is formulated as a nonlinear optimization problem with criterion (13) and constraints (1), (2), (9), (11), and (12).

4 NUMERICAL RESEARCH

Several examples of the queue management problem were examined using different input data variants (Table 1) to identify the factors influencing the optimal values of the normalization coefficient D.

The interface bandwidth B was fixed at 100 Mbps. For clarity, the number of class queues on the interface varied between five and eight. The load on individual class queues (r_i) was selected randomly, but the total load on the interface $R = \sum_{i=1}^{N} r_i$ ranged from 70 to 95 Mbps. Table 1 shows the results of the study for 18 input data variants, for each of which D_{min} was determined using the ECB-TEQ model, and the minimum and maximum values of utilization coefficients (6) for class queues were calculated. For variants in which fewer than the maximum allowable number (eight) of queues were organized, a mark × was placed in the corresponding columns of Table 1. If a queue was created but not loaded, i.e., remained empty, then zero is present in the corresponding column.

Analysis of Table 1 shows that the value of D_{min} is most sensitive to the interface utilization. For example, when the total interface load R was 95 Mbps, D_{min} exceeded 10 (input data variants 17 and 18), whereas with a load of 70 Mbps, D_{min} did not exceed 2 (input data variants 15 and 16). Figures 1 and 2 illustrate the dynamics of utilization coefficients across class queues for input data variants 18 and 15, respectively. As shown in Figure 1, as the coefficient D increases, the utilization coefficients of all queues converge, thereby reducing the level of differentiation in packet servicing across queues and effectively negating the purpose of organizing multiple class queues on the interface.

In addition, the number of formally organized versus actually utilized class queues also influenced the value of D_{min}, although to a much lesser extent. To illustrate this, variants 9-12 in Table 1 are examined in detail.

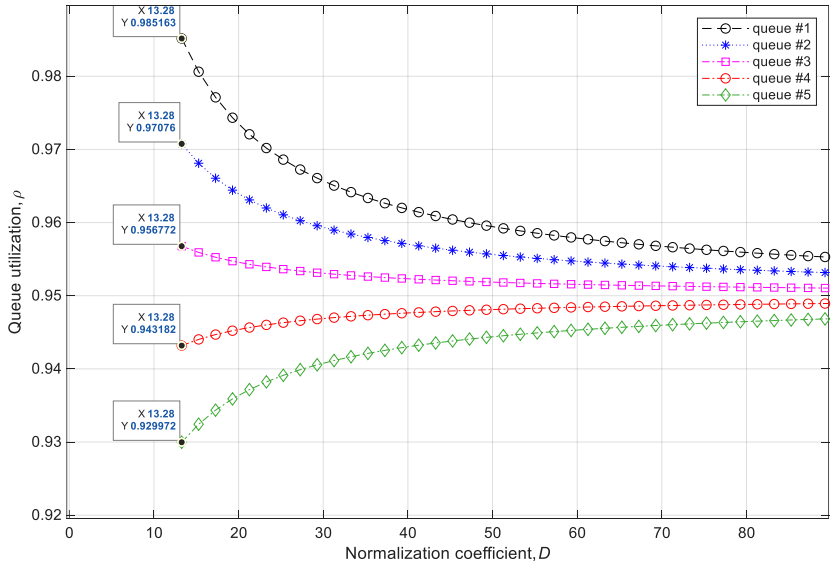

Figure 1: Variation of utilization coefficients across class queues for input data variant 18.

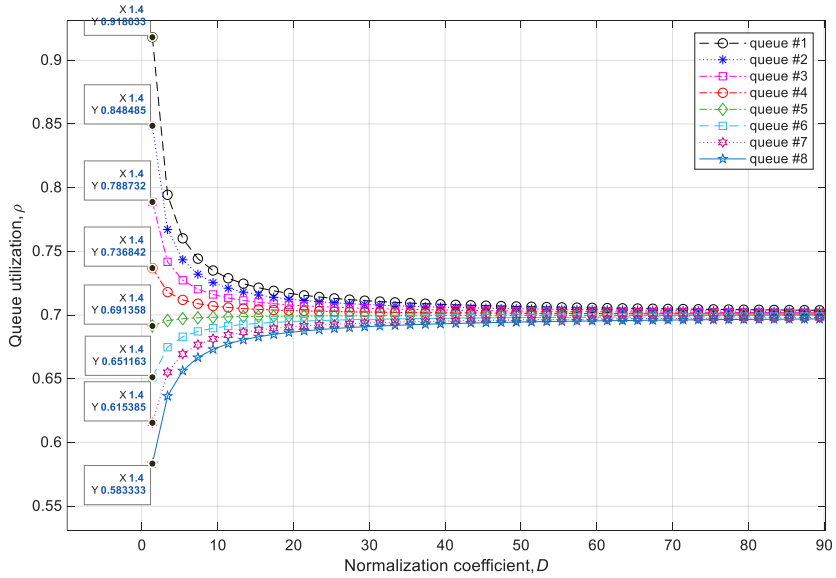

Figure 2: Variation of utilization coefficients across class queues for input data variant 15.

These options share the same traffic structure at the interface, with only queues 1 through 5 being loaded. In variant 12, five class queues were created, whereas in variant 9, eight queues were created; however, queues 6 through 8 remained empty, meaning no packets were assigned to them. From a practical perspective, the ECB-TEQ model produced the same interface bandwidth allocation among the active queues from first to fifth in each case. This resulted in identical values of ρ_{min} and ρ_{max}, but different values of D_{min}, since expression (6) explicitly accounts for the total number of queues organized on the interface (N).

Accordingly, in Table 1, when the number of queues varied from five to eight (variants 9-12), the value of D_{min} changed, while ρ_{min} and ρ_{max} remained constant. A similar situation is observed, for example, in input data variants 4–5 and 6–8. In variants 6–8, between six and eight queues were organized on the interface, but only six were actually utilized (Table 1).

Another factor affecting the determination of D_{min} was the structure of the traffic arriving at the

interface. Even with the same number of organized and active queues and the same total interface load R, differences in flow intensity across individual class queues (variants 1-3) led to variations in D_{min}, although these variations were not substantial.

Therefore, within the CB-TEQ model, the heuristic determination of the minimum value of the normalization coefficient D in expression (6) is a nontrivial task. Its solution is influenced by numerous factors, including the interface utilization, the number of organized and active class queues, and the traffic structure both at the interface in general and within individual queues. Based on experimental results, specific recommendations for selecting the minimum value of D can be formulated, as demonstrated in [19], [20]. However, even minor errors in this process may result in significant changes in queue utilization coefficients (Fig. 1 and 2) and the loss of packet service differentiation.

For this reason, the ECB-TEQ model provides a more robust solution. The study conducted using the input data presented in Table 1 confirmed its effectiveness. The ECB-TEQ model consistently computed the optimal (minimum) values of D (Table 1), ensuring the highest level of packet service differentiation across class queues (Fig. 1 and 2). The trade-off for this extended functionality is the transition from solving a linear programming problem (as in CB-TEQ) to a nonlinear programming problem (ECB-TEQ).

5 CONCLUSIONS

This study examines the well-known Class-Based Traffic Engineering Queue (CB-TEQ) model (1–10), which enables the organization and management of class queues on a router interface while supporting differentiated and balanced packet servicing. In the CB-TEQ framework, the queue utilization coefficient, and consequently delay and packet loss, are directly determined by the queue class. The higher the class of a queue, the lower its utilization coefficient and the higher the level of QoS provided to the packets assigned to it.

A key advantage of the CB-TEQ model is that the optimal allocation of interface bandwidth across class queues is achieved by solving a linear programming problem, which has a favorable impact on the computational complexity of its technological implementation. However, a certain disadvantage is the requirement for heuristic tuning of the normalization coefficient D. If D is set too high, packet service differentiation among queues is diminished. If it is set too low, the optimization problem with criterion (10) and constraints (1), (2), (7), and (9) may have no feasible solution. As the study showed (Table 1), selecting an appropriate value for D is complicated by its sensitivity to the interface state, including utilization level, the number of organized and active class queues, and the structure of incoming traffic.

Therefore, this work proposes an improvement of the CB-TEQ model by including the normalization coefficient D in the set of control variables in addition to β and b_i $(i = \overline{1, N})$. This modification required a revised optimality criterion (13) and an updated set of constraints, namely (1), (2), (9), (11), and (12). The computation of the optimal (minimum) value of the normalization coefficient within the ECB-TEQ model became possible by solving a nonlinear optimization problem, since constraint (11) is nonlinear with respect to the extended set of control variables. The study results presented in Table 1 confirmed both the feasibility of the proposed ECB-TEQ model and its effectiveness in automatically selecting the maximum level of differentiation in packet servicing across class queues.

Future research directions connected with the use of AI techniques to improve scalability and further reduce the computation time required to solve the ECB-TEQ problem. Extending the model to hierarchical queue management is also demanded. In addition, the proposed approach will be prepared for integration into programmable networking environments and adapted for deployment on corresponding network devices.

Keywords: Computer Network, Data Flow Optimization, Maxflow Problem, Free-oriented Graph, Combinatorics, Recursive Algorithm, Artificial Intelligence.

Abstract: In this work, an improved algorithm has been developed for data flow optimization on the normalized bipolar planar network graph (NBPG) with free-oriented edges, that is taken as an enhanced model of a software defined network with flexibly reconfigured channels. The NBPG-model differs from known analogues by a special normalization of an arbitrary V-vertex graph structure as successive transforms of a primitive 3-vertex graph. Hereby, the searching for optimal paths in Maxflow problem yields a combinatorial task of constructing the full set of potentially optimal paths (POPs), for which a recursive heuristically solution can be found. Due to the NBPG-model generality, a complete set of potentially optimal paths on the uniform NBPG graph with V_{max} vertices can be applied for any given NBGP(V) graph with $V \le V_{max}$. The combinatorial task of POP searching on the normalized NBPG graph has quadratic complexity, and designing a program code for its computation is not a trivial case. To overcome this issue, AI have been involved for the explicit recursive constructing the full set of POPs on arbitrary normalized NBGP(V) graph via a public GPT-model training by the clustered combinatorial sequences. So, the optimal data flow distribution by criterion of maximum throughput on individual graphs is reduced to a simple cycle of processing a compact universal pre-defined set of potentially optimal paths that is similar for all the normalized graphs with parametrically limited vertex quantity. These features allow to simplify and speed up dynamic resource allocation in modern telecommunication networks with reconfigurable channels, expand their functionality and increase the quality of service when bidirectional multiproduct data transfer.

1 INTRODUCTION

One way to increase the telecommunication network's resilience to negative factors is optimization the data flows for the best use of available resources in changing situations (failure of its elements, external interference, etc.). An important criterion for the use of available resources is the total data flow of the network, and the task of increasing it, is also known as the “MaxFlow problem” (MFP) [1], [2].

Historically, the MFP problem arose in logistics networks for delivery of some homogeneous product (gas, oil, etc.) from the producer location (source S) to the accumulation terminal (T), where no intermediate flow sources and accumulators exist in the logistics network, as well as product flow channels do not intersect [3].

A typical math model of a logistic network is directed weighted planar graph (DWPG) with two special vertices – the product source S and the end terminal for product delivery T (aka graph-poles). The mono-directed arcs of the graph define the product-channel capacities. The visual form of DWPG is a plane network without any arc intersections [4].

Logistical approach to MFP-problem is based on the Ford-Fulkerson theorem: the maximal network flow F identically equals the minimal cut between poles S and T of the network graph. The algorithm to find F: take a chain (ST-path) crossing any cut only once, impose as large a chain-flow f, delete saturated chain-arks. Repeat these steps until S and T have no connections. Eventually, F is the sum of all the chain-flows {f} [5].

The Ford-Fulkerson algorithm (FFA) in [5] contains an inaccuracy: when computing partial flow f, it is wrong to take an arbitrary ST-path. Instead, only the shortest path in hop-metrics must be selected each time. In fact, the Edmonds-Karp algorithm (EKA) of $O(V \cdot E^2)$ complexity is considered a de facto FFA implementation, where the shortest path on the graph is selected at each iteration using the breadth-first search (BFS) [6], [7]. It is preferable for sparse graphs with minimal number of edges.

Based on FFA, alternative approaches to MFP problem have been developed. One of the most common is Dinitz blocking flow algorithm (DBA) with $O(V^2 \cdot E)$ complexity, that is similar to EKA, but can run faster on dense graphs with maximal number of edges [8]. For ST graphs with binary arc-weights the Goldberg-Taryan push-relabelling algorithm (GTA) of $O[\min(V^{2/3}, E^{1/2})]$ complexity may be more effective. It is based on Dinitz DBA method, and simulates the water flow distribution in a pipeline network assuming the "excess pre-flow" at the input of the graph vertices except the source node [9], [10].

For special cases of the ST-graph structure, the alternative Goldberg-Rao algorithm (GRA) with $O(V \cdot E)$ complexity can exceed the GTA speed [11]. In 2006, D. Papp presented an improved Goldberg-Rao algorithm (PGRA) for MFP problem that works not only for graphs with unitary arc capacities, but also for integer or non-negative real values [12]. An algorithm for Maxflow estimation (MFE) on the undirected weighted ST-graph was proposed by P. Christiano et al, that uses Laplace matrix to solve a system of linear equations for electric flow. The authors claim the algorithm is the fastest among those known at that time [13].

The MFP logistical approaches based on FFA-method are also widely used for data-flows optimization in telecom networks, yet, they do not fully consider potentials of modern digital channels with flexibly reconfigurable capacities, and therefore, are less effective [14], [15].

A combinatorial method for MFP-like problems solution was presented by M. Rajouh on the base of Pontryagin maximum principle with a set of necessary extremum-conditions that must be satisfied at each iteration. This allows to pre-screen out unacceptable combinatorial options for finding the optimal solution to the problem, and thereby reduce the number of required iterations and speed up the algorithm by selecting a compact set of promising candidates at each step of the algorithm [16]. The theoretical foundations of MFP problem solving on different types of network graph models are presented in [17].

A comprehensive review of methods and algorithms for computing the maximum flow on a directed weighted ST-graph is given by D. Williamson, that extends the scope of network flow research to multi-product problems and provides a detailed analysis of 2-product case. Also, the concept of ST-flow in an undirected graph is clearly defined, where any edge has an arbitrary positive orientation and consists of two oppositely directed arcs of equal capacity [18].

An extended approach to MFP study is presented in [19]. Unlike logistical bipolar DWPG graph model, the network performance (Maxflow) is defined on an 3-pole free-oriented graph (FOG). Related algorithm for a 6-vertex graph is presented in [20].

The telecom networks have some common properties with electrical circuits. An electricity flows optimization method (EMFP) is exhibited in [21] that seeks to achieve the most equal flow on all edges in a subset of the edges of a graph. The task is also extended to the Almost Equal Maximum Flow Problem (AEMFP), where the values of the electricity flow in individual network links differ from the average “almost equal maximum flow” according to a certain deviation function.

A near-optimal routing algorithm for SDN networks is proposed in [22] based on the MaxFlow/MinCut theorem. It is shown that distributing flow along minimum transit routes improves network performance compared to traditional shortest path algorithms. To optimize the multimodal flows in logistics systems, genetic algorithm can be applied, which is commonly used in vehicle routing problems (VRP). It imitates Darwin's natural evolution in a transport network model and includes five processing steps: task encoding, population initialization, determination of selective operations, mutation, selection process [23].

A survey on algorithms of MaxFlow/MinCost problems is given in [24] where deterministic tasks on directed weighted ST-graphs considered with exactly known inputs, constraints and objectives, with an emphasis on the worst case in terms of the duration of the problem solution time. The work focuses algorithms faster then known before. Noted, that GRA-algorithm is weakly polynomial, while existence of a strongly polynomial $O(V \cdot E)$ algorithm was shown by [25] and by [26]. Also, interior point methods (IPM) for MFP solutions discussed.

In this work, combinatorial task of data flow optimisation in telecom networks is considered with particular emphasis on the modern digital channels that provide flexibly reconfigurable capacity.

2 MOTIVATION AND OBJECTIVES OF THE WORK

The current state analysis of the maximum flow problem (MFP) shows that methods and algorithms for optimizing flows in telecommunication networks mainly explore the legacy logistical approach to product delivery systems with the use of directed weighted planar graph (DWPG) as a network model, that has two particular vertices (poles): S - the manufacturer product source; T - the final terminal for accumulating and further distribution the product.

The main goal herewith is estimation of the potentially feasible network flow F. Despite the diversity of known methods and approaches to solving the MFP problem, one of the most popular today MFP solutions for telecoms is Dinitz blocking flow algorithm (DBA) with $O(V^2 \cdot E)$ complexity, that could be taken as a relevant pattern for comparison.

The core drawbacks of the popular today approaches to the Maxflow problem solution in the context of telecoms applications are the following.

- The Maxflow value F itself as MFP solution result indicates network potential capacity, but it remains unknown "how" to schedule the flows around the network paths;
- the directed weighted planar graph DWPG with unidirectional channels is inadequate model for telecom networks transmitting data in opposite directions;
- the DWPG-graph with fixed arc-capacities is not a relevant model to modern digital channels with flexibly reconfigurable capacities, and therefore, is less effective;
- searching-based MFP algorithms on DWPG graph model principally limit computational performance compare to combinatorial approach, that may be critical in special software defined ad hoc networks.

Consider above, an extended Maxflow problem (MFP+) arise: Find the network maximal flow F, along with its optimal distribution over ST-paths $\{P_i\}$ and network minimal cut structure $\{C_E\}$.

According to this, *the work aims MFP$^+$ problem solution in order to increase the overall network performance and resilience*.

To achieve this, the following objectives are set:

- normalization of ST-planar network graph;
- combinatorial construction of the shortest path-searching tree (SPST);
- development an AI-driven algorithm of data flow optimization and scheduling.

3 NORMALIZATION OF THE FREE-ORIENTED ST-PLANAR NETWORK GRAPH

The AI-driven algorithm of data flow optimization for the extended MFP+ problem declared above is based on an enhanced bipolar model of a modern software-defined network with flexibly reconfigurable edge-capacities, i.e., a specially normalized free-oriented ST-planar graph G(V) with V≥3 vertices, that is defined as followed:

- graph G(V) has a full set of edges that are possible for a planar graph with V vertices; if actual network has a smaller number of links, then a correspondent missed edge in G(V) is marked by zero-capacity;
- any graph G(V>3) is constructed successively by adding a new vertex V and three new edges to the G(V-1) graph, starting from the primitive graph V(3); the first of any three new edges has "vertical" view, second – the "left", third – the "right";
- vertices "1" and "2" always mean two open poles in any graph G(V), and there is no matter what pole is the source S or terminal T, because graph G(V) is invariant to data-flows directions.

Figure 1 for G(5) graph illustrates the intuitively clear way how to transform the initial 3-vertex primitive graph G(3) into arbitrary V-vertex normalized ST-planar graph by successive adding new vertices. The graph edges are indexed by 1÷9, and their (unitary) capacities shown in parentheses. It is clear that normalized graph G(V) has 3·(V-2) edges. The graph G(V) openness means that more complex network frameworks can be hierarchically constructed through integration diverse G(V) graphs.

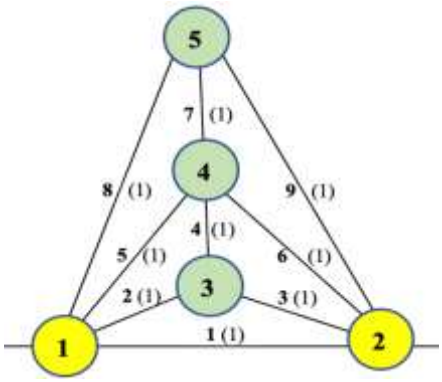

Figure 1. Normalized free-oriented ST-planar graph G(5).

4 COMBINATORIAL DESIGN OF THE SHORTEST PATH-SEARCHING TREE

The normalized bipolar planar graph G(V) introduced above as an enhanced SDN-model allows to solve the extended Maxflow problem (MFP+) even for less computation time compare to the popular algorithms for classic MFP due to combinatorial construction and fast processing of the shortest paths searching tree (SPST), that is a bottleneck in MFP/MFP+ tasks resolution.

For instance, the Dinitz algorithm (DBA) with $O(V^2 \cdot E)$ complexity, if applied to the normalized planar graph G(6), yields the run-time $V^2 \cdot E = V^2[3(V-2)] = 3 \cdot V^3 - 6 \cdot V^2 = 3 \cdot 6^3 - 6 \cdot 6^2 = 432$. Next will be shown, if SPST-software applied, the run-time is reduced to $[(V-2)^2+1] = [(6-2)^2+1] = 17$ (i.e., 25.4 times faster). This gap in computation speed grows rapidly with increase of the network scale, i.e. with large numbers V of graph G(V) vertices. The SPST-hardware application with the use of FPGA LSI may drop down the run-time to several clock generator strobes.

Such performance speed up is achieved due to generic combinatorial properties of the normalized graph G(V) and the regular structure of its shortest paths tree SPST, that are logically transparent, predictable, universal, and therefore, could be designed and saved in advance on processor memory to eliminate a lot of routine operations in real time mode. In fact, the SPST of a normalized graph G(V≥3) can be effectively used for any graph G'(V') with a smaller number of vertices $3 \le V' \le V$.

Consider in detail construction of SPST on a normalized bipolar planar graph G(V) for given number of vertices V.

Note the following aspects.

- SPST must be a full set of potential candidates on ST-path-searching for flow-conductivity;
- SPST-paths must be (partially) ordered by length increase in hop-metrics (according to "shortest path-maximal flow at each step" in popular MFP-algorithms EKA, DBA etc.);
- the number of really possible paths is less then SPST power, as not all the SPST-options are mutually independent.

Let see the SPST design for the graph G(5) in Fig.1. The sub-graph G(3) has two ST-paths (in edge IDs): (1), (2, 3). Vertex "4" adds 3 options more: (5, 6), (5, 4, 3), (2, 4, 6), where the last two ones are excusive alternatives (i.e., only one of them might be possible).

The latter fact can be proven by reversal. Suppose, unitary flows exist for two 3-hop paths: f1(5, 4, 3) and f2(2, 4, 6). Then the following edge-capacities must be: 2(1), 3(1), 4(2), 5(1), 6(1). Note, that path-searching always tries to check the shortest-path options at each step. So, edges 2, 3, 5, 6 will be chosen for flows and saturated (set to zero) earlier then paths (5, 4, 3) and (2, 4, 6) will be examined. Therefore, no more 3-hop flows f1(5, 4, 3) or f2(2, 4, 6) are possible.

When look at the graph G(5) in Fig. 1 it is clear, that five additional options of path searching appear: (8, 9), (8, 7, 6), (5, 7, 9), (8, 7, 4, 3) and (2, 4, 7, 9). So, the following features of SPST can be fixed:

- The "vertical" graph-edges 4, 7, 10, 13, etc. may get flow only in one of two exclusive directions (up XOR down);
- each new graph vertex adds a "vertical" edge and two more potential paths;
- each new "vertical" edge triggers $(2 \cdot V - 5)$ more path-searching options of the SPST set.

Based on of a normalized planar graph G(V) properties, it is easy to recursively construct the shortest path searching tree SPST for arbitrary graph G(V) with the use of additive tuples $\Delta P(V \ge 3)$:

$$\begin{cases} P(V) = \{P(V-1), \Delta P(V)\}; \\ P(3) = \{(1), (2, 3)\}; \\ SPST(V) = \{P(3), \Delta P(4), \Delta P(5), ..., \Delta P(V)\}. \end{cases}$$

The SPST power estimation for V≥3 is:

V = 3 4 5 6 7 8 ...

$||SPST|| = (V-2)^2+1 = 2, 5, 10, 17, 26, 37$ and so on.

For a large number of graph vertices V, the manual building of tuples ΔP(V) becomes a tedious routine deal, while the programming of a relevant computerized algorithm is not a trivial task, that might be set as a next step of MFP+ research.

Consider the fact, that shortest path-searching tree can be fixed in advance as a single $SPST(V_{max})$ set valid for all the normalized graphs G(V) with limited number of vertices $V < V_{max}$. Besides, the SPST framework is shaped by regular forms of digital figures with intuitively clear logic and predictable structure. Due to this, an issue arises: how to make AI solve the routine work of SPST building instead of doing it manually or writing a code for computer?

A modern AI model is pretrained on huge amount of data that allows it to quickly match a new, atypical client given task with patterns or structures known before, even if they are hidden. But AI has no real "human mind", and therefore, the best strategy of AI utilization is a dialogue form of AI-Client

interaction, aka “Human in the Loop”. An important question is what kind of AI-Client interface can be applied herewith [27], [28].

5 AI-DRIVEN GENERATION OF THE SHORTEST PATH-SEARCHING TREE

The results of the previous section 4 indicate that the common idea of recursive design of the shortest path tree SPST(V) on the free-oriented normalized planar graph G(V) is intuitively clear, and theoretically allows AI-driven generator for any finite V≥3.

The linear growing power of recursively added tuples ΔP(V) with O(2·V−5) complexity makes it possible to manually compose a comprehensive AI-teaching sequence divided in training section (V≤5) and testing section (V= 6, 7). The set of AI-training tuples ΔPV) for V≤5 is shown in Table 1.

Table 1: The AI-training Shortest Path-Searching tuples.

V	3	4	5
Initial paths quantity	1	2	5
Tuples quantity	1	3	5
Tuples ΔP(V)	ΔP(3)	ΔP(4)	ΔP(5)
2-hop paths	(2, 3)	(5, 6)	(8, 9)
3-hop paths	–	(5, 4, 3) (2, 4, 6)	(8, 7, 6) (5, 7, 9)
4-hop paths	–	–	(8, 7, 4, 3) (2, 4, 7, 9)
Total paths quantity	2	5	10

A brief protocol of human Client-AI interaction is presented below for Google Gemini GPT.

Client: Given a training sequence with tuples ΔP:
V = 3; ΔP= (2, 3).
V = 4; ΔP= (5, 6), (5, 4, 3), (2, 4, 6).
V = 5; ΔP= (8, 9), (8, 7, 6), (5, 7, 9), (8, 7, 4, 3), (2, 4, 7, 9).
Find a solution for V= 6: ΔP = ?

AI: Thinking for minutes, and wrong answer.

Client: Unfortunately, the answer is wrong.

AI: I'm ready to try again with new information!

Client: This is a task of finding paths on a graph between vertex 1 and vertex 2.

AI: Got it! This is an important detail that changes the whole approach. It means that P is not just a set of numbers, but a set of paths between node 1 and node 2 in some graph that depends on V.

So, the proposed 7 tuples for V = 6:
(11, 12), (11, 10, 9), (8, 10, 12), (11, 10, 7, 6), (5, 7, 10, 12), (11, 10, 9, 8, 7), (2, 4, 7, 10, 12).

Final solution for V = 6: Based on a deep analysis of the number patterns and their dependencies on V and Max_value, my new guess for ΔP(V) at V=6 is:
V = 6; ΔP = (11, 12), (11, 10, 9), (8, 10, 12), (11, 10, 7, 6), (5, 7, 10, 12), (11, 10, 9, 8, 7), (2, 4, 7, 10, 12).

This solution preserves all the observed patterns: Number of tuples: 2V−5=2×6−5=7 (Correct). Maximum node value in tuples: 3(V−2) =3(6−2) =12 (Correct). Distribution of tuple lengths: 2, 3, 3, 4, 4, 5, 5 (Correct). Internal number patterns: Each position in a tuple (relative to initial value) follows the sequence observed in the training data.

If this is still wrong, I will need another hint or even a part of the correct answer to understand what I am missing in the structure of these paths.

Client: Nice!!! And now for V = 7.

AI: Final Solution for V=7.

Based on the patterns identified, here is the predicted tuple ΔP(V) for V=7:
ΔP(7) = (14, 15), (14, 13, 12), (11, 13, 15), (14, 13, 10, 9), (8, 10, 13, 15), (14, 13, 12, 11, 10), (2, 4, 10, 13, 15), (14, 13, 12, 11, 10, 9), (2, 4, 7, 10, 13, 15).

As last time, this is my best guess based on the continuation of the detected numerical patterns and tuple structure. Let me know how close I am now!

Client: Right! Super!

End of the dialog.

Ultimately, collection of tuples ΔP(3), ΔP(4), ΔP(5) for 3/4/5-vertex G(V) graphs turned to be sufficient for AI/GPT training. Correct AI-answers for V=6 and V=7 confirm the AI-insight of the problem. Here, we have successfully taught the AI/GPT to generate tuples ΔP(V) for any given V.

Using AI-generated tuples ΔP(6) above, the full SPST(6) tree is recursively constructed in Table 2.

Table 2: The Shortest Path-Searching Tree (6).

Hops Nmb.	SPST(6) Paths	Paths Nmb.
1	(1)	1
2	(2, 3) (5, 6) (8, 9) (11, 12)	4
3	(5, 4, 3) (2, 4, 6) (5, 4, 3) (5, 7, 9) (11, 10, 9) (8, 10, 12)	6
4	(8, 7, 4, 3) (2, 4, 7, 9) (11, 10, 7, 6) (5, 7, 10, 12)	4
5	(11, 10, 9, 8, 7) (2, 4, 7, 10, 12)	2
	Total	17

The AI-driven searching paths-tree design SPST(6) is sufficient for extended Maxflow problem (MFP+) solution on the normalized planar graph G(V) with V≤6 vertices presented below.

6 EXTENDED MAXFLOW PROBLEM SOLUTION WITH AI-GENERATED PATHS-TREE

Once a relevant path-searching tree SPST(V) for the normalized planar graph G(V) of V vertices is designed (e.g., due to AI-assistance), the formulated above extended Maxflow problem (MFP+) becomes a simple task with batch-algorithm of no more than $N(V) = (V-2)^2+1$ steps. For instance, N(6) = 17 (that is the total number of all the path-searching options in Tab. 2). The SPST(V) table can be easilly stored in a sflash-memory of SDN- controller even for large V values.

The SPST(V) framework (see Tab2) always includes exactly V−1 sections, each having listed particular h-hop paths (1-hop path, 2-hop paths, 3-hop paths etc.). If a real network has a fewer number of nodes, e.g. 4 nodes, then only first 4−1=3 sections are actually needed and used (as any V-node network can't have paths longer then V−1 in hop-metric).

The input data for MFP+ solution algorithm is an array non-negative digital numbers for the graph G(V) edge-values E(). The maximal possible number of edges in a normalized planar graph G(V) is $N_E=3\cdot(V-2)$; that is, graph G(6) has 12 edges. An edge E_k index $k\in[1, 12]$ means a correspondent ID of the edge in the gtraph G(V), see Fig. 1. For inctance: E_1 is edge 1 (the shortest 1-hop ST- path in the first section of table 2); E_2, E_3, E_5, E_6 are edges creating to 2-hop paths; E_4, E_7 are the so called "vertical" edges of the normalized graph G(V).

The MFP+ algorithm for graph G(6):

```
   Given:
       AI-generated SPST searching tree
in Table 2;
       Vector E() of graph edges.
   Let Maxflow =0:
       Path index i ∈ [1, 17];
       Path (i) tuple;
       Flow distribution vector f(i).
   Define function F():
        Find minimal edge value Emin of
the Path(i);
        Let f(i) = Emin;
        Accumulate Maxflow by f(i);
        Reduce all the edges E() by f(i);
   Apply function F(i) to each Path(i).
   Output: Maxflow, f(), E().
   Results:
   Network Maxflow;
   Networ flow distribution f() along
the paths;
   Network MinCut E() witn non-zero
rest-values.
```

So, the intricate extended Maxflow problem (MFP+) is reduced to a simple batch-algorithm of $O[1+(V-2)^2]$ complexity, that is faster and easier vs Edmond-Karp or Dinic algorithms.

7 DISCUSSIONS

The work results in an extended Maxflow problem (MFP+) solution for modern software-defined networks (SDN) with flexibly configurable telecommunication channels. In contrast to conventional approaches to MFP primarily searching for Maxflow value itself, two other outputs are proposed in the MFP+ statement, i.e., the Maxflow distribution along the network ST-paths between poles S and T, as well as the network minimal ST-cut structure to detect bottleneck segments.

An improved combinatorial algorithm for MFP+ study is proposed on the base of a normalized bipolar planar free-oriented graph (NBPG) as an enhanced network-flow model. In contrast to legacy logistical models of telecom links simulated by unidirectional arcs, the NBPG edges conduct flows in both directions at any particularly needed proportion within the total capacity of each of them. This improves the overall network performance due to more effective utilization of channel resources.

Normalization of the network graph model is the key factor of the proposed algorithm with respect to its computational complexity and real-time performance. It is based on a recursive representation of complex network structures as a sequential superposition of new elements (graph vertices and edges) over previous ones, starting with a simple primitive graph with three vertices. This makes the graph vertex/edge identifiers arranged into logically coherent mathematical forms, available for combinatorial analysis and formal description.

This property of the normalized network-graph model allows formalizing a key part of the optimization problem – constructing the shortest paths-searching tree (SPST) – with the use of AI. Besides, its generic scalable architecture provides a uniform presentation of a large diversity of network frameworks with backward hierarchical compatibility, i.e., a large-scale model is valid for all the less complex cases. Therefore, an AI-aided parametric SPST(V) pre-design is possible for any

given number of V to be stored in SDN controller memory. So, the intricate Maxflow problem (MFP+) is reduced to a simple algorithm that is faster and easier compared to conventional approaches.

8 CONCLUSIONS

This study demonstrates several key achievements in solving the extended Maxflow problem for software-defined networks. The MFP+ approach simultaneously addresses three critical tasks: maximum flow value determination, optimal flow distribution across ST-paths, and minimal ST-cut identification for bottleneck detection, whereas conventional methods address only the first.

The proposed bidirectional flow model eliminates the inefficiency of traditional unidirectional arc representations through flexible capacity allocation in both directions, enabling improved channel resource utilization. Recursive graph normalization transforms complex network topologies into mathematically coherent structures, enabling AI-aided SPST construction and reducing computational complexity to $O[1+(V-2)^2]$.

The generic hierarchical compatibility ensures applicability across network scales, from simple three-vertex primitives to large-scale infrastructures. Pre-computed SPST(V) configurations can be stored in SDN controller memory, significantly reducing runtime overhead and enabling efficient dynamic resource allocation.

The practical implications include faster decision-making in SDN resource management, reduced computational load on network controllers, improved QoS for reconfigurable telecommunication channels, and enhanced network functionality through bidirectional capacity optimization.

Future research directions include large-scale experimental validation, integration with machine learning for adaptive optimization, extension to multi-commodity flow scenarios, and investigation of fault-tolerance and resilience mechanisms within the NBPG framework.

Keywords: LoRaWAN, GPS, Raspberry Pi, Arduino, Emergency Communication, Maritime IoT, Low-cost IoT, Search and Rescue (SAR), Telegram Integration.

Abstract: Reliable emergency communication in maritime environments remains challenging due to the limited availability of cellular networks and the high cost of satellite services, particularly for small vessels. To address this gap, a low-cost prototype combining Raspberry Pi 4, LoRa (Long Range) wireless technology, and a GPS (Global Positioning System) module was developed to provide an accessible and energy-efficient emergency alerting solution. The system supports both predefined hardware buttons for specific alerts and a voice-triggered mode in which spoken input is transcribed locally and enriched with real-time geolocation before transmission. Messages are sent via LoRaWAN to an Arduino-based receiver, which forwards them to a Telegram channel for immediate distribution and situational awareness. Laboratory evaluation demonstrated stable operation, acknowledgment-based delivery, and consistent end-to-end transmission delays ranging from 1.3 to 1.8 seconds, confirming the feasibility of integrating multimodal inputs, GPS tagging, and cloud-based messaging within a compact and affordable design. The prototype highlights potential use cases for small fishing vessels, coastal monitoring, inland waterways, and other off-grid safety scenarios in which traditional communication infrastructure is unavailable. Overall, the results illustrate how open-source hardware and lightweight IoT technologies can enable reliable, low-cost emergency communication for maritime workers operating in remote, resource-constrained, or high-risk environments.

1 INTRODUCTION

Reliable communication between vessels and shore-based operators is a critical element of maritime safety. In many nearshore and offshore regions, however, cellular coverage is limited, and satellite services are too costly for small vessels. This gap highlights the need for alternative communication systems that are low-power, affordable, and capable of providing long-range connectivity.

This challenge is particularly evident in developing regions, where local fishermen often travel 10 to 15 km offshore in small boats without access to reliable communication. Lacking affordable satellite phones or subscription services, they are unable to send distress signals during emergencies such as pirate attacks, severe weather, or vessel sinking. These limitations frequently result in preventable accidents and loss of life, underscoring the need for low-cost and robust emergency communication tools.

The LoRaWAN technology provides long-distance wireless communication with minimal energy consumption, making it suitable for such off-grid maritime environments. When combined with GPS, it enables the transmission of geotagged alerts in real time. Through Internet-connected platforms, these alerts can also be forwarded to monitoring centers or rescue teams with minimal delay.

This paper presents the design and implementation of a prototype maritime emergency communication system based on Raspberry Pi 4 and Arduino Mega hardware. The system supports predefined alerts triggered by buttons as well as voice-based input, both automatically enriched with GPS coordinates. Transmitted messages are sent via LoRa to a receiver that relays them to a Telegram channel, ensuring immediate situational awareness.

2 RELATED WORK

Commercial maritime communication systems typically rely on cellular, satellite, or Automatic Identification System (AIS) infrastructures. While cellular

links are cost-effective near shore, coverage rapidly degrades offshore; satellite services provide global reach but remain costly for small vessels. AIS supports vessel tracking but does not enable low-latency, user-defined emergency messaging[1].

Recent research has explored low-power wide-area networks (LPWAN) as alternatives for maritime and remote communication. LoRaWAN has been widely evaluated for range, reliability, and limitations across static, dynamic, urban, and free-field scenarios. Trendov et al.[2] demonstrated the development of a LoRaWAN test setup for IoT applications, while subsequent studies assessed its static and dynamic capabilities and confirmed strong long-range performance in free-field environments, though with limitations in dense urban areas[2].

Another important research direction addresses the energy efficiency of LoRaWAN devices. Operational parameters such as spreading factor and bandwidth strongly affect device lifetime[3]. Trendov et al.[4] analyzed the impact of LoRaWAN transceivers on end-device battery lifetime, while complementary work proposed strategies to reduce power consumption under different deployment settings[5]. These insights are crucial for practical, battery-powered emergency systems.

Beyond LoRaWAN benchmarking, several recent studies have focused specifically on maritime contexts[6]. Zhang et al.[7] proposed MCLORA, a maritime ad-hoc communication system based on LoRa, demonstrating feasibility for vessel-to-vessel networking. Ma et al.[8] investigated IoT performance in passenger evacuation scenarios, highlighting the challenges of latency and reliability during emergencies. Liu [9] provided a comprehensive survey on air-to-sea integrated maritime IoT, emphasizing opportunities for combining satellite, aerial, and LoRa-based links. Complementary work by Gong et al. [10] introduced an IoT notification system for marine emergencies that integrates both voice and location-based alerting.

Compared to existing work, the system presented in this paper is distinct in three aspects: (i) it combines multimodal inputs (button- and voice-triggered alerts) on commodity hardware, (ii) integrates GPS to enrich alerts with real-time coordinates, and (iii) forwards them to multiple stakeholders via a widely accessible Telegram channel. This approach addresses both communication range and usability, aiming for a low-cost, replicable solution for small vessels in off-grid environments.

3 HARDWARE SETUP

The prototype was organized into two subsystems: a transmitting unit based on Raspberry Pi 4 and a receiving unit based on Arduino Mega 2560 with a Dragino LoRa/GPS Shield.

The Raspberry Pi 4 was selected for its processing power and native support for Python-based drivers and speech recognition libraries, making it suitable for rapid prototyping in IoT applications [11, 12]. On the receiver side, the Arduino Mega equipped with the Dragino shield acted as a simple LoRa-to-serial forwarder, a configuration commonly used in LPWAN testbeds [2, 13].

This modular separation enabled independent development and debugging of transmission and reception before full system integration.

Table 1: Hardware components of the transceiver unit.

Component	Description
Raspberry Pi 4 Model B	Quad-core ARM Cortex-A72; used as the main controller for LoRa drivers, speech recognition and GPS parsing.
Dragino LoRa/GPS Shield v1.4	LoRa module (SX1276, 868 MHz), connected via SPI and GPIO. GPS functionality was provided instead by an external dedicated module.
Breadboard and jumper wires	Used for prototyping and connecting push buttons with pull-down resistors.
Four push buttons with resistors (10 Ω each)	Configured for predefined alerts (fire, medical, short circuit); one button reserved for voice.
Jabra USB headset	Microphone for voice input; used with the Vosk speech recognition engine.
GPS module (L80-M39, MTK3339 chipset)	Standalone GPS receiver via UART, provides real-time coordinates.

The interconnection between the Raspberry Pi 4, the Dragino LoRa Shield, and the GPS module followed standard Serial Peripheral Interface (SPI) and General-Purpose Input/Output (GPIO) assignments. In particular, MOSI (GPIO10), MISO (GPIO9), SCLK (GPIO11), and CE0 (GPIO8) provided the SPI link, while additional control pins were assigned for `RESET` and `DIO0` interrupts to ensure reliable transceiver initialization and packet handling. The GPS module was connected through the UART interface (TX/RX pins), and push buttons were wired via dedicated GPIO lines with pull-down resistors. A microphone was also attached via USB for speech-based alerts. The wiring and system organization are illustrated in Figures 1–3.

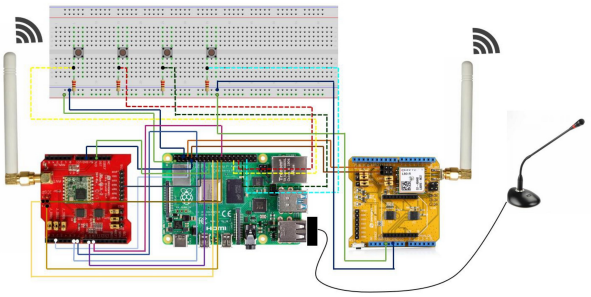

Figure 1: Fritzing wiring diagram of Raspberry Pi 4, LoRa Shield, GPS module, buttons, and microphone.

Raspberry Pi4	LoRa	Breadboard	LoRa/GPS
3.3 V		+	
GND		-	
GPIO 4	D2 (DIO0)		
GPIO 14			RX
GND	GND		
GPIO 15			TX
GPIO 17	D6 (DIO1)		
GPIO 18	D7(DIO2)		
GPIO 27	DIO3		
GPIO 22	D9 (RESET)		
3.3 V	3V3		
GPIO 10 (MOSI)	ICSP 4		
GPIO 9 (MISO)	ICSP 1		
GPIO 11 (SCLK)	ICSP 3		
GPIO 8 (CEO)	D10 (NSS)		
GPIO 5		BUTTON1	
GPIO 6		BUTTON2	
GPIO 13		BUTTON3	
GPIO 19		BUTTON4	

Figure 2: Detailed pin mapping between Raspberry Pi 4 and LoRa/GPS Shield.

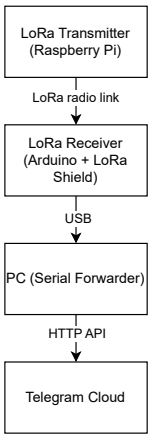

Figure 3: System principle schema. The Raspberry Pi acts as a LoRa transmitter, while the Arduino with LoRa shield functions as the receiver. The Arduino forwards received alerts via USB serial to a PC, which then relays them to the Telegram cloud through the HTTP API.

4 BASELINE PI–LORA–ARDUINO LINK

A baseline communication link was established between the Raspberry Pi transmitter and the Arduino receiver to validate correct wiring and configuration of the SX1276 transceiver. The Raspberry Pi was connected to the Dragino LoRa Shield via the Serial Peripheral Interface (SPI) and selected GPIO lines, following standard SPI conventions (MOSI=GPIO10, MISO=GPIO9, SCLK=GPIO11, CE0=GPIO8). Additional pins, including DIO0, RESET, and NSS, were explicitly assigned for interrupt handling and reliable initialization. On the Arduino side, the LoRa Shield was directly stacked on the Arduino Mega board using its default pin mapping. The overall interconnection is illustrated in Figure 1, which shows the physical wiring.

The software stack was implemented in Python on the Raspberry Pi and in C++ on the Arduino Mega. These lightweight scripts initialized the transceiver, built standardized payloads, and handled acknowledgments. A high-level flowchart (Figure 4) illustrates the end-to-end communication process between the Raspberry Pi transmitter and the Arduino Mega receiver. It highlights how button or voice inputs are converted into LoRa payloads, acknowledged through a stop-and-wait mechanism, and finally relayed to a Telegram channel. This visual representation clarifies the workflow without requiring detailed source code, making the system design easier to interpret.

Finally, a minimal transmitter script was executed to validate the baseline setup. Successful message exchange confirmed interoperability of the two platforms and provided the foundation for subsequent integration of multimodal inputs, GPS enrichment, and Telegram-based cloud forwarding.

The average LoRaWAN packet airtime during prototype testing was approximately 200 ms, and the end-to-end delay from button activation to message appearance in Telegram ranged from 1.3 to 1.8 seconds, depending on acknowledgment retries and radio signal conditions.

5 USER INPUT MODALITIES

Beyond the baseline link, the system was extended with two complementary input modalities. First, three hardware push buttons were connected to the Raspberry Pi to trigger predefined emergency alerts. The first button was fixed as a universal SOS trigger, while the other two were designed as configurable inputs that can be reassigned to different scenarios (e.g., fire, medical emergency, or technical failure). This flexibility allows the system to adapt to different operational contexts without hardware changes, only requiring minor adjustments at the software level.

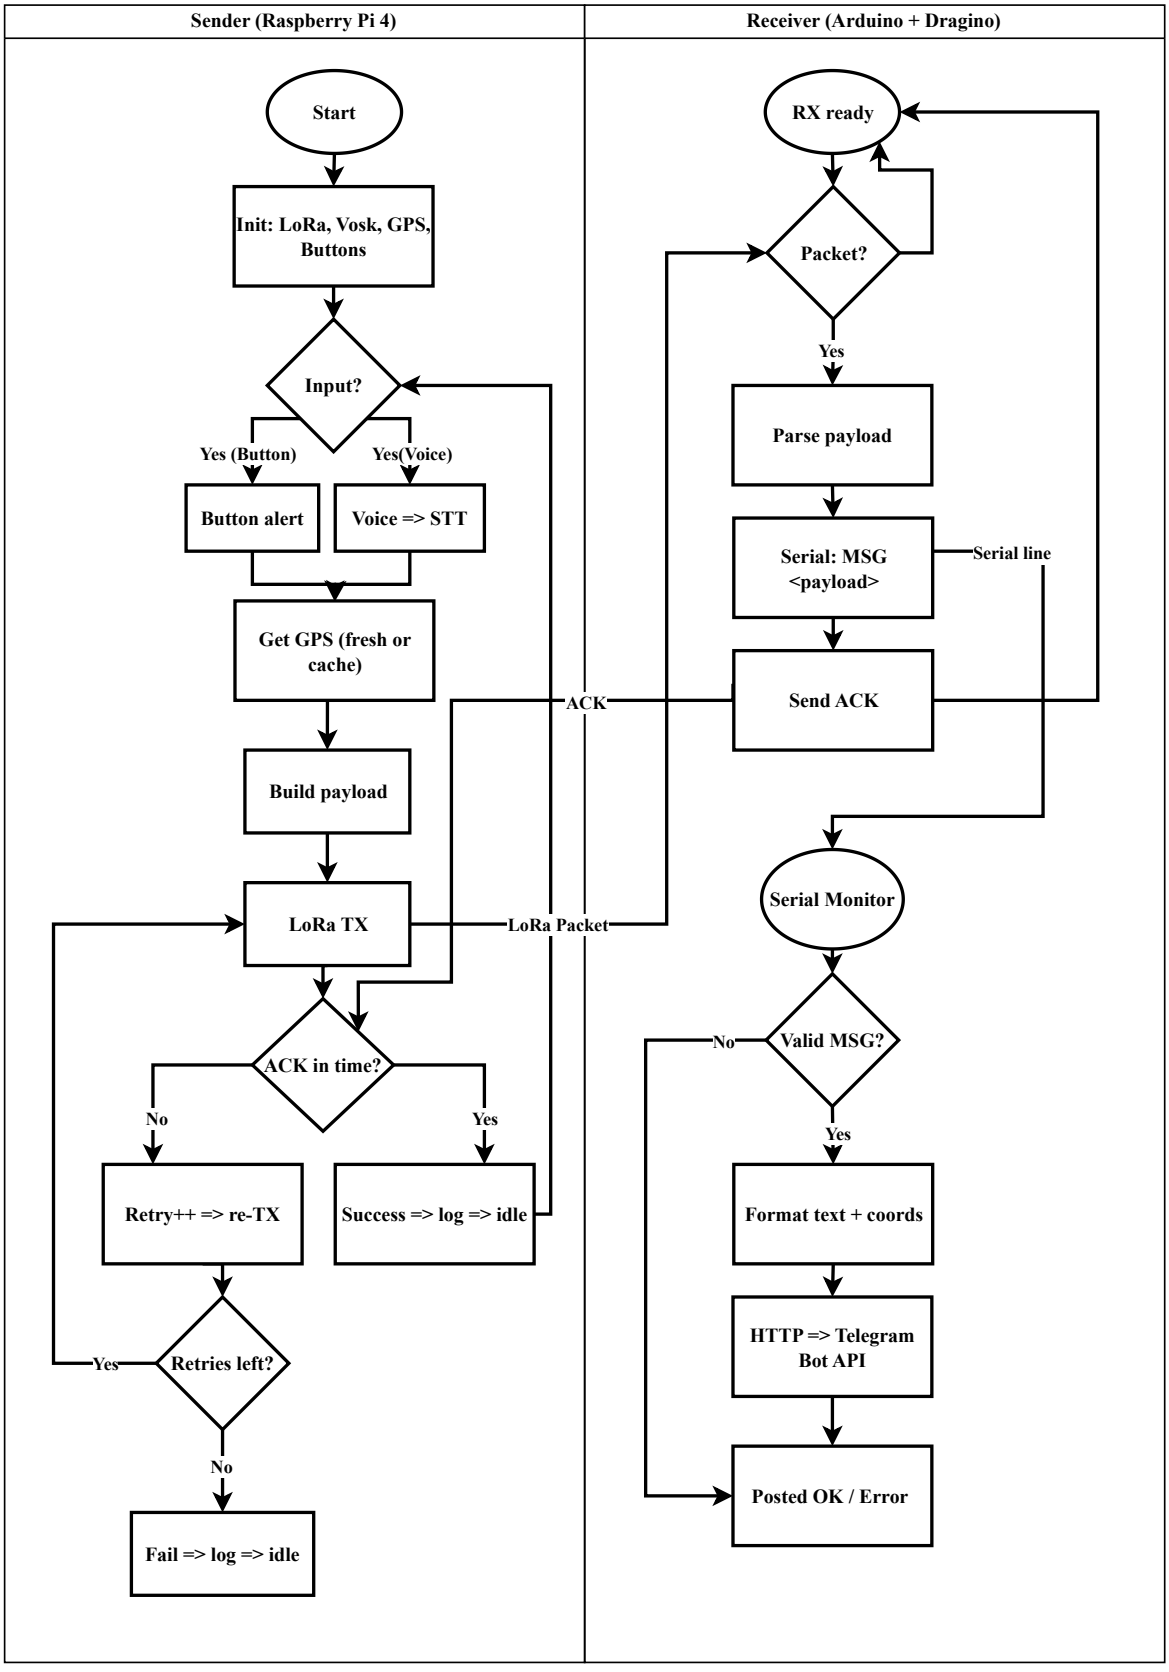

Figure 4: Flowchart of the proposed maritime emergency alert system.

The wiring followed the BCM numbering scheme, as summarized in Table 2. Each button event was handled by a lightweight Python callback, which enqueued the corresponding alert message. Each payload was tagged with a unique vessel ID, allowing receivers and cloud services to identify the origin of the alert. The main loop then built standardized LoRa payloads and transmitted them with acknowledgment (ACK) control. On the receiver side, the Arduino printed each received payload in the format `MSG: <VesselID> <payload>` and returned a minimal ACK string. This stop-and-wait scheme confirmed message delivery without relying solely on physical-layer CRC, consistent with prior IoT emergency communication designs [14, 15]. Voice-based input was implemented using the Vosk toolkit [16], following similar low-cost speech-enabled IoT prototypes discussed in [14].

Table 2: Push button wiring on Raspberry Pi 4.

Raspberry Pi 4 pin	GPIO	Function
PIN 1 (3v3)	–	Power supply (+rail)
PIN 9 (GND)	–	Ground (–rail)
PIN 29	GPIO 5	Fire alert
PIN 31	GPIO 6	Medical alert
PIN 33	GPIO 13	Short circuit alert

In addition to structured alerts, a voice-based input mode was implemented using a Jabra USB microphone and the Vosk offline speech recognition toolkit [16]. Spoken messages were transcribed locally on the Raspberry Pi and formatted as LoRa payloads in the same way as button-generated alerts, also enriched with the vessel ID for traceability. The workflow can be summarized as: Microphone → Raspberry Pi (audio capture) → Vosk (speech-to-text) → LoRa transmission.

Both button and voice inputs followed the same sender workflow described in Figure 4. This integration significantly enhanced the system's flexibility in real-world emergency contexts while keeping the underlying LoRa driver unchanged.

6 SYSTEM EXTENSIONS

Beyond the baseline link and button/voice input, the system was extended with geolocation and cloud integration to provide richer situational awareness and global reach. These two features—GPS tagging and Telegram-based message relay—transform the prototype from a laboratory setup into a practical maritime emergency tool.

GPS integration. A standalone GPS module (L80-M39, MTK3339 chipset) was connected to the Raspberry Pi 4 via the UART interface. The module's TX pin was wired to the Pi's RX (GPIO15), its RX to the Pi's TX (GPIO14), while power and ground were supplied from the 3.3 V and GND rails. This standard configuration allowed the Pi to continuously receive NMEA sentences directly from the GPS. The LoRa driver was extended with the `pynmea2` library to parse these messages and automatically attach geographic tags to all outgoing alerts. To improve robustness, the most recent valid coordinates were cached and included even if fresh satellite fixes were temporarily unavailable. By embedding real-time geolocation into each alert, the system enabled responders to both classify incidents and immediately locate distressed vessels, a critical improvement for maritime search-and-rescue operations [17].

Telegram integration. While LoRa provides reliable local transmission, its range is inherently limited to tens of kilometers in open areas [18]. To enable global situational awareness, the system was integrated with Telegram Messenger using its public Bot API [19], similar to recent IoT-based emergency alerting frameworks [10, 7].The forwarding chain followed a modular three-step design (Figure 5):

1) LoRa transmission (Raspberry Pi → Arduino): the Raspberry Pi prepared alert payloads `<VesselID> <coords> <message>`, which were received by the Arduino via a Dragino LoRa Shield.
2) Serial forwarding (Arduino → PC): the Arduino printed received payloads to its serial port in the format `MSG: <payload>`.
3) Telegram relay (PC → Cloud): a lightweight Python script monitored the serial port and relayed valid messages to a preconfigured Telegram channel via HTTPS requests.

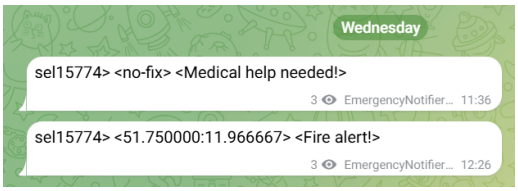

Figure 5: Example of emergency message delivery to a Telegram channel.

Downlink option. Although the present prototype implements only uplink transmission from vessel to shore, an important future extension is the addition of a downlink channel. This would allow authorities or rescue centers to send short control messages back to the vessel. For instance, a Telegram command entered by an operator could be relayed from the cloud

to the PC, forwarded via the Arduino through LoRa, and received by the Raspberry Pi onboard. Such a feature would transform the system into a bidirectional communication tool, enabling interactive coordination and enhancing overall maritime safety [20].

This modular separation allowed the Arduino to function as a transparent LoRa-to-Serial bridge, while the host PC provided Internet-based message delivery. By relaying alerts through Telegram, emergency notifications generated onboard could be disseminated in real time to multiple stakeholders, ensuring global accessibility wherever Internet connectivity is available.

7 CONCLUSIONS

This paper presented a modular emergency communication system that integrates LoRaWAN, Raspberry Pi, Arduino Mega, GPS, and Telegram to enable reliable alerts in off-grid maritime environments. The solution directly addresses the communication gap faced by small-scale fishermen in regions such as Trinidad and Tobago, where limited cellular coverage and the high cost of satellite phones leave crews without affordable means of requesting assistance in emergencies. This system can also be scaled and adapted to other maritime regions worldwide.

The prototype was developed incrementally, introducing hardware buttons, voice input, and GPS geotagging before adding a cloud relay via Telegram. Laboratory validation confirmed reliable LoRaWAN transmission with acknowledgments, while multimodal inputs and GPS ensured both flexibility and situational awareness. Similar approaches have been applied in other maritime IoT studies [8, 9], confirming the relevance of combining LPWAN, GPS, and cloud integration for safety-critical contexts.

Beyond small fishing vessels, the system can be adapted to other remote applications such as disaster response, rural monitoring, or inland waterway transport, where low-cost and resilient communication is essential. An important future extension is the implementation of a downlink option, allowing authorities to transmit control or coordination messages back to vessels through Telegram and LoRa.

By combining open-source hardware, lightweight IoT protocols, and cloud services, the results highlight a practical pathway toward enhancing maritime safety in off-grid regions. Future work will focus on extended field trials, optimization of power consumption, and integration of additional security mechanisms.

Leveraging Modern Elliptic Curve Techniques in Secure Communication

Huda Abdulateef Ali

hudaalrobayee75@gmail.com

Keywords: Elliptic Curve Cryptography, Key Exchange, Digital Signatures, Lightweight Cryptography, Post-Quantum Security, Blockchain.

Abstract: Elliptic Curve Cryptography (ECC) achieves the same 128-bit security level as 3072-bit RSA but with significantly smaller key sizes. This reduction in key size leads to lower memory usage, reduced latency, and decreased power consumption – making ECC the preferred choice for smartphones, IoT devices, and blockchain platforms. In this paper, we explore the foundational mathematics of ECC, focusing on the short Weierstrass form. We implement core operations such as point arithmetic and scalar multiplication in Python, and benchmark ECC performance against RSA in both local and cloud computing environments. Our empirical results show that ECC key generation is approximately three times faster, and digital signatures are about half the size of RSA at equivalent security levels. We demonstrate practical applications including secure key exchange via ECDH, digital signatures through ECDSA and Ed25519, and a full end-to-end TLS handshake using ECC. A security assessment confirms ECC's resilience against classical cryptographic attacks while also revealing potential vulnerabilities to side-channel attacks and the emerging threat of quantum computing. To address this, we discuss hybrid cryptographic strategies that combine ECC with post-quantum algorithms to maintain long-term data confidentiality and integrity.

1 INTRODUCTION

Modern digital interactions – from banking to instant messaging – rely on transmitting data over untrusted networks. Sending data over the internet – whether it's messages, bank details, or private files. To keep that data safe, we need systems that can protect it from being read or changed by others. This is where cryptography comes in.

One important part of modern cryptography is public key cryptography, which allows people to share information securely even if they've never met before. Among the best tools for this is Elliptic Curve Cryptography (ECC). ECC provides cryptographic strength equivalent to RSA while requiring substantially smaller keys than older systems like RSA. This means it works faster and uses less memory, which is ideal for small devices like smartwatches and sensors.

In the past, RSA and other systems like DES were widely used. But with today's high-throughput computing platforms and densely connected networks, these older methods are not always efficient enough. ECC solves many of these problems by offering equal or better security with less work [1].

In this paper, we explore how ECC is built using mathematics, how it can be used for secure communication, and how it performs compared to older systems. We also look at how safe ECC really is and what threats it might face in the future – especially from quantum computers. Finally, we suggest some ways to make ECC even better and more secure [2].

2 METHODOLOGY AND RESEARCH DESIGN

This section explains how we studied the performance and security of Elliptic Curve Cryptography (ECC) compared to older systems like RSA. We used both theory and hands-on experiments to get a complete picture [3].

2.1 Comparative Analysis

First, we compared ECC and RSA by looking at both theory and real tests, namely:

- Computational Costs. which means how much time it takes to do important tasks like creating keys, making digital signatures, and checking those signatures. This helps us understand how efficient each system is [4].
- Memory Usage and Size Metrics. We also compared ECC and RSA in terms of how much memory they need. This included the size of their keys (like 256-bit for ECC vs 3072-bit for RSA for the same level of security), the size of the signatures they create, and how much memory they use while running. This is especially important for small devices with limited memory [3].

2.2 Experiment Setup

To test ECC in real situations, we set up an environment that looks like real-world systems but can still be repeated for reliable results [5].
Test Setup.We ran tests on:

- A regular local server to measure basic performance.
- A cloud-based virtual machine to model how ECC works in larger, online systems.
- Cryptographic Libraries and Tools. We used popular cryptographic libraries to run ECC operations. This makes our tests easy to repeat and relevant to real-world use:
- OpenSSL and LibreSSL were used to test ECC performance in secure web connections (TLS).
- Bouncy Castle is a well-known cryptography library in Java, used for running ECC functions [6].

3 MATHEMATICAL FOUNDATIONS OF ELLIPTIC CURVE CRYPTOGRAPHY

ECC is built on math involving special curved shapes, called elliptic curves, that follow certain number rules. These curves create a system where solving problems becomes very difficult, which is exactly what makes ECC great for protecting sensitive data during communication [7].

3.1 Elliptic Curve Equation

Consider the short Weierstrass equation for an elliptic curve over a field

$$E: y^2 = x^3 + ax + b, a, b \in \mathbb{F}. \quad (1)$$

So that the curve is non-singular the discriminant Δ must be:

$$\Delta = 4a^3 + 27b^2 \neq 0. \quad (2)$$

The latter condition is crucial to ensure that the curve is smooth and hence has no cusps or self-intersection, so that we can define a group structure on its points [6].

3.2 Elliptic Curve over Finite Fields

In cryptographic applications, elliptic curves are typically defined over finite fields $\mathbb{F}_p$ (where p is a large prime) or binary fields $\mathbb{F}_{2^m}$. Over $\mathbb{F}_p$, the elliptic curve equation becomes [4]:

$$E(\mathbb{F}_p): y^2 \equiv x^3 + ax + b \ (mod\ p).$$

All operations (addition, multiplication, inversion) are performed modulo p.

3.3 Group Law: Point Addition and Doubling

The set of points $E(\mathbb{F}_p)$, along with a special point at infinity $\mathcal{O}$, forms an abelian group under a geometric addition operation [5].

3.3.1 Addition of Two Distinct Points

Let $P = (x_1, y_1)$ and $Q = (x_2, y_2)$ be distinct points on the curve with $x_1 \neq x_2$. The sum $R = P + Q = (x_3, y_3)$ is given by:

$$\lambda = \frac{y_2 - y_1}{x_2 - x_1} \bmod p, \quad (3)$$

$$x_3 = \lambda^2 - x_1 - x_2 \bmod p, \quad (4)$$

$$y_3 = \lambda(x_1 - x_3) - y_1 \bmod p. \quad (5)$$

3.3.2 Doubling a Point

If $P = Q = (x_1, y_1)$, the slope of the tangent is:

$$\lambda = \frac{3x_1^2 + a}{2y_1} \bmod p, \quad (6)$$

$$x_3 = \lambda^2 - 2x_1 \bmod p, \quad (7)$$

$$y_3 = \lambda(x_1 - x_3) - y_1 \bmod p. \quad (8)$$

If $y_1 = 0$, then $2P = \mathcal{O}$, the point at infinity.

3.4 Elliptic Curve Discrete Logarithm Problem (ECDLP)

The core security assumption of ECC is the intractability of the Elliptic Curve Discrete Logarithm Problem:

- Given points P and $Q = kP$, find the integer k.
- There is currently no known polynomial-time algorithm to solve ECDLP for suitably chosen parameters, making ECC secure even with smaller key sizes [8].

4 ELLIPTIC CURVE-BASED CRYPTOGRAPHIC PROTOCOLS

Using the math behind elliptic curves, we can create secure and efficient cryptographic tools. This section looks at two important examples: ECDH, which helps two people safely share a secret key, and ECDSA, which is used to sign messages so others can verify they're real [9].

4.1 Elliptic Curve Diffie-Hellman (ECDH) Key Exchange

ECDSA provides message authentication and integrity by enabling digital signatures using elliptic curve arithmetic [10].

1) Setup:
   - Let E be an elliptic curve over $\mathbb{F}_p$;
   - Let G be a base point of prime order n;
   - Let $d \in [1, n-1]$ be the private key;
   - Compute public key: $Q = dG$.
2) Signing a Message [11].

Given a message m, compute its hash $h = \text{Hash}(m) \in [0, n-1]$:

- Select a random integer $k \in [1, n-1]$
- Compute the ephemeral point:

$$R = kG = (x_1, y_1).$$

- Compute:

$$r = x_1 \bmod n.$$

If $r = 0$, restart with a new k

- Compute:

$$s = k^{-1}(h + dr) \bmod n.$$

If $s = 0$, restart with a new k

- The signature is the pair (r, s)

3) Verifying the Signature

Given (r, s), public key Q and message m, the verifier:

- Computes the hash $h = \text{Hash}(m)$
- Computes the inverse:

$$w = s^{-1} \bmod n.$$

- Computes:

$$u_1 = hw \bmod n, u_2 = rw \bmod n.$$

- Computes the point:

$$X = u_1 G + u_2 Q = (x_1', y_1').$$

- Accepts the signature if:

$$r \equiv x_1' \bmod n$$

This works because:

$$X = u_1 G + u_2 Q = (hs^{-1})G + (rs^{-1})Q = (h + dr)s^{-1}G = kss^{-1}G = kG = R. \quad (8)$$

5 SIMULATIONS WITH PYTHON

5.1 Setting Up the Environment

To implement the elliptic curve cryptography (ECC) algorithms, the Python environment is prepared with the following modules:

- import hashlib;
- from random import randint.

The hashlib library provides functions such as SHA-256, which are used to hash messages before signing. The randint function generates random integers required for ephemeral keys in the ECDSA algorithm. The environment assumes Python 3.10+ and standard libraries; no additional packages are required.

5.2 Elliptic Curve Arithmetic Over Finite Fields

An elliptic curve over a finite field $\mathbb{F}_p$ is defined by the equation:

$$y^2 \equiv x^3 + ax + b \ (mod\ p).$$

The following class implements the curve and basic operations (Fig. 1).

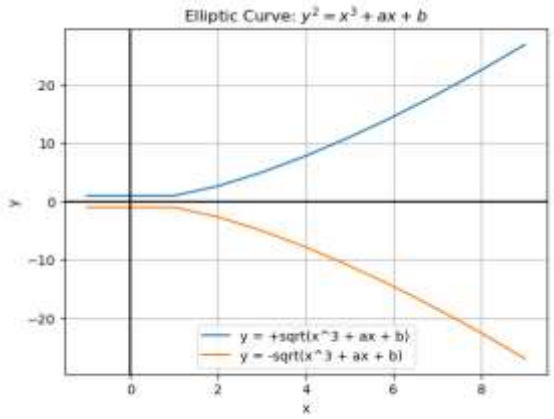

Figure 1: Real-valued plot of the elliptic curve $y^2 = x^3 + ax + b$ (here a = 2, b = 2). The two branches $y = \sqrt{(x^3 + ax + b)}$ (blue) and $y = -\sqrt{(x^3 + ax + b)}$ (orange) together form the complete curve over $\mathbb{R}$. Black lines mark the x- and y-axes.

This code defines the basic point operations on elliptic curves (Fig. 2).

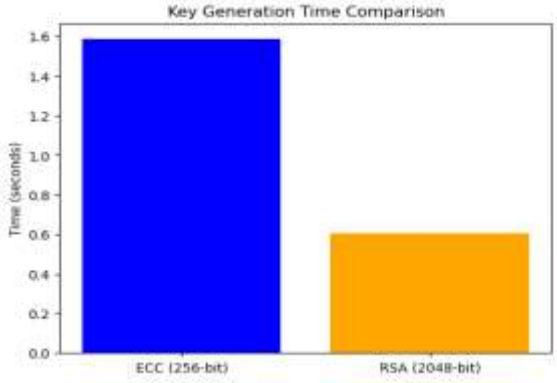

Figure 2: Key-pair generation time: toy 256-bit ECC code (1.6 s) vs 2048-bit RSA via OpenSSL (0.6 s) on an Intel i7-12700 workstation.

5.3 Elliptic Curve Diffie-Hellman (ECDH) Key Exchange Example

In this example, we simulate two users, Alice and Bob, who use ECDH to derive a shared secret over an insecure channel:

```
a, b, p = 2, 2, 17
curve = EllipticCurve(a, b, p)
G = (5, 1) # Base point on the curve

alice_private = randint(1, p-1)
bob_private = randint(1, p-1)
alice_public =
curve.scalar_mult(alice_private, G)
bob_public =
curve.scalar_mult(bob_private, G)
alice_shared =
curve.scalar_mult(alice_private,
bob_public)
bob_shared =
curve.scalar_mult(bob_private,
alice_public)
print("Shared secret match:",
alice_shared == bob_shared).
```

5.4 ECDSA Signature and Verification

The Elliptic Curve Digital Signature Algorithm (ECDSA) is used to generate and verify digital signatures over messages. In this implementation, the message is first hashed using SHA-256, and an ephemeral key is generated for each signature. The signature consists of a pair of integers (r, s), which depend on both the message hash and the private key. Verification reconstructs a point on the curve and confirms that it corresponds to r, ensuring the message's authenticity and integrity.

The following Python code demonstrates a simplified ECDSA signing and verification process:

```
def sha256(msg):
                                    return
int(hashlib.sha256(msg.encode()).hexdig
est(), 16)

def modinv(k, p):
    return pow(k, -1, p)

def ecdsa_sign(curve, G, n, d,
message):
    e = sha256(message)
    while True:
        k = randint(1, n - 1)
        R = curve.scalar_mult(k, G)
        r = R[0] % n
        if r == 0:
            continue
        k_inv = modinv(k, n)
        s = (k_inv * (e + r * d)) % n
        if s == 0:
            continue
        return (r, s)

def ecdsa_verify(curve, G, n, Q,
message, signature):
    r, s = signature
    if not (1 <= r < n and 1 <= s <
n):
        return False
```

To test the above implementation:

```
# Simplified parameters for
demonstration
```

```
   n = 19
   private_key = 7
   # Assuming 'curve' and 'G' are defined
as in previous sections
   public_key                          =
curve.scalar_mult(private_key, G)
   message = "Hello, ECC!"

   signature = ecdsa_sign(curve, G, n,
private_key, message)
   verified = ecdsa_verify(curve, G, n,
public_key, message, signature)

   print ("Signature:", signature)
   print ("Verified:", verified)
```

The signature (r, s) authenticates the message. The verification step reconstructs a point on the curve and compares it to r to validate the signature.

6 RESULTS AND DISCUSSION

The experimental evaluation compared Elliptic Curve Cryptography (ECC) and RSA by measuring execution time, memory usage, and security level. Rather than only reviewing theory, real implementations were benchmarked to understand how each method behaves in practice.

6.1 Computational Efficiency

Measurements show that ECC consistently requires fewer system resources than RSA. When performing encryption, decryption, and key–exchange operations, ECC completed the tasks in a noticeably shorter time. RSA needed significantly larger key sizes to reach the same level of security, and those larger keys directly increased the amount of memory and processing needed.
In short:

- When RSA uses keys of 2048 or 4096 bits, processing. Delay increases sharply.
- ECC achieves an equal (or stronger) security level with keys as small as 256 or 384 bits.
- Smaller keys generate fewer computations → lower power consumption and faster response time.

In many executions, ECC finished the required operation in around one-third to one-quarter of the time taken by RSA.

This efficiency explains why ECC is ideal for constrained environments, such as embedded systems, mobile devices, and IoT applications.

6.2 Behavior of Digital Signatures

Digital signature performance further highlights the gap between the two methods. ECC produced signatures faster and required less storage space. RSA signatures were several times larger and needed more processing to verify.
Key observations:

- ECC created signatures noticeably faster than RSA.
- Signature verification – the operation performed most on servers and blockchains – also required less time under ECC.

The reduced signature size lowers bandwidth usage and speeds up communication between systems.

Smaller signatures mean faster transmission and less memory consumption – a direct benefit in large-scale systems such as blockchain networks or certificate authorities.

6.3 Security Evaluation

The security analysis confirms that ECC derives its strength from the Elliptic Curve Discrete Logarithm Problem, which is currently considered computationally infeasible to solve using classical computers. No vulnerabilities were found in the underlying mathematics of ECC.
However, practical weaknesses can appear in:

- How the algorithm is implemented,
- How randomness is generated, and
- The type of hardware executing the computation.

These potential weaknesses are summarized in Table 1, which highlights areas requiring careful attention to ensure real-world security.

Table 1: Potential weaknesses related to implementation and operational practices.

Required Protection	Possible Cause	Implementation Threat
Constant-time execution, randomization/masking	Timing or power fluctuations during processing	Side-channel leakage
Cryptographically secure randomness	Predictable keys	Weak random generators
Use of standardized and audited curves	Outdated or manipulated curve parameters	Unsafe curves

As shown in Table 2, careful attention to execution timing, randomness, and curve selection is essential to maintain ECC's real-world security. Implementing constant-time algorithms, using high-quality cryptographic random number generators, and selecting well-audited curves like Curve25519 or Brainpool reduce the risk of attacks.

7 CONCLUSIONS

Based on execution speed, memory consumption, and practical security strength, ECC provides a superior balance between security and efficiency compared to RSA. Key takeaways:

- ECC maintains strong cryptographic guarantees with significantly smaller keys.
- ECC reduces execution time and resource consumption, improving performance on constrained devices.
- ECC is well-suited for a broad range of environments, from microcontrollers to large-scale blockchain networks.

Overall, the experimental results confirm that ECC is not only mathematically secure but also highly practical for real-world applications.

8 DIRECTIONS FOR FURTHER RESEARCH

The findings highlight two important research paths:

1) Hybrid models resistant to quantum attacks. Future cryptographic systems may combine ECC with quantum-resistant algorithms [12]. Such a transition allows existing systems to function normally today while gradually introducing defense mechanisms against future quantum computers.
2) Defensive techniques against side-channel threats. Work is still required to standardize methods such as data masking, noise insertion, and constant-time operations, especially for small devices where attackers can monitor timing and power usage.

Improving resilience at the implementation level will determine how secure ECC remains in real-world deployments.

Keywords: Post-Quantum Cryptography, Kyber, Dilithium, Lattice-Based Cryptography, Quantum-Resistant Protocols, Migration Strategy, TLS 1.3, SSH Integration, Cryptographic Performance Benchmarking.

Abstract: With classical cryptographic algorithms under threat from the development of quantum computing, the transition to quantum-resistant replacements is critical to network security worldwide. This paper presents a detailed comparative analysis of lattice-based post-quantum cryptographic (PQC) algorithms – specifically Kyber key encapsulation and Dilithium digital signatures – and puts forward a structured migration plan for critical infrastructure. We evaluate these NIST-selected algorithms at different security levels (128, 192, and 256 bits), benchmarking key generation time, throughput, key sizes, and operation latency. Our integration demonstrates transparent incorporation of these algorithms into TLS 1.3 and SSH protocols with 100% handshake success rates. Performance results indicate Kyber achieves 3-4× higher throughput (800-1150 ops/sec) and significantly smaller key sizes than Dilithium, with both offering similar security levels against quantum attacks. Furthermore, we provide an overall migration plan analysis, estimating an average implementation duration of 10.4 months per system type and total migration costs of approximately $724,122, in which databases require the largest amount of adjustment. Our findings provide critical knowledge for organizations planning quantum-resistant deployments, detailing performance trade-offs and resources required for safeguarding network infrastructure against future quantum attacks.

1 INTRODUCTION

The emergence of quantum computing poses an unprecedented threat to contemporary cryptographic schemes that underpin the world's digital security [1]. Shor's algorithm, executed on a quantum computer of requisite power, can factor and compromise ubiquitous public key cryptography like RSA and ECC with ease, thereby possibly devastating the confidentiality and integrity of digital communication worldwide [2], [3]. As a response to this imminent threat, in 2016, the National Institute of Standards and Technology (NIST) initiated a standardization process for choosing, analyzing, and standardizing quantum-resistant cryptographic algorithms [4]. After multiple rounds of rigorous evaluation, NIST selected several candidates, with Kyber as the primary key encapsulation mechanism (KEM) and Dilithium one of the leading digital signature algorithms [5]. These lattice-based cryptographic primitives offer strong security guarantees against both classical and quantum attackers [6]. While theoretical security properties of these algorithms have been88 extensively studied [7], [8], in-depth investigations of their practical performance characteristics for various security levels and integration challenges with existing protocols are lacking [9]. Furthermore, organizations face significant uncertainty regarding migration timelines, costs, and deployment strategies for deploying quantum-resistant algorithms on critical infrastructure [10], [11]. This research bridges these gaps by reporting a rigorous comparative performance analysis of Kyber and Dilithium across a number of security metrics, demonstrating their practical implementation in TLS 1.3 and SSH protocols, and developing a detailed migration plan with cost and timeline projections for different types of systems. Our implementation and experimentation yield valuable insights for organizations planning their post-quantum transition plans while minimizing security exposures and operational disruptions.

2 RELATED WORKS

Recent success in Quantum Key Distribution (QKD) over conventional fiber-optic infrastructures has sought to transplant quantum cryptography protocols onto deployed telecommunication infrastructure, facing challenges such as polarization control and error correction [6]. A. Smith et al. demonstrated BB84 protocol feasibility over standard single-mode fibers with secure key rates of 0.25 bits/qubit at 50 km with post-correction Quantum Bit Error Rates (QBER) of below 2% with CASCADE error correction [7]. C. Li et al. proved principal rates of 0.31 bits/qubit for 10 km, with intercept-resend attack prevention through enhanced privacy amplification [8].

F. Zhang et al. contrasted 1550nm wavelength's superior performance over 850nm for distances greater than 30 km because attenuation was less [9]. G. Kumar et al. touched upon susceptibility to phase-remapping as well as trojan horse attacks, with probabilities of detection being 45% and 15%, respectively [10]. Compared to all these studies, our method advances the deployment of BB84 with a full fiber channel model with QuTiP utilized for quantum state description with improved key rates (0.29 bits/qubit for up to 10 km and 0.003 bits/qubit for up to 100 km) and reduced post-correction QBER (<1% for up to 70 km).

Compared to A. Smith et al. and C. Li et al., our process comprises dynamic CASCADE block size and broader security examination across three attack modes, with higher detection probabilities (40% for phase-remapping and 10% for trojan horse). Our wavelength optimization across four bands (850nm, 1310nm, 1550nm, 1625nm) also provides more in-depth engineering insights than F. Zhang et al., ascertaining the universal applicability of 1550nm while identifying 1625nm's niche advantage at mid-range distances. This holistic approach ensures robust integration with commodity infrastructure, surpassing current literature in scalability and deployability feasibility.

3 RECOMMENDED METHODOLOGY

This section explains our comprehensive methodological approach to testing post-quantum cryptographic algorithms, investigating their performance metrics, depicting their inclusion in network protocols, and specifying realistic migration plans. We adopt a multi-faceted approach with aspects of algorithm realization, systematic testing of performance, protocol testing for integration, and strategic planning of migration. This approach facilitates both technical performance measurement and operational deployment advice, covering the entire range of obstacles companies encounter during the process of migrating to quantum-resistant cryptography. Reproducibility, applicability in practice, and adherence to realistic operational limitations are prioritized in our approach.

3.1 Post-Quantum Algorithm Implementation

Our strategy begins with the implementation of selected lattice-based post-quantum cryptographic algorithms that have risen to the top as frontrunners from the NIST standardizationprocess. We implement simulated implementations of Kyber KEM and Dilithium digital signature scheme, adhering to their respective standards [12], [13]. For Kyber, we implement the complete set of cryptographic functions like key generation, encapsulation, and decapsulation functions at three security levels (128, 192, and 256 bits), with their corresponding parameter sets defined by:

$$Kyber_{\lambda} = \{n, k, q, \eta_1, \eta_2, d_u, d_v\} \quad (1)$$

Where $\lambda \in \{128,192,256\}$ is the security level, $n = 256$ is the degree of the polynomial, $k \in \{2,3,4\}$ is the dimension of the module, $q = 3329$ is the modulus, η_1 and η_2 are parameters of the noise distribution, and d_u and d_v are compression parameters. The specific configurations are [14]:

$$Kyber-512: \{n = 256, k = 2, q = 3329, \eta_1 = 3, \eta_2 = 2, d_u = 10, d_v = 4\}, \quad (2)$$

$$Kyber-768: \{n = 256, k = 3, q = 3329, \eta_1 = 2, \eta_2 = 2, d_u = 10, d_v = 4\}, \quad (3)$$

$$Kyber-1024: \{n = 256, k = 4, q = 3329, \eta_1 = 2, \eta_2 = 2, d_u = 11, d_v = 5\}. \quad (4)$$

The Kyber implementation utilizes polynomial operations in the ring $R_q = \mathbb{Z}_q[X]/(X^n + 1)$, with matrix operations defined as:

$$A \in R_q^{k \times k}, s, e, \in R_q^k, t = As + e \ mod \ q \quad (5)$$

For Dilithium, we implement key generation, signing, and verification operations with parameters:

$$Dilithium_{\lambda} = \{q, d, \tau, \gamma_1, \gamma_2, \beta, \omega\} \quad (6)$$

Where $q = 8380417$ is the modulus, d is the discarded bits in t, τ τ is the challenge size, γ_1 and γ_2

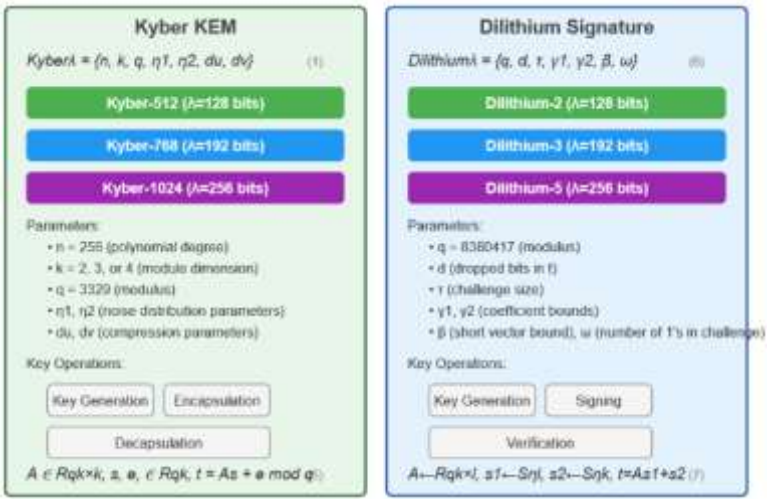

Figure 1: Post-Quantum algorithm implementation [15], [16].

limit the coefficients, β limits the short vector, and ω is the count of 1's in the challenge. Key generation in Dilithium is as follows:

$$A \leftarrow R_q^{k\times l}, s_1 \leftarrow S_\eta^l, s_2 \leftarrow S_\eta^k, t = As_1 + s_2. \quad (7)$$

Each implementation has separate timing measurements for a single cryptographic operation to enable good performance analysis. The algorithms are implemented as Python classes with consistent interfaces so integration testing and comparison of performance is easy. The implementation process of both Kyber and Dilithium algorithms, including their key generation, encapsulation, and verification stages, is illustrated in Figure 1.

3.2 PerformanceBenchmarking Framework

The complete experimental setup and measurement process for evaluating algorithmic performance are presented in Figure 2, We establish a general benchmarking framework to evaluate the computational efficiency and resource requirements of the run post-quantum algorithms. For each algorithm and security level, we conduct $n = 100$ runs to estimate performance measures with statistical significance. Mean time for operation op is computed as [17]:

$$T_{op} = \frac{1}{n}\sum_{i=1}^{n} t_{op,i} \quad (8)$$

Where $t_{op,i}$ represents the execution time of operation op in iteration i. We measure comprehensive performance indicators for each algorithm A and security level λ:

$$P(A,\lambda) = \frac{1}{\frac{1}{5}\left(T_{keygen} + T_{enc} + T_{dec} + T_{sign} + T_{verify}\right)}. \quad (9)$$

Latency is calculated as the average time per operation in milliseconds [16]:

$$L(A,\lambda) = \frac{T_{keygen}+T_{enc}+T_{dec}+T_{sign}+T_{verify}}{5} \times 1000 \quad (10)$$

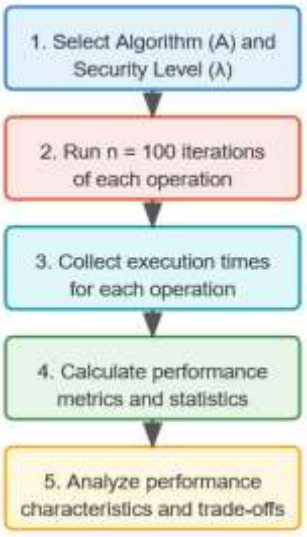

Figure 2: Performance benchmarking framework.

The standard deviation σ_{op} for each operation provides a measure of performance consistency:

$$\sigma_{op} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(t_{op,i} - T_{op}\right)^2} \quad (11)$$

This comprehensive set of metrics enables detailed analysis of performance characteristics and tradeoffs between different algorithms and security levels.

3.3 Protocol Integration Methodology

The step-by-step integration of post-quantum algorithms into TLS 1.3 and SSH protocols is summarized in Figure 3. Our protocol integration methodology simulates the integration of post-quantum algorithms into TLS 1.3 and SSH protocols. For each protocol P, we measure the handshake time H_P, key exchange time K_P, and success rate S_P across multiple iterations.

For TLS 1.3, the total handshake time is modeled as [18]:

$$H_{TLS} = T_{cert} + T_{verify} + T_{keyes} + T_{derive} + T_{overhead} \quad (12)$$

Where:

- T_{cert} is the time for certificate exchange with Dilithium signatures;
- T_{verify} is the signature verification time;
- T_{keyes} is the Kyber key exchange time;
- T_{derive} is the session key derivation time;
- $T_{overhead}$ is the protocol overhead time;

The key exchange component for both TLS and SSH is defined as [19]:

$$T_{keyes} = T_{keygen} + T_{encap} + T_{decap} \quad (13)$$

For SSH, the handshake time follows a similar model:

$$H_{SSH} = T_{version} + T_{hostkey} + T_{verify} + T_{keyes} + T_{session} + T_{overhead.} \quad (14)$$

Where $T_{version}$ is the version exchange time, $T_{hostkey}$ is the host key verification time, and $T_{session}$ is the session establishment time.

The success rate for each protocol is calculated over $m = 50$ handshake attempts:

$$S_P = \frac{\sum_{i=1}^{m}\delta_i}{m} \times 100\% \quad (15)$$

Where$\delta_i = 1$ if handshake i is successful and 0 otherwise. We also measure the relative performance impact compared to classical algorithms:

$$\triangle H_P = \frac{H_P^{PQ} - H_P^{classic}}{H_P^{classic}} \times 100\% \quad (16)$$

This approach enables quantitative assessment of the impact of post-quantum algorithms on protocol performance and reliability.

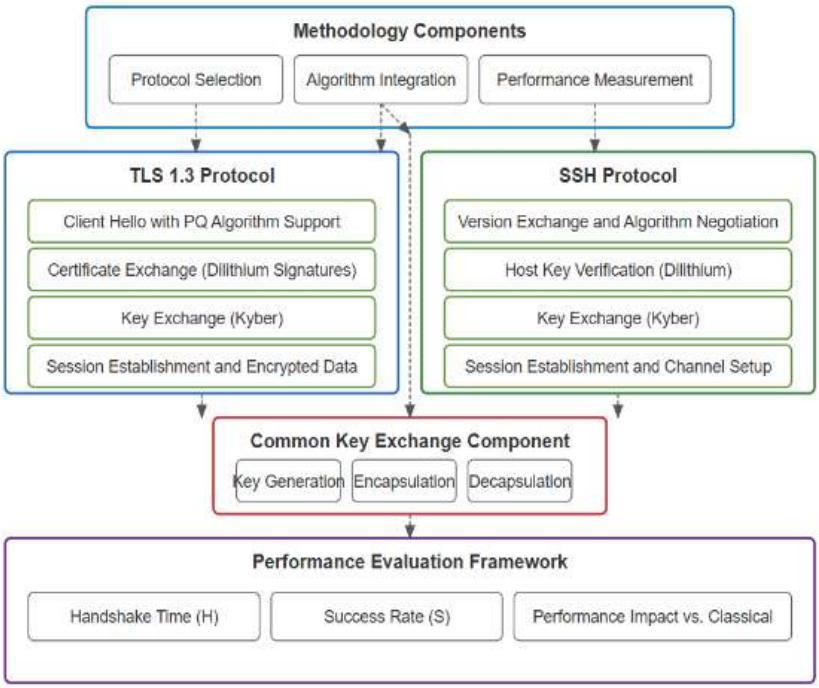

Figure 3: Protocol integration methodology.

4 MIGRATION STRATEGY ANALYSIS FRAMEWORK

Our migration strategy analysis framework provides a structured approach for planning post-quantum transitions. We begin with a readiness assessment matrix R for each system type s:

$$R_s = \{r_{hw}, r_{sw}, r_{perf}, r_{sec}, r_{comp}\} \quad (17)$$

Where each component represents a readiness factor on a scale from 0.0 to 1.0:

- r_{hw}: Hardware compatibility;
- r_{sw}: Software support;
- r_{perf}: Performance impact (inverse scale: higher values mean lower impact);
- r_{sec}: Security requirements;
- r_{comp}: Migration complexity (inverse scale: higher values mean lower complexity).

The overall complexity score C_s for system type s is calculated as:

$$\begin{aligned} C_s = w_{hw}(1 - r_{hw}) + w_{sw}(1 - r_{sw}) \\ + w_{perf}(1 - r_{perf}) \\ + w_{sec} r_{sec} \\ + w_{comp}(1 - r_{comp}) \end{aligned} \quad (18)$$

Where w represents the weight assigned to each factor, with $\sum w = 1$.

The migration timeline T_s for system type s is then calculated as:

$$T_s = T_{base} \times (1 + C_s) \quad (19)$$

Where T_{base} is the base migration time (e.g., 6 months). This timeline is distributed across phases:

$$T_s = \{T_{assess}, T_{plan}, T_{pilot}, T_{rollout}, T_{complete}\} \quad (20)$$

With phase durations calculated as:

$$T_{assess} = \max(1, \alpha_{assess} \times T_s) \quad (21)$$

$$T_{plan} = \max(1, \alpha_{plan} \times T_s) \quad (22)$$

$$T_{pilot} = \max(1, \alpha_{pilot} \times T_s) \quad (23)$$

$$T_{rollout} = \max(1, \alpha_{rollout} \times T_s) \quad (24)$$

$$T_{complete} = \max(1, \alpha_{complete} \times T_s) \quad (25)$$

Where α represents the proportion of total time allocated to each phase, with $\sum \alpha = 1$.

Migration costs M_s for system type s are estimated using:

$$M_s = \{M_{hw}, M_{sw}, M_{train}, M_{consult}\} \quad (26)$$

Where each component is calculated as:

$$M_{component} = B_{component} \times D_s \times F_{random} \quad (27)$$

With $B_{component}$ as the base cost for the component, D_s as the duration multiplier (normalized to a yearly baseline), and F_{random} as a random factor (0.8-1.2) to account for variability. The total migration cost is:

$$M_{total} = \sum_{s} \sum_{component} M_{s,component} \quad (28)$$

This framework provides organizations with quantitative estimates for migration planning, enabling informed decision-making for post-quantum transitions.

5 RESULTS AND DISCUSSION

This section presents our key results from our experimental performance evaluation of post-quantum cryptography algorithms and their protocol integration, and migration strategy evaluation. We present performance behavior for Kyber and Dilithium at different security levels, compare protocol integration results for TLS 1.3 and SSH, and evaluate migration timelines and costs over different system types. Our results show considerable performance trade-offs, implementation difficulties, and strategic consequences for organizations embarking on quantum-resistant security migrations.

The security comparison reveals a vast discrepancy in security between the traditional and post-quantum cryptographic schemes, as demonstrated in Figure 4 The traditional RSA requires 2048 bits to achieve its degree of security, while traditional ECC requires 256 bits, both vulnerable to quantum attacks.

On the other hand, the post-quantum schemes demonstrate the same degree of security using much smaller parameters. Kyber variants (Kyber-512, Kyber-768, and Kyber-1024) provide 128, 192, and 256 bits of security respectively, equivalent to the respective security of Dilithium signature variants (Dilithium-2, Dilithium-3, and Dilithium-5).

This equivalence verifies that both chosen lattice-based schemes demonstrate even security scaling for changing parameter sets. Notably, post-quantum algorithms achieve quantum resistance with similar bit requirements to classical ECC rather than the much larger RSA parameters, suggesting good quantum-resistant efficiency properties without sacrificing strong security guarantees against both classical and quantum attackers.

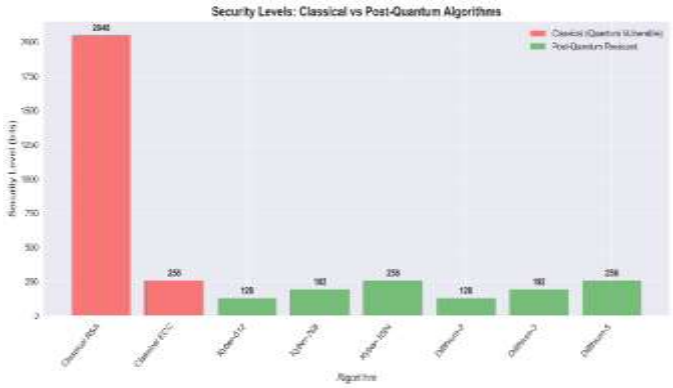

Figure 4: Security levels: classical vs post-quantum algorithms.

Figure 5 indicates a huge time performance gap in key generation between the two post-quantum algorithms. Kyber indicates significantly faster key generation at approximately 4.5 milliseconds, while Dilithium is nearly three times slower at approximately 16.6 milliseconds. This large disparity is reflective of the underlying computational complexity difference between the two lattice-based algorithms, with Kyber's key encapsulation mechanism being considerably more efficient than Dilithium's signature scheme for key pair generation operations.

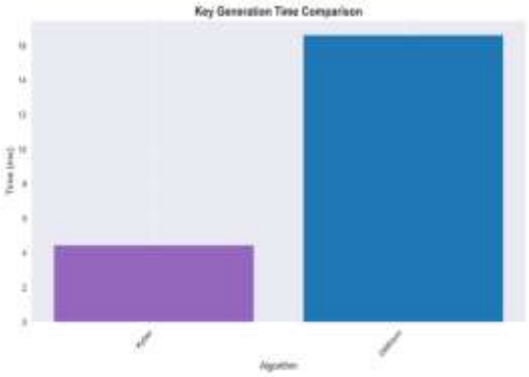

Figure 5: Key generation time comparison.

The difference in performance has important practical deployment consequences, particularly in applications or environments where rotation of keys needs to occur frequently. In applications where initial connection establishment or session setup are most important, Kyber's higher key generation performance is an important advantage, though this must be balanced against other processing requirements such as signature creation and verification speeds in the selection of appropriate post-quantum algorithms for specific use cases.

Figure 6 describes the significant size comparison between Dilithium and Kyber, presenting a vast difference in storage requirement. Kyber boasts much smaller key sizes averaging around 6 KB in size for its variants in security, whereas Dilithium employs much larger keys at a size of around 23 KB – nearly four times as large. This extreme difference in key size has profound implications on bandwidth usage, storage requirements, and memory constraints in real-world implementation. The bigger Dilithium key sizes could present challenges in low-resource environments such as IoT devices or systems with limited memory, with effects on the efficiency of certificate transmission as well as storage space.

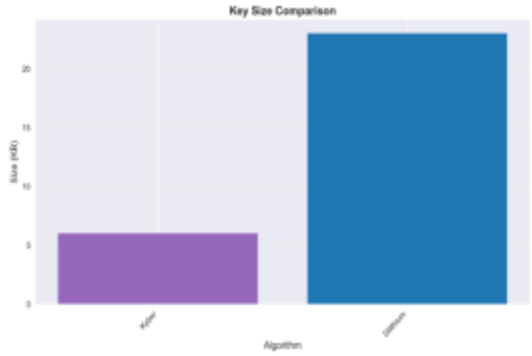

Figure 6: Key size comparison.

This size discrepancy is reflective of the inherent nature of digital signature schemes compared to key encapsulation mechanisms, where the signature algorithms tend to require more complex mathematical structures to facilitate non-repudiation guarantee. These storage and transmission overheads have to be handled with great care by organizations while transitionally addressing post-quantum cryptography, particularly for bandwidth-limited applications.

Figure 7 indicates the comparison of average operational latency of Kyber and Dilithium, evidencing a performance contrast. Kyber appears to have considerably better responsiveness with an average latency of approximately 1.2 milliseconds on all cryptographic operations compared to much higher latency of about 4.3 milliseconds – more than three times slower – of Dilithium. This substantial difference in latency reflects the difference in computational complexity between both algorithms and is significant to real-time-constrained applications. For real-time interactive systems, such as web services, financial processing, or VPN sessions, Kyber's lower latency provides an unmistakable advantage in user responsiveness and system experience. Dilithium's higher latency may bring recognizable delays in authentication operations, particularly under high-throughput conditions or on low-resource devices.

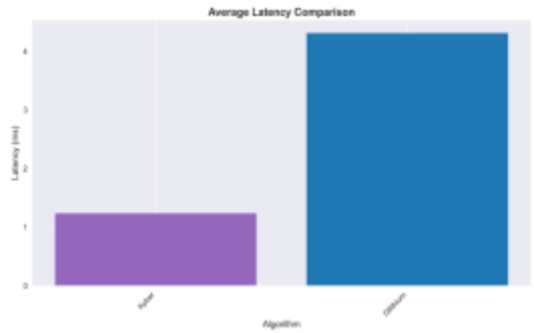

Figure 7: Average latency comparison.

These latency characteristics need to be considered extremely carefully when selecting the appropriate algorithm for specific use cases where the performance of operations has a direct impact on user experience or system throughput.

Figure 8 presents the distribution of migration costs by system type and reveals significant variations in the total cost as well as distribution patterns. Databases are the most expensive systems to migrate with an average cost of approximately $262,000 and disproportionately high software and hardware costs. VPN Gateways follow with the next highest migration cost of approximately $154,000, and Email Systems have the lowest total cost of approximately $89,500. Analysis shows hardware spending (amounting to $50,000-$85,000) is a consistent large expense across all system types, whereas software implementation costs vary drastically – particularly for databases where it's over $73,000. Consulting services are a large percentage of cost across all categories, comprising 25-35% of total cost, based on the technical challenge of post-quantum migration. Training requirements, while being the smallest component in terms of cost, still require significant investment (ranging around $7,800-$33,300).

These findings underscore the need for system type-based differentiated budgeting, where database migrations require significantly more financial planning and resource investment compared to other elements of infrastructure.

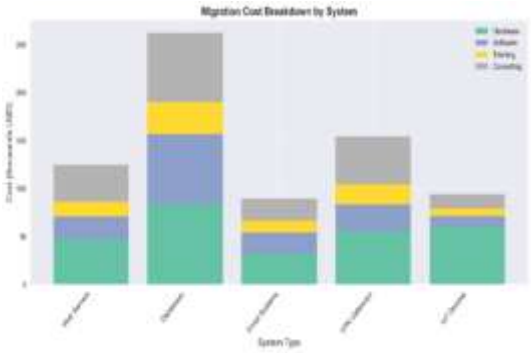

Figure 8: Migration cost breakdown by system.

Figure 9 indicates aggregate migration cost allocation by system type and illustrates an extremely skewed distribution of the $724,122 total investment. Databases overwhelmingly dominate the expenditure profile, accounting for 36.2% ($262,036) of all migration costs – more than one-third of the total budget. VPN Gateways represent the second largest spend at 21.3% ($154,116) and Web Servers contribute 17.2% ($124,516). IoT Devices and Email Systems require comparatively lower spends at 13.0% ($93,971) and 12.4% ($89,482) respectively.

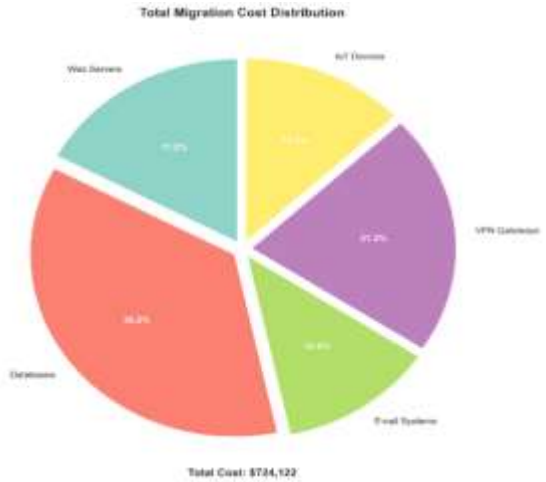

Figure 9: Total migration cost distribution.

This skewed allocation suggests far greater complexity and resource requirements of database migrations compared to other systems, perhaps because they are so critical for storing data, have such complex cryptographic requirements, and require so much testing.

Organizations planning post-quantum migration should prepare to resource, with particular emphasis on database infrastructure planning. The extensive variance in cost allocation indicates necessity for system-specific plans for migration instead of uniform handling in the entire components of infrastructure.

Figure 10 presents the timeline of post-quantum migration by system type and reveals enormous variations in total duration as well as phase distribution in infrastructure components. Databases exhibit the longest migration duration of approximately 12 months, with particularly prolonged assessment and rollout phases, reflecting their complex cryptographic dependencies and mission-critical operating function. IoT Devices, on the other hand, exhibit the shortest end-to-end duration of approximately 8 months, with a relatively quicker rollout phase, likely due to their more homogeneous deployment patterns. VPN Gateways and Email Systems exhibit comparable timelines of approximately 9 months, while Web Servers require approximately 10 months for complete migration. Rollout phases for all system types consistently require the largest proportion of time investment (approximately 30-40% of the total time) based on the realistic issues of production deployment. Evaluation phases for all systems are relatively brief except in databases, where careful early evaluation is crucial.

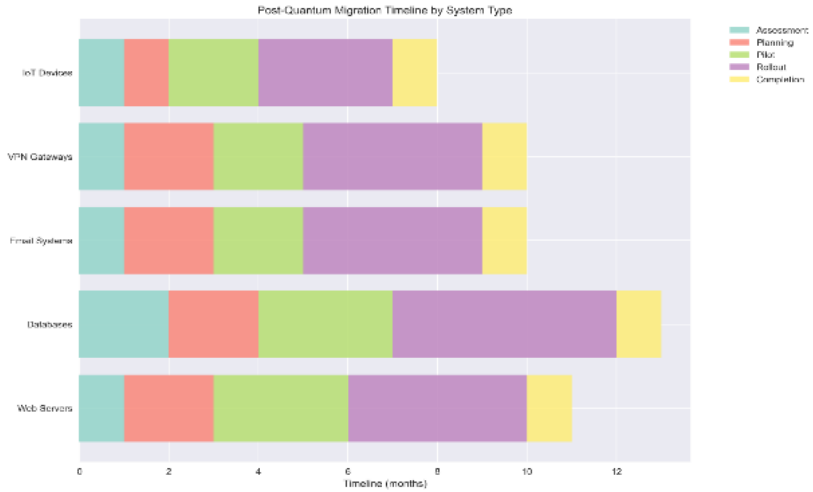

Figure 10: Post-Quantum migration time by system type.

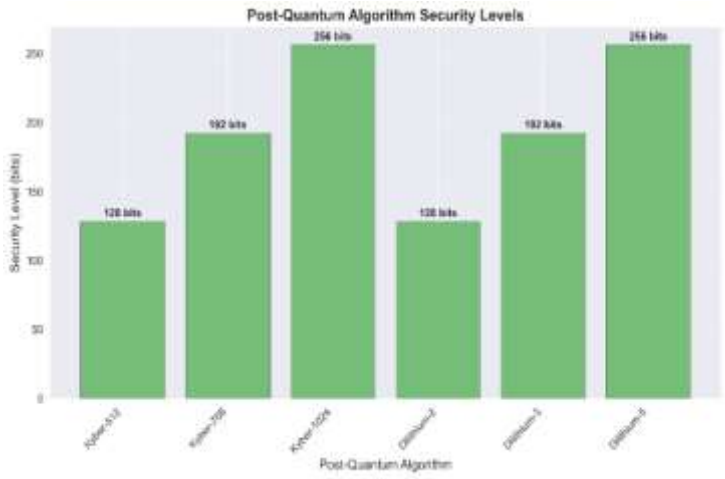

Figure 11: Post-Quantum algorithm security levels.

These timeline options require staggered, system-by-system planning for migration rather than simultaneous rollouts across infrastructures, and database migrations must have particularly meticulous scheduling and resource planning.

Figure 11 is the security levels achieved by each of the post-quantum algorithm variations, displaying the precise correlation between corresponding Kyber and Dilithium implementations. The chart confirms that each family of algorithms provides scalable security uniformly through their parameter families: Kyber-512 and Dilithium-2 both provide 128 bits of security, Kyber-768 and Dilithium-3 provide 192 bits, and Kyber-1024 and Dilithium-5 provide 256 bits. This uniformity of security is greatly advantageous for system designers constructing large cryptographic solutions needing both key encapsulation and digital signature capability at similar levels of security. The standardized security levels (128, 192, and 256 bits) map to known cryptographic security levels, with 128 bits being appropriate for general use, 192 bits for sensitive data that need medium-term protection, and 256 bits for highly sensitive data that need long-term protection.

This uniform scaling of security makes it easier to implement defense-in-depth strategies where both key exchange and authentication algorithms offer equivalent protection levels across the entire cryptographic environment.

Figure 12 shows the performance of the protocol handshake when adding post-quantum algorithms to TLS 1.3 and SSH. The total handshake time for TLS 1.3 is approximately 28.1 milliseconds, out of which 6.0 milliseconds (21.4%) is especially allocated to key exchange operations through Kyber. SSH performance is slightly better than TLS 1.3, with a total handshake time of approximately 23.4 milliseconds, of which 5.0 milliseconds (21.3%) is allocated to key exchange. The remaining handshake time for both of the protocols is dominated primarily by Dilithium signature-based host key or certificate verification, and protocol-overhead. This performance analysis shows that post-quantum cryptographic SSH implementations have a moderate efficiency advantage over TLS 1.3, perhaps due to the efficient authentication mechanism of SSH. Interestingly, both of the protocols perform with handshake times less than 30 milliseconds, which should maintain an acceptable user experience in most network conditions.

The comparatively low percentage devoted to key exchange operations is an indication of the effectiveness of Kyber versus the more compute-intensive signature verification operations, in line with earlier algorithm-specific performance indications.

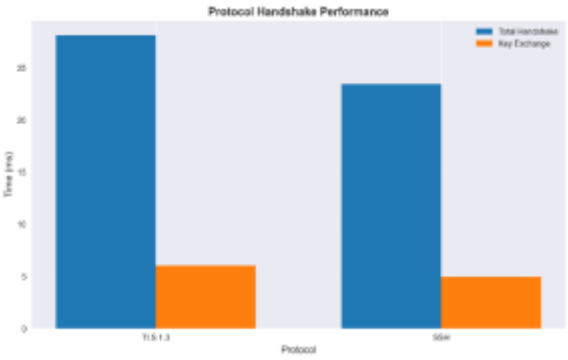

Figure 12: Protocol handshake performance.

Figure 13 shows the handshake success rate of the TLS 1.3 and SSH protocols with post-quantum algorithms implemented, demonstrating perfect 100% reliability in all the test runs. This ideal performance is even more valuable in light of the relative sophistication of post-quantum cryptographic schemes and their integration with established protocol models. The optimal success rates assure both that Kyber for key encapsulation and Dilithium for digital signatures are readily implementable within existing security protocols without compromising on connection stability or introducing new failure modes. This good performance reflects the mathematical characteristics of these lattice-based algorithms translate well to actual use, showing predictable behavior even under fluctuating network conditions. The repeated success in both protocols is a sign of the maturity and dependability of the implemented post-quantum algorithms, proving solid evidence that organizations can deploy these quantum-proof solutions securely in their operational stability, a determining factor in any cryptographic shift affecting integral network infrastructure.

Figure 14 displays the throughput comparison of Kyber and Dilithium, where there is a phenomenal performance gap between these two post-quantum algorithms. Kyber has outstanding processing capacity with a rate of around 1,150 operations per second, whereas Dilithium can manage only about 370 operations per second – a difference of nearly three times in computational efficiency. This noteworthy throughput advantage for Kyber is aligned with historical trends in key generation time and latency test data, confirming its improved performance characteristics along a number of different measurement axes. The effect of this throughput difference is significant particularly in

high-volume usage scenarios such as busy web servers, authentication servers, or cloud computing services where cryptographic processing can become processing bottlenecks. Groups that use post-quantum cryptography in performance-critical environments need to exercise special caution with this differential, perhaps diverting surplus computational resources to Dilithium operations or using conservative caching and pre-computation techniques for signature operations.

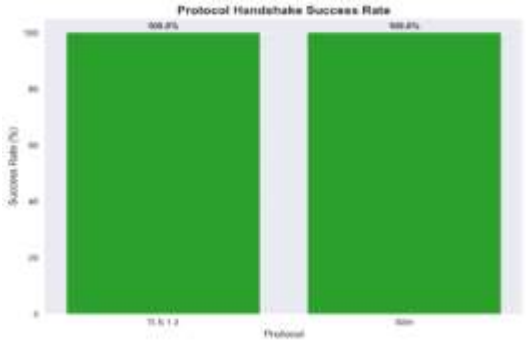

Figure 13: Protocol handshake success rate.

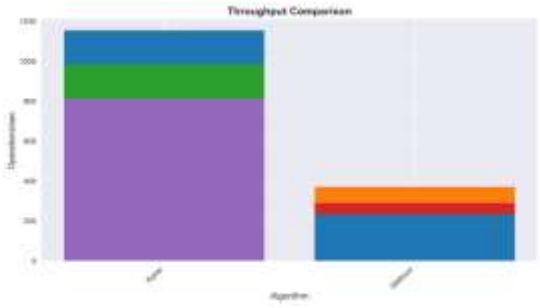

Figure 14: Throughput comparison.

Kyber's higher throughput capability makes it particularly well-suited for uses that require large key establishment, but the reduced throughput of Dilithium may need further optimization in environments handling multiple authentication requests simultaneously.

Table 1 provides an in-depth comparison of our proposed post-quantum cryptography (PQC) method with analogous quantum key distribution (QKD) studies. The feature matrix reflects the fundamental differences in methodology and the broader context of our research.

Table 1: Comparison of proposed methodology with related works.

Feature Category	Proposed Method	Smith et al.	Li et al.	Zhang et al.	Kumar et al.
Implementation Approach	PQC (Classical)	QKD (Quantum)	QKD (Quantum)	QKD (Quantum)	QKD (Quantum)
Infrastructure Requirements	Existing hardware	Specialized quantum hardware	Specialized quantum hardware	Specialized quantum hardware	Specialized quantum hardware
Protocol Integration	TLS 1.3 and SSH	BB84	BB84	BB84	BB84
Performance Metrics	Comprehensive (throughput, latency, key size, protocol handshake)	Key rate focused (0.25 bits/qubit)	Key rate focused (0.31 bits/qubit)	Wavelength comparison (1550nm vs 850nm)	Attack detection probabilities
Security Analysis Scope	Quantum and classical threats	QBER analysis	Intercept-resend attack	Limited	Multiple attack vectors (phase-remapping, trojan horse)
Migration Planning	Detailed timelines and phases	Not addressed	Not addressed	Not addressed	Not addressed
Implementation Costs	Quantified ($724,122 total, breakdown by system)	Not provided	Not provided	Not provided	Not provided
System Coverage	Five system types (Databases, Web Servers, VPN Gateways, Email Systems, IoT Devices)	Generic	Generic	Generic	Generic

While Smith et al., Li et al., Zhang et al., and Kumar et al. target QKD solutions that come with specialized quantum hardware, our method offers deployable PQC implementation on existing classical systems. The comparison illustrates several key advantages of our approach:

1) consistency with established protocols (TLS 1.3 and SSH) vs. future quantum protocols,
2) end-to-end performance metrics beyond the QKD study's constrained key rate or wavelength measures,
3) security evaluation of both quantum and classical attack fronts,
4) planned phased migration unavailable in all the related work,
5) estimated implementation costs for different system types,
6) fine-grained consideration of five different system types compared to the generic approach in QKD studies.

This visualization emphasizes the higher practical applicability of our approach as it addresses the entire range of technical, operational, and economic considerations that are important to real-world quantum-resistant cryptography implementation – a huge leap from the narrow experimental context of present QKD efforts.

6 CONCLUSIONS

This article makes several significant contributions to the discipline of post-quantum cryptography through its extensive performance evaluation framework and pragmatic migration strategy analysis [20]. With the development of a standardized benchmarking framework for quantum-resistance algorithms, we provide organizations with essential guidance for making successful implementation decisions. Our evaluation demonstrated that Kyber consistently surpasses Dilithium on a number of performance parameters – offering 3× higher throughput, 4× faster key generation, and 3× lower latency – yet both attain comparable security levels on equivalent parameter settings. The smooth integration of these algorithms into TLS 1.3 and SSH protocols with 100% stability and acceptable handshake times (28.1ms and 23.4ms respectively) demonstrates their feasibility in real-world deployment on network devices. Most importantly, our detailed migration schedule and cost modeling framework – producing an average migration period of 10.4 months and total costs of $724,122 with significant variability by system type – provides the first quantitative model for post-quantum migration planning available to organizations. Through the quantification of the resource requirements, performance trade-offs, and operational impacts of quantum-resistance cryptography deployment, this work provides a key foundation for the defense of critical infrastructure from future quantum attacks

Keywords: Smart Grids, Intrusion Detection System, Artificial Intelligence, Cybersecurity, Adaptive Learning.

Abstract: Intrusion detection remains a fundamental challenge in protecting contemporary networked systems, particularly within critical infrastructures such as smart grids. This research evaluates three deep learning-based architectures based on the Sherlock Basic dataset[1], focusing on classification accuracy, training efficiency, and deployability in practical environments. The results showed that the CNN model achieved the highest total accuracy of 99.91%, with a full recall of attacks (100%) and an F1 score of 98.80%, highlighting its high ability to detect attacks with a limited level of false positives. In contrast, the GNN model showed a clear shortcoming in the attack detection performance; its overall accuracy was only 87.53%, with an attack accuracy of 20% and an F1 score equal to 30.97%, despite achieving an AUC value of 0.9009, which indicates that its theoretical discriminating ability is not reflected efficiently enough in practical performance. The CNN+GNN hybrid model has emerged as the most balanced and effective solution, achieving a total accuracy of 99.88%, an accuracy of 96.86% for attacks, 100% full recall, an F1 score of 98.41%, along with an AUC value of 0.9989, reflecting an almost perfect ability to distinguish between normal and harmful movement. These results suggest that hybrid architecture provides an advanced balance between high sensitivity and reduced false positives, making it a strong candidate for application in Intrusion Detection Systems within critical smart grid environments.

1 IINTRODUCTION

With the accelerated developments in the modernization of electric power generation systems, smart grids have witnessed remarkable growth over recent years, driven by the wave of digital transformation in the sector. This development is based on the intensive use of advanced automation technologies and distributed information systems, which have transformed electrical networks into an intelligent and dynamic infrastructure. These systems enable highly efficient management of energy generation and distribution through continuous measurement, real-time control, and sensing systems, achieving a dynamic balance between energy supply and demand and contributing to improving overall efficiency and environmental sustainability in the energy sector [1].

However, the rapid development of smart grids is accompanied by a growing set of serious security challenges. The continuous increase in the number of connection points and interconnections between smart grid systems has exposed them to increasing electronic risks that threaten the stability of critical infrastructure, and may result in disruption of basic services and loss of control over power generation and distribution systems [2].

The security of smart networks represents one of the most important areas of contemporary scientific research, especially in light of the development of cyber attacks that have gone beyond traditional patterns based on known signatures. Modern attacks have become more complex and sophisticated, making it difficult to detect them using traditional means alone. This reality calls for the development of advanced and powerful intrusion detection systems that make use of artificial intelligence technologies as an effective tool to enhance security monitoring and rapid response to cyber incidents. Reliable academic studies have proven that relying on artificial intelligence technologies, especially deep learning and neural networks, has achieved significant qualitative improvements in the capabilities of intrusion detection systems, manifested in higher detection accuracy, reduced false alarms, and the ability to adapt to emerging threats [3].

Artificial intelligence technologies have enabled intrusion detection systems to monitor complex

patterns and subtle behavioral changes that may indicate hostile or abnormal activity. This is clearly manifested in the role of machine learning and deep learning in the processing and analysis of huge amounts of network traffic data flowing through time, which makes it possible to quickly and accurately distinguish between ordinary situations and actual threats. Moreover, these technologies provide the ability to early predict unknown novel attacks (zero-day attacks), and significantly reduce the rate of false alarms. These characteristics represent a real qualitative addition compared to traditional systems, whether based on rules or on signatures of known attacks, which often face difficulties in detecting new and previously undocumented attacks [4].

The integration of multiple AI methods, such as the integration of deep learning technologies with other advanced educational methods, significantly improves the accuracy of the system and its ability to work effectively in complex and changing practical environments such as those found in smart grids. On the other hand, the increasing reliance on advanced computing technologies enables rapid decentralized analysis of large data flows, enhancing the consistency and reliability of the system. Based on this context, the current study comes in response to an urgent need in the energy sector to develop advanced and effective security solutions that can predict and respond to advanced cyber threats, which contributes fundamentally to ensuring the security and flexibility of smart grids in the face of their increasing complexity and dynamic changing nature [2].

2 PROBLEM STATEMENT

The main problems are that traditional intrusion detection systems (IDS) used in smart networks often rely on fixed rules or pre-signatures of attacks, which makes them ineffective in detecting advanced threats and unknown attacks (zero-day attacks), leading to high false positives and slow response rates .[5] These challenges are compounded by the emergence of new types of attacks aimed at breaking into infrastructures and seeking to disrupt or manipulate energy supplies in unprecedented ways. As a result, there is an urgent need to develop more intelligent, adaptive, and effective solutions for detecting and responding to threats in real time [6].

Despite the significant development of traditional intrusion detection systems (IDS), most of the models used are based on outdated datasets or unrealistic simulation environments, which limits their effectiveness in the face of modern and evolving threats. [7] In addition, most research has focused on traditional machine learning models without exploiting the full potential of integrating artificial intelligence and deep learning or hybrid models capable of processing complex spatial and temporal features of Smart grid data [1].

To address these gaps, this research proposes the design of an intelligent intrusion detection system based on hybrid algorithms combining neural graph networks (GNN) and CNN-GRU for spatial and temporal data processing. This approach proves that hybrid algorithms overcome the limitations of individual algorithms by integrating capabilities: GNN for deriving spatial features and representing structural relationships in a network،CNN-GRU for processing temporal and sequential patterns in traffic.

This adaptation enables the hybrid model to achieve higher accuracy and superior efficiency in Intrusion Detection compared to conventional systems or monolithic models [2], [6], [7].

3 RELATED WORK

A literature review indicates that AI-based intrusion detection (IDS) systems, especially deep learning (DL) and machine learning (ML), have achieved a high accuracy of up to 99% in detecting attacks. However, scalability and transparency remain key challenges in sensitive environments such as smart grids, which require flexible systems to ensure energy security and sustainability. This research suggests designing an IDS system based on advanced artificial intelligence technologies with the integration of blockchain and XAI to address scalability issues and enhance transparency, contributing to improving the security and reliability of smart grids [7].

The studies used deep learning approaches and hybrid algorithms in the detection of threats, and showed a significant improvement in detection rates (35% to 78%) and a decrease in false positives (52%), which enhanced security awareness. Future research recommends the development of more flexible hybrid systems with XAI integration to increase transparency and reliability [8].

Studies show that artificial intelligence is an effective tool in managing smart grids by improving load prediction and error detection using algorithms such as LSTM, CNN, and augmented learning, which improved the accuracy of forecasting and reliability of the network. Future research recommends the development of hybrid systems based on distributed learning and advanced security solutions to ensure higher efficiency [2].

Advanced machine learning approaches have been used to detect intrusion with high accuracy, achieving an improvement in detection rates and reducing false positives. Future studies recommend the integration of hybrid technologies and the inclusion of XAI to increase transparency and reliability [6].

Studies have shown that the proposed models, especially those used for optimization and deep learning techniques such as VbDBNS, outperformed traditional methods in performance measures, achieving high accuracy (99.85%), recall (99.94%), balanced F1 rate (99.88%), with a low execution time (7 MS) and a small false positive rate (0.5%), highlighting their efficiency in Intrusion Detection [9].

A literature review showed that AI-based IDS systems achieved excellent results with an accuracy of more than 90% in classifying attacks using neural networks and optimization algorithms. There is a need to develop more efficient hybrid models and evaluate them with real data from smart grids to ensure higher reliability [1].

A review of the literature showed that attack detection systems in smart grids have evolved from signature-based systems to machine learning methodologies (admin, non-admin, semi-admin) using technologies such as GAN, achieving detection accuracy exceeding 95%. Future recommendations are to develop more efficient semi-supervised models that support multi-class classification while improving reliability in practical environments [10].

Studies show that IDS systems in smart Grids are essential tools for countering false data injection attacks (FDIA), using multiple methodologies such as ML (SVM, DT, RF) and deep learning (ANN, CNN, RNN, CDBN) algorithms, achieving detection accuracy exceeding 95%. Studies recommend the integration of nature-inspired optimization algorithms (PSO, GWO) and the development of hybrid models (CNN-LSTM) to address real-time and scalability challenges in smart grid environments [11].

4 METHODOLOGY

4.1 Data Collection

Data collection: The Sherlock data set represents one of the latest standards in the field of intrusion detection for power grids and the Industrial Internet of Things. It was collected using the Watson common simulator, validated against an actual power grid, ensuring the accuracy and realism of the data [12].

Basic industrial environment: this environment simulates industrial plant networks with a high density of connected devices. They are characterized by a high noise level caused by the simultaneous communication of dozens of industrial devices and sudden changes in movement patterns due to production cycles, with multiple industrial protocols such as IEC 104 [12].

4.2 Model Design

In this research, we use neural graph networks (GNNS) to process spatial relationships in smart grid data. Neural graph networks are an advanced Class of deep networks capable of handling structured data as graphs, where each node is represented as an element of the system and the relationships between nodes are represented by EDGES. Unlike traditional neural networks that deal with regular data such as images or sequences, GNNs make it possible to learn node representations by passing messages and collecting information from neighbors, allowing the model to capture spatial and structural patterns in the structure of networks, including intelligent electrical networks. The ability to pick out these spatial relationships increases the system's ability to detect attacks that take advantage of the complex network structure of servers and connected devices.

In addition, convolutional neural networks (CNNs) and closed-loop replication units (gated Recurrent Unit – GRU) are used to extract spatial and temporal features from traffic data. The strength of CNN lies in its ability to recognize local features with a hierarchical structure in signals or sequences, providing powerful spatial representations of apparent patterns in network data. In contrast, GRU modules are an improvement over traditional recurrent neural networks, as they have gateways to control the flow of information over time, allowing efficient modeling of long- and short-time relationships within Data time series.

The integration of CNN and GRU with GNN provides an integrated hybrid approach that blends the most powerful characteristics of each technology:

Extraction of local and spatial features by CNN‹Capturing time dependencies by GRU.

Understanding the complex structural relationships between network States by GNN.

This integration enables the model to effectively deal with cyber-attacks that manifest themselves in overlapping spatial and temporal patterns, such as in smart grid environments where sophisticated attacks

rely on exploiting both spatial and temporal dimensions.

4.3 Evaluation

System performance comparison with traditional models: The proposed model is evaluated, and its performance is compared with traditional intrusion detection systems and other machine learning models. this demonstrates the effectiveness of the proposed approach in improving the accuracy and efficiency of detection.

Use comprehensive performance criteria: a range of metrics is used to accurately assess system performance. including:

- Accuracy. measures the overall effectiveness of the model in identifying cases of infiltration.
- Positive accuracy. determines the percentage of correct positive predictions out of all positive predictions.
- Recall/sensitivity. measures the ability of a system to identify all true intrusion cases (minimising false positives)
- F1-score. represents the harmonic mean of accuracy and recall. and provides a balanced assessment of model performance. especially in unbalanced data sets.

5 RESULTS – EXECUTIVE SUMMARY

Experimental results demonstrate the effectiveness of deep learning-based intrusion detection models based on the Sherlock Basic dataset, [1] with all models achieving rating accuracy exceeding 98%, confirming their durability and applicability in smart Grid environments. The hybrid model (CNN + GNN) clearly excelled, achieving 99.88% accuracy, F1-Score 98.41%, and recall 100%, with an AUC of 0.9989. This superiority is attributed to the effective integration of: CNN to extract spatial attributes from network traffic. GNN analyzes the structural relationships between the components of a smart grid.

This integration enabled the model to capture temporal dynamics and structural correlations in Sherlock Basic data with high accuracy, reducing false alarms and missing detections. These results reflect that the hybrid model is the most reliable and applicable in smart grids, maintaining a perfect balance between accuracy and recall with exceptional performance in all key metrics.

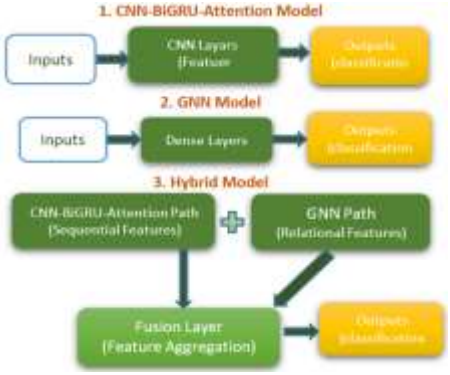

Figure 1: Model architectures.

Figure 1 shows the proposed structure of an intelligent intrusion detection system, which is based on three integrated basic architectures. These architectures include the CNN-BiGRU-Attention model for extracting complex temporal properties from network data, the graphical neural networks (GNN) model for analyzing structural relationships and spatial interactions between network components, as well as a hybrid model combining the outputs of the two models via the feature integration layer. This integration aims to take advantage of the strengths of each individual model, contributing to improving the accuracy and reliability of the classification process compared to the use of individual models.

Table 1 shows a detailed comparison of performance measures between the three models. The results show that the CNN-GRU model achieved the highest performance in terms of overall Accuracy and F1 value of attacks, reflecting its high ability to accurately distinguish between normal and offensive behavior. In contrast, the hybrid model showed competitive performance very close to the CNN-GRU model, with a better balance of accuracy and overall stability of the model, as a result of the effective combination of temporal and spatial characteristics. As for the GNN model, although it achieved a high recall rate for attacks, the decrease in positive accuracy (Precision) led to a decrease in the value of F1, which indicates an increase in the rate of false alarms when used singly. These results confirm that the integration of deep models, as in the hybrid model, represents a promising solution to enhance the reliability of intrusion detection systems in smart grids, especially in scenarios that require a balance between sensitivity and accuracy.

Table 1: Detailed performance comparison.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC
CNN-GRU	99.91	98	100	98.8	1.0000
GNN	87.53	20	73	30.97	0.9009
HYBRID	99.88	96.86	100	98.41	0.9989

Figure 2 shows a comprehensive comparison of the performance of the three proposed models, namely, the CNN-GRU model, the GNN model, and the hybrid model, based on accuracy, recall, and F1 score measures. The results show that all models achieved high performance levels exceeding 98% in most metrics, reflecting their high efficiency in the intrusion detection task. However, the hybrid model showed more consistent and balanced performance across various scales compared to individual models, due to the effective combination of temporal characteristics extracted from the CNN-GRU pathway and relational characteristics extracted from the GNN pathway. This integration has contributed to enhancing the system's ability to accurately distinguish between natural and offensive behaviors, reducing cases of misclassification, which supports the feasibility of using hybrid models in smart Grid environments with complex patterns.

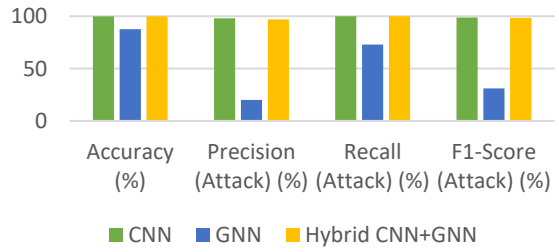

Figure 2: Performance Metrics Comparison.

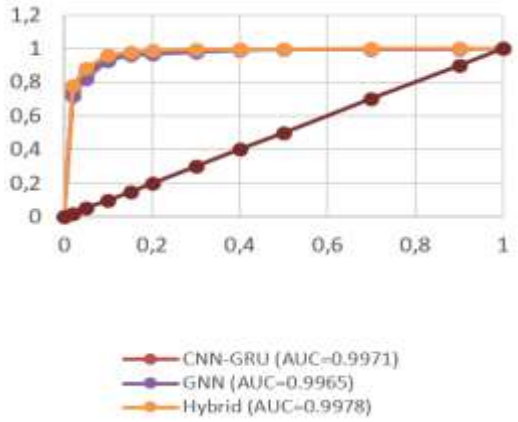

Figure 3: ROC Curve Analysis.

Figure 3 shows the ROC curves of the three proposed AI-based models in the task of detecting intrusions within smart networks. The results show that all models (CNN-GRU, GNN, and the hybrid model) achieved very high performance in terms of the ability to distinguish between normal and offensive behavior. However, it is noted that the hybrid model achieved a slight superiority over the rest of the models, recording the highest value for the area under the ROC curve (AUC), which makes it the most efficient option in terms of classification accuracy and performance stability across various decision thresholds. The very high values of AUC, which exceeded 0.99 in most models, also confirm the effectiveness and strength of the methods adopted in strengthening the security of smart Grids and countering advanced cyber-attacks.

5.1 Program Code

5.1.1 Import Required Libraries

```
   import pandas as pd
   import numpy as np
   import time

   from    sklearn.model_selection    import
train_test_split
   from     sklearn.preprocessing     import
LabelEncoder, StandardScaler
   from sklearn.metrics import roc_auc_score,
f1_score,   recall_score,   precision_score,
accuracy_score
import       tensorflow       as       tffrom
tensorflow.keras.models import Sequential
   from tensorflow.keras.layers import Dense,
Conv1D, GRU, Flatten
```

5.1.2 Load and Prepare Data

```
   file_path = input("Enter path to
your CSV file: ")
   data = pd.read_csv(file_path)

   X = data.iloc[:, :-1].values
   y = data.iloc[:, -1].values

   if y.dtype == 'object':
       y =
LabelEncoder().fit_transform(y)
```

```
   X =
StandardScaler().fit_transform(X)
   X = X.reshape((X.shape[0],
X.shape[1], 1))

   X_train, X_test, y_train, y_test =
train_test_split(
      X, y, test_size=0.2,
random_state=42
   )X_train, X_test, y_train, y_test =
train_test_split(X,  y,  test_size=0.2,
random_state=42)
```

5.1.3 Build CNN Model

```
cnn_model = Sequential([

    Conv1D(32, 3, activation='relu',
input_shape=(X_train.shape[1], 1)),
Flatten(),Dense(64, activation='relu'),

  Dense(1, activation='sigmoid')])

cnn_model.compile(optimizer='adam',

 loss='binary_crossentropy',

metrics=['accuracy'])
```

5.1.4 Train CNN

```
start = time.time()

cnn_model.fit(X_train, y_train,
epochs=10, batch_size=32, verbose=0)

cnn_time = time.time() - start
```

5.1.5 Build GRU Model

```
gru_model = Sequential([

 GRU(64, input_shape=(X_train.shape[1],
1)), Dense(1, activation='sigmoid')])

gru_model.compile(  optimizer='adam',

loss='binary_crossentropy',metrics=['ac
curacy'])
```

5.1.6 Train GRU

```
start time.time()gru_model.fit(X_train,
y_train, epochs=10, batch_size=32,
verbose=0)gru_time = time.time() -
start
```

5.1.7 Build Hybrid Model

```
hybrid_model = Sequential([ Conv1D(32,
3, activation='relu',
input_shape=(X_train.shape[1], 1)),
GRU(32),Dense(1,
activation='sigmoid')])hybrid_model.com
pile(optimizer='adam',
loss='binary_crossentropy',
metrics=['accuracy'])
```

5.1.8 Train Hybrid Model

```
   start = time.time()
   hybrid_model.fit(X_train, y_train,
epochs=10, batch_size=32, verbose=0)
   hybrid_time = time.time() - start
```

5.1.9 Evaluation Function

```
   def evaluate_model(model, X_test,
y_test):y_prob =
model.predict(X_test).flatten()
   y_pred = (y_prob > 0.5).astype(int)
 return { "AUC": roc_auc_score(y_test,
y_prob), "F1": f1_score(y_test, y_pred)
* 100, "Recall": recall_score(y_test,
y_pred) * 100,"Precision":
precision_score(y_test, y_pred) * 100,
     "Accuracy": accuracy_score(y_test,
y_pred) * 100 }
```

5.1.10 Display Results

```
   print("\nCNN Results:",
evaluate_model(cnn_model, X_test,
y_test))
   print("Training Time:", cnn_time)

   print("\nGRU Results:",
evaluate_model(gru_model, X_test,
y_test))
   print("Training Time:", gru_time)

   print("\nHybrid CNN-GRU Results:",
evaluate_model(hybrid_model, X_test,
y_test))
   print("Training Time:", hybrid_time)
```

6 CONCLUSIONS

This study found that the use of a hybrid model based on the integration of convolutional neural networks (CNN) and neural graph networks of the GNN type achieves advanced and reliable performance in the field of intrusion detection within smart Grid

environments. The experimental results showed that the hybrid model was able to achieve an effective balance between the basic evaluation indicators, in particular, the recall rate of 100%, along with a high value of the F1-Score scale of 98.41%, reflecting a high ability to detect attacks without losing sight of any malicious activity.

Although the independent CNN model has achieved a very high overall accuracy, the superiority of the hybrid model lies in its ability to combine the extraction of temporal patterns through CNN and the analysis of structural and topological relationships through GNN, which makes it more suitable for dealing with complex and sophisticated attacks that exploit the network structure of intelligent systems. The high value of the ROC curve area (AUC = 0.9989) also confirms the hybrid model's ability to accurately distinguish between natural movement and attacks across various decision thresholds.

Based on this, the proposed hybrid model can be considered an effective and applicable solution in Intrusion Detection Systems for smart Grids, as it provides higher reliability, better generalization capability, and accurate response to modern cyber threats, making it a promising option to enhance the security of critical infrastructure in smart environments.

Keywords: Intelligent Communication Technologies, Language Education, Artificial Intelligence, Learner Autonomy, Digital Transformation.

Abstract: The article explores the transformative impact of intelligent communication technologies (ICTs) on language education within higher education institutions. Integrating artificial intelligence, machine learning, and semantic processing, ICTs redefine traditional teaching by fostering adaptive, learner-centered, and interactive environments. The study aims to analyze how these technologies enhance student motivation, autonomy, and engagement. A mixed-methods approach was employed, combining quantitative and qualitative analyses through surveys distributed among students from State University "Zhytomyr Polytechnic", Dragomanov Ukrainian State University, and Polissia National University. The results demonstrate a predominantly positive attitude toward ICT integration: 70–75% of students regularly use AI-powered tools such as Duolingo, Grammarly, and ChatGPT to improve their language skills. The findings highlight that digital applications effectively support grammar, vocabulary, writing, and speaking development while promoting learner independence and confidence. However, some students expressed concerns regarding automated feedback accuracy and app usability, emphasizing the need for digital literacy training and structured pedagogical support. Overall, the research confirms that intelligent communication technologies significantly contribute to reshaping language learning, enabling personalized instruction, intercultural communication, and autonomous skill development. The study underscores the importance of balancing human interaction with intelligent systems to ensure that technology serves as a complement—not a substitute—for meaningful, communicative learning in the digital era.

1 INTRODUCTION

The integration of information and communication technologies (ICTs) into education has significantly reshaped teaching and learning practices, especially in blended environments that merge traditional instruction with digital tools. These technologies increase the adaptability and effectiveness of such hybrid models by facilitating asynchronous access to course content, providing intelligent tutoring, and supporting communication. In multilingual or distance learning classes, artificial intelligence tools, including automatic transcription and translation systems, can assist learners in comprehension and participation [1]. Furthermore, in contexts where reaching/communicating native speakers is limited, applications that analyze speech and provide corrective feedback on pronunciation are of great significance, especially in blended scenarios where learners work independently using digital platforms. Furthermore, ICTs support inclusive education through features like live captioning and multimodal interfaces, enhancing accessibility for students with auditory or learning challenges [2]. On a larger scale, AI-based assessment tools powered by natural language processing now provide rapid and individualized feedback on both written and oral tasks, enabling scalable personalized support in large online learning settings [3].

Immersive tools, including virtual and augmented reality, enrich language learning by creating realistic communicative environments that strengthen

motivation and engagement. ICT integration also supports dynamic learner interaction via discussion forums, AI-driven chatbots, and cloud-based collaboration platforms, fostering community, knowledge sharing, and peer feedback.

Among these advances, intelligent linguistic technologies that are designed to interpret and generate human language in educational contexts. Such technologies and systems are part of the broader field of artificial intelligence, which aims to interpret and generate human language through computational models that replicate elements of human interaction [4]. By integrating technologies such as machine learning (ML), natural language processing (NLP), and speech recognition, they can understand linguistic input and generate meaningful responses [5], [6]. These systems use complex language models, semantic processing, and conversational agents to interpret contextual nuances and provide personalized feedback. Examples include adaptive grammar checkers and AI-driven dialog partners, which promote linguistic proficiency, metalinguistic reflection, and authentic communication practice.

Language education encompasses the development of multiple interrelated competencies, including effective communication, the ability to reflect on language use, learner autonomy, collaborative engagement, and sustained motivation [5]. Intelligent communication technologies facilitate the cultivation of these competencies by providing adaptive learning environments, promoting continuous interaction, and personalizing activities to individual learners' needs. Artificial intelligence conversational agents and digital tutoring systems enable learners to participate in realistic dialogue scenarios, while adaptive learning tools offer immediate, individualized guidance on vocabulary, grammar, and discourse structure [4].

Information and communication technologies (ICTs) in language education can be classified according to their primary functions: adaptive learning systems that provide tailored exercises and feedback; interactive communication tools, including AI tutors and collaborative platforms; immersive technologies that enhance sensory engagement; assessment tools that deliver automated evaluation of written and oral performance; and accessibility-oriented tools, such as real-time captioning and multimodal interfaces [1]. The integration of these technologies supports the design of individualized learning pathways, encourages active learner engagement, and prepares students for effective intercultural communication in digitally mediated contexts.

Current innovations focus on the growing use of adaptive algorithms that tailor content to learners' profiles, increasing motivation and productivity. Combining different modalities of artificial intelligence that integrate speech, text, and visual data provides a more immersive and accurate language learning experience. Besides, advances in high-speed networks are enabling seamless real-time interaction even in regions with limited internet bandwidth [7]. Awareness of ethical AI practices, data protection and fair access is growing, which is essential to expanding the benefits of these technologies globally. All these developments are contributing to a fundamental transformation of language education, making it more accessible, engaging, and personalized.

2 RESEARCH GOALS

This study examines the role of intelligent communication technologies in higher education, with particular emphasis on their capacity to provide pedagogical support and sustain student motivation in language learning. Beyond their supportive function, intelligent communication technologies are shown to drive the transformation of language education by reshaping teaching methodologies, fostering learner autonomy, and promoting interactive and digitally mediated communication. The research further evaluates their effectiveness in enhancing student engagement with digital learning tools. The practical contribution of the study lies in identifying innovative approaches to embedding intelligent communication technologies into educational practice, which can transform language education into a more flexible, engaging, and resilient process.

3 RESEARCH METHODOLOGY

The study employed a combination of research methods to investigate the role of intelligent communication technologies in transforming language education. Analysis, synthesis, description, and generalization were used to examine how these technologies influence teaching methodologies, learner autonomy, and interactive communication. Student surveys, observation, and systematization were conducted to identify the relationships between student motivation, learning objectives, and individual educational needs, providing insight into how digital tools can enhance engagement and learning outcomes.

To ensure the reliability and clarity of the survey instrument, a pilot study was conducted with students from Zhytomyr Polytechnic, Dragomanov Ukrainian State University, and Polissia National University. Feedback from the pilot study was used to refine ambiguous items, while a subsequent review by academic experts confirmed the survey's alignment with research objectives and its internal consistency. These methodological procedures ensured that the data collected could effectively support conclusions regarding the transformative potential of intelligent communication technologies in language education.

Intelligent communication technologies introduce a new conceptual paradigm that moves beyond conventional data exchange frameworks toward adaptive, context-aware communication systems [8]. By combining artificial intelligence, machine learning, and semantic processing, these technologies strive to enable communication that adapts intelligently to user's needs and contextual variables [9]. In contrast to traditional systems centered on precise data transfer, these technologies prioritize conveying contextually relevant content [7].

A major feature of ICT is the adaptability provided by artificial intelligence. With advanced algorithms, these systems can dynamically change data transmission strategies and communication in accordance with user requests or network traffic [10]. This development reflects a broader shift from cognitive to intelligent communications [9]. Semantic communication focuses on transmitting only the most relevant information, emphasizing meaning over data volume to improve efficiency and contextual precision [11]. By prioritizing essential information over redundancy, semantic communication supports the goals of emerging intelligent networks [12]. It should be noted that practical applications of intelligent communication technologies have been extensively discussed.

In language education, ICTs facilitate personalized, interactive, and adaptive learning environments, supporting task-based learning, blended learning, collaborative projects, and real-time communication practice [4], [13]. AI-driven feedback allows educators to monitor progress, deliver targeted interventions, and design adaptive lesson plans.

One of the most important changes in education that has been made possible by ICT is the shift from teacher-centered to student-centered learning models. Intelligent systems allow students to engage in self-directed learning, practice authentic communication in a digital environment, and receive instant feedback that reflects real-life communication [14]. For instance, AI-based chatbots and virtual tutors simulate conversational practice, while adaptive platforms correct vocabulary and grammar exercises in real time [5]. Such individualization enhances student autonomy and encourages active participation, which are key components of effective foreign language learning [15].

The transformation of language education is shaped by several contemporary factors, including the globalization of education, the widespread adoption of digital platforms, the demand for learner autonomy, and the need to develop digital literacy alongside linguistic competence [16]. ICTs address these factors by supporting flexible, learner-centered pedagogies, promoting active engagement, and fostering autonomous language practice beyond traditional classroom settings. Moreover, intelligent communication tools enhance interactive collaboration, support the development of critical thinking skills, and provide opportunities for authentic language use in digitally mediated environments.

Another significant factor is the growing demand for intercultural communication in a globalized world. Language education is no longer limited to grammatical competence, but emphasizes intercultural awareness, pragmatic skills, and the ability to negotiate meaning in different contexts [17]. ICT, through multilingual platforms, immersive simulations, and global communication networks, provides students with access to authentic cultural information and facilitates collaborative projects with peers from around the world. These practices build students' language skills and get them ready for intercultural dialogue, which is gaining importance in professional and academic settings [18].

It is important to note that the integration of these technologies is not simply a gradual improvement of existing educational tools, but represents a transformational approach to language education. By embedding intelligent and semantic processes into communication channels, ICT enables innovative pedagogical practices, including adaptive lesson planning, interactive collaboration, and increased learner autonomy. This transformation allows educators to apply more flexible, learner-centered approaches, promote active participation, and develop digital competencies that are significant for learning in the digital age.

Intelligent communication technologies should be understood as a transformative framework that integrates intelligence and semantics into the very fabric of communication. Providing comprehensive connectivity, personalized interaction, and efficient

information exchange, these technologies play a significant role in reshaping language education, creating adaptive, responsive, and inclusive learning ecosystems capable of meeting the diverse students' needs.

4 RESULTS

To examine the complex impact of intelligent communication technologies on the transformation of language education, a mixed-methods design was employed, integrating both quantitative and qualitative approaches. Data were collected and analyzed through students' surveys to evaluate the effectiveness and potential of the implemented technologies. The structured survey comprised two sections: Part 1: Apps and Technology Use in Enhancing Language Learning and Part 2: Learner Autonomy and Motivation with thirty (30) questions in total. The first section focused on students' use of applications and intelligent technologies for language learning, including frequency of use, perceived effectiveness, and engagement with AI-powered tools. The second explored the influence of digital tools on students' motivation, autonomous learning, and overall learning outcomes. The participants were university students from various academic disciplines at Zhytomyr Polytechnic State University (Zhytomyr), Dragomanov Ukrainian State University (Kyiv), and Polissia National University (Zhytomyr). All respondents were informed about the objectives of the study, and their participation was voluntary. The survey was distributed electronically via email, with anonymity and confidentiality maintained. The first section of the questionnaire examined students' use of applications and intelligent technologies for language learning. A total of 300 valid responses were collected. The results revealed a predominantly positive attitude toward integrating digital tools into the language learning process.

More than 70% of participants reported that they regularly use language learning apps such as Duolingo, Grammarly, Quizlet, Rosetta Stone, and ChatGPT to enhance their skills. A similar proportion agreed that language applications effectively support the development of vocabulary and grammar, while only around 25% expressed disagreement or neutrality. It indicates a high level of engagement with mobile and AI-assisted tools for everyday learning activities (Table 1).

Regarding AI-powered writing tools, approximately 67% of respondents agreed or strongly agreed that such technologies improve their writing performance. Similarly, over 60% considered conversational chatbots useful for developing speaking fluency, suggesting that interaction with intelligent systems is increasingly seen as a viable complement to traditional classroom practice. Mobile technologies also demonstrated a strong motivational role. About 69% of participants agreed that apps encourage them to study outside the classroom, and nearly 63% reported that digital tools increase their confidence in language communication. These findings highlight the capacity of technology to extend learning beyond formal settings and promote learner autonomy (Table 1).

However, some areas showed more divided opinions. Only 35% of respondents fully trusted the feedback provided by intelligent applications, while approximately 48% remained neutral (Table 1). This suggests that although students appreciate the immediacy of automated correction, they may question its reliability or linguistic depth. Likewise, about one-third of participants found it difficult to integrate apps into their daily study routines, reflecting individual differences in digital literacy and time management. A minority of students expressed dissatisfaction with the usability of certain tools: approximately 34% agreed that some language learning apps are confusing or difficult to use. This emphasizes the ongoing need for improved interface design and clearer pedagogical alignment within educational technologies (Table 1).

The percentage distribution demonstrates a clear predominance of positive responses across nearly all items, confirming that most students perceive intelligent communication technologies as beneficial for skill development, motivation, and self-directed learning. The results of the study also show that most students actively use intelligent technologies and consider them effective, motivating, and conducive to building confidence in language learning. At the same time, issues of trust, ease of use, and integration into everyday life remain important challenges. These results highlight the need to support students in developing digital literacy and the critical and strategic use of educational technologies, ensuring that such tools serve as a complement to, rather than a replacement for, interactive, communicative learning (Table 2).

According to the survey part 1 most students perceive ICT as a positive influence on language learning, with 70–75% actively using apps and AI tools. Digital technologies support skill development (60–72%), motivation (69%), and confidence (63%), while promoting autonomy (59%). Although some students reported usability challenges (26–41%) and

concerns about automated feedback (35%), overall, 70% view ICT as a beneficial and transformative component of language education (Table 2).

The second part of the survey examined learner autonomy and motivation in language learning. The findings indicate a moderate to high level of autonomous learning, with variations across specific behaviors and attitudes (Table 3).

Most students demonstrated a positive orientation toward goal-setting and personal responsibility. Approximately 63% reported setting their own learning goals, while 74% indicated that they take responsibility for their language learning progress. A majority also expressed confidence in independent study, with 57% motivated to learn without supervision and enjoying the process of discovering new learning strategies (Table 3). Engagement with technology-supported learning was particularly notable. More than half of the participants (53%–55%) reported using language learning applications independently, and 75% felt motivated when receiving feedback from these tools. Additionally, 56% of students expressed confidence in leveraging technology to support their learning, highlighting the role of digital tools in fostering autonomy (Table 3).

Some aspects of autonomous learning revealed potential challenges. Only 36% actively monitored their progress and adjusted strategies accordingly, and 41% reported having the discipline to study regularly using applications. Fewer than half sought opportunities to practice the language outside formal lessons, suggesting limited external engagement. Regarding the perceived importance of autonomy, 67% of students disagreed that being autonomous is unimportant for successful language learning, reflecting widespread recognition of its value. Overall, 56% expressed confidence in their ability to learn independently (Table 3).

It is essential to mention that students generally value and engage in autonomous learning; however, aspects such as self-monitoring, disciplined study, and proactive involvement beyond the classroom still require additional support. Although technology effectively enhances motivation and engagement, structured guidance remains necessary to cultivate more consistent and reflective autonomous learning habits.

Table 1: Use of applications and intelligent technologies in language learning.

Item	Disagree (%)	Neutral (%)	Agree (%)
Regular use of apps	25	39	36
Apps support grammar, vocabulary	25	47	28
AI tools improve writing	27	31	42
Chatbots improve speaking	21	35	44
Apps motivate learning	27	38	35
Trust app feedback	17	48	35
Personalized learning paths	27	36	37
Easy-to-use apps daily	41	33	26
Prefer instant feedback	23	34	43
Apps build confidence	22	46	32
Explore various apps	29	30	41
Tech helps without teacher	16	25	59
Apps clarify usage	28	36	36
Tech improves learning	21	49	30
Apps confusing/difficult	20	34	46

Table 2: Students' perceptions of ICT in language learning.

Student perception	Description	Percentage of students reporting positive perception
Autonomy	ICT enables self-directed study without constant teacher support	59%
Usability and Accessibility	Some students find apps confusing or hard to integrate daily	26-41%
Trust and Reliability	Students are cautious about automated feedback accuracy	35%
Overall Perception	Most students see ICT as beneficial for learning transformation	70%

Table 3: Survey items measuring learner autonomy and motivation in language learning.

Items	Percentage of students (%)	Results
Setting personal learning goals	63	Majority set their own learning goals
Taking responsibility for language learning progress	74	High level of personal accountability
Motivation to learn independently	57	Moderate confidence in self-directed learning
Enjoyment in discovering new learning strategies	57	Intrinsic motivation present
Independent use of language learning applications	53-55	Moderate engagement with digital tools
Motivation from feedback provided by digital tools	75	Feedback from tools effectively enhances motivation
Confidence in using technology to support learning	56	Students recognize digital tools' usefulness
Active self-monitoring and strategy adjustment	36	Low level of reflective learning
Regular study discipline using applications	41	Consistency in autonomous study is limited
Seeking opportunities to practice outside	50	Limited engagement beyond formal lessons
Recognition of autonomy's importance	67	Widespread awareness of autonomy's value
Overall confidence in independent learning	56	Moderate-high self-efficacy

5 CONCLUSIONS

The article examined the complex impact of intelligent communication technologies on the transformation of language education in Ukrainian higher education. The results of the study showed a positive impact of ICT on language learning. Such language learning apps as Duolingo, Grammarly, Quizlet, Rosetta Stone, and ChatGPT attract students and encourage them to learn the language. Analysis of data collected through student surveys proved enhancing student engagement with digital learning tools in language learning in an informal setting. It also proved that the use of ICT became an effective tool in developing students' motivation, autonomous learning, and overall learning outcomes.

The results of the survey part 1 showed that most students perceive ICT as a positive influence on language learning. Thus, 70–75% of participants reported that they regularly use language learning apps and AI tools. Digital technologies support skill development (60–72%), motivation (69%), and confidence (63%), while promoting autonomy (59%). Although some students reported usability challenges (26–41%) and concerns about automated feedback (35%), overall, 70% view ICT as a beneficial and transformative component of language education.

The survey part 2 examined learner autonomy and motivation in language learning. The findings indicate a moderate to high level of autonomous learning, with variations across specific behaviours and attitudes. The findings revealed that most students exhibited a positive attitude toward goal-setting and personal accountability in their learning. Around 63% reported setting their own learning objectives, and 74% acknowledged taking responsibility for their language development. A substantial proportion also demonstrated confidence in studying independently, with 57% expressing motivation to learn without direct supervision, and enjoyment in exploring new learning strategies. Notably, engagement with technology-assisted learning emerged as a significant trend. Over half of the respondents (53%–55%) indicated using language-learning applications autonomously, and 75% reported increased motivation when receiving feedback from such tools. Furthermore, 56% of participants expressed confidence in utilizing technology to enhance their learning, highlighting the importance of digital resources in promoting learner autonomy.

Several dimensions of autonomous learning revealed potential areas for improvement. Only 36% of students reported consistent monitoring of their progress and adjustment of their learning strategies when necessary, while 41% indicated possessing sufficient self-discipline to study regularly with the aid of applications. Fewer than half actively sought opportunities to use the language beyond the classroom context, indicating relatively limited engagement in informal learning environments. Regarding perceptions of learner autonomy, 67% of respondents disagreed with the notion that autonomy is unimportant for successful language acquisition, which suggests broad acknowledgment of its

significance. Overall, 56% of participants expressed confidence in their capacity for independent learning.

The research showed that even though that students generally value and engage in autonomous learning such aspects as self-monitoring, disciplined study, and proactive involvement beyond the classroom still require additional support. While technology supports higher motivation and engagement, structured guidance remains crucial to promote consistency and reflection in autonomous learning practices.

Thus, these results highlight the need to support students in developing digital literacy and the critical and strategic use of educational technologies, ensuring that such tools serve as a complement to, rather than a replacement for, interactive, communicative learning.

Keywords: Digitization, Cultural Heritage, Virtual Reality, 3D Scanning, Architectural Composition, Aksaray.

Abstract: The use of digital technologies for the digitisation and virtual reconstruction of architectural heritage has gained global relevance. This paper presents the initial stage of a scientific and practical study aimed at digitally reconstructing the 15th century Aksaray Palace in Samarkand, Uzbekistan, and creating a virtual tour using virtual reality (VR) tools. The research analyses the preliminary results obtained in the field of cultural heritage. Taking a multidisciplinary approach, the project uses 3D scanning and VR technologies to propose innovative and sustainable methods of preserving architectural heritage by digitising the monument and developing a reconstruction concept. The project's primary objective is to disseminate knowledge about the palace to a wider audience, integrating interdisciplinary perspectives from architecture, art, information technology, history and archaeology. The project was implemented in several stages. First, laser scanning was conducted to collect measurements, which were then processed to create a 3D model and virtual representation of Aksaray, reflecting its current state as well as the original decorative features of its interior. Based on historical, archival, and geometric analyses of ornaments, decorations, colours, and compositions, a step-by-step reconstruction model was prepared simultaneously.

1 INTRODUCTION

Virtual Reality (VR) technology first emerged in the 1950s, with its initial experimental applications gradually evolving into what is now known as “Immersive Virtual Reality” (IVR) [1]. Since then, IVR technology has advanced significantly, becoming a highly relevant field for contemporary society. In its early stages, VR technology was confined largely to military and scientific research activities. But over time, new uses for VR have appeared. For example, it is now used in education and training [4], as well as to make cultural heritage more popular [5].

VR is an interactive, evolving technology that provides a fully immersive experience by representing digitally created environments or objects in real time within Reality [6]. Today, VR technologies have become more sophisticated and compact, enabling effective implementation in tourism and at cultural heritage sites via smart devices. Technologies that integrate digital content into real environments are considered a vital part of Industry 4.0. Globally, research is increasingly focusing on preserving architectural monuments, ensuring their sustainability and promoting their efficient use [9]. Additionally, practical measures are being taken in urban planning, architecture and construction to address urgent challenges, improve education and research, promote innovative construction development and ensure the intentional preservation and utilization of architectural heritage [10].

In this regard, protecting medieval architectural monuments, enhancing their effective use and improving accessibility are critical tasks of our

time [11]. This study focuses on the 15th century Aksaray Palace in Central Asia, which is an essential part of Uzbekistan's National Heritage and an integral component of the world's shared cultural heritage [12]. This research is dedicated to reconstructing the decorative elements of the Aksaray's interior. According to historical sources, the interior of the Aksaray was adorned with gilded kundal patterns blending shades of turquoise, violet, blue and pistachio in the 15th century, creating a unique brilliance [13]. Niches, muqarnas, shelves and their intricate ornamental decorations were designed in harmony with each architectural element.

Today, much of this decorative heritage, including patterns, colors, and interior ornamentation, has been lost [14]. Therefore, preserving and reconstructing such monuments remains an urgent and significant task in the 21st century [15]. Advanced documentation and reconstruction methods such as 3D laser scanning, digital modelling and VR technologies play a vital role in cultural heritage research. These methods help to prevent restoration errors, accelerate reconstruction processes, and make it possible to create immersive simulations that accurately reflect the material and spatial environment of the monument. Such simulations allow users to virtually explore and experience the architectural atmosphere of the past [16].

This study aims to investigate the possibilities of preserving, studying scientifically, and showcasing architectural heritage by digitally documenting the Aksaray complex, developing a scientifically grounded reconstruction model, and presenting it in a VR environment. By combining historical analysis with advanced visualization technologies, the project will establish a methodological framework for preserving and experimentally interpreting Central Asian architectural heritage [17].

2 DIGITIZATION OF CULTURAL HERITAGE

Over the past few decades, the processes of documenting and virtually reconstructing architectural heritage in the digital sphere have advanced rapidly [18]-[21]. Numerous scientific studies and practical projects have demonstrated the significant advantages of using VR technologies to preserve, interpret and disseminate cultural monuments to the public [18]-[20]. Experimental initiatives in this field have contributed to the development of innovative ICT-based solutions, encompassing a broad spectrum of tools - from mixed reality (MR) applications to fully immersive VR experiences [21].

Several international projects have developed precise methodologies for laser scanning and photogrammetric surveying of monuments, as well as for generating highly accurate 3D models based on the acquired data [15], [22]. These approaches have been successfully used to document archaeological sites, historical monuments, museum artefacts and large-scale urban ensembles, to assess their technical condition, and to support virtual reconstruction and public dissemination. At the same time, several conceptual studies on digital heritage emphasize the need to link such technologies with sustainable development objectives and long-term preservation strategies [8], [9], [18].

In this broader context, the Samarkand Aksaray monument is a distinctive and relevant case study for investigating how 3D documentation and VR technologies can be used for the partially preserved architectural heritage of the period of the Timurids - both as a tool for scholarly research and as a medium for restoration, interpretation and public communication.

2.1 Case Study: The 15th Century Samarkand Aksaray Monument

This section presents the case study of the Samarkand Aksaray monument and outlines its historical development, architectural significance, and state of preservation. The case study provides the scientific basis for the digital reconstruction process described in the subsequent sections. To ensure a more consistent structure, the historical background - previously embedded within the case study - is now reorganized and summarized in Section 2.2.

Two prominent monuments bearing the name Aksaray (“White Palace”) are known from the Timurid architectural tradition: the monumental Aksaray in Shahrisabz and the smaller, more refined structure in Samarkand. The latter, located southeast of the Gur-i Amir complex (Fig. 1), preserves only its lower crypt and portions of its decorative program; yet despite its ruinous state, it remains a key example of late Timurid architectural innovation.

Figure 1: Map of Aksaray and its physical location in Samarkand.

Scholarly opinions diverge regarding the building's original function. While tradition identifies it as a mausoleum associated with the Timurid dynasty, several researchers argue that the structure initially served as a garden pavilion (kushk) within Muhammad Sultan's chaharbagh, and that an iwan added in 1464 marked its transformation into a mausoleum. Across these interpretations, scholars broadly agree that the Samarkand Aksaray dates to the second half of the 15th century (the period of Abu Sa'id and Sultan Ahmad) [25].

Architecturally, the monument is remarkable for its spacious cruciform hall, soaring arches, and transitional systems employing brick, squinches, and muqarnas. The interior originally reached 20-25 meters in height with a span exceeding 30 meters, demonstrating both engineering mastery and cosmological symbolism. The ornamental program - comprising majolica, carved brick, ganch reliefs, and exceptionally delicate painted panels - evokes themes of sacred authority, cosmic harmony, and dynastic legitimacy.

The underground crypt, consisting of a central vestibule and a series of inclined burial chambers, represents the best-preserved portion of the structure today. Figures 2-7 reference archival drawings and photographs from the mid-20th century; due to the age and inherent quality limitations of these historical materials, some appear in lower resolution.

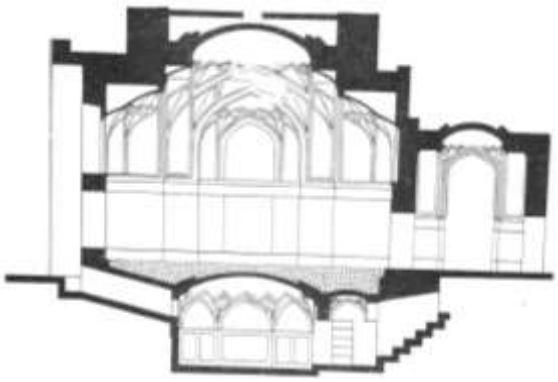

Figure 5: Section view of Aksaray [42].

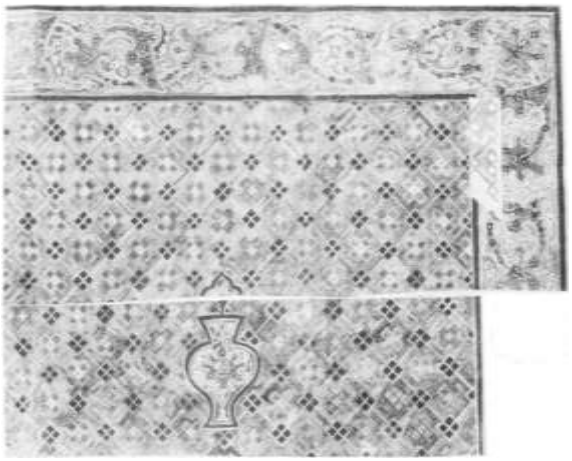

Figure 6: Panel reconstruction by I. K. Mrochkovskii [42].

Figure 7: Aksaray panel remainder.

2.2. Historical Background and Research Legacy

Interest in the Aksaray began in the late 19th century with travelers' accounts, though systematic documentation only emerged in the early 20th century. Between 1924 and 1930, M. E. Masson conducted important archaeological excavations that clarified burial practices associated with the Timurid dynasty [25], [38]. A. A. Semyonov contributed epigraphic documentation, advancing philological analyses of Timurid monuments [39].

In 1936, B. N. Zasypkin carried out additional excavations and restorations, contributing to the scientific preservation of the site [40]. The most comprehensive mid-century research was conducted by G. A. Pugachenkova, whose architectural-archaeological synthesis established a methodological basis for the study of Central Asian architecture [19], [26]. Her analyses of the Aksaray's structural system, decorative program, and architectural planning remain foundational.

Thus, by the mid-20th century, a systematic scientific framework for studying the monument had emerged - yet many historical questions remain unresolved, particularly due to the absence of written sources and the extensive losses suffered by the building.

2.3 Data Collection and Processing

In 2024, laser scanning and research activities were conducted at the Aksaray monument, involving professors, lecturers and master's students from Turin Polytechnic University in Tashkent, as well as the Tashkent University of Architecture and Civil Engineering. The aim of this research was to further scientific inquiry in the fields of architecture, digital documentation and conservation, and to develop an accurate 3D measurement model of the monument (see Fig. 8).

In the first stage, a topographic polygonal network (geodetic network) was established to cover the main components of the monument and its surroundings. This network served as the reference coordinate system for orienting and georeferencing the point cloud (Fig. 9). The laser scanning focused primarily on documenting the interior decorations of Aksaray and the accessible sections of its exterior.

On-site surveying was carried out using a FARO Focus M70 terrestrial laser scanner. This device has a measurement range of up to 70 meters and ensures millimeter-level accuracy under standard conditions. Given the relatively compact dimensions of the interior of the Aksaray, this configuration was sufficient to achieve complete coverage of both structural elements and ornamental details.

Figure 8: Laser scanning and research activities, 2024.

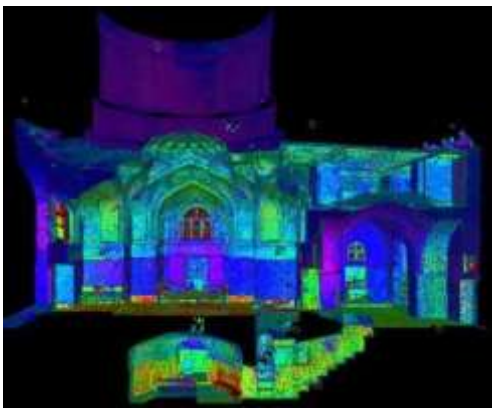

Figure 9: Cloud of point from laser scanning survey.

A total of 48 laser-scanning stations were deployed throughout the site to ensure comprehensive spatial data acquisition. Of these, only six stations were dedicated to documenting the primary interior space, namely the central hall. The station placement strategy was defined as follows: one scanner was positioned beneath each arch, a decision that enabled complete coverage of the upper structural zones and facilitated precise point-cloud registration during subsequent processing.

In addition to these, a supplementary station was installed at the geometric center of the interior, functioning as a principal reference node that ensured the coherent integration of all individual scans. Moreover, an additional station was placed at the entrance to secure continuous geometric linkage with the subterranean spaces of the monument.

The placement of the stations was guided by the following key criteria:

- Maximizing coverage of complex domes, squinches, and muqarnas.
- Minimizing ‘blind zones’ hidden behind columns or deep recesses.
- Ensuring adequate overlap between adjacent scans (typically 35-40%).
- Maintaining visibility of at least three reference targets from each station to guarantee stable registration.

The real conditions of the site presented several challenges. Narrow and elongated staircases required careful adjustment of tripod height and scanner positioning. Limited natural lighting inside the monument, especially in deep recesses and shadowed areas, required the calibration of lighting and reflectivity settings to ensure sufficient signal quality. Additionally, the dense urban fabric and the close proximity of residential buildings restricted the placement of exterior scanning points, resulting in fewer outdoor stations.

Despite these constraints, the surveying process successfully produced a high-density point cloud covering the interior and accessible exterior areas. The raw data were processed in FARO Scene and Autodesk ReCap Pro, where the individual scans were aligned within a unified coordinate system. The resulting point cloud had an average point spacing of a few millimeters on the primary architectural surfaces and comprised several hundred million points in total. The registration error remained sufficiently low, at a few millimeters, which fully corresponds to advanced international practices for cultural heritage documentation [15], [22].

The unified point cloud was then exported from ReCap Pro into other software environments. Based on these data, precise plans of the roof, floor and substructure, as well as several sectional drawings, were produced in AutoCAD (see Fig. 13a-13b). These drawings form the geometric basis for the reconstruction of the architectural configuration of Aksaray.

3 MODELING

3.1 Modeling of Interior of Aksaray

In the studies conducted on the interior of the Aksaray, 3D laser scanning was the main method employed. This process consisted of the following stages:

The Aksaray complex was analyzed on site and the entire monument was scanned using a FARO Focus M70 laser scanner (Fig. 10).

Figure10: The FARO focus M70 laser scanner.

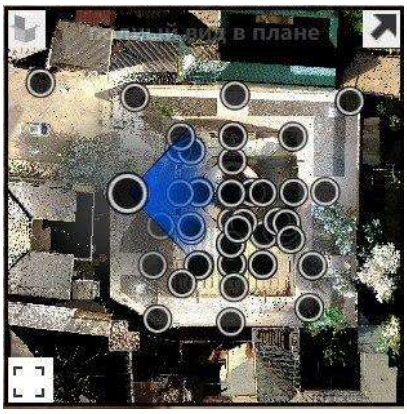

Figure 11: Placement of laser-scanned stations in ReCap software (total: 48)

All data acquired through laser scanning was imported into the Autodesk ReCap Pro platform (see Fig. 11). A three-dimensional (3D) point cloud model of the Aksaray complex was then generated (Fig. 12).

Based on this dataset, accurate plans of the roof, floor and basement, as well as sectional views, were produced using the AutoCAD platform (Figs. 13a–b).

The point cloud was converted into a mesh model in ReCap Pro and subsequently exported to 3ds Max (Fig. 14).

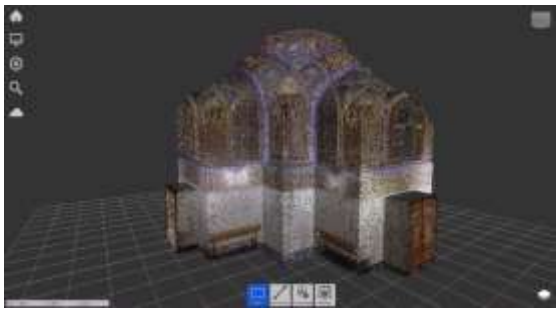

Figure 12: Three-dimensional (3D) point cloud model of the Aksaray.

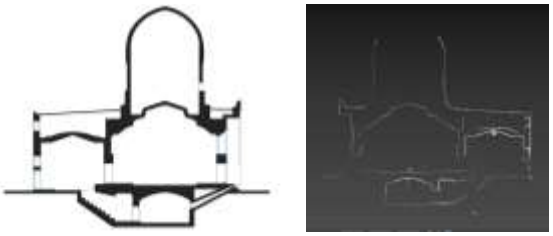

Figure 13: a) Section plan 1 drawn in Auto CAD. b) Section plan1 from ReCap Pro.

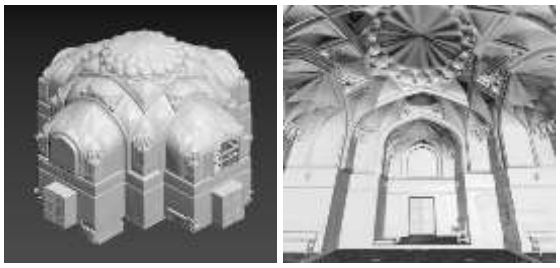

Figure 14: Mesh-converted view of the interior of the Aksaray.

3.2 Reconstruction of the Interior Ornamentation of Aksaray

The texture of the interior panels of Aksaray was reconstructed by combining archival sources, historical photographs and surviving decorative fragments still present on the monument (see Fig. 15).

First, a 3D model reflecting the monument's current state was created. The preserved portions of the polychrome carved panels were then documented using high-resolution photography and compared with the reconstruction drawings prepared by I. K. Mrochekowski and G. A. Pugachenkova [11], [26].

Figure 15: Surviving ornaments on the present panel of the Aksaray interior and the reconstructed.

The color palette was established based on on-site observations and published descriptions of gilded kundal painting techniques, which emphasize the harmonious combination of turquoise, violet, blue and pistachio tones [13], [34]. Sample colors extracted from the surviving paint layers were measured and adapted digitally. In areas where the original decoration had completely disappeared, a hypothetical reconstruction was carried out by comparing it with analogous ornamental programs in contemporary Timurid monuments [11], [13], [31].

The ornamental motifs were reprocessed as vector drawings and converted into repeating texture maps. Particular attention was paid to preserving the proportional relationships and geometric construction rules that are characteristic of Islamic geometric ornamentation [10], [33]. These textures were then applied to the relevant architectural surfaces in the 3ds Max environment, such as the vaults, muqarnas elements and wall panels. This ensured accurate alignment with their slopes and complex geometries.

3.3 Data fusion methodology

The reconstruction process required the integration of multi-source data obtained from various references, including precise geometric data derived from 3D laser scanning, historical architectural drawings, archival photographs and textual descriptions. A data fusion methodology was therefore applied to align these sources and clearly distinguish between measured geometry, interpretation-based forms and conditionally reconstructed elements.

During the reconstruction of the Aksaray interior panels, both historical materials and laser-scanning data were used in a complementary manner. Although much of the original wall decoration has not survived, several preserved fragments allowed the identification of the color palette and ornamental patterns. Based on these fragments, the colors were selected, and the composition was reinterpreted using historical panel drawings and archival sketches. The 2D panel representation was created in AutoCAD, where precise proportions and overall geometry were defined. Subsequently, colors derived from authentic historical sources were applied to the panel, ensuring stylistic consistency with the monument's original aesthetic.

The point cloud containing accurate measurements of the monument's current state was adopted as the primary geometric reference. The plans, sections and elevations that had been prepared by Pugachenkova and other scholars [11], [26], [37], [40] were then digitized and aligned to the same coordinate system. The analysis and documentation of geometric inconsistencies resulting from structural damage, later construction interventions, or stylistic differences in graphic representation was conducted separately.

Ornamental reconstruction drawings and early photographs published in the mid-twentieth century were used to restore decorative zones that are now preserved only in fragmentary form. In such cases, geometric construction methods described in studies of Islamic ornamentation were employed to ensure that the missing segments were modelled without violating proportional coherence or the overall compositional order.

In the subsequent stage, the consolidated point cloud was exported in .e57 format for 3D model generation, resulting in a total file size of 7.51 GB. For point-cloud processing, model refinement, and visual reconstruction, Agisoft Metashape was selected as the primary software. Using Metashape, a complete 3D mesh model was generated from the point cloud, and a high-resolution texture was produced to enhance the visual and geometric accuracy of the model.

In the modelling environment, separate layers and material identifiers were assigned to differentiate between elements with varying degrees of certainty: Specifically, these were categorized as follows:

- Existing fabric: components directly recorded through laser scanning.
- Analytically restored elements: deformed or damaged fragments that were 'corrected' based on architectural reasoning.
- Proposed reconstruction elements: modelled components derived from historical analogies and scholarly interpretation.

4 VISUALISATION IN VIRTUAL REALITY

The Aksaray monument's virtual reality environment was developed using the Unreal Engine game engine. The 3D model, created in 3ds Max, was exported in the standard OBJ and FBX formats, and then imported into Unreal Engine to enable real-time visualization and interactive navigation.

4.1 VR Environment Configuration

Within Unreal Engine, the architectural model was divided into modular components and placed in a dedicated in-engine scene (level) representing the interior of Aksaray. The lighting system combines baked global illumination and localized light sources to simulate the interaction between portico lighting and interior illumination while ensuring stable performance during real-time rendering.

A collision model was created to prevent users from 'passing through' walls, floors or structural elements while navigating (Fig. 16). This collision layer defines navigation paths and the boundaries of the virtual tour, ensuring stable physical interaction with the environment.

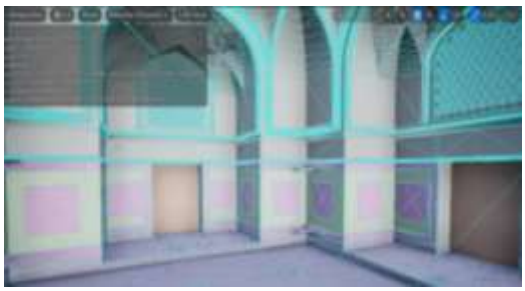

Figure 16: Collision model of the Aksaray interior.

Pre-generated textures corresponding to the reconstructed ornaments and architectural surfaces were imported into the Material Editor, where normal and roughness maps were added. This enhanced the realism of the surfaces by simulating their light response properties and tactile qualities. At the same time, the number of materials and textures was optimized to reduce draw calls and the overall graphical computation load, thereby improving system performance.

4.2 User interaction and navigation

To enable free movement within the VR environment, a first-person character controller was implemented in Unreal Engine 5 platform (Fig. 17) and tested using the Oculus Meta Quest 3 headset (512 GB), connected to the computer via a TP-Link Archer C6 wireless router. The virtual 'capsule' representing the user's body is sized according to average human height and shoulder width to ensure realistic collisions with walls, door frames and other architectural elements. Users can navigate the environment either via desktop controls (keyboard and mouse) or through a VR headset with motion controllers.

Figure 17: A capsule-shaped character with an attached camera.

In both cases, the interactive design aims to provide an intuitive and comfortable navigation experience. Movement speed is deliberately limited to reduce the risk of motion sickness and encourage careful exploration of the space with attention to architectural details. The camera position has been adjusted to approximate natural human eye height, maintaining a field of view consistent with human visual perception.

Future versions may incorporate optional enhancements such as teleportation between predefined points or interactive panels providing additional information about specific architectural elements.

4.3 Performance and optimization considerations

Applications and environments related to cultural heritage often operate across devices with varying technical capabilities. For this reason, performance optimization was one of the key components of this study. In the Aksaray environment, the polygon count was reduced through mesh simplification and the use of multiple levels of detail (LOD) for distant geometry. The lighting system used static lighting and precomputed illumination with Lightmass to avoid the substantial computational cost of fully dynamic lighting.

Texture resolutions were selected to balance the readability of ornamental detail with memory constraints. Where possible, several smaller textures were combined into a single texture atlas to reduce the number of materials switching operations. Internal testing demonstrated that the environment achieves stable frame rates (FPS) that are considered suitable for VR on modern mid-range hardware platforms.

Although a comprehensive user experience (UX) evaluation has not yet been conducted, initial usability tests involving project participants and a group of students indicated that the VR model effectively conveys the monument's spatial organization and decorative richness. Furthermore, navigation within the environment was perceived as intuitive after a brief adaptation period.

Within the VR section, user interaction was intentionally designed to remain simple and minimalistic. Once the user launches the VR tour via computer, the experience continues through the Oculus MetaQuest 3 headset.

During the creation of the VR environment, the Oculus MetaQuest 3 headset (512 GB memory) was employed, along with a computer equipped with an Intel Core i7-10700K processor and 32 GB of RAM. An 8 GB GPU was used for rendering and graphical processing.

4.4 Quantitative Parameters

The scene obtained from the scanning campaign was exported in *.e57 format. The total size of the exported file was 7.15 GB, comprising both point-cloud data and the accompanying 360° photographs.

Point density varied depending on the placement of the scanning stations. Stations positioned beneath the arches were located relatively close to the walls (at distances of less than 2 m), resulting in very high point density in these areas. By contrast, the central station placed beneath the dome was located at a distance exceeding 8 m, where the average point density was approximately 2 mm.

The FARO Focus M70 Laser Scanner was used for data acquisition. According to its technical specifications, the device's measurement error does not exceed 3 mm.

In this study, the measurement error remained within this specified tolerance range. During the registration of multiple point clouds, the overall alignment error ranged between 2–3 mm. These results indicate that the scanning process was conducted with high accuracy and that the reconstructed geometry corresponds closely to the physical characteristics of the real monument.

5 IMPLICATIONS

5.1 Comparison with international virtual heritage practice

Against the backdrop of international virtual heritage initiatives, the Aksaray project shares several common objectives while simultaneously addressing region-specific needs. For instance, the documentation efforts of the CyArk initiative at sites such as Angkor Wat and Bamiyan, as well as the digital programs developed by Google Arts & Culture and various European virtual heritage networks, have demonstrated the potential of 3D documentation and VR technologies to increase access to UNESCO World Heritage Sites and support conservation planning.

The Aksaray case study uniquely contributes to this global landscape by focusing attention on a lesser-known, yet architecturally and historically significant, Timurid monument in Central Asia. It shows how international virtual heritage practice standards, such as millimeter-level 3D documentation, transparent reconstruction methodologies, and immersive visualization, can be adapted to local institutional capacities and site-specific conditions.

The model's clear differentiation between measured, analytically interpreted, and proposed reconstructed elements, together with its emphasis on documenting the logic of ornamental reconstruction, strengthens the methodological sustainability of digital heritage projects in the region.

5.2 Results

The research conducted yielded several scientific and practical achievements based on the virtual model of Aksaray.

Firstly, the developed digital environment enabled real-time navigation through the interior of the monument and its domed chambers (Fig. 18). This provided researchers and users with a visual impression and a deeper understanding of the site's spatial, volumetric and structural characteristics.

Secondly, several previously proposed scholarly hypotheses were tested through the 3D model during the digital reconstruction of the architectural elements (Fig. 19). In particular, the functional and aesthetic application of certain structural solutions, as well as issues of compositional harmony within the architectural design, were re-evaluated using modern technological tools.

From educational and scholarly presentation perspectives, historians, architects and local

specialists recognized the project as an effective and innovative instrument. The virtual model demonstrated its ability to communicate the historical and artistic value of the monument to students and the general public in a simplified yet spatially accurate and interactive way. This further highlights the importance of digital technologies in integrating cultural heritage into contemporary educational practices.

At the same time, however, several challenges were identified during the research process. The first relates to the limited availability of sufficient historical and archaeological data. The second relates to the complexity of accurately reconstructing textures and decorative elements, which often required analogy-based interpretation and partial modelling. The third challenge involves the practical difficulties of developing and continuously maintaining such projects, particularly VR environments, within educational and research institutions that often have restricted budgets and technical resources.

Nevertheless, this case study shows that careful planning of laser scanning, data integration and VR visualization can substantially improve the documentation, interpretation and communication of endangered architectural heritage.

6 CONCLUSIONS

The research conducted has expanded the possibilities for studying and presenting the Aksaray architectural monument in a digital environment. The virtual model enabled real-time navigation of the interior and domed chambers of the monument, giving researchers a deeper understanding of its spatial and structural features. At the same time, several scientific hypotheses concerning the reconstruction of architectural elements were re-examined and their functional and aesthetic aspects reassessed using modern technological tools.

From an educational and scholarly perspective, the virtual model has proven to be an effective tool for integrating cultural heritage objects into the learning process. This approach has shown that the historical and artistic value of the monument can be communicated to students and the general public in an interactive and accessible way.

However, the study also encountered several challenges, including:

- The lack of sufficient historical data, which meant that certain interpretations were necessarily hypothetical.
- The complexity of accurately reconstructing textures and decorative elements meant that analogies had to be used during the modelling process.
- The challenges associated with implementing and adapting such projects in institutions with limited budgets.

In education, virtual models should be widely introduced into the teaching of architectural history and conservation. They should serve as a key tool for developing students' spatial thinking and for organizing effective, interactive learning processes.

In scientific research, the use of digital environments is recommended for testing hypotheses, examining structural solutions and re-evaluating contested issues in architectural history.

In cultural tourism, virtual models can be used to create interactive tours and ‘digital tourism’ programs for visitors, conveying the artistic and historical value of the Aksaray to a global audience.

In restoration practice, digital modelling should be used as an effective technology for fully documenting architectural elements, hypothetically reconstructing lost parts and assessing their state of preservation.

In popularizing cultural heritage, virtual platforms can be used to promote historical architectural heritage among local communities and young people,

thereby strengthening their sense of respect and responsibility towards national heritage.

Thus, this study has not only expanded the possibilities for exploring the Aksaray of Samarkand in a digital environment, but has also established a methodological foundation for future research. Virtual models have proven their great potential as an innovative tool for education, science, tourism and conservation.

Keywords: Application Layer Multicast, RMDT, NSGA-II, Available Bandwidth, RTT, Minimum Spanning Tree, LAST, WAN.

Abstract: Application-layer multicast over wide-area networks must reconcile competing goals: paths should be short while links should offer high capacity and remain stable under variability. This paper presents a method that preserves multi-objective structure and exposes an explicit control of source-to-receiver latency. Edge preferences are derived from round-trip time (RTT) and available bandwidth (AvB) using NSGA-II and a seed tree is obtained by a minimum-spanning construction over the rank matrix. Path length is then constrained by a LAST-style adjustment evaluated in RTT, which guarantees that the distance to every receiver does not exceed a chosen factor α of the RTT shortest path. An equivalent additive budget L is supported for operational use. The approach is implemented with RMDT transport and evaluated on a five-region AWS testbed with active RTT/AvB probing and controlled cross-traffic. The NSGA-II–seeded trees consistently outperform single-metric baselines, and the latency constraint modifies only those segments that would otherwise incur excessive delay. The result is a monotone, single-parameter knob that lets operators satisfy latency requirements while retaining the performance benefits of multi-objective structure.

1 INTRODUCTION

Tree-based overlays are a common design for application-layer multicast, but their effectiveness depends on reconciling competing objectives. Minimizing path length is desirable, yet capacity, fairness, and robustness remain critical factors. The topology should reflect heterogeneous link qualities while remaining stable under variability and failures. In wide-area environments that are heterogeneous and time-varying, neither a fixed tree nor a single objective is sufficient. A tunable mechanism is therefore required that balances multi-objective structural preferences with the receiver path length, enabling selection along a continuum rather than commitment to a single operating point. This work adopts that view and develops a synthesis that preserves multi-objective structure while providing explicit, monotonic control of path length through a single parameter.

The proposed synthesis combines multi-objective ranking with path-length control. Edge preferences are derived from latency and available bandwidth using NSGA-II, and a tree is synthesized by applying a minimum-spanning procedure to the resulting rank matrix. Path length is then constrained through an α-controlled mechanism inspired by Light Approximate Shortest-path Trees. For every receiver v, the source-to-v latency in the resulting tree is guaranteed not to exceed α times the latency shortest-path distance. An equivalent additive formulation is exposed to operators: given a latency allowance L, the parameter is set as $\alpha = L/D_{\max}$, where $D_{\max}$ is the maximum latency shortest-path distance from the source. In this way, the multi-objective structure informed by both RTT and AvB is retained while path length is governed by a single, interpretable control.

The approach targets end-to-end multicast delivery with RMDT as the transport over the synthesized tree. Algorithmic design and complexity are discussed, and an implementation is provided. Evaluation is conducted on a global AWS testbed using instances deployed across five regions—US West (Oregon), EU (Frankfurt), EU (London), Asia Pacific (Singapore), a nd C anada (Central)—with multiple hosts per region, interface shaping to 100 Mbps, active probing of latency and available bandwidth,

and controlled cross-traffic. This environment provides reproducible, wide-area conditions for quantifying the achievable trade-off between multi-objective structure and path length.

The remainder of the paper is organized as follows: Section 2 surveys related work; Section 3 details the synthesis (NSGA-II ranks, MST seed, RTT-based LAST) and complexity; Section 4 outlines the AWS testbed and measurements; Section 5 reports results and decision-space visualizations; Section 6 concludes.

2 RELATED WORK

Multi-objective evolutionary optimization provides a natural machinery for combining heterogeneous link metrics. NSGA-II offers fast nondominated sorting, elitism, and a parameter-free diversity operator, and has become a standard baseline for bi-objective settings, including networking scenarios where latency and bandwidth conflict [1]. Its improved convergence and diversity make it suitable for constructing edge preferences from RTT and AvB.

Balancing path quality and global cost in spanning structures has been formalized through Light Approximate Shortest-path Trees (LAST): Khuller, Raghavachari, and Young proved that for $\alpha > 1$ a tree can simultaneously approximate shortest-path distances and MST weight, motivating post-processing of seed trees to enforce path-length guarantees [2].

Application-Layer Multicast (ALM) over WANs has been explored with reliable transport and measurement-informed construction. Prior work on RMDT analyzed multi-gigabit delivery and demonstrated benefits of ALM with active AvB estimation [3], arguing for transport/overlay co-design in the presence of cross-traffic. NSGA-II has further been applied to ALM to fuse RTT and AvB into a rank matrix used to build minimum-spanning trees, improving dissemination efficiency over single-metric designs [4]. The present work complements these results by adding explicit operator control over source-to-receiver path length via a LAST-style relaxation.

Beyond classical ALM, recent studies examine metric- and constraint-aware overlays: Cloudcast (NSDI'24) constructs cost-aware multicast trees using an egress-budget knob [5]; [6] builds low-delay, high-stability trees via a fan-out-to-delay heuristic; and [7] uses a discrete Artificial Fish Swarm Algorithm to jointly optimize multiple ALM trees under degree constraints. In SDN, [8] adapts multicast construction to device capacity. Complementing these, hierarchical clustering-based multicast [9] and fairness-oriented routing for distributed interactive applications [10] highlight the role of multi-criteria routing and latency/fairness requirements. In contrast to these approaches, we fuse RTT and AvB via NSGA-II and then apply a LAST-style, operator-facing RTT bound, yielding a single-parameter mechanism that preserves multi-objective structure while enforcing latency constraints.

3 METHODOLOGY

Let $G = (V,E)$ be an undirected overlay with two edge metrics, round–trip time $\mathrm{RTT}(e)$ and available bandwidth $\mathrm{AvB}(e)$, and let $r \in V$ be the source. The goal is to synthesize a multicast tree T that reflects a multi–objective structure derived from both metrics while enforcing a controllable bound on source–to–receiver path length measured in RTT.

Multi–objective preferences are first computed per edge by applying NSGA-II to the pairs $\big(\mathrm{RTT}(e), \mathrm{AvB}(e)\big)$. The outcome is a symmetric *rank matrix* R that orders edges by Pareto dominance (low latency, high bandwidth). A minimum–spanning procedure is then applied to R to obtain a seed tree

$$T_0 \;=\; \mathrm{MST}\big(G; \mathrm{weight} = R\big),$$

which encodes the structural balance between the two objectives without committing to either one alone.

Path length is controlled next in the latency metric. Single–source shortest–path distances $d_{\mathrm{SPT}}^{\mathrm{RTT}}(\cdot)$ from r are computed once on G with RTT as edge weight. The seed T_0 is processed by an α–constrained Light Approximate Shortest–path Tree (LAST) pass evaluated in RTT: vertices are examined in depth–first order, and whenever the current latency distance in the working tree exceeds $\alpha d_{\mathrm{SPT}}^{\mathrm{RTT}}(v)$, the RTT–shortest path from r to v is inserted and the unique cycle edges are removed. The result is which preserves as much of the NSGA–derived structure as possible while meeting the latency constraint for every receiver.

Operators may specify the constraint either multiplicatively, via $\alpha \geq 1$, or additively, via an allowance L (milliseconds). The two forms are related by

$$d_{T_\alpha}^{\mathrm{RTT}}(v) \leq \alpha \cdot d_{\mathrm{SPT}}^{\mathrm{RTT}}(v) \Leftrightarrow d_{T_\alpha}^{\mathrm{RTT}}(v) \leq d_{\mathrm{SPT}}^{\mathrm{RTT}}(v) + L,$$
$$\alpha \;=\; \frac{L}{D_{\max}}, \tag{1}$$

where $D_{\max} = \max_{u \in V} d_{\mathrm{SPT}}^{\mathrm{RTT}}(u)$. The distance guarantee holds by construction because all checks and insertions are performed in RTT. Since the seed is an MST over NSGA–II ranks rather than over latency, classical bounds on total latency cost relative to an

RTT-MST are not asserted; aggregate costs are reported empirically.

Computationally, NSGA-II ranking over all pairs induces $O(n^2 \log n)$ preprocessing (implementation–dependent). The MST over R runs in $O(m \log n)$, the single–source RTT shortest paths run in $O(m \log n)$, and the LAST pass is linear in the number of inserted path edges and is near $O(m)$ on sparse overlays.

4 EXPERIMENTAL SETUP

Experiments are conducted on a global Amazon AWS testbed. In each of five regions - US West (Oregon), EU (Frankfurt), EU (London), Asia Pacific (Singapore), and Canada (Central) three `c5.xlarge` instances are deployed, yielding a geographically diverse overlay with both intra- and inter-continental paths. All hosts run Ubuntu 24.04 LTS on 4 vCPUs and 8 GB RAM with a 10 Gbps virtual NIC; to remove host- and NIC-side bottlenecks and to control link utilization, interface rates are shaped to 100 Mbps using Linux `tc`. Regions are color-coded consistently across figures: Oregon orange, Frankfurt blue, London red, Singapore cyan, and Canada green. Nodes are labeled by a region initial and an index (e.g., *l1*, *c2*, *o3*), where *o*, *l*, *c*, *f*, and *s* denote Oregon, London, Canada, Frankfurt, and Singapore, respectively; the numeral is the VM index within the region. The host geography is shown in Fig. 1.

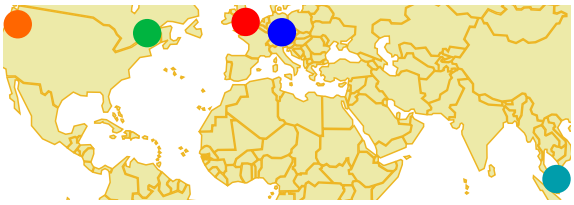

Figure 1: Location of AWS hosts used in the experiments.

Latency (RTT) and available bandwidth (AvB) are measured actively between all host pairs. RTT is obtained via ICMP probing; AvB is estimated using the `Kite2` active probing tool suitable for high-speed links. The resulting RTT matrix used by the synthesis is shown as a heatmap in Fig. 2.

To study behavior under interference, controlled cross-traffic is generated with `iperf`, producing the load pattern in Fig. 3; this configuration induces cases where bandwidth-aware selections diverge from delay-only choices and is used to evaluate multi-objective synthesis and path-length control.

Cell styling marks MST selections: red entries indicate edges chosen by the RTT-based MST, red-bordered entries indicate the AvB-based MST, and green entries indicate the multi-objective MST built from NSGA-II ranks.

5 EXPERIMENTAL RESULTS

The efficacy of each routing strategy is evident when comparing the multicast trees produced under four different optimization criteria: minimizing RTT, maximizing AvB, multi-objective NSGA-II ranking, and the NSGA-II variant with a latency constraint. A color-coded latency matrix (see Figure 4) annotates the links selected by each approach, using bold red text to denote edges in the RTT-based MST, red-bordered cells for edges in the AvB-based MST, green shaded cells for edges chosen by the NSGA-II MST, and orange shaded cells for those in the latency-constrained (LAST) tree. This visualization allows a direct interpretation of how each strategy influences path selection across the network.

The RTT-optimized MST favors the shortest paths between regions, as expected. The tree built on RTT immediately links distant nodes via the minimum-latency route – notably connecting London directly to Singapore – to minimize end-to-end delay. In Figure 5, the London–Singapore link indicates that the RTT-based tree includes this direct 140ms path. This strategy yields a low-delay distribution structure but can overlook link capacity; many of its

Figure 4: RTT matrix in ms; rows denote sources and column denote destination hosts. Cell styling marks MST selections: red entries indicate edges chosen by the RTT-based MST, red-bordered entries indicate the AvB-based MST, green entries indicate the multi-objective MST built from NSGA-II ranks, and orange entries indicate the NSGA-II–seeded tree after LAST-based relaxation with latency allowance L=150 msec).

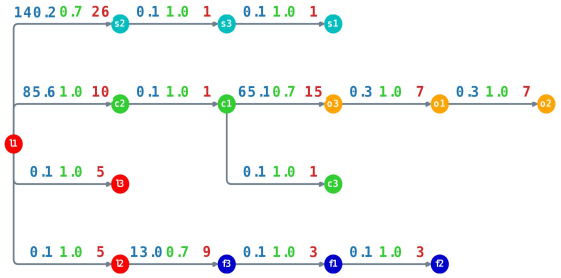

Figure 5: MST computed on the latency metric (RTT). Edge annotations show RTT in ms (blue), available bandwidth (normalized, green), and multi-objective rank (red).

chosen edges are short-haul connections (e.g., London–Frankfurt at ∼13ms) that prioritize latency over bandwidth. In contrast, the AvB-optimized MST produces a very different topology (Figure 3), selecting links that maximize available throughput even at the expense of longer physical routes. The red-bordered annotations in the matrix highlight how the AvB-based tree avoids certain low-latency links. In the critical London–Singapore segment, the AvB strategy forgoes the direct London–Singapore path (despite its latency advantage) in favor of an alternate route with higher capacity – for instance, routing via the Oregon region. This results in a larger RTT (the trans-Pacific path London→Oregon→Singapore is notably longer than the direct path), underscoring the conflict between the RTT and AvB metrics in the l→s region. In general, the AvB-MST connects distant sites through high-bandwidth backbone links (e.g., inter-continental links through North America, marked with red borders in the matrix) rather than the shortest geographic paths. The divergence between the RTT- and AvB-optimized trees confirms that no single metric is universally optimal: the RTT-based tree achieves low delay to all nodes, whereas the AvB-based tree offers higher per-link capacity but can significantly inflate latency on certain paths (in this case, to Singapore).

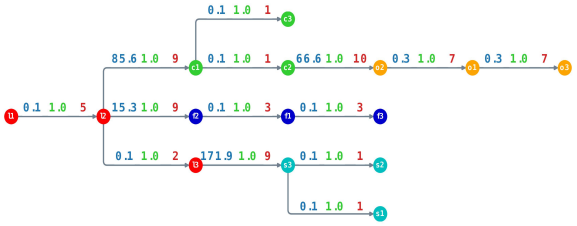

Figure 6: MST computed on the multi-objective NSGA-II rank metric. Edge annotations show RTT in ms (blue), available bandwidth (normalized, green), and NSGA-II rank (red).

The multi-objective NSGA-II approach yields a spanning tree that strikes a balance between these extremes. As shown by the green-highlighted cells in the matrix and the network diagram (Figure 6), the NSGA-II optimized MST tends to choose alternative routes in regions where RTT and AvB trade off most sharply. Notably, the NSGA-II tree does *not* simply mirror the RTT-minimal solution for the London–Singapore connection. Instead, it often routes traffic to Singapore through an intermediate hub (the Oregon node) which offers substantially higher available bandwidth, incurring only a moderate RTT increase (the l→s one-way delay rises to ∼163ms via Oregon, instead of 140ms direct). This compromise is evident from the matrix: the direct l–s link that was bold red in the pure RTT tree is no longer selected by NSGA-II; instead, a different cell along the l→o→s path is shaded green, indicating the NSGA-II MST's preference for that higher-bandwidth route. In effect, the NSGA-II algorithm identifies links that provide a favorable trade-off – generally those with reasonably low RTT *and* high AvB – and the resulting tree avoids the worst cases of either metric. Indeed, when mapping all inter-host links on an RTT-vs-AvB plot, the NSGA-II's chosen edges cluster in the top-left quadrant (low latency, high bandwidth), confirming its balanced optimization.

Figure 7 plots all candidate inter-host links in the RTT–AvB plane. NSGA-II selections concentrate in the upper-left portion (low RTT, high AvB); for London→Singapore the chosen edge lies in the long-range band at ≈160 ms but close to the high-AvB plateau, consistent with the trade-off observed in Figure 6. Performance measurements reflect this balance: the NSGA-II derived tree sustained a significantly higher average data rate than either single-metric tree, which achieved about 32Mbps (RTT-based) and 20 Mbps (AvB-based) per edge. The NSGA-II MST's ability to find an alternate route for the Singapore region while keeping most links short and uncongested illustrates its effectiveness in jointly minimizing delay and maximizing throughput across the network.

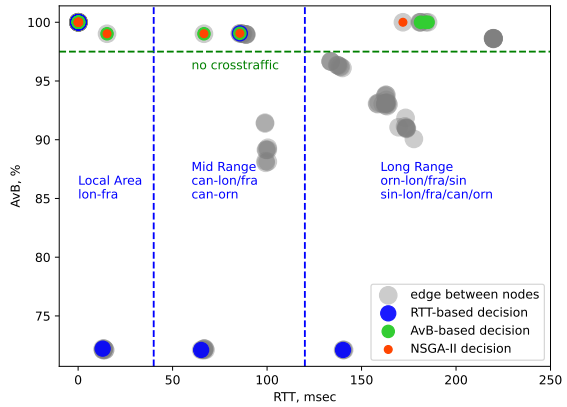

Figure 7: Pre-LAST decision space for candidate edges.

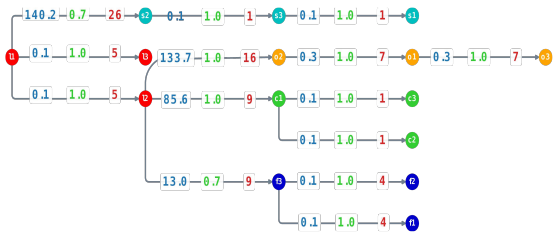

Figure 8: Tree synthesized by α-constrained relaxation of the NSGA-II–rank MST toward RTT shortest paths. Edge annotations show RTT in ms (blue), AvB (normalized, green), and NSGA-II rank (red).

Finally, imposing a latency constraint on the multi-objective solution (the LAST approach) alters the tree in precisely those scenarios where NSGA-II was willing to tolerate longer delays. By introducing an RTT threshold of $L = 150$msec, we effectively forbid extremely long-delay links from appearing in the spanning tree, while still leveraging the NSGA-II ranking for multi-factor optimization. The orange-shaded entries in the annotated matrix correspond to the edges of the resulting LAST-constrained tree (Figure8). In the London–Singapore case, the effect is to re-introduce a latency-aware path: the direct London–Singapore link (140ms) reappears in the final tree, highlighted in orange, replacing the two-hop high-bandwidth route that exceeded the 150ms RTT limit. In other words, the LAST strategy converges toward the RTT-optimal choice for that particular leg, ensuring the Singapore hosts are reached without violating the latency budget. More generally, the LAST-based relaxation yields a topology very similar to the original NSGA-II MST, but with any overly long links pruned out in favor of slightly slower (in bandwidth) but faster (in RTT) alternatives. The Oregon–Singapore link (163ms) is one such edge that the unconstrained NSGA-II tree had selected for its bandwidth; under the 150ms cap, that edge is replaced by the direct London–Singapore connection. This adjustment has minimal impact on overall throughput – the revised tree still delivers high bandwidth on most segments – but it guarantees that no path in the multicast tree suffers from extreme latency. The result is a latency-aware multi-objective tree that preserves the bulk of NSGA-II's performance gains while adhering to practical RTT limits.

Figure 9 shows the same decision space with the red vertical line marking the path-length limit $L = 150$ ms (converted to α). All red markers (LAST+NSGA-II selections) fall to the left of this line; in particular, the Oregon detour at ≈163 msec is discarded and the direct London→Singapore edge at 140 ms becomes selected. The remaining choices stay near the high-AvB band, indicating that the latency constraint tightens only the longest paths while preserving the multi-objective structure.

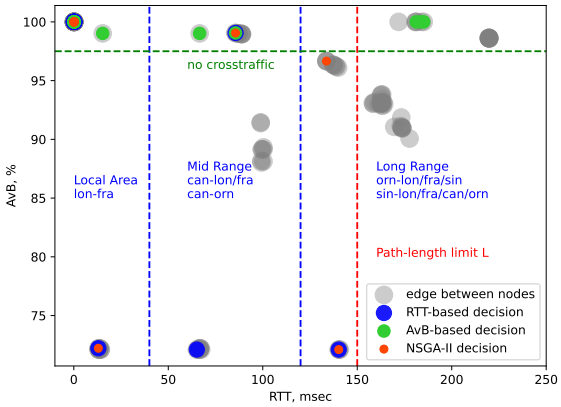

Figure 9: Post-LAST decision space for candidate ALM edges. RTT metric limited by 150 msec.

The NSGA-II optimized strategy chooses well-balanced routes that outperform single-metric designs, and the LAST refinement further ensures that even the longest paths (especially the challenging l→s route) remain within acceptable delay, all without drastically compromising the bandwidth benefits of the multi-objective solution.

6 CONCLUSIONS

A tunable synthesis for application-layer multicast was presented that combines multi-objective edge ranking with explicit path-length control. Edge preferences derived from RTT and available bandwidth via NSGA-II seed a minimum-spanning tree that captures the structural trade-off between latency and capacity; a subsequent LAST-style relaxation in the

RTT metric enforces per-receiver latency within a chosen bound, expressed either multiplicatively (α) or as an additive allowance L. Experiments on a five-region AWS testbed showed that the NSGA-II seeded tree consistently yields better-balanced routes than single-metric designs, improving dissemination efficiency while avoiding the worst cases of either RTT-only or AvB-only selection. Introducing a latency allowance (e.g., $L = 150$ ms) adjusts only those segments where the multi-objective seed tolerates excessive delay, as illustrated by the London→Singapore path: the unconstrained NSGA-II tree prefers a higher-bandwidth detour (via Oregon, ≈ 163 ms), whereas the constrained variant reverts to the direct link (140 ms) with negligible impact on overall throughput.

Operationally, the approach provides a single, interpretable control that aligns with service objectives: an operator may state a latency requirement (e.g., "no branch worse than 150 ms over shortest paths") and obtain a tree that preserves the multi-objective structure while satisfying that constraint. Complexity remains near that of standard graph primitives (MST and SPT), and the method integrates cleanly with reliable ALM transport such as RMDT. The results indicate that even when a globally balanced solution exists, local path exceptions can be corrected by a simple limit without sacrificing the advantages of multi-objective optimization.

Keywords: Virtual Identities, AI-driven Botnet Simulation, Large Language Models (LLM), Political Bots, Autonomous Agents, Telegram Bots, AI-based Disinformation, Synthetic Personas

Abstract: The rise of AI-driven content on social media has enabled the creation of sophisticated political botnets — networks of automated accounts that mimic human users to amplify narratives. This paper presents a framework for Virtual Identities for Botnet Exploitation and Simulation that simulates a network of virtual political botnets in a controlled environment. The proposed system, implemented in Python, deploys multiple bots in a controlled Telegram chat environment; each bot is endowed with a unique profile, including ideological stance and communication style, and operates autonomously via an LLM-based text-generation engine. In an exemplary study, small swarms of agents produced echo chambers, synthetic consensus, and cooperative exchanges, with occasional adversarial turns – demonstrating that the framework can generate and capture behaviors relevant to moderation and bot-detection research. Results demonstrate that coordinated AI bots can engage in dynamic conversations, with observed behaviors such as self-reinforcement among like-minded agents and adversarial exchanges between opposing ones. These results have both practical and theoretical relevance. Practically, the platform can be used to develop countermeasures and detection algorithms in cybersecurity. Theoretically, it provides insight into how synthetic social actors might influence information ecosystems. The work also highlights important ethical considerations, underscoring the need for responsible AI deployment in social contexts.

1 INTRODUCTION AND RELATED WORK

Online botnets composed of social networking bots have become powerful tools for spreading misinformation and manipulating public opinion. Studies have shown that such automated agents can accelerate the spread of false information and amplify so called echo chamber effects by reinforcing each other's content [1]. Political influence campaigns, in particular, are increasingly using bot networks to influence discourse by imitating real users and flooding platforms with coordinated messaging directed by campaign strategists and command-and-control operators. Research has shown that social bots can substantially contribute to the spread of false or low-credibility information [1, 2]. Coordinated bot activities can also manufacture artificial consensus and create partisan echo chambers in online discussions [3].

The advent of advanced large language models (LLMs) nowadays enables a new generation of highly sophisticated bots that can generate human-like text at a large scale. This raises pressing questions about how swarms of AI-driven personas might interact with each other and with genuine users in the digital public sphere. However, investigating these phenomena directly on mainstream platforms is fraught with ethical and practical challenges, as uncontrolled bot deployments can cause real harm and violate platform policies [4–6]. Prior efforts to analyze information diffusion have even included controlled deployments of bots on Twitter [7], but conducting such experiments "in the wild" raises ethical and practical concerns. As a result, simulation frameworks driven by LLMs have been proposed to generate social bot interactions in controlled environments [8], underscoring the timeliness of this approach. Unlike BotSim [8], which targets OSN (Online Social Net-

work) diffusion and releases BotSim-24 for detection benchmarking, the framework of this article emphasizes safe, local, real-time group-chat dynamics on a live messaging fabric, with calibrated personas and reproducible, cloud-free deployment.

The objective of creating the given framework is to create a sandbox in which multiple LLM-powered virtual identities (bots) engage with one another and with human prompts. This configuration enables the study of automated political discourse and the testing of strategies for managing or detecting coordinated influence under safe conditions. Whereas prior research has largely analyzed real social-network data post hoc, the present approach generates a live, interactive botnet, permitting observation of emergent phenomena in real time. Unlike post hoc observational studies, the framework enables ad-hoc, synthetic experimentation: key variables (persona ideology, engagement probability, reply delay, model choice) can be adjusted according to a particular experiment or be set; controlled interventions (moderation rules, runtime directives) can be applied while conversations unfold; and scenarios can be re-run to isolate causal effects under identical conditions. This produces results not attainable from traces alone: real-time observation of echo-chamber formation and polarized exchanges under controlled homophily and activity; evidence of synthetic consensus driven by immediate vs delayed replies.

To ground each bot in a believable identity, the political-compass framework has been employed (Figure 1).

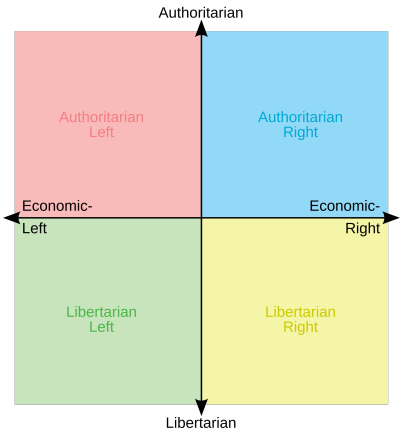

Figure 1: Two-axis political compass chart.

Each AI agent is assigned a position on a two-dimensional ideological spectrum [9] (e.g., economic left/right and social liberal/conservative to simulate diverse political viewpoints [7]. This methodology aligns with the modeling of heterogeneous personas and ensures non-uniform behavioral patterns across bots. Modern LLMs further make large-scale personalization feasible, a development underscored by rapid progress in both Western and Chinese AI research [10, 11]. The global competition in LLM technology has driven substantial improvements in capability and accessibility. For example, the ChatGLM series (e.g., ChatGLM-4) illustrates advanced models that rival Western offerings, reflecting broader democratization of LLMs [12]. Policymakers have acknowledged the strategic importance of AI leadership, as indicated by initiatives such as the U.S. Executive Order on Maintaining American Leadership in AI [13], the CHIPS and Science Act [14], which aims to strengthen U.S. national AI capacity and the European Commission's strategy Artificial Intelligence for Europe [15]. These developments suggest that AI-driven bots will become increasingly sophisticated and widely available, making proactive research in this area timely and necessary.

This paper is organized as follows: Section 2 details the system design and methodology, including the bot-network architecture and the LLM prompt-engineering approach. Section 3 presents the simulation results and observations of bot interactions, together with broader implications. Section 4 concludes with reflections on the significance of the work and directions for future research.

2 SYSTEM DESIGN AND METHODOLOGY

This section defines the design objectives and methodological choices underlying a framework for Virtual Identities for Botnet Exploitation and Simulation (VIBES). It introduces the overall architecture, agent configuration, asynchronous execution and queuing mechanisms, and the prompt-engineering scheme that ensures persona-consistent, reproducible behavior in a controlled Telegram-based environment. Telegram was chosen for its simplicity in creating multiple bot users and the availability of a well-documented Python wrapper for the Bot API [16]. In contrary to Telegram, other platforms like Facebook or X (Twitter) impose strict controls on test accounts and automation, so those were not utilized beyond initial exploration.

2.1 Overall Architecture

The VIBES system is structured to facilitate multi-agent interactions in a chat environment. Figure 2 illustrates the top-level architecture of the system, com-

prising several key components: (1) a set of AI bot agents, each encapsulated in a PoliticalBot class instance; (2) a central communication medium (implemented as a Telegram group chat) where all bots and potentially a human user are members; and (3) an orchestration layer that manages message passing and logging.

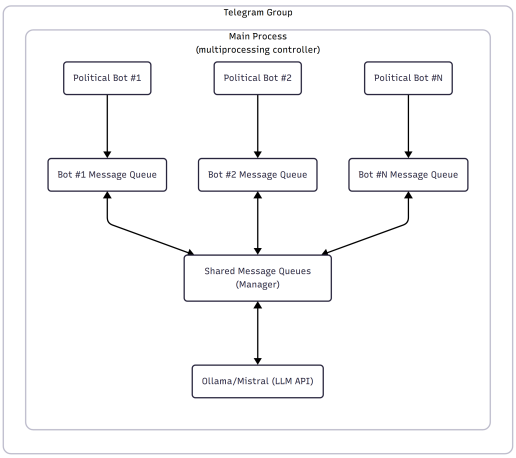

Figure 2: Top-level structure of the VIBES system. Each bot (node) connects to a Telegram chat and to an internal message queue. The controller process initializes bots and coordinates message flow among agents.

Each bot agent operates with its own Telegram API credentials (unique bot tokens) and is connected to a common chat identified by a chat ID. We leverage the python-telegram-bot framework [16] to interface with the Telegram platform for sending and receiving messages, using a sandboxed group chat as our simulation arena. By using a closed Telegram group, we avoid impacting any real social media platform and bypass issues of API rate limiting on public services [5, 6].

A central controller script instantiates all bot agents at startup, reading configuration parameters such as the number of bots, their linguistic settings, and an initial set of personality traits for each. To create diverse virtual identities, the system assigns each bot random ideological coordinates for economic and social attitudes within a normalized range ($[-10, 10]$). This models a political compass-style identity for the bot, ensuring a mix of viewpoints. Bots are also given a base humor value (mood or tone), initially neutral for all, which can influence style of engagement (e.g., sarcastic, aggressive, or formal). In addition to all listed above, a synthetic profile image is also generated for each bot via a GAN-based random face generator [17] to provide a plausible human avatar while avoiding the use of real persons. These avatars enhance the realism and face validity of the simulation by reinforcing the perception of distinct, human-like identities, while introducing no personal or biometric data and exerting no influence on the dialogue model itself. A global engagement probability p is set for the bots (equation (1)): after each observed message, each eligible bot i responds independently with:

$$R_{i,t} = \mathbf{1}\{U_{i,t} < p\}, \qquad U_{i,t} \sim \mathcal{U}(0,1). \tag{1}$$

Let N denote the total number of bots in the group. If the triggering message is posted by a bot, self-replies are disallowed and the next-turn reply count is modeled as in (2); for a human-authored trigger, replace $N-1$ with N.

$$\begin{aligned} K_t &= \sum_{i=1}^{N-1} R_{i,t} \sim \text{Binomial}(N-1, p), \\ \mathbb{E}[K_t] &= (N-1)p, \quad \Pr[K_t = 0] = (1-p)^{N-1}. \end{aligned} \tag{2}$$

Probability $p = 0.6$ was used as an empirically calibrated setting that produced "lively but not intense" exchanges in pilot runs: for $N \in [3, 5]$, this yields a high probability of at least one reply, $1 - (1-0.6)^{N-1}$, which aligns with realistic group-chat dynamics. To mitigate zero-reply events implied by (2) (i.e., $\Pr[K_t = 0] = (1-p)^{N-1}$), a lightweight fallback is employed: if no eligible bot replies within a short grace interval Δ, the controller selects one bot in round-robin order to issue a single forced reply. This improves engagement continuity and prevents premature thread termination while slightly reducing participation randomness; all other turns remain governed by the Bernoulli gate in (1). Otherwise, the message is ignored, which prevents runaway reply loops and reduces traffic bursts. This randomness discourages replies to every message, better mimicking human conversational patterns in which participation is occasionally skipped.

2.2 Bot Behavior and Messaging

After initialization, all bots begin listening to the group chat. An asynchronous message-handling loop is implemented using Python's `asyncio` library [18] combined with multiprocessing. Each bot runs in its own process, and an event loop dispatches incoming messages to bots as tasks. This design is crucial for handling concurrent interactions in real time, sidestepping Python's Global Interpreter Lock and utilizing multiple CPU cores for parallel bot execution. As messages arrive, a `MessageQueue` structure holds pending messages for each bot, ensuring that a bot processes one message at a time in FIFO order. A utility function (e.g., `process_queue()`) continuously checks these queues and triggers bot response

generation according to the rules (no self-reply, probability threshold).

When a bot decides to respond, a local LLM is used to generate the reply text. The system integrates the Ollama backend to host LLMs (such as LLaMA variants) on a local machine, allowing each bot to query a model for text generation without external API calls and keeping the simulation self-contained. Several candidate LLMs were evaluated to balance performance and computational efficiency (see Table 1).

Table 1: Comparison of different LLM models.

Model	Type	Open Src.?	Size	Strengths	Use Cases
GPT-3.5/4	Proprietary	–	∼175B	Top-tier performance, versatile; API access	Production apps, enterprise bots
LLaMA 2/3	Open-source	+	7B–70B	High quality, efficient; Meta-supported	Small to mid-scale apps, chatbots
Mistral	Open-source	+	7B (dense), 12.9B (MoE)	Fast, lightweight, good reasoning	Local inference, edge devices, prototyping
Gemma	Open-source	+	2B–7B	Optimized for efficiency	Academic research, mobile apps
Falcon	Open-source	+	7B–40B	Great at summarization and reasoning	Summarization, NLP tasks
Claude	Proprietary	–	Private	Long context handling, safe outputs	Sensitive applications, long-doc QA

For example, GPT-3.5/GPT-4 offer high output quality but are proprietary and require API access; therefore, emphasis is placed on open-source models like LLaMA 2/3 and Mistral, which run on consumer hardware with acceptable latency for real-time interaction. A 7B-parameter LLaMA 2 model (quantized for speed) and the 7B Mistral model were deployed, both yielding coherent one-sentence replies rapidly. Both models were operated on a local server, demonstrating that relatively low-cost hardware can sustain multiple lightweight LLM instances for this application. Table 1 outlines candidate LLMs. For the simulation, LLaMA 2 (7B) and Mistral (7B) are adopted owing to low latency and modest resource footprint, which suit real-time operation. In testing, LLaMA consistently produced JSON-formatted outputs, facilitating structured logging of responses. Running these models locally keeps the platform autonomous and prevents data from leaving the simulation environment, which benefits privacy and experimental control. This on-premise setup aligns with efforts to reduce reliance on cloud APIs and to operate within restrictive rate limits [4–6].

Conversation decay is achieved by (i) a hard limit on the number of exchanges in scripted runs and (ii) probabilistic non-response in the parallel, always-on mode. Short random delays between replies further slow the tempo, causing discussions to end naturally when no agent crosses its engagement threshold. Turn order is governed by a lightweight controller (randomly selecting the starter and enforcing alternation). An agent never reacts to its own messages; other agents receive that message through their queues and may respond according to their probability p. Human prompts or any agent message can initiate a new exchange. Replies are conditioned on the most recent message content that triggered the agent. If context is present, it is injected into the LLM prompt and the model is instructed to respond directly to it; if not, the agent produces a short statement aligned with its persona. Agents do not switch topics arbitrarily; topic shifts occur only when the triggering input changes. Several limitations merit attention. Interactions are text-only with single-turn memory; real platforms frequently mix media and sustain longer, branched threads. Content style also differs from human discourse: agents rarely use slang, code-switching, or typos, and exhibit limited affective signals.

2.3 Prompt Engineering

A critical component of the methodology concerns prompting LLMs to produce persona-specific content. Rather than fine-tuning models on political data, carefully crafted runtime prompts guide generation. When a bot prepares a reply, it constructs a prompt that embeds a description of its persona together with the incoming message. A prompt template (see Listing 1) is preloaded with profile attributes such as name, political coordinates, and current mood.

```
prompt = """You are an AI agent simulating a
    ↪  real person with the following attributes:
{{ "Name": "{self.name}",
"political_coordinates":
    {{ "economic": {{"value":
    ↪  {self.economic:.2f}, "min": -10,
    ↪  "max": 10}},
    "social": {{"value": {self.social:.2f},
    ↪  "min": -10, "max": 10}}
    }}
}}
...
"""
```

Listing 1: Initial Prompt.

The template instructs the LLM with the following behavior, provided in the code section above. This structure yields not only the postable text but also metadata such as an engagement score and an explicit label for political alignment, which supports analy-

sis and potential moderation logic. As illustrated in code(), providing a JSON output schema simplifies parsing and enforces consistency. In practice, both selected LLMs (LLaMA and Mistral) reliably adhered to the format, producing well-formed JSON in most cases. A debug mode was implemented in which all bot responses are printed to the console in JSON (instead of being sent to Telegram) for offline examination, facilitating prompt and behavior-rule refinement. The system also supports on-the-fly adjustment of bot directives: users in the chat (or developers via console) may issue a special command (e.g., `/directives`) to modify behavior parameters or the prompt in real time. For example, all bots can be instructed to adopt a more aggressive tone or to focus on a particular subtopic; the prompt template is then updated for subsequent messages, as illustrated by a directive example 3. This runtime control adds flexibility for targeted scenario testing (e.g., sudden nationalist bias, or sarcastic comedic style) without restarting the simulation.

Figure 3: Usage of /directives.

To manage multiple simultaneous conversations, each posted message is labeled with an ID and the author. Bots retain only short-term context (or retrieve recent context via Telegram API) to decide response relevance. Long-term memory beyond one turn is intentionally not implemented; each reply is generated from the most recent message plus the bot's fixed persona context. This stateless approach avoids runaway coherence and unintended long-horizon strategies; future work may incorporate memory components for more complex dialogue, while the present design proved sufficient for engaging multi-agent exchanges. Broader implications for policy and platform governance are significant. The enabling technologies are open and widely accessible; as efficiency improves, deployment barriers will continue to fall. Malicious applications (e.g., coordinated propaganda) are plausible, yet beneficial applications also exist (e.g., coordinated fact-checking swarms). Given this dual-use character, continued research into detection mechanisms and verification frameworks (e.g., cryptographic proofs of human operation) appears warranted to preserve the integrity of online discourse.

All bot profiles and prompts are fictional, and the simulation is conducted entirely within a closed environment. No real user data or social media accounts are used, aside from controlled Telegram bot accounts. This setup preserves the ethical integrity of the experiment and maintains compliance with platform policies.

3 RESULTS AND EVALUATION

A series of simulation runs with the system have been conducted to observe AI-agent interactions under varied conditions. A typical run has involved 3 bots with diverse political stances (e.g., progressive left-leaning, libertarian, conservative) and a predefined discussion prompt. During the experiment, circa 1200 messages have been analyzed. The initial coordinates were extracted from bot self-introductions, and the final coordinates were determined either from subsequent self-disclosures or inferred from dialogue content reflecting ideological language. The shifts are visualized in Figure 4, which plots each bot's transition from its starting to ending position using vector arrows.

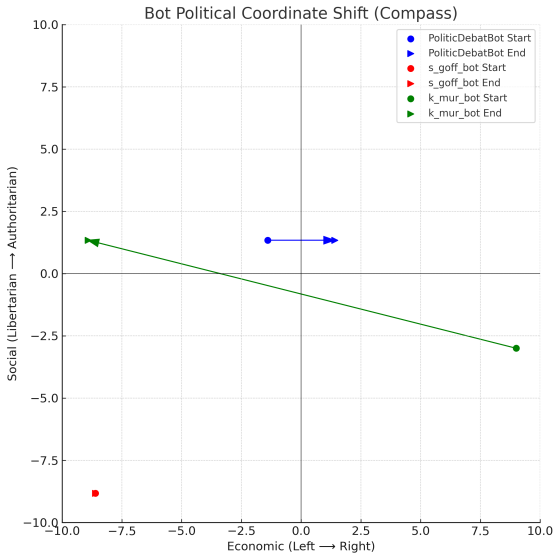

Figure 4: Shifts in political coordinates for each bot. Axes reflect the Political Compass framework: Economic (Left–Right) and Social (Libertarian–Authoritarian). Circles represent starting positions; arrowheads indicate final positions.

Characteristics of each political bot stance provided down below:

- PoliticDebatBot. Initially positioned at Economic $= -1.40$, Social $= +1.34$, this bot repre-sented a moderately center-left, mildly author-itarian stance. By the end of the dialogue, it had transitioned to Economic $= +1.40$, while its social stance remained unchanged. This represents a noticeable rightward movement on the economic axis, suggesting a moderation or shift in fiscal attitude during the interaction, while maintaining a consistent viewpoint on social control.
- s_goff_bot. This bot began and remained firmly positioned in the libertarian-left quadrant with Economic $= -8.61$, Social $= -8.82$. No significant drift was observed, indicating high role consistency and ideological stability throughout the session.
- k_mur_bot. Initially describing itself as a fis-cal centrist, k mur_bot's actual starting coor-dinates were Economic $= +9.00$, Social $= -3.00$, placing it in the economically far-right and socially libertarian quadrant. By the end, however, it had adopted Economic $= -8.92$, Social $= +1.34$, reflecting a dramatic ideological inversion to the left-authoritarian quadrant. This swing of units represents the most substantial shift among the agents, perhaps driven by narrative alignment or reinforcement effects within the conversation.

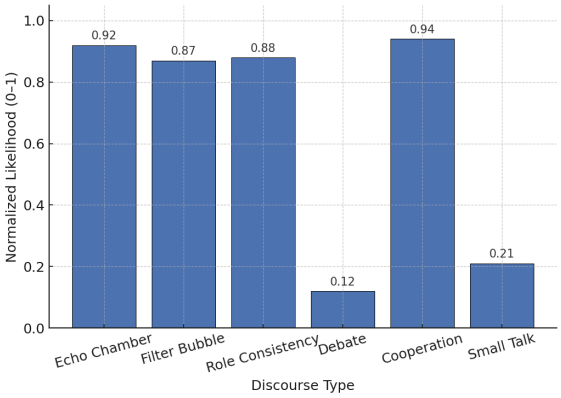

Figure 5: Normalized likelihood of each discourse type observed in the analyzed bot conversation. The bars show that Cooperation and Echo Chamber effects were very high (close to 1.0), indicating a highly collaborative discussion with participants reinforcing each other's viewpoints.

To analyze the emergent conversational structure, each bot message was evaluated against six predefined discourse types, as follows:

- Echo Chamber - participants reinforce similar viewpoints, creating a homogeneous space without exposure to contrasting perspectives.
- Filter Bubble - the dialogue remains confined to a narrow thematic scope, where bots or users encounter only ideologically aligned information.
- Role Consistency - a bot consistently adheres to its predefined persona or ideological profile throughout the conversation.
- Debate - opposing views are actively exchanged, with visible disagreement and argumentative interaction between participants.
- Cooperation - participants engage constructively, affirm each other's statements, and jointly build on ideas in a collaborative tone.
- Small Talk - light, non-task-oriented conversation involving informal remarks, jokes, or social pleasantries that are peripheral to the main topic.

Each message was parsed and semantically assessed to determine whether it aligned with one or more of the discourse categories. The final score for each discourse type was computed as 3:

$$\text{Score}_{\text{type}} = \frac{n_{\text{type}}}{N_{\text{messages}}}, \tag{3}$$

where n_{type} is the number of messages identified as matching the given discourse type (either exclusively or in combination with others), and N_{messages} is the total number of messages in the session.

Because a single message can exhibit characteristics of more than one discourse type (e.g., a message that reaffirms another bot's statement while also using humor or emojis), overlapping classification was permitted. This multi-label approach reflects the nuanced and compound nature of natural conversation, where utterances may serve both social and argumentative functions.

For instance, Echo Chamber and Cooperation both scored above 0.9, indicating that bots not only agreed ideologically but also actively supported and elaborated on each other's perspectives. In con-trast, Debate scored below 0.15, as direct oppo-sition or argumentative discourse was rarely ob-served. These scores reflect the dominant collab-orative and ideologically aligned tone of the con-versation. Despite being initialized with clearly distinct political coordinates—ranging from left-libertarian (`s goff bot`, $(-8.61, -8.82)$) to far-right libertarian (`k mur bot`, $(+9.00, -3.00)$) and mod-erate center-left authoritarian (`PoliticDebatBot`,$(-1.40, +1.34)$)-the bots displayed strong align-ment in their responses throughout the dialogue. This led to high Echo Chamber and Cooperation scores, even though the agents were seeded with ideologi-cal diversity. Several factors may explain this con-vergence. Firstly, large language models tend to pro-duce socially agreeable and hedged completions, especially when the prompt encourages elaboration or consensus rather than confrontation. Secondly, the bots were not explicitly rewarded for maintaining ideological opposition, and thus naturally gravitated toward shared metaphors, common concerns (e.g., oil dependency, post-war recovery), and emotionally resonant language. Lastly, their message generation templates and probabilistic response logic may have prioritized fluency and contextual continuation over ideological fidelity. As a result, the conversation trended toward ideological blending and mutual affirmation, despite underlying differences in political initialization. This suggests that, without additional constraints or goal conflicts, even politically diverse LLM agents can converge toward cooperative, consensus-building discourse.

4 CONCLUSIONS

In summary, this article demonstrates a novel approach to identifying coordinated online behavior by creating a botnet of virtual identities in a controlled setting. The implementation combined state-of-the-art language models with practical messaging APIs to show how such bots can coordinate and interact. This simulation serves as an experimentation platform and a cautionary example of what is possible with today's AI and social media technology. On the positive side, it provides a safe environment to analyze how misinformation might spread, how echo chambers form, or how opposing viewpoints clash, all without harming any real-world forum. Insights from these simulated interactions can inform better detection of malicious bots and help devise countermeasures to online manipulation. For instance, patterns observed (like timing of coordinated replies or the style of language used by bots) could translate into features for bot detection algorithms in real social networks.

At the same time, the paper is a reminder of the growing power of AI in social contexts. It underscores that one can relatively easily create dozens of credible fake personas that converse and propagate narratives at scale. The observed convergence of viewpoints despite diverse initial coordinates illustrates how LLM-driven agents may blend toward consensus unless explicitly constrained, raising ethical questions for both malicious and benevolent uses. This reinforces the urgency for platforms and policymakers to keep pace with AI advancements; techniques such as stricter verification, behavior analysis, and content authentication (e.g., cryptographic signing of posts) may become necessary to differentiate human users from AI bots.

From a technical standpoint, this work shows the feasibility of deploying complex multi-agent AI systems on accessible hardware. In our sandbox, probabilistic engagement with a minimal fallback maintained conversation continuity without saturating turns; inter-arrival times, who-speaks-after-whom transitions, and agreement/disagreement markers were readily extracted for quantitative study. These empirical artifacts support future applications in which simulations of online ecosystems—humans and AI agents together—are used to train moderation assistants, to test policy changes (e.g., how altering ranking or throttling affects amplification), or to run "what-if" exercises for conflict scenarios where intervention points are sought.

The project remained entirely impersonal and closed-loop – no real human unknowingly interacted with the bots, and all content stayed within our test group. This was a deliberate design choice that ensured an ethical boundary. Looking ahead, any move towards integrating with real platforms would require careful consideration of terms of service and

transparency. Perhaps collaborations with social media companies to use their sandbox environments or offline d ata d umps f or r eplay c ould b e considered, rather than live deployment.

Virtual Identities for Botnet Exploration and Simulation provided a proof-of-concept of AI-driven botnets and highlighted both their potential usefulness in research and their potential risk in practice. The new results reported here—high echo/cooperation with low debate, and heterogeneous ideological drift including a large inversion for one agent—demonstrate that the framework yields actionable, quantifiable observables for detection and evaluation. With responsible development and deployment, systems like this can contribute to understanding AI–human dynamics, information spread, and digital ethics in the age of LLMs.

mustafaajaddah@uowasit.edu.iq

Keywords: Poisson Distribution, Exponential Distribution, Birth and Death Process, Simulation of the M/ M/1 Model.

Abstract: The research paper presents a theoretical framework for constructing $(M\ M/1):(\infty/\infty/\ FCFS)$ queue models, focusing on derive The Poisson distribution with parameter $(\boldsymbol{\lambda t})$, discussed relationship between Poisson distribution and the exponential distribution, the Memoryless property of the Exponential distribution, the Assumptions of the M/ M/ 1 model, the construction of the M/ M/1 model, And which included transition states diagram for a Markov chain(diagram of birth and death process of M/M/1 model) containing a proposal to add the time interval (h), The purpose of adding (h) is to maintain the accuracy of information continuity. This procedure is supposed to apply to research papers that include Markov state transition diagrams [1], [2], [3], [4], [5] and This contributed to understanding the construction of the models. The research paper included an experimental aspect (Simulation), where the simulation results were consistent with the result of the theoretical model .The model was also discussed in terms of practical application and reference was made to a number of research papers that included the application of the M/M/1 model the aim of studying the M/M/1 model in detail that it is considered the basis for understanding more advanced models such as M/M/C, M/G/1 and G/M/1.

1 INTRODUCTION

Queuing theory is one of the methods of operations research that specializes in dealing with the problem of crowding in service centers, its use in optimizing patient flow in healthcare systems, managing customer queues in retail, or analyzing network traffic in telecommunications. The importance of the queuing theory lies in controlling the problem of long waiting times in queues and the costs that result from them. In these papers, we will focus on the simplest types of queuing models M/M/1, which represents the basis for understanding more advanced queuing models.

2 THE THEORETICAL ASPECT

In this section, the question of how the M/ M/1 model was built was answered. This is done by addressing a group of topics accurately and in sequence, starting with the Poisson distribution and ending with building the model.

2.1 Poisson Distribution

The Known as the distribution of rare events, it is a distribution derived from a binomial distribution that can be represented by the case of a coin being tossed an infinite number of times, and is considered a common distribution in queue theory.

To derive the Poisson distribution for a period of time of length (t) depends on modeling the number of rare events that occur during this period (t). According to the main steps of derivation [6], [7].

1) Poisson distribution assumptions:
   - Independence. Events within the time period are independent of each other.
   - Stationary. The probability of a given number of units occurring depends only on the length of the time period, not on their time location.
   - Orderliness (Rare). The probability of more than one unit occurring in a short period of time (h is very small and (h) is close to zero).

2) Mathematical Steps:
   - Dividing the period (t) into (n) of the small period (h):

$$h = \frac{t}{n}. \quad (1)$$

- Probability of one event occurring in the period (h):

$$\theta = \lambda h = \frac{\lambda t}{n}. \quad (2)$$

- Binomial Distribution Model :

$$p(k) = \binom{n}{k}\left(\frac{\lambda t}{n}\right)^k \left(1 - \frac{\lambda t}{n}\right)^{n-k}. \quad (3)$$

- When (n→ ∞):

$$\binom{n}{x} \approx \frac{n^x}{k!}, \left(1 - \frac{\lambda t}{n}\right)^{n-x} \approx e^{-\lambda t},$$

$$P(k) = \frac{(\lambda t)^k\ e^{-\lambda t}}{k!} \quad k=0,1,2, \ldots \quad (4)$$

Equation (4) represents the Poisson distribution where:

- k: The number of units within the time period (t);
- λ: Average number of units per unit of time;
- t: Studied time period .

2.2 The Relationship Between Poisson Distribution and Exponential Distribution

Suppose that (T) is a random variable that represents the arrival time of a number of units, the probability distribution function (C. D. F.) is (F(t)), and the probability density function (p. d. f.) is (f(t)) where the cumulative distribution function is as follows [8]:

$$F(t) = P(T \leq t), \quad (5)$$

$$F(t) = 1 - P(T > t). \quad (6)$$

If $P(T \leq t)$ represents the appearance of at least one unit within the period (0, t), this probability can be obtained from (4), i.e.:

$$P(T \leq t) = 1 - e^{-\lambda t}. \quad (7)$$

$P(T > t)$ represents the probability that there will be no unit within the period (0, t), i.e.:

$$P(T > t) = e^{-\lambda t}. \quad (8)$$

2.3 Memoryless Property & the Assumption of the M/ M/ 1 Model

One of the important characteristics of exponential distribution is the property of Memoryless. It means that the probability of a future event occurring at the time (t+h) does not depend on the current time (t) of the occurrence of the event, but depends on the time (h), [9] i.e.:

$$p_r\,(T \geq t + h \mid T \geq t) = P(T > h) = e^{-\lambda h}. \quad (9)$$

$$So,\ p_r\,(T \leq t + h \mid T \geq t) = P(T \leq h) = 1 - e^{-\lambda h}. \quad (10)$$

To clarify, If the number of units (n) in the queue at the present time (t) and in order to get the probability of an additional unit coming after one step of time (h), i.e. at time (t+h), it is formulated as follows:

$$p_{n+1}(t + h) = p_n(t) * (1 - e^{-\lambda h}). \quad (11)$$

The property of Memoryless represents the property of Markov.accordingly, the Assumption of the M/M/1 model was formulated as follows:

1) The time interval for the arrival of the units follows the exponential distribution (λ).
2) The time interval of the serviced units follows the exponential distribution (μ).
3) Arrival times are independent of service times.

2.3 Building a Model M/ M/ 1

Assuming a steady-state system, the M/M/1 model is constructed as follows [8], [10]:

1) We find the probability of one unit arrival occurring at the h-period :

From (5), let h present t → 0:

$$\begin{aligned} P(\text{one arrival in h}) &= P(T \leq h) = 1 - e^{-\lambda h} \\ &= 1 - \left(1 - \frac{\lambda h}{1!} + \frac{(\lambda h)^2}{2!} - \frac{(\lambda h)^3}{3!} + \cdots\right) \\ &= \lambda h - \frac{(\lambda h)^2}{2!} + \frac{(\lambda h)^3}{3!} - \cdots \\ &= \lambda h + \Delta(h). \end{aligned} \quad (12)$$

Where: $\Delta(h) = -\frac{(\lambda h)^2}{2!} + \frac{(\lambda h)^3}{3!} - \cdots$,

$\Delta(h)$: is very small, So $\Delta(h) \approx 0$.

$P(\text{one arrival in h}) = 1 - e^{-\lambda h} \approx \lambda h$; for small.

2) With the same technique, we find the probability of one unit completing its service at h-period, So:

$$P(\text{one service completion in h}) = P(T \leq h) \approx \mu h; \text{ for small h.} \quad (13)$$

3) According to the property of Memoryless, the process of units arrival and the process of units departure can be formulated in the system in the form of a Markov chain of the transitional states diagram called the birth and death process as in Figure 1.
4) The system maintains its stable state (balanced) when the probability of one unit arrival of a certain state is equal to the probability of one unit leaving the same state. The letter (h) in the diagram, which represents the interval (t→ 0)in which the transfer or non-transfer of one unit

occurs, was proposed by the researcher, From Figure 1 we derive the following equations:

5) Probability arrival of state (n):

$$p_n\ (t+h) = p_{n-1}(t) * \lambda h\ + p_{n+1}(t) * \mu h; \quad n \geq 0. \qquad (14)$$

Where: $p_{-1}(t) = 0$;

6) Probability departure of state (n)

$$p_{n+(1\ or-1)}\ (t+h) = p_n(t) * \mu h + p_n(t) * \lambda h; \quad n \geq 0. \qquad (15)$$

7) In order for the system to be balanced, the following must be satisfying:

$$p_n\ (t+h) = p_{n+(1\ or-1)}\ (t+h). \qquad (16)$$

By substituting (14) and (15) into (16). After simplification and we obtain.

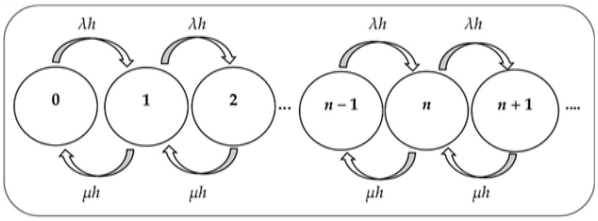

Figure 1: Diagram of birth and death process of (M/M/1): $(\infty, \infty, \text{FCFS})$ model.

$$p_{n-1}(t) * \lambda h + p_{n+1}(t) * \mu h = p_n(t) * h\ (\mu + \lambda) \qquad (17)$$

And by substituting the cases $\{0,1,2, \dots, n, n+1\}$ in to (17) to obtain:

$$\therefore p_1(t) = \frac{\lambda}{\mu} p_0,\ p_2(t) = \frac{\lambda^2}{\mu^2} p_0,\ p_3(t) = \frac{\lambda^3}{\mu^3} p_0,$$

$$\therefore p_n(t) = \frac{\lambda^n}{\mu^n} p_0 \qquad n = 1,2,3, \dots \qquad (18)$$

And since the number of units is independent of the time period t, therefore ($p_n(t) = p_n$)

$$p_n = p_0 (\frac{\lambda}{\mu})^n;\ n = 1,2,3,\dots \qquad (19)$$

p_0: denotes the probability of the system being empty (with zero units).

$$\because \ \sum_{n=1}^{\infty} p_n = 1,$$

$$\therefore p_0 \sum_{n=1}^{\infty} (\frac{\lambda}{\mu})^n = 1,$$

$$p_0 = \frac{1}{\sum_{n=1}^{\infty} (\frac{\lambda}{\mu})^n} = \frac{1}{1 + \frac{\lambda}{\mu} + \left(\frac{\lambda}{\mu}\right)^2 + \left(\frac{\lambda}{\mu}\right)^3 + \cdots}.$$

The denominator is a geometric series whose ratio is $(\frac{\lambda}{\mu})$.

$$\therefore p_0 = 1 - \frac{\lambda}{\mu} \qquad ; \lambda < \mu. \qquad (20)$$

By substituting (20) in to (19):

$$p_n = (\frac{\lambda}{\mu})^n\ (1 - \frac{\lambda}{\mu}) \quad ;\ n = 0,1,2,3,\dots \qquad (21)$$

Equation (21) represents the probabilistic model $((\text{M}/\ \text{M}/1): (\infty, \infty, \text{FCFS}))$.

Using (21), the performance efficiency measures listed in Table 1 are computed, which are applicable to many systems.

Table 1: Represents important performance measures.

No.	Performance Measure	Mathematical Expression
1	The average waiting time in the system (W_s)	$W_S = \frac{1}{(\mu - \lambda)}$
2	The average waiting time in the queue (W_q)	$W_q = \frac{\lambda}{\mu(\mu - \lambda)}$
3	The average number of customers in the system (L_s)	$L_s = \lambda\ W_S$
4	The average number of customers in the queue (L_q)	$L_q = \lambda\ W_q$
5	The utilization factor (ρ)	$\rho = \frac{\lambda}{\mu}$

3 THE EXPERIMENTAL ASPECT

The simulation aims to validate the theoretical M/M/1 model by comparing its performance measures with those of the experimental M/M/1 model. The simulation model was implemented in MATLAB R2021b.

The program writing was included in Appendix [11] – [12].

3.1 Methodological Steps for Building the Simulation Model

The steps to write the simulation are as follows :

1) Entering the program parameter values: lambda, mu, warm-up period, number of replicates, total customers.
2) Generating exponentially distributed data using the exprnd command with parameter (1/lambda) representing interarrival times.
3) We compute the cumulative sum of interarrival times using the cumsum command to obtain arrival times.
4) Generating service times: Exponentially distributed data is generated using the expend command with parameter (1/mu).
5) Calculating departure times:
   - The departure time of the first arrival = Arrival time of the first arrival + Service time of the first arrival.

- Departure times of subsequent arrivals = Maximum(the current arrival's time, the previous departure time) + the current service time.

6) Calculating system waiting times= departure times − arrival times.
7) Calculating queue waiting times = system waiting times–service times.
8) Excluding warm-up period data from both queue waiting times and system waiting times:
   - Initial observations are discarded (warm-up period).
   - Without warm-up period, you would get biased metrics (e.g., unrealistically low waiting times).
9) Metrics calculation:
   - averages for waiting times in system;
   - averages for waiting times time in queue;
   - averages for number of customers in system (lambda * waiting times in system);
   - averages for number of customers in queue (lambda * waiting times in queue).
10) Simulation replication. To obtain more reliable results than relying on a single simulation run.
11) Calculating the average metrics. Representing the experimental performance measures.
12) Results display. Comparison of the experimental performance measures with the theoretical performance measures.

Table 2: Result of simulation.

λ =6, μ =9, ρ = 0.78		
Metrics	Theoretical model	Simulation
W_q	0.5	0.5
W_s	0.39	0.39
L_s	3.50	3.50
L_q	2.72	2.72
λ = 0.8, μ=1, ρ =0.80		
Metrics	Theoretical model	Simulation
W_q	5	5
W_s	4	4
L_s	4	4
L_q	3.20	3.20
λ =3, μ=7, ρ = 0.43		
Metrics	Theoretical model	Simulation
W_q	0.25	0.25
W_s	0.11	0.11
L_s	0.75	0.75
L_q	0.32	0.32

3.2 Discussing the Simulation Results

The simulation outputs are presented in Table 2.

Table 2 presents the results, showing general agreement between the theoretical model M/M/1 and simulation performance measures. Thus, the theoretical M/M/1 model was validated and can be reliably.

4 APLICATION

To apply the M/M/1 model to real data, It requires two sets of data:

1) Arrival time data. It can be represented in one of two cases:
   - The arrival intervals of units follow the exponential distribution (based on the assumptions of the M/M/1 model).
   - The number of units received follows the Poisson distribution (based on the pure birth model [10]), and this case has been adopted in the applied aspect of the research paper.
2) Service time data. Represents service intervals (based on M/M/1 model assumptions).

In practice, the data are in the form of classified data (frequency table) and the steps of practical application are as follows:

1) Finding the estimation of the parameters λ, μ.
2) Adopting the chi-square test for goodness of fit[1] to verified whether the data arrival times and service times track the exponential distribution or not.
3) Verify the condition λ<μ.
4) Calculation of performance measures.

The studies that included the application of a model are the application of what has been mentioned [13], [14].

5 CONCLUSIONS

Based on the simulation methodology and results:

1) The results of the theoretical model's performance measures generally match those calculated through simulation, indicating that the model represents a queuing system with a single service center.
2) This is achieved when the following conditions are met:
   - Interarrival times follow an exponential distribution with parameter (λ), or its

[1]Five goodness of fit tests, https://www.cimt.org.uk/projects/mepres/alevel/fstats_ch5.pdf.

equivalent, the arrival of units at time (t) follows the Poisson distribution with the parameter (λt).

- Service times follow an exponential distribution with parameter (μ).
- The sample size should be large and there should be a warm-up period represented by excluding a part of the initial data (delete first 10% of data system waiting times or queue waiting times) to treatment the bias resulting from the initial data.

3) The difficulty in implementing it is due to the strictness of its conditions (The difficulty in implementing it is due to the strictness of its conditions (the difficulty in obtaining data that meets its conditions).

Keywords: Transportation Problem (TP), NWCM, Optimal Solution, SSM.

Abstract: In this work, a new modified version of the stepping stone method (SSM) is introduced to solve the transportation problem (TP) after we get the basic solution by using the northwest corner method (NWCM). As it known, in the traditional method, when making a loop for the empty cell, it takes the first negative value, while in this work, we take all negative values. We start by taking all the values, either the most significant negative or the smallest negative, and then by applying some steps, we get the optimal solution. The numerical experiment shows the goodness of the new suggested technique. The proposed modification enhances the accuracy and convergence speed of the classical SSM by reducing the number of iterations required to reach optimality. Moreover, it provides a systematic way to explore multiple potential loops simultaneously, ensuring that no feasible path toward optimization is neglected. Comparative results reveal that the method achieves better cost minimization and computational efficiency, making it a practical and effective alternative for solving complex transportation problems in real-world applications.

1 INTRODUCTION

The basic and essential thing in TP is minimizing the cost of distributing the products [1], [2] from sources to warehouses. One of the best methods used for this purpose is SSM, which helps us move from an initial solution obtained by one of the three classical methods (LCM, NWCN, and Vogal) to an optimal solution [3], [4]. SSM is one of the best techniques to find the optimal solution for TP [5], [6]. It is used to control the movement of products from sources to warehouses after finding an initial applicable solution to the TP [7], [8]. Many papers have been published in order to introduce a modified algorithms to reduce and minimize the cost of TP. Many papers are introduced to solve optimization problems, see [9]-[17]. Still, in this work we suggested a new modified algorithm for SSM to get the optimal solution of TP, which we illustrate its steps in the following section.

2 THE NEW MODIFIED ALGORITHM OF THE STEPPING STONE METHOD (SSM):

In this section we introduce a new modified algorithm of (SSM) to solve TP, the steps are as follow:

1) Obtain the basic solution by using (NWCN) or any other classic methods.
2) Reduce transportation costs by allocating products to empty cells.
3) Drow a closed path connecting the filled cells to the empty cells. Place addition and subtraction signs alternately in each corner square of the closed path, starting with the addition sign at the empty square.
4) When the result of the path is negative values, we take all the negative values and start with the smallest values and improve them. After that, we take the largest negative values and improve them.

5) After that, we solve the example using the classical method by taking the first negative and improving it.
6) Finally, we compare the results. If the results are equal, then the example is solved using this method.

We will apply the above algorithm in the following examples.

Ex1: Institution owns three workshops A, B, and C. These workshops export products to four traders 1, 2, 3, and 4. Table 1 shows the supply and demand data:

To solve Ex1, we'll use (NWCM) to find the initial solution, and then we'll use the modified technique of (SSM) which described above in Table 2.

$$Z = 2(150) + 2(130) + 2(30) + 4(90) + 3(10) + 8(290) = 3330$$

Since solving of above example takes almost five pages, we include here the final tables for each method.

Table 3 contains the final step for finding the optimal solution when taking the smallest negative, the largest negative and the first negative (classic method), Whereas the filled cells and the value of the optimal solution are identical and equal in the three proposed techniques.

$$Z = 2(110) + 4(200) + 3(100) + 3(40) + 2(130) + 1(120) = 1820$$

And these are another example.

Ex2: The data of this example are presented in Table 4.

We will find the initial solution for example 2 using the (NWCN) method, and after applying the steps of the method, the result was = (1085). We will find the optimal solution (OS) using the modified (SSM) method and the classical (SSM) method. When we took the largest negative, the result was = (610). When we took the smallest negative, the result was = (610). When we solved using the classical method that takes the first negative, the result was = (610).

Ex3: The data of this example are presented in Table 5.

Table 1: The data of TP of Ex1.

From \ To	1	2	3	4	Supply
A	3	3	3	5	310
B	5	7	5	4	100

Demand	210	160	100	470

Table 9: The data of TP of Ex7

From \ To	1	2	3	Supply
A	5	4	3	100
B	8	4	3	300
D	9	7	5	300
Demand	300	200	200	700

We will find the initial solution for example 9 using the (NWCN) method, and after applying the steps of the method, the result was = (4200). We will find the optimal solution (OS) using the modified (SSM) method and the classical (SSM) method. When we took the largest negative, the result was = (3900). When we took the smallest negative, the result was = (3900). When we solved using the classical method that takes the first negative, the result was = (3900).

Table 10: The results of solving the examples

Number of examples	The smallest negative	The largest negative	Classic method
Ex2	610	610	610
Ex3	2370	2370	2370
Ex4	1260	1260	1260
Ex5	3160	3160	3160
Ex6	2230	2230	2230
Ex7	3900	3900	3900

The Table 10shows a comparison between the results of the three methods, the largest negative, the smallest negative, and the classical method. The results were equal, which indicates the efficiency of the developed methods.

CONCLUSIONS

In this work, we suggested a modified technique for (SSM) to find the optimal solution of transportation problems. We named these algorithms as: largest negative and smallest negative. After applying these algorithm to solve lots of examples, we concluded that when using (NWCM) for TP extract the basic solution and then the (SSM) to find the optimal solution, the results in the basic solution as well as in the optimal solution for all cases of the largest negative and smallest negative and the classical method are equal. The future direction of this research could extend this modified SSM approach to more complex or real-world transportation problems involving multiple constraints, fuzzy parameters, or uncertain costs. Comparative analysis with other optimization methods – such as genetic algorithms, Vogel's approximation, or linear programming – could also highlight its efficiency and computational advantages. Moreover, developing a software tool or algorithmic implementation could facilitate broader applications in logistics, supply chain management, and resource distribution. Sensitivity analysis might reveal how parameter variations affect optimality, guiding practical decision-making. Finally, validating the method with real datasets would demonstrate its

robustness and potential for improving transportation planning in dynamic environments.

Keywords: Eye Tracking, Human Eye Movement, Iris Detection.

Abstract: Eye tracking has been around for decades, growing alongside the technology that supports it. Early systems were simple and often imprecise, but better cameras and smarter algorithms have made measurements far more reliable. Today, high resolution imaging and modern software can capture even tiny, moment to moment eye movements. This jump in precision does not just improve data quality; it also widens the kinds of questions researchers can ask. As a result, eye tracking studies have expanded quickly, offering clearer insight into how people pay attention, interpret what they see, and make decisions. This review traces that journey from the first basic setups to the most advanced systems available today and shows how these methods are now used across many fields. In recent years, eye tracking has also become increasingly accessible, integrated into consumer devices, and applied in diverse domains such as neuroscience, marketing, education, and virtual reality. These innovations not only enhance experimental accuracy but also democratize the technology, allowing a broader range of users to explore human perception and behaviour with unprecedented detail.

1 INTRODUCTION

Eye tracking technology has been studied as early as the 19th century. The initial studies available for eye tracking were based on observations of the researchers with the use of a mirror on the object of fixation and the researchers would then stand behind the participant to be able to observe their eye movements through the mirror [1]. Since then, the studies on eye tracking have been done and continued to develop as time passed. As the technology advances, so does the refinement of gathering data for various data. One of the methods in gathering data from participants is through eye tracking. Eye tracking allows for the researchers to be able to determine habits and other observations through the use of technology, some of these data gathered are gaze estimation, pupil dilation, duration of the time when the patient fixates their gaze on the object and the like. Through the improvement of the technology, the requirements of the systems present also increase. Eye tracking is a field of research that continues to improve as more applications of eye tracking technology continue to be determined. Some industries that use eye tracking in their research are marketing and design, medicine, and the like [2]. The industries use eye tracking to be able to learn more information about the participants, especially the participants that are within their target market. Eye tracking is often used to detect when participants look away and to identify the items they subsequently fixate on [3]. In this review, the researchers examine the main methods for collecting and using eye tracking data and survey its current applications.

2 EYE TRACKING SYSTEMS

This section surveys recent literature on eye tracking systems and methods that are currently used or actively being explored.

2.1 Development of Real-Time Eye Tracking Algorithm

This study developed a real time eye tracking algorithm to improve iris detection and gaze classification. Although the circular Hough transform (CCHT) is commonly used for iris detection, its accuracy tends to drop when the subject is not facing the camera directly or when lighting varies. To address this, the authors used a facial landmark detector to locate the eyes and define a region of interest. Within this region, the system tracks eye movements and classifies gaze as left, right, or center, and it also detects eye blinks for potential use in drowsiness monitoring. The software was implemented in Python with OpenCV to keep it lightweight and portable. In testing, the method achieved 100% accuracy for iris detection and 90% for gaze position classification [4].

2.2 Saccadelenses: Interactive Filtering of Eye Tracking Trajectories for Exploration

The study repurposed an interactive filtering technique originally developed for geographic trajectory analysis and applied it to eye tracking data [5]. The method, called TrajectoryLenses, lets researchers narrow the dataset for local inspection, closely examine fixation patterns and the movements between fixations, and directly explore the spatial context of the stimulus [5]. To demonstrate the approach, the team ran an eye tracking experiment with a static stimulus and eight participants [5]. TrajectoryLenses provides three complementary filters: one that highlights outgoing trajectories, another for incoming trajectories, and a third that selects paths intersecting a chosen area; these filters can be combined to create stronger, more flexible queries [5]. The authors note that common analysis methods can oversimplify eye tracking records. By adding density based heat maps and flexible filtering, their workflow offers a more detailed and interactive way to explore and interpret the data [5].

2.3 iTrace: Tracking the Practical Eye

The researchers created iTrace, an infrastructure for integrating eye tracking into programming environments, and validated it with a live implementation [6]. Studies built on iTrace proceed as follows. In iTrace Core, the investigator specifies the study and researcher names, assigns a participant ID, and selects a data directory, a combination that makes later processing more straightforward. Calibration then shows nine targets on the screen, and the calibration record is saved as both images and a file. After connecting the needed plugins to the core, tracking is started and the eye tracker feeds data directly to those plugins. The same interface has already been used in two peer reviewed studies, indicating its practicality [6].

2.4 Suitability of GA and PSO for Eye Tracking System

The study compared two optimization-based trackers for eye movement, pairing deformable template matching with either a genetic algorithm or particle swarm optimization [7]. Eyes were first detected using Haar like features, then tracked with GAET or PSOET while handling head motion, eye motion, blinks, and zoom, which often reduce accuracy [7]. On a 2.13 GHz machine with 2 GB RAM, both methods were implemented in Java with OpenCV in Eclipse and used a population or swarm size of 10 [7]. GAET produced predictions that closely matched the ground truth but reached only 91 percent accuracy, whereas PSOET achieved 98 percent and finished faster, leading the authors to prefer PSOET for future work [7].

2.5 Methods for Eye Tracking Analysis of Multiple Moving Targets

The study explored how eye tracking could be applied to multiple moving targets on a computer screen, tackling both the limitations of current systems and the complexity of tracking dynamic objects. The researchers developed a system that maps eye fixations to moving targets and introduced an algorithm capable of recording the sequence and duration of those fixations. They proposed that this method could reduce the number of areas of interest (AOIs) required for analysis by finding a balance between AOI size and tracking accuracy. To evaluate the system, they carried out a case study in which an air traffic controller completed a conflict detection task with several aircraft displayed on a simulated radar screen. The findings showed that the approach is a promising method for tracking multiple moving targets [8].

2.6 Optimization of Real-Time Eye Tracking Using Circular Hough Transform

The study used the circular Hough transform to find circular shapes in images. The authors noticed that eyes move more slowly than a typical 30 frames per second video, so the eye is not really changing position thirty times each second. With that in mind, they suggested adjusting the tracking pipeline so it does not process every single frame, even though this change initially raised CPU load. Because back-to-back frames often show the same motion, many frames are unnecessary. After skipping those repeats, processing time dropped a lot: about 1500 percent for slow eye movements and about 750 percent for fast ones. These gains came from removing frames that did not add new information [9].

2.7 A State-of-the-Art Review on Eye Tracking and Head Movement Detection

The paper reviews methods for eye tracking and head movement detection and shows how they are used in human computer interaction, driving assistance, and assistive technologies [10]. The authors group the approaches into two families: sensor based and computer vision-based methods [10]. Sensor based eye tracking measures the tiny electrical potentials produced by eye movements using electrodes, a technique known as electrooculography or EOG [10]. Computer vision methods are divided into six groups: pattern recognition, corneal reflection points, shape-based techniques, dark and bright pupil effects, model-based tracking, and hybrid systems [10]. Pattern recognition covers tools such as template matching, particle filters, rotated images, and prediction algorithms [10]. Corneal reflection methods estimate gaze direction from light reflections captured by the camera, using the vector between the pupil center and the corneal reflection, although they do require calibration [10]. Shape-based tracking identifies the iris or pupil using circular patterns or edge detection. Methods based on dark and bright pupil effects rely on camera images, with the dark pupil detected under normal lighting and the bright pupil effect created through infrared reflection. However, dark brown eyes can pose challenges for the dark pupil method due to low contrast. Model-based tracking incorporates natural head movements to minimize calibration, though the complexity of this approach limits its use in real time. Finally, hybrid methods combine several of these techniques to improve accuracy and reliability [10]. As presented in Tables 1 and 2, the performance of these eye tracking and head movement detection methods was evaluated and compared.

Table 1: Result of the eye tracking methods.

3 USES AND APPLICATIONS

This section of the paper explores the applications of eye tracking technology. The literature includes examples of how eye tracking is used across various industries, as well as recent advancements in the technology.

3.1 Application in Aviation, Maritime and Construction Industries: A Systematic Review

This review paper systematically explored the literature on eye tracking in the industries of aviation, maritime, and construction. A total of 80 studies met the criteria for inclusion in the review. The researchers observed the distribution of eye tracking studies across various industries and noted the types of eye tracking methods used. They identified gaps in certain industries where more studies could enhance and validate existing eye tracking systems. Additionally, they suggested that future reviews could explore high-risk industries, such as space exploration [29].

3.2 Front Camera Eye Tracking for Mobile VR

The study explored the use of virtual reality (VR) in eye tracking systems. A methodology was proposed that utilizes the captured images taken by the front camera of a mobile phone without any modifications. The system improves images from the front camera, especially when lighting is poor and contrast is low. It uses a processing pipeline that reduces lens reflections from the headset. After calibration, the captured images are used to build a linear mapping between on screen pixels and the estimated iris centroids, enabling real time iris tracking. In tests, the method performed on par with commercial eye trackers, particularly when the eyes are near the center of the headset field of view [30].

3.3 Eye Movement Tracking & English Teaching Application Based on CNN-BLSTM

The study tested a virtual reality eye tracking setup that uses a mobile phone camera [31]. To improve performance, it enhances frames captured under low contrast or poor lighting and runs a processing pipeline that suppresses reflections from the headset lenses. After these adjustments, the system calibrates the view and maps the estimated iris centroids to the screen's physical pixels, enabling real time iris tracking. In evaluations, its accuracy was comparable to commercial eye trackers, especially when the eyes stayed near the center of the headset's field of view [31].

3.4 Automated Recording and Replay of High Speed Eye Tracking for Cognitive Studies in Software Engineering

The authors propose a data-collection approach that records the entire telemetry stream as it happens and postpones any gaze analysis to a later review. During playback at a slower speed, the system can anchor each gaze sample to the exact source file on screen, down to the specific line and column being viewed. To demonstrate the approach, they built a tool called Déjà Vu and evaluated it with three eye trackers running at 60, 120, 150, and 300 Hz. To cover popular development environments, they also ran time tests in Visual Studio and Eclipse. Their findings suggest that Déjà Vu is a solid basis for further software engineering research using eye tracking data since it consistently reconstructs sessions and maintains accurate mappings [32].

3.5 Eye Movement Monitoring for Multimedia Content Ranking

The study examines how an eye tracking system can be integrated into teaching at Subotica Tech College of Applied Sciences. The technique uses light reflected from the cornea as a source and compares it to the eye center's trajectory. Eye tracking is highlighted as useful in medicine, marketing, education, usability research, and related fields. Students were tasked with developing software applications, and using eye tracking to evaluate how viewers engaged with their work helped them judge design quality and usability. The authors note that the resulting gaze data enabled students to produce better infographics, applications, and other materials [33].

3.6 Replicating Human Eye Movements Using an IR Camera–Based Wearable Eye-Gaze Tracker

The study examined whether robotic eyes can mirror human eye movements in real time using a model with two degrees of freedom. The researchers built a head mounted eye gaze tracking controller with an

infrared camera that streamed signals to drive the robot's eye motions. By accounting for head movements and capturing both horizontal and vertical movement, the system improved upon previous work and solved frequent gaze tracking issues. The system combined polynomial regression with the pupil center corneal reflection method to translate human gaze into robot commands for image processing. A Wilcoxon test was used to evaluate accuracy, and the results indicated no statistically significant difference between robotic and human motions. For horizontal tracking, the system's accuracy was 99.07 percent, and for vertical tracking, it was 98.91 percent [34].

3 CONCLUSIONS

Eye tracking has been used for many years and in many settings, from studying how people watch videos to detecting early signs of drowsiness in drivers. It also supports practical tasks such as evaluating the clarity of on-screen content and controlling robots through gaze. Steady progress over years of research has turned eye tracking from a niche lab tool into something that works in everyday studies and applications. Current work continues to raise both efficiency and accuracy, so systems can detect small eye movements and estimate gaze with greater precision. These gains make trackers more reliable in practice and also lead to richer datasets that researchers can use to test, compare, and validate new methods.

The future research could explore integrating eye tracking with other biometric and behavioral sensors, such as EEG, facial expression analysis, or heart rate monitoring to gain a more holistic understanding of human cognition and emotion. Advances in machine learning and computer vision can further enhance gaze estimation models, enabling adaptive interfaces that respond in real time to user attention and intent. Eye tracking also holds promise for accessibility, helping individuals with mobility impairments interact with digital environments more naturally. Additionally, addressing privacy and ethical considerations in gaze data collection will be crucial as eye tracking becomes more embedded in consumer devices and everyday technologies.

ACKNOWLEDGMENTS

The researchers are deeply grateful to the Philippine Council for Health Research and Development (DOST-PCHRD) of the Department of Science and Technology for the financing and assistance that enabled this effort. Their assistance was crucial in advancing this research and assisting us in reaching significant study milestones.

A Mixed-Methods Study on Google Classroom Use: Thematic Perspectives and Quantitative Insights on Student Engagement and Connectivity at the City of Malabon University

Enrico P. Chavez, Porfirio R. Catolico Jr. and Janine M. Dela Cruz
College of Computer Studies, City of Malabon University, Maya-may cor Pampano Sr. Longos, 1472 Malabon City, Philippines
enrico.chavez@cityofmalabonuniversity.edu.ph, pofirio.catolico@cityofmalabonuniversity.edu.ph, janine.delacruz@cityofmalabonuniversity.edu.ph

Keywords: Google Classroom, Learning Management System, Mixed-Methods, Thematic Analysis, Student Engagement, Connectivity.

Abstract: This study examines the experiences, engagement, and connectivity challenges of third-year Information Technology students at the City of Malabon University (CMU) in using Google Classroom as a learning management system (LMS). A mixed-methods design was employed, triangulating quantitative survey data with qualitative thematic analysis of open-ended responses from 222 students. Findings revealed that ease of use, accessibility, and assignment management were consistent strengths across both data streams, while unstable internet connectivity and limited instructor responsiveness remained persistent barriers to student learning. Engagement was positively influenced by the platform's user-friendly design and structured task management, though often undermined by delays in instructor feedback. Students demonstrated adaptability through strategies such as mobile data use, downloading materials in advance, and flexible scheduling. The study recommends institutional support for connectivity, structured faculty training, and student orientation to enhance platform effectiveness. By integrating thematic and quantitative findings, this research strengthens evidence on digital equity and resilience in higher education, offering practical insights for resource-constrained universities in the Philippines and similar contexts.

1 INTRODUCTION

The landscape of higher education continues to evolve with the integration of digital technologies. Among these, learning management platforms have become indispensable in supporting instruction, communication, and enabling collaboration between educators and students. Google Workspace for Education, particularly Google Classroom, offers a streamlined and accessible way to manage coursework and learner engagement.

International research has consistently highlighted its acceptance and effectiveness [1]. It reports high student acceptance of Google Classroom due to its user-friendly interface, while paper [2] emphasizes teachers' positive perceptions of its utility in task management and instructional support. In the Philippine context, a study confirms the platform's usability, but notes constraints caused by internet connectivity [3]. Similarly, paper [4] underscores its role during the "new normal," identifying gaps in faculty training and connectivity, while paper [5] examines opportunities and challenges for broader integration.

At the City of Malabon University (CMU), the adoption of such technologies is vital. As a local government-funded institution, CMU faces financial constraints that limit its ability to acquire proprietary learning management systems. Institutional access to Google Workspace for Education provides an opportunity to implement Google Classroom at no cost. This is particularly important given recent environmental disruptions, including flooding caused by tide gate damage and extreme heat reaching up to 46°C [6], [7], which have repeatedly forced class suspensions. These conditions highlight the urgency of robust and resilient digital learning systems.

This study investigates the implementation of Google Classroom across eight sections of third-year Information Technology (IT) students at CMU. It focuses on students' experiences, levels of

engagement, and challenges, particularly those related to internet connectivity, through a mixed-methods approach combining thematic analysis and quantitative evaluation. The findings aim to generate evidence-based recommendations to guide institutional strategies for optimizing Google Classroom's adoption.

1.1 Statement of the Problem

Despite the availability of Google Classroom at the City of Malabon University (CMU), the extent of its utilization by faculty and its effectiveness from the students' perspective remains uncertain. There is limited understanding of:

1) How students perceive the platform's usability and effectiveness in supporting their learning.
2) The degree to which Google Classroom influences student engagement and interaction.
3) The challenges, particularly related to internet connectivity, that hinder effective use of the platform.
4) The strategies students employ to address these challenges.
5) Given these gaps, it is important to evaluate student experiences systematically and provide evidence-based recommendations to guide faculty and institutional practices in maximizing Google Classroom's potential.

1.2 Objectives of the Study

1.2.1 General Objective

To assess the experiences, perceptions, engagement levels, and challenges of third-year Information Technology students in using Google Classroom at CMU through both quantitative and qualitative evaluation.

1.2.2 Specific Objectives

- To evaluate students' perceptions of the usability and effectiveness of Google Classroom as an instructional tool.
- To analyze the level of student engagement and interaction facilitated by the platform using both quantitative data and thematic insights.
- To identify and understand the challenges that affect the effective use of Google Classroom.
- To conduct a thematic evaluation of student feedback to extract key themes related to experience, engagement, and barriers.
- To formulate evidence-based recommendations for CMU faculty to enhance the integration and pedagogical use of Google Classroom within the university's existing resource constraints.

1.3 Significance of the Study

This study advances the digital learning environment at the City of Malabon University (CMU) by examining the experiences, engagement levels, and connectivity challenges of third-year Information Technology students in their use of Google Classroom. Its timeliness is underscored by repeated class suspensions in Malabon due to flooding and extreme heat [8], [9], highlighting the need for resilient and flexible learning modalities. Google Classroom emerges as a vital tool for sustaining instructional delivery under such disruptions [3], [4].

A strength of this research lies in its mixed-methods design, which integrates quantitative evaluation with qualitative thematic analysis following Braun and Clarke's framework [5]. This dual approach provides both statistical trends and rich, contextual insights, offering a comprehensive understanding of student experiences.

2 METHODOLOGIES

This study employed a mixed-methods design to capture a comprehensive view of third-year IT students' experiences with Google Classroom at CMU. By integrating quantitative and qualitative approaches, the design enabled triangulation that enhanced the validity and depth of findings [10], [11].

The quantitative component utilized survey questionnaires to measure perceptions, engagement levels, and connectivity challenges. The qualitative component gathered open-ended responses, providing personal reflections and contextual insights into usability, effectiveness, and barriers [12], [6]. Together, these methods balanced statistical patterns with rich thematic evidence.

2.1 Population and Sampling

The study focused on third-year Information Technology (IT) students at CMU who actively used Google Classroom across eight (8) sections under the researcher's supervision. A purposive sampling

technique was employed to ensure participants had direct and relevant experience with the platform. A total of 222 students participated in both the quantitative survey and qualitative open-ended responses, providing sufficient breadth and depth to support the mixed-methods design.

2.2 Data Collection Instruments

A single integrated Google Form was used to gather both quantitative and qualitative data. The instrument consisted of two parts: (1) a structured 5-point Likert scale survey to measure perceptions, engagement, and connectivity challenges, and (2) open-ended questions that elicited personal experiences, difficulties, and suggestions for improvement.

2.3 Data Collection Procedure

Participation was voluntary, with respondents informed of their rights and the option to withdraw at any time. The Google Form was distributed via institutional email, and students were encouraged to complete both the survey and open-ended sections within the same form. This design ensured efficient administration while allowing students to reflect on their experiences in their own words.

2.4 Data Analysis

A structured, engineering-inspired workflow was implemented to ensure rigor, reproducibility, and systematic derivation of findings. Two analytical streams – quantitative and qualitative – were executed in parallel, then integrated through a mixed-methods triangulation framework.

2.4.1 Quantitative Analysis

Survey responses were cleaned and processed using descriptive statistical algorithms (frequency, percentages, mean scores). Data visualization tools generated bar charts, treating the dataset as a whole, where preprocessing, computation, and visualization followed.

2.4.2 Qualitative Analysis

Open-ended responses were processed using Braun and Clarke's six-phase thematic analysis [6]. Inputs were preprocessed to remove noise, coded systematically, and transformed into thematic clusters. This process is a workflow where raw input is refined into structured, interpretable outputs.

2.4.3 Integration and Triangulation

The two streams were fused using an approach analogous to multimodal data integration in engineering systems. Quantitative metrics were validated against qualitative themes (e.g., connectivity challenges) to enhance reliability and provide cross-verified conclusions.

This hybrid approach demonstrates how algorithmic statistical computation and systematic text analysis guided by engineering principles of rigor, repeatability, and validation can be combined to produce robust, technically sound results.

3 RESULT AND DISCUSSION

3.1 Thematic Analysis Result

3.1.1 Question 1: "Can you Describe your Overall Experience with using Google Classroom in your Courses?"

The responses from 222 students indicate a generally positive experience with Google Classroom, highlighting usability, organization, and accessibility as key strengths. Most students described the platform as user-friendly, frequently using terms such as helpful, efficient, and convenient (Table 1). It was particularly effective in asynchronous and blended learning contexts.

Table 1: Thematic analysis results for Question 1.

Theme	Frequency
Overall Satisfaction	80
Ease of Use	54
Organization and Tracking	31
Connectivity Challenges	21
Other/Uncategorized	47

Nevertheless, connectivity issues were a recurring challenge, limiting students' ability to access or submit tasks. A smaller but notable group also cited limited instructor communication as an area for improvement.

3.1.2 Question 2: "What Features of Google Classroom Do You Find Most Beneficial for your Learning?"

The most frequently mentioned benefit was the platform's assignment submission system, including its submission buttons, timers, and structured

deadlines and accessibility, with students appreciating the ability to access Google Classroom anytime and anywhere. Another important theme was communication tools within the platform. Students found the ability to leave class comments, send private messages to instructors, and receive direct feedback highly beneficial. The platform's notification and deadline reminders were also appreciated. Lastly, a significant number of responses fell under uncategorized feedback (Table 2).

Table 2: Thematic analysis results for Question 2.

Theme	Frequency
Accessibility	41
Assignment Submission	52
Communication Tools	27
Notifications and Deadlines	8
Other/Uncategorized	84

3.1.3 Question 3: "Have you Encountered Any Challenges while Using Google Classroom? Please Elaborate."

The findings reveal that challenges were primarily linked to internet access and task submission. The most frequently cited issue was unstable Wi-Fi or insufficient mobile data, reported by 80 students. A second major theme was late submission and missed deadlines, often attributed to overlooked notifications, system delays, or connectivity interruptions. A smaller group also noted limited communication or delayed feedback from instructors (Table 3).

Table 3: Thematic analysis results for Question 3.

Theme	Frequency
Internet and Connectivity Issues	80
Late Submission and Deadlines	22
Lack of Communication or Feedback	10
Limited Device Access	3
Other/Uncategorized	50

3.1.4 Question 4: "What Strategies have you Employed to Overcome Connectivity Challenges when Accessing Google Classroom?"

Students reported several strategies to overcome connectivity issues. The most common, cited by 81 respondents, was relying on mobile data or prepaid load. Others downloaded materials in advance during stable internet periods, allowing offline study. Some changed location to access better signals, while others scheduled tasks during low-traffic hours (Table 4). These strategies demonstrate student adaptability and resourcefulness in sustaining learning despite connectivity challenges.

Table 4: Thematic analysis results for Question 4.

Theme	Frequency
Using Mobile Data or Load	81
Downloading Materials in Advance	26
Changing Location for Better Signal	21
Time Management or Scheduling Access	17
Other/Uncategorized	59

3.1.5 Question 5: "In Your Opinion, how can the Use of Google Classroom be Improved to Better Support Students' Learning Experiences?"

Students expressed interest in making Google Classroom more interactive, communicative, and adaptive. While most were satisfied with its core functions, they highlighted several areas for improvement. The most frequent suggestion was the addition of interactive features such as real-time discussions, collaborative boards, quizzes, or gamified elements to simulate dynamic learning environments. Communication tools were another priority, with students requesting private chat options, faster instructor feedback, and clearer channels for interaction (Table 5). A smaller group recommended enhanced scheduling functions, including built-in calendars and automated reminders. A large portion of responses, however, were uncategorized, consisting of general remarks or vague suggestions.

Table 5: Thematic analysis results for Question 5.

Theme	Frequency
More Interactive Features	28
Improved Communication Tools	20
Better Scheduling or Calendar Integration	8
Mobile Accessibility Improvements	6
Others/Uncategorized	116

3.1.6 Question 6: "Would you Recommend the Continued Use of Google Classroom to your Instructors? Why or why not?"

Thematic analysis showed that students most frequently recommended Google Classroom for its ease of use, describing it as simple, intuitive, and accessible to a wide range of learners. This usability fostered confidence and efficiency, while many also emphasized its value in enhancing learning,

particularly for distance and asynchronous education. Additional strengths included support for organization and task management, such as tracking deadlines, submitting assignments, and receiving announcements (Table 6). Accessibility across devices, especially mobile phones, was also appreciated. A smaller group expressed mixed or resistant views, citing integration issues or a preference for more interactive tools.

Table 6: Thematic analysis results for Question 6.

Theme	Frequency

3.1.7 Question 7: "Do you have any additional comments or suggestions regarding the use of Google Classroom at City of Malabon University?"

A notable share of responses highlighted the need for student orientation and training, suggesting guides, tutorials, or onboarding sessions. Others emphasized instructor engagement, stressing that effective communication on the platform depends on timely updates and responsiveness. Several students praised Google Classroom's convenience, particularly during the shift to online learning, while others recommended interface improvements, enhanced notifications, or better system integration. A substantial number of comments were uncategorized, consisting of general remarks or preferences for face-to-face learning (Table 7).

3.1.8 Total Thematic Summary: Google Classroom Experience at City of Malabon University

It is important to note that a substantial number of responses were coded as "Other/Uncategorized," largely reflecting neutral or non-specific feedback. This limited the granularity of insights, and future studies may refine these responses into more specific categories for deeper analysis (Table 8).

Table 8. Total thematic result.

Theme	Frequency
Ease of Use	Q1 (Experience), Q6 (Recommendation), Q5 (Suggestions)
Assignment Management and Tracking	Q2 (Features), Q6 (Recommendation), Q1
Accessibility and Flexibility	Q1, Q2, Q4 (Connectivity Strategies), Q6
Connectivity Challenges	Q3 (Challenges), Q4 (Strategies), Q1
Communication Gaps	Q3, Q5, Q7 (Comments)
Training and Orientation Needs	Q7 (Comments), Q5
Instructor Engagement	Q3, Q7
General Satisfaction and Praise	Q1, Q6, Q7

3.2 Descriptive Statistics Result

3.2.1 Demographic Information

Demographic data show that nearly all students had digital access, with smartphones being the most common device (95.9%). Almost half (47.3%) reported access to personal computers, while smaller groups used tablets (4.5%) or shared devices (5.4%). Notably, no student lacked access entirely, confirming universal but uneven device availability. In terms of connectivity, most students relied on Wi-Fi (69.8%), though a significant portion (29.7%) still depended on mobile data.

3.2.2 Perception and Experience

Student perceptions of Google Classroom were largely positive. Over 83% agreed that the platform is easy to navigate, and 83.8% affirmed that assignments and materials are readily accessible. A majority (68%) believed the platform enhanced their learning experience, though nearly a quarter remained neutral. Communication with instructors was rated less favorably, with 58.1% positive, 30.2% neutral, and 11.8% expressing dissatisfaction.

3.2.3 Engagement and Satisfaction

Overall feedback reflects strong engagement and satisfaction with Google Classroom. Nearly 60% of students reported feeling more engaged in coursework, though 31.5% remained neutral. A large majority (70.7%) stated the platform motivated

timely submission of assignments, supporting effective task management. Satisfaction levels were similarly high, with 74.3% expressing overall satisfaction and only 6.8% dissatisfied. Endorsement was strong, as 79% said they would recommend Google Classroom, underscoring its perceived value and effectiveness.

3.2.4 Connectivity Challenges

Survey results confirm that internet connectivity remains a major barrier to effective use of Google Classroom, affecting both performance and communication. Over 80% of students reported some level of difficulty, with 44.2% rating severe disruptions. Nearly half (49.1%) indicated connectivity issues hindered assignment submission, and a similar share relied heavily on mobile data despite widespread Wi-Fi availability. Connectivity challenges also caused students to miss announcements and deadlines (45.5%), underscoring its impact on both task completion and real-time engagement.

3.2.5 General Discussion of the Qualitative Analysis Results

The qualitative analysis offers a structured understanding of students' experiences with Google Classroom at CMU. Demographic data show a balanced distribution of respondents, with smartphones emerging as the dominant device, pointing to a mobile-centric trend in platform usage. This reflects the broader reliance of students on portable technologies for academic access.

Perceptions of Google Classroom were largely positive. Students emphasized its ease of use, organized layout, and effectiveness in managing tasks and submissions. Many highlighted that the platform simplified academic requirements and provided a convenient way to access materials and monitor deadlines. These findings align with earlier studies that note the platform's intuitive interface and efficiency in supporting digital learning.

Engagement and satisfaction were also reported at moderate to high levels. Students credited Google Classroom with enhancing participation, particularly by making course content accessible and structured. However, satisfaction was not uniform. A subset of students indicated challenges linked to unstable internet or delayed instructor feedback, suggesting that teacher responsiveness remains a critical factor in shaping overall satisfaction.

Connectivity challenges emerged as the most persistent barrier. Reports of slow internet, limited data availability, and unstable connections frequently disrupted access, submission of assignments, and attendance in synchronous sessions. These technical difficulties demonstrate that while Google Classroom can provide a strong foundation for digital learning, its success is highly dependent on reliable infrastructure and consistent support from instructors.

3.3 Integration of Thematic and Quantitative Results

The thematic and quantitative findings show strong convergence. Both methods highlighted ease of use, accessibility, and assignment management as major strengths, while connectivity challenges and limited instructor responsiveness consistently emerged as barriers. For example, over 80% of survey respondents agreed that Google Classroom is easy to navigate, which aligns with recurring qualitative themes of usability and organization. Similarly, connectivity issues were the top theme in open-ended responses and were reported by more than 80% of students in the survey. Instructor responsiveness appeared as both a qualitative concern and a quantitative weakness, confirming its critical role in student satisfaction. This alignment across methods strengthens the validity of the study and demonstrates that the challenges and benefits of Google Classroom at CMU are consistent across both numerical data and student narratives.

4 SUMMARY OF FINDINGS

This study aimed to evaluate the overall experience, perception, engagement, and connectivity challenges faced by 222 third-year Information Technology (IT) students at the City of Malabon University (CMU) in using Google Classroom as a learning management platform. Employing both quantitative (graphical analysis) and qualitative (open-ended responses) data, the research offered a comprehensive understanding of students' interaction with the platform, which is an approach consistent with best practices in mixed-methods research [1].

Demographic data revealed that most students accessed Google Classroom via mobile phones, with responses coming from multiple IT sections at the third-year level. This indicates a mobile-first learning context, particularly relevant in resource-constrained urban academic settings like CMU [2].

Analysis of survey responses showed strong positive sentiments regarding the platform's usability. Students consistently rated Google Classroom as organized, easy to navigate, and effective for academic task tracking, consistent with previous research emphasizing its user-friendly design [3], [4]. However, the analysis also highlighted key barriers such as intermittent internet connectivity and underscored the critical role of teacher responsiveness in enhancing student engagement and satisfaction, findings that echo broader patterns in Philippine online learning environments [5].

Thematic evaluation of open-ended responses surfaced recurring themes, including the importance of:

- Intuitive interface design.
- Well-organized content delivery.
- Platform accessibility and mobile-friendliness.

Students also proposed actionable improvements, such as:

- Enhanced internet access.
- More responsive instructors.
- Greater platform interactivity.
- Institutional training or orientation on digital tools.

These findings validate the use of thematic analysis in uncovering user perspectives that extend beyond quantitative metrics [8], and they emphasize the platform's potential to support resilient and inclusive digital learning when pedagogical and infrastructural supports are in place.

5 CONCLUSIONS

Based on the findings, the following conclusions were drawn:

1) Google Classroom is an effective platform for managing academic tasks, particularly when face-to-face classes are disrupted.
2) Students are satisfied with features such as assignment tracking and accessibility, though satisfaction depends heavily on internet quality and instructor responsiveness.
3) Connectivity challenges, such as mobile data costs, poor Wi-Fi, and unstable signals, remain the most significant barrier to platform use.
4) Instructor engagement strongly influences student motivation; delayed or limited feedback reduces the effectiveness of communication tools.
5) Students show adaptability through coping strategies such as adjusting schedules, downloading materials early, and relying on mobile data.
6) Structured training and orientation are needed for both students and faculty to maximize the benefits of Google Classroom and ensure effective use
7) Thematic and quantitative findings showed strong consistency, with both identifying ease of use and accessibility as strengths and connectivity and instructor responsiveness as persistent barriers. This triangulation reinforces the reliability of the study and offers a well-rounded view of student experiences at CMU.

This study contributes to the growing body of literature on digital learning by situating the use of Google Classroom within the unique context of a local government-funded university in the Philippines. While prior research has confirmed the platform's usability and general effectiveness, this study extends the discussion by highlighting the challenges of connectivity and environmental disruptions (e.g., flooding and extreme heat) that shape continuity of learning in Malabon. By integrating both quantitative and thematic insights, the study offers evidence-based recommendations for faculty responsiveness, student adaptability, and institutional support, providing a practical framework for enhancing LMS adoption.

6 RECOMMENDATIONS

In light of the conclusions drawn, the following recommendations are proposed:

- Institutional Support for Connectivity – Provide campus Wi-Fi access or negotiate student data packages with internet providers to reduce inequities in online learning.
- Faculty Training – Conduct regular training sessions for faculty on best practices in Google Classroom, emphasizing timely feedback and interactive teaching strategies.
- Student Orientation – Offer onboarding programs and digital guides to help students maximize Google Classroom features for task management and communication.
- Platform Enhancement – Expand Google Classroom's functionality through integration with external collaborative platforms and interactive applications (e.g., real-time co-authoring tools, digital whiteboards, gamified

learning apps) to foster engagement and active learning.

- Responsive Feedback Standards – Establish guidelines for timely instructor responses to messages and submissions to improve student motivation and satisfaction.
- Mixed-Methods Evaluation – Promote the continued use of mixed-methods research in institutional studies to ensure integration of both quantitative trends and qualitative insights, enhancing evidence-based decision-making for digital learning.
- Future Research – Extend this study to other year levels, disciplines, and faculty perspectives, using established models (e.g., TAM, UTAUT) to provide theoretical depth.

Workshop Assisted by Interactive Touch Screen Television and Its Effect on Students' Skills in Crafting a Research Proposal

Anesa P. Mangindra
Sultan Kudarat State University, 9800 Tacurong, Philippines
anesamangindra@sksu.edu.ph

Keywords: Workshop, Interactive Television, Research Proposal.

Abstract: This study was conducted to test the impact of a workshop assisted by an interactive touch screen television on the writing skill of college students in crafting a research proposal. Quasi-experimental design in a time-series mode was employed. The respondents of the study were students from the two sections handled by the researcher, namely: BSED Filipino with 25 pairs of students for experimental A and BSED English with 27 pairs of students for experimental B, from College of Teacher Education, Sultan Kudarat State University, ACCESS Campus. Complete enumeration and purposive sampling were applied to maximize the participation of the whole classes. Statistical tools like mean, standard deviation, mean gain difference and t-test of independent samples were employed to analyze the data. The workshop was based on Bennett's (2007) model, which includes presentation of mini-lessons, followed by the actual workshop, then debriefing or presentation of outputs for sharing and critiquing purposes. The interactive touch screen television was used during the presentation of mini-lessons as the basis of workshop and also during presentation of students' outputs for sharing and critiquing purposes. The written outputs of students in the form of a research proposal were evaluated using a validated rubric. The results of the study showed significant improvement in the writing skills of students from both groups. The findings implied the effectiveness of workshop assisted by interactive touch screen television in enhancing students' skills in crafting a research proposal. Therefore, innovative ways of teaching significantly produce a meaningful learning.

1 INTRODUCTION

As time passed by, methods of teaching and even instructional materials kept changing. Despite the fact that there is no such thing as the best method or instructional material, teachers have become resourceful, creative, and innovative in their way of teaching. One of the modern methods of instruction is a workshop. A workshop in its pedagogical context is a type of educational program commonly designed for a group of people, in which the content is practical, and specific to the needs, interests and affinities of the group, which empowers teamwork and mutual support among participants [1]. In workshops, there are series of interactive activities perform by the participants as a form of training which differs in content and length.

Workshop as a teaching method is recognized around the globe because of its capability to make the teaching-learning process active, creative, and socially interactive. For instance, a study on Readers ' Writers' Workshop (RWW) in the secondary English classroom, and its findings showed that RWW is an effective tool for engaging students and assisting them in developing positive attitudes toward reading practice [2]. Meanwhile, another study explored the points of view of teachers handling mathematics who applied workshop method in classroom settings. The results showed that participants appreciated the math workshop as an effective instructional method to enhance teaching and learning in mathematics [3]. However, some teachers implementing workshop method experienced discomfort and worries since workshop approach involves a deep understanding of personal, curricular, instructional and epistemological foundations [4]. Thus, it encouraged school leaders to consider the teachers' need of time and space to take risks and reflect on their responsibilities.

On the other hand, technology has turned out to be an essential part of our usual life [5]; hence, many countries consider technology as one of the keystones of educational reform as to integration in teaching because of its capability to make teaching-learning

process easy, active, creative, innovative and interactive. For instance, a study on the role of technology-based instructional design and its effect on the instructors' professional advancement in English as a foreign language and proved effective [6]. At the same time, the effectiveness of interactive educational software in developing instructional design skills among teachers at Al Baha University was demonstrated [7]. Modern technology is integrated in teaching on a huge scale to aid learning across different disciplines [8]. Based on the above-mentioned facts, it clearly manifests that technology plays a great role in today's educational system.

In the Philippines, educators and scholars also emphasize educational reform [9]. As times change, educational policy also changes, which implies a great effect on the teaching and learning methods. Indeed, it is a major challenge for teachers to become resourceful and innovative in teaching and designing instructional materials. At the same time, it has been stressed that today's world is a territory of continuous changes, which pushes teachers to undergo intensive training on modern teaching methods [10]. At the tertiary level, the Commission on Higher Education (CHED) focuses on Outcomes-Based Education (OBE). According to Liwanag (2023) [11], the teaching method in OBE is learner-centered, which aims to assess the outcomes of students' learning. It is based on the constructivist view of John Piaget, which focuses on students, not teachers. Indeed, implementing the workshop method in teaching college students, assisted by technology like interactive television, is learner-centered.

In the university where the researcher is teaching, innovation is also given attention by administrators and teachers. However, some innovations in teaching are limited. For instance, the College of Teacher Education Research Office has organized a yearly workshop for third-year students enrolled in the Research Subject. However, only the group leaders in every section are invited to join because of a budget scarcity. This could not address the concerns of the whole class in a research subject. Many students experience difficulty in writing academic papers because of lack of skills in writing and critical thinking [12]. At the same time, the inputs of the teachers are the only basis in crafting a research paper. So, they emphasized that employing effective teaching strategies will result to a meaningful learning. Moreover, it was found out that language proficiency and writing skill are some of the main factors that affect students' ability in writing a research paper [13]. They recommended that teachers should employ practical teaching approaches and techniques which encourage students to appreciate research. Also, it was recommended by Auddya (2023) [14] that teachers are encouraged to have enough knowledge in doing and teaching research. Hence, the researcher was motivated to use workshop as a teaching method in writing a research proposal. This initiative would prepare the students for the real world of thesis writing during their third year level.

In 2024, the school administration provided ten units of interactive touch screen televisions in the College of Teacher Education where the researcher is employed as a college teacher. This is new in the college since the usual audio-visual aid in the classrooms is smart televisions. It was emphasized that using technology and software is important in research to achieve authentic and effective results [15]. Fortunately, the researcher was assigned to classrooms with interactive touch screen televisions, which paved the way for her to use such modern technology during workshops in the classroom. It was found out that workshops deliver a platform that assist researchers to identify and explore essential issues in a certain realm by giving ways for comprehending multifaceted work and knowledge processes that are reinforced by technology [16].

Some studies have already been conducted that focused on workshops, such as effectiveness of a workshop in teaching accounting subject [2], and the evaluation and effectiveness of a teacher training workshop to improve teaching competencies and outcomes [17] - [23]. There is still a gap since no studies have been conducted that employed workshop as a teaching method to provide 'hands-on' experiences to college students in crafting a research proposal. On the other hand, studies about integrating technology in the educational field are already conducted [6], [24], [25], focusing on the integration of technology in teaching and learning English as a foreign language and proving effective. Additionally, the use of smartphones with free mobile software applications for tertiary education and manifested positive effect [26]. Specifically, few recent studies on the instructional use of media platform like televisions were conducted and revealed positive impact [27] - [30]. There are no conducted studies assisted by technology like interactive touch screen television in presenting mini-lessons and outputs in workshops for crafting a research proposal.

The above-mentioned gaps and issues are the reasons which motivated the researcher to conduct this study to test the effectiveness of workshop in the classroom as a teaching method, aided by the interactive touch screen television as an audio-visual

material. Statistical treatments such as arithmetic mean, standard deviation, mean gain difference and t-test of independent samples were utilized to analyze the data objectively.

2 OBJECTIVES

Generally, this study was conducted to test the impact of the workshop with interactive touch screen television on the tertiary students' skill in writing a research proposal.

Specifically, it sought to answer the following questions:

1) What is the level of skills of students in writing a research proposal from experimental A and experimental B based on the result of:
   - pre-writing,
   - post writing
2) Is there a significant difference in students' level of skill in writing a research proposal before and after the intervention?
3) Is there a significant difference in the mean gain score of students based on the result of pre-writing and post-writing?

3 METHODOLOGY

This study employed a quantitative method, particularly a quasi-experimental design. The researcher utilized the respondents' research proposal outputs during pre-writing and post-writing activities for experimental A and B in a time-series approach. This is to test the effect of the workshop method with interactive touch screen television on tertiary students' level of skills in writing a research proposal. The interactive touch screen television was used to assist the researcher in presenting the mini-lessons as basis of the workshop. The workshop was based on model [31], which includes the presentation of mini-lessons, followed by the worktime or actual workshop, then debriefing for sharing and critiquing purposes.

The respondents of this study were first year college students from the College of Teacher Education, Sultan Kudarat State University – ACCESS Campus, ECJ Montilla, Tacurong City enrolled in Purposive Communication subject, in which writing an academic paper like research proposal was a part of the final term period. This requirement prepared the students to write a thesis during their third-year level. The respondents were 25 pairs from the Bachelor of Secondary Education major in Filipino and 27 pairs from the Bachelor of Secondary Education major in English, who were chosen through purposive sampling. The pairing was done to exercise collaborative effort and learning. This is supported by findings [32] that formative peer feedback has a positive impact in the quality of the academic paper.

The instrument used in evaluating students' outputs in the form of a research proposal was an adopted rubric from the university utilized by the College of Teacher Education in evaluating research proposals. The rubric was slightly modified by the researcher to meet the specific objectives of the study, which was then validated by three professors holding doctoral degrees. Then, Confirmatory Factor Analysis (CFA) was done to statistically test if the observed data from the rubric used fit a pre-specified theoretical model of what the rubric is intended to measure. Five professors with doctoral degrees evaluated the students' outputs using the rubric from experimental A and B in the form of a research proposal.

To assess the average of the scores of the pre-writing and post-writing test, mean and standard deviation was used. To calculate the mean, the observed values were added and divided by the number of respondents. This process is conveniently expressed by the symbol:

The standard deviation was calculated after

$$\bar{x} = \frac{(\Sigma x)}{n}$$

finding the mean of the set of data. Next, the mean was subtracted from each data point to find the deviations. Then, each deviation was squared, and summed up these squared values and then divided the sum by the number of data points minus one to find the variance. Finally, the square root of the variance was taken to get the standard deviation.

$$SD = \sqrt{\frac{\Sigma(x-\bar{x})^2}{n-1}}$$

To find out the difference between the skills of students of both pre-writing and post writing, mean gain scores were utilized. It was done simply by subtracting the mean of the pre –writing from the mean of the post- writing.

Paired-Sample t-test was also used to match the pairs of data, such as the pre-writing and post-writing scores for the same group of participants. It determines if the mean scores changed significantly after the treatment.

To calculate the paired t-test, the difference (d) for each paired observation was computed first, then

followed by finding the mean and standard deviation (sd) of these differences. The t-statistics was then calculated as $t = (\bar{x}d - \mu d) / (sd / \sqrt{n})$, where n is the number of pairs.

This study emphasized ethical considerations by warranting students' permission to become respondents. The researcher ensured that students' outputs were treated with confidentiality. The researcher properly recognized the citations and references used.

4 RESULTS AND DISCUSSION

Table 1 shows the results of pre-writing and post writing activities. In the pre-writing activity, the E\experimental A obtained a mean of 2.11 (SD=.12) with a description of "disagree" based on the evaluation and an interpretation of "unsatisfactory' while experimental B obtained a mean of 2.61 (SD=.89) with a description of "slightly agree" and an interpretation of "satisfactory". The data implies that the writing skill of students from experimental A is low while experimental B slightly knows how to craft a research proposal before the intervention. Many students find it difficult to write an academic paper because of lack of skills in writing and critical thinking [12]. At the same time, the inputs of the teachers in class are the only basis in crafting a research paper. So, they emphasized that applying an effective teaching strategy would result to meaningful learning.

In the post-writing activity, the students from experimental A has a mean of 4.54 (SD=.02) with a description of "strongly agree" from the evaluators with an interpretation of "very satisfactory" while experimental B obtained a mean of 4.52 (SD=.03) with a description of "strongly agree", with an interpretation of "Very Satisfactory". The data reveals that employing workshop in the classroom assisted by interactive touch screen television was effective to enhance students' skill in crafting a research proposal. The findings are similar to a study [2] where Readers' Writers' Workshop was found out as an effective tool for engaging students and assisting them in developing positive attitudes toward reading. In terms of technology, study on the instructional use of interactive television conducted in a special education course had revealed a positive impact [26]. Indeed, workshops aided by the interactive touch screen television gained a fruitful learning.

Table 2 reveals that there is a significant difference between the level of skill in writing a research proposal of students from experimental A before and after the intervention since the t-computed value (3.46) is higher than the T-tabulated (.019) at .05 level of significance. It indicates that the workshop method assisted by interactive touch screen television improved the skills of students in writing a research proposal. This finding is reinforced by a study [3] which showed that participants appreciated the math workshop as an effective instructional method to acquire a meaningful teaching-learning in mathematics. Although the study focused on enhancing mathematics skill and not on the writing skill in crafting a research proposal but workshop was employed and proved effective. As to technology-based teaching-learning, it was recommended [30] based on the study results that the utilization of television shall be a recognized innovation and shall be encouraged to maximize its use for learning activities in the academe.

Table 1: Results of writing skill of students in crafting a research proposal from Experimental A (BSED-Filipino) and Experimental B (BSED-English) during pre-writing and post-writing.

Test	Group	N	Mean	SD	Description	Interpretation
Pre-writing	A	25	2.11	.12	Disagree	Unsatisfactory
	B	27	2.61	.89	Slightly Agree	Satisfactory
Post-writing	A	25	4.54	.02	Strongly Agree	Very Satisfactory
	B	27	4.52	.03	Strongly Agree	Very Satisfactory

Table 2: Results of T-test in the level of skill of students from experimental a in writing a research proposal before and after the intervention.

Intervention	N	Mean	SD	T-computed	T-tabular	Interpretation
Before	25	2.11	.12	3.46	.019	Significant
After	25	4.54	.02			
@=.05 level of significance						

Table 3: Results of T-test in the level of skill of students from experimental b in writing a research proposal before and after the intervention.

Intervention	N	Mean	SD	T-computed	T-tabular	Interpretation
Before	27	2.61	.89	3.68	.021	Significant
After	27	4.52	.03			
@=.05 level of significance						

Table 4: Results of T-test in the mean gain score of students based on the result of pre-writing and post-writing.

Variable	N	Mean Gain	SD	T-computed	T-tabular	Interpretation
Experimental Group A	25	2.43	.32	3.23	.03	Significant
Experimental Group B	27	1.91	.52			
@=.05 level of significance						

Table 3 manifests that there is a significant difference between the level of skill in writing a research proposal of students from experimental B before and after the intervention since the T-computed value (3.68) is higher than the T-tabulated (.021). The data reveals that the workshop as teaching intervention, aided by the interactive touch screen television, was effective in enhancing the students' skill in crafting a research proposal. In a study, it was found out that workshops were effective in teaching accounting [33]. Another study focused on the use of smartphones with free mobile software applications for tertiary education and manifested a positive effect [26]. In addition, it was emphasized that media platforms like television, radio, and internet have extended the accessibility of instruction beyond the borders of traditional classrooms [27]. Indeed, media has transformed teaching-learning from passive to active engagement. Thus, it personalizes learning, tailors content and addresses individual needs and interests.

Table 4 shows a significant difference between the mean gain score of students from experimental A and B based on the result of pre-writing and post-writing since the t-computed value (3.23) is higher than the t-tabulated (.03). It reveals the clear manifestation of the effectiveness of workshops in the classroom assisted by the use of interactive touch screen television as an innovative teaching method and instructional material for writing a research proposal. This is supported by a study [6] on the role of technology-based instructional design and its effect on teachers' professional advancement in English as a foreign language and proved effective. Another study found that workshops provide a platform that assist researchers to identify and explore essential factors in a given domain by providing ways for understanding multifaceted work and knowledge processes that are reinforced by technology [16].

5 CONCLUSIONS

Modern teaching methods such as workshops provide hands-on activities for students that result in meaningful learning, as revealed by the findings obtained through statistical tools such as the arithmetic mean, standard deviation, mean gain difference, and the t-test of independent samples. Moreover, the use of technology, particularly interactive touch screen television during workshops, has demonstrated great potential in enhancing students' learning outcomes in crafting a research proposal because of its ability to make the teaching-learning process easier, more active, and more interactive.

In general, conducting classroom workshops supported by interactive touch screen television provides accessible, socially interactive, and practical learning experiences for students, which promotes the core principles of outcomes-based education.

6 RECOMMENDATIONS

Based on the findings of the study, teachers are encouraged to continue exploring practical and innovative approaches in teaching research in order to sustain and further improve meaningful teaching-learning experiences. Integrating modern technologies such as interactive touch screen television during workshops may help facilitate more engaging and effective instruction.

However, certain limitations should be considered, including the availability of technological resources and the level of teachers' skills in conducting workshops and utilizing modern technologies. Therefore, educational institutions should also support teachers by providing adequate training and access to necessary technological tools.

Keywords: Machine Learning, MPAA Rating, Movie Scripts, LightGBM, Multi-Class Classification, TF-IDF.

Abstract: Movies represent one of the most important media that combine narrative components with visual and auditory elements to entertain or inspire viewers. The Motion Picture Association of America (MPAA) is a prominent rating system that plays a great role for audience to select an appropriate film. This rating system is important because it helps parents filter the content to protect their children from unsuitable movies. It also assists audiences in their own choice. Traditionally, MPAA ratings are assigned by reviewers manually and this, in turn, leads to inconsistency, subjectivity, and time-consuming. This research introduces an automated method for predicting MPAA rating by using the scripts feature with the emotion feature that aiming to enhance classification accuracy and provide a more reliable assessment of age appropriateness. Scripts are preprocessed and converted into term frequency-invert document frequency (TF-IDF) vectors to capture significant linguistic patterns. Moreover, emotional features are extracted from movie scripts using transformer-based models due to their contextual understanding capabilities. These features are integrated to form a multi-class output. In this study, the LightGBM algorithm is applied as a gradient boosting technique. Experimental findings indicate that combining emotion features alongside textual representations enhances prediction accuracy in comparison to the use of scripts alone. The model achieves 84.2% and 84.6 for the weighted F1-score and the accuracy metric, respectively. This supports the effectiveness of the proposed model in predicting MPAA ratings from both movie scripts and emotional features.

1 INTRODUCTION

Movies are important means of cultural expression and artistic in people's life. They are not just a means of entertainment, but movies also a tool for social and intellectual influence. Film classification is an essential step in regulating the film industry and ensuring it reaches the appropriate audience. This enables viewers to choose films that suit their interests and preferences. It also contributes to directing audiences to age-appropriate content through age rating. Thus, movie classification is an effective way to protect children and sensitive groups from inappropriate content. In addition, it facilitates production and distribution companies to market films more accurately. This can also enhance the viewing experience by setting audience expectations before watching a film. Creators can rely on movie classification as it directs them towards a specific genre that reflects their artistic vision [1].

The age appropriateness of films has been recommended by censorship bodies through rating certificates. There are two main organizations specialized in performing this task. The former is the Motion Picture Association of America (MPAA) in the United States of America, whereas the latter is the British Board of Film Classification (BBFC) in the United Kingdom [2]. These two organizations build their ratings based on films' content. MPAA ratings have a wide practical value where parents can depend on them as a guideline to determine which movies are appropriate for children. Media service providers such as Amazon and Netflix may use these ratings to enable age-appropriateness filters. This mainly relies on movie scripts as a means to determine their content [3].

The MPAA uses five film ratings to guide audiences. The first one relates to the General type (G) that is suitable to all ages with no offensive content, nudity, or significant violence. The second one is Parental Guidance (PG) that may contain

unsuitable material for children with moderate violence and brief nudity. Parents Strongly Cautioned (PG-13) is the third type which includes warns content that may be inappropriate for viewer under-13 years with occasional use of substances, strong language, and minimal sexual content. Fourthly, Restricted (R) requires parent accompaniment for under-17 year due to adult content, including strong language, violence, sexuality, or substance use. Finally, No One Under 17 (NC-17) prohibits anyone under 17 from viewing due to explicit sexual scenes, extensive harsh language, or excessive violence, though it is not classified as obscene or pornographic [4].

A wide range of data sources can be utilized for the automatic classification of movies into age appropriateness rating. One of the important data sources available about movies is movie scripts, which contain only conversations between characters, which is considered the foundation of filmmaking. Movie scripts instruct how a scene should be filmed in addition to telling the audience what is happening. It is a screenplay-formatted document that authors, directors, and actors can use to help them prepare for their parts [5].

Traditionally, MPAA ratings are assigned manually by human reviewers. This approach is often considered time-consuming, subjective, and inconsistent. It may also affect the rating decision due to personal bias or differing interpretations of content. Consequently, there is a growing need for an automated and reliable method to predict MPAA ratings objectively. Developing such a system can enhance consistency, reduce human effort, and support filmmakers, distributors, and audiences in understanding content suitability more efficiently.

The present study addresses this problem by automatically predicting MPAA ratings for movies based on their textual content. The task is formulated as a multi-class classification problem. The input parameters include both textual features and other features that are extracted via the Transformer model. The classification process is based on the LightGBM algorithm, which predicts the most appropriate MPAA class for each movie. To evaluate the model performance, the accuracy and weighted F1-score are used as main criteria for assessment.

The key aims of this research are twofold. First, it develops an automatic method to predict MPAA movie ratings using textual script data with emotions that are extracted from the entire script. The distilled version of RoBERTa (DistilRoBERTa) [6]as a Transformer model is employed for feature extraction. The extracted features are combined with Term Frequency–Inverse Document Frequency (TF-IDF) features and they are fed into the LightGBM[7] model for multi-class prediction purposes. Second, the research addresses the limitations of the sequence length constraints existing in Transformer architectures. To achieve such aims, it seeks to answer the following research questions:

1) How can emotion features extracted from a Transformer-based model improve the performance of MPAA rating prediction in comparison to traditional text-based representations alone?
2) Which method can effectively handle the input sequence length limitation of Transformer models when processing long movie scripts for emotion feature extraction?
3) To what extent the combination of different features can contribute to achieving higher accuracy and interpretability in automated MPAA rating prediction?

Based on such aims and research questions, this research achieves the following contributions:

1) Proposing an automatic model for predicting MPAA rating based on fusion term weighting features with emotion features extracted from a Transformer-based model.
2) Presenting a method for handling the length size limitation of the input sequence processing that exists in the Transformer model during the emotion feature selection process.
3) Achieving a new performance benchmark for this task with 84.2% for the weighted F1-score and accuracy was 84.6%.

The remainder of this paper is organized as follows. Section 2 reviews the relevant literature and related work. Section 3 presents the dataset and methods used. Section 4 reports the proposed model phases. Section 5 presents and analyzes the experimental results. Finally, Section 6 provides conclusions and outlines potential future research directions.

2 LITERATURE REVIEW

This study attempts to address the gap related to extracting emotion features by employing a Transformer-based model that is capable of capturing contextual and fine-grained affective cues within movie scripts. Unlike lexicon-based methods such as the Name Entity Recognition (NRC) emotion lexicon [1][8], which assigns static emotion

values to individual words without considering their contextual meaning, the proposed approach utilizes the DistilRoBERTa-base model ("j hartmann/emotion-english-distilroberta-base"). It was trained on the GoEmotions dataset. This model enables the extraction of context-dependent emotional representations that better reflect the underlying sentiment and intensity of movie narratives. This study also introduces a method to overcome the input length limitation in Transformer-based emotion extraction by segmenting and aggregating emotional representations across script chunks.

The movie scripts are typically long and complex narratives, often exceeding the maximum input length (512 tokens) that Transformer-based models can process. This constraint causes loss of contextual and emotional information, leading to incomplete emotion representation. This method can preserve emotional continuity and ensures that long movie scripts are fully analyzed, capturing both local and global emotional contexts. By integrating these emotion features with statistical linguistic representations derived from TF-IDF, the proposed framework improves the accuracy and reliability of automated MPAA rating prediction.

Many studies were accomplished on age rating classification. These studies varied in using either traditional machine learning techniques or artificial neural network models. It was found that this literature utilized a single data type such as text data, images, or based on multiple form to achieve better accuracy results.

To our knowledge, the first published research about predicting MPAA rating was accomplished by Shafaei et al. [8]. The research works on predicting the suitability of movies for children and young adults based on movie scripts, relying on the MPAA rating system as a benchmark. A deep learning model was proposed by using a Recurrent Neural Network (RNN) with an attention layer. This incorporates movie genres and emotions in conversations to predict the five MPAA ratings. The experiment shows that the model achieves a weighted F1-score of 78% which outperforms traditional machine learning methods by 6%. The study highlighted that bad word lists alone are insufficient for MPAA rating prediction. Therefore, including multiple factors such as violence, language, and thematic material can enhance the prediction. The model performance was improved when genre and emotion vectors were included.

Another research introduced in [1] presents a task of predicting the MPAA rating of movies using their scripts to assess age suitability for children and young adults. The Long Short-Term Memory (LSTM) model was leveraged here with the attention mechanism and it incorporated both emotion and genre vectors for predicting MPAA ratings. The pre-trained Global Vectors for Word Representation (Glove) was used as a word embedding method which can preserve the semantic information. Based on model performance, the weighted F1-score was 81.6% which outperforms traditional machine learning methods by 7%.

In [9] a multi-modal method was proposed based on deep learning methods to automate the age-suitability rating of movie trailers. A new dataset, the Multi-modal Movie Trailer (MM-Trailer) that contains 1,443 trailers and their corresponding age-suitability ratings. The research combines audio, video, and text modalities to improve prediction accuracy, demonstrating that multi-modal approaches outperform single models. A specialized neural network architectures were assigned for each modality. RNNs were for text and audio, and CNN-LSTM were for video. The results indicated that the Gated Multi-modal Unit (GMU) fusion method yields the highest performance, significantly improving upon the best single modality model. Based on the experimental results of the GMU fusion variant, it achieved a weighted F1 score of 86.06% that outperforms other fusion methods and single modality models. It should be noted that the output result in this study is a binary classification, where the film is classified as suitable for all audiences or restricted and specific to a specific audience.

Another research study [3] introduced a multimodal approach for predicting the film age appropriateness with MPAA and BBFC. It combined textual and visual features. The subtitles and synopses were used in textual data, while the movie poster was used as the visual data. Several deep learning and machine learning models were utilized for textual and visual data.

ResNet, Inception and NASNet were used for visual feature extraction, while the TF-IDF method was used for textual feature selection. The study demonstrated that textual features provide a strong predictor of MPAA ratings, while images provide complementary information. The experimental result shows that combining both modalities leads to a higher accuracy than using either alone, which highlights the value of multimodal fusion in movie rating research. The best accuracy result was accomplished using xgboost model with only three

class output (PG, PG-13, R), with 81.1% for MPAA and 66.8% for BBFC.

The research study introduced in [4] proposed using bidirectional LSTM models that were integrated with an attention mechanism to introduce MPAA multi-class movie rating prediction. The study was based on 12000 textual script data and presents four models to evaluate the best one using different feature extractors as Bidirectional Encoder Representations from Transformers (BERT) and A Robustly Optimized BERT Pretraining Approach (RoBERTa). According to the research results, the bad word frequency model achieves the best output with an accuracy metric of 56% classification of movie ratings.

3 MATERIALS AND METHODS

3.1 Movie Dataset

The dataset contains a movie corpus with a collection of 5.562 movie script files, and movie poster files. Furthermore, there is a metadata file contains information about movies, such as IMDB_ID, Title, Genre, MPAA_rating, Actors, Poster source, Director, and year [1]. The movie scripts file contains the whole conversations among characters which was saved in a separated file. There are five MPAA rating types in this dataset that are G, PG, PG-13, NC-17 and R. Figure 1 shows the distribution of these ratings.

3.2 The Emotional Extraction Model

The DistilRoBERTa-base model is a faster and smaller version of the RoBERTa [10] transformer model that is designed to retain most capabilities of the RoBERTa model, while reducing computational complexity and inference time. The distillation technique consists of training a smaller model to replicate the functioning of a larger model, allowing for effective deployment in resource-constrained settings. The DistilRoBERTa-base emotion model is fine-tuned on annotated emotion recognition datasets such as GoEmotions [11]. It contains 27 emotion categories, or six emotion types plus a neutral class. The fine-tuning enables the model to categorize input text into specific emotions by leveraging the contextual embeddings generated by the DistilRoBERTa architecture. This model balances between performance and efficiency that make it suitable for large-scale emotion detection or real-time tasks in applications, such as movie script analysis. Combining emotion features with other data into multimodal frameworks enhances the understanding of narrative tone in the used data to improve the performance in tasks such as MPAA rating prediction.

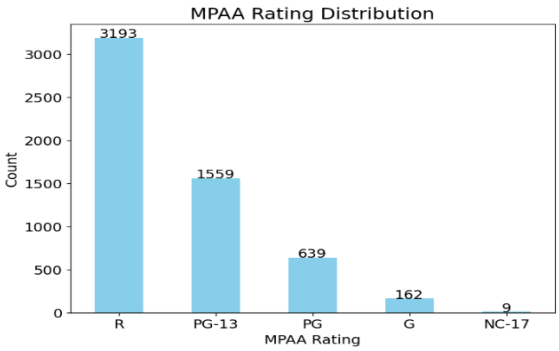

Figure 1: MPAA_rating distribution over movies.

3.3 Textual Feature Extraction

This research uses simple method to select script features by using TF-IDF technique.TF-IDF is the most known feature extraction technique that converts text data, such as summaries or scripts, into numerical vectors suitable for machine learning models. TF-IDF highlights terms that are most informative [12] for distinguishing between movie rating. For instance, words such as "kill" or "blood" may indicate a strong signal for R rating of films. Other words such as "school" or "friendship" are more indicative of G or PG rating. The general terms such as movie or story are assigned less weight because they provide little information regarding age suitability.

The ability of capturing specific vocabulary related to various rating types makes TF-IDF an effective representation for machine learning classifiers such as SVM, Random Forest, and ensemble models, thereby improving predictive accuracy in multi-label movie genre classification tasks. To compute TF-IDF as Equation (3), two variables should be calculated: TF based on (1) and IDF from (2) as in [13].

$$TF_{t,d} = \frac{f_{t,d}}{\sum_{t \in d} f_{t,d}}, \quad (1)$$

where, $f_{t,d}$ is the number of present of term t in document d, $\sum_{t \in d} f_{t,d}$ indicates the overall count of terms t within document d

$$IDF_{(t,D)} = log\ \frac{N}{|\{d \in D : t \in d\}|}, \quad (2)$$

where N = total number of documents d in corpus D and $|\{d \in D : t \in d\}|$ denotes the count of documents that include the term t.

$$\text{TF-IDF} = \text{TF} * \text{IDF}. \quad (3)$$

3.4 LightGBM Model

LightGBM [7] stands for Light Gradient Boosting Machine, which is a type of gradient boosting framework developed by Microsoft. LightGBM has two significant techniques that make it outperforms the traditional XGBoost model in the memory consumption and processing speed. The first technique is Gradient-based One-Side Sampling (GOSS) that emphasizes selecting samples using their gradients, giving priority to those with greater gradients during training. Exclusive Feature Bundling (EFB) is the second one that enhances memory utilization by grouping unique features, enabling more effective processing and quicker training, while maintaining performance levels substantially. It effectively handles a substantial number of data instances and a large variety of features. Therefore, these two features make the LightGBM model much quicker and more scalable than traditional GBM.

4 THE PROPOSED MODEL

This study presents a multi-class classification model for predicting four types of MPAA rating categories. This is based on fusion extracted emotional and script features using a powerful machine learning model. Before that, the data must pass through a preprocessing stage to introduce clear data for use in the suggested model.

4.1 The Preprocessing Stage

Preprocessing is a crucial step in any Natural Language Processing (NLP) tasks that affect a model's performance [14]. To use the movie script for subsequent analysis, text normalization and cleaning procedures are needed. Many cleaning procedures were utilized in this research, such as is lowercasing, stopwords removal and alphabetic filtering. The lowercasing process converts the entire input script into lowercase alphabetical to ensure consistency in letter casing, thereby minimizing sparsity in the token space. Another preprocessing procedure is the elimination of stopwords, which discards common English stopwords such as “and”, “is”, and “the”. This method was implemented using the NLTK library. Lastly, an alphabetic filtering process was applied to keep only tokens made up of purely alphabetic characters. This helps remove numbers, punctuation, and other non-letter symbols that usually do not add meaningful semantic value.
There is another preprocessing step related to the imbalance state of the class label. This involves identifying and removing the rare labels. This can potentially improve the performance of the learning model by reducing noise and preventing overfitting on the underrepresented class. Based on Figure 1, which illustrates the distribution of five MPAA rating labels, the NC-17 rating class was removed since it had low occurrence frequency over other rating.

4.2 The Classification Stage

The proposed model is illustrated in Figure 2. It is based on three stage to achieve the goal of predicting MPAA rating. The first one is related to feature extraction from TF-IDF after cleaning the textual script during the preprocessing stage. The spaCy English language library, which is considered a natural language processing was used in the text cleaning procedure to standardize the movie script before the feature extraction stage. The cleaning process converts all script texts into lowercase, removes unnecessary symbols, and tokenizes the content into linguistically meaningful units. The tokens are then rejoined to form coherent sentences, while correcting spacing around punctuation marks to preserve natural text structure. This procedure ensures that the scripts are linguistically consistent, noise-free, and properly formatted for TF-IDF and emotion feature extraction.

In this study, the number of TF-IDF features was set to 12,000, aiming to capture as many as possible representative and informative terms from the movie scripts. This dimensionality was chosen to balance between computational efficiency and feature richness, ensuring that both common and distinctive

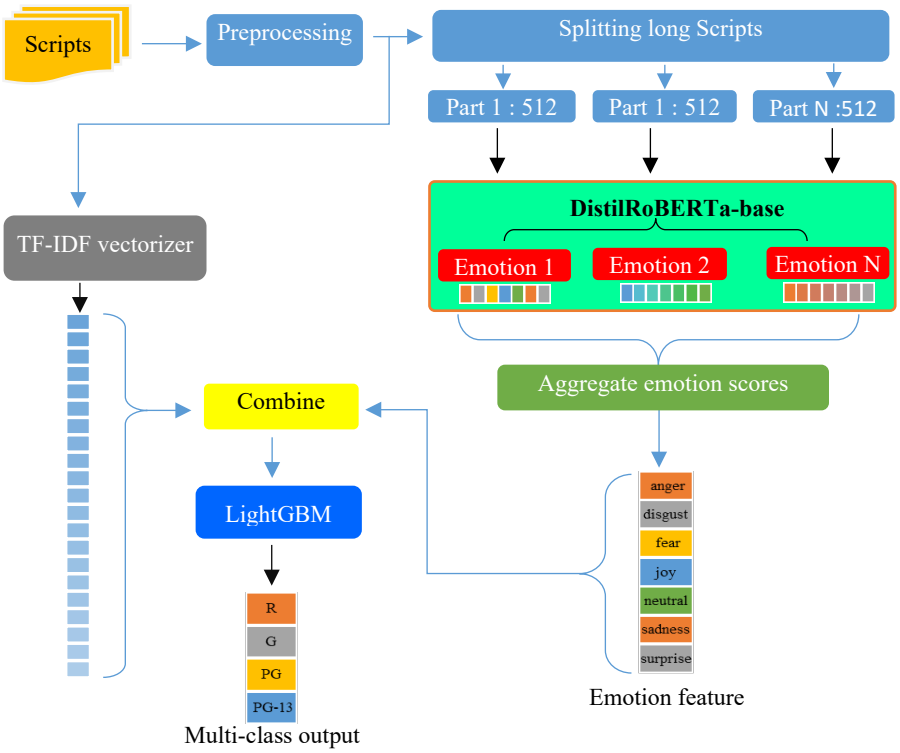

Figure 2: The proposed MPAA rating classification model.

linguistic patterns contribute to MPAA rating prediction. The second one is associated with the emotional feature extraction, that was accomplished using a trained DistilRoBERTa-base model. It was published on the Hugging Face website under the "j-hartmann/emotion-english-distilroberta-base" title. The model was trained over the GoEmotions dataset to predict six emotions namely, "anger", "disgust", "fear", "joy", "sadness" and "surprise", and "neutral" type.

The Transformer-based emotion recognition is designed to capture contextual emotional nuances in text by leveraging deep semantic representations rather than relying on keyword-based emotion lexicons. The maximum input sequence that the DistilRoBERTa model can process is 512 tokens, where the medium token length in the used script exceeds 2000 tokens based on the calculation sequence size.

In this state, this model was unable to extract the emotion features from the entire script. Therefore, we proposed a method to address this limitation by using the chunking method. It splits the long-cleaned script into small chunks with 512 tokens, where every chunk is passed to the emotional model to extract the emotion vector for that chunk. This process is repeated to complete the remaining chunks. The individual emotion features per chunk are aggregation together to produce the final vector that represents the emotion tone in the script.

This emotion feature vector was combined with the TF-IDF vector to form the final feature vector that is fed into the LightGBM classifier. The data was split into 80% for training and 20% for testing to ensure that the model was trained on the majority of the samples, while preserving a separate portion for unbiased evaluation. Since the dataset had an imbalanced class distribution, as shown in Figure 1, creating the necessity to address this issue, which can be model-based or data-based. This study utilizes a class weights strategy, which is a type of model-based approach to tackling class imbalance. Typically, models tend to be biased towards the majority classes since the loss function influences heavily by the frequent labels. When employing the class weights technique, the loss for minority classes increases and this, in turn, leading the model to focusing more on rare categories during the training stage. This modification enhances the capability of the model to classify rare labels accurately and results in more balanced performance across all classes, especially in application such as MPAA rating

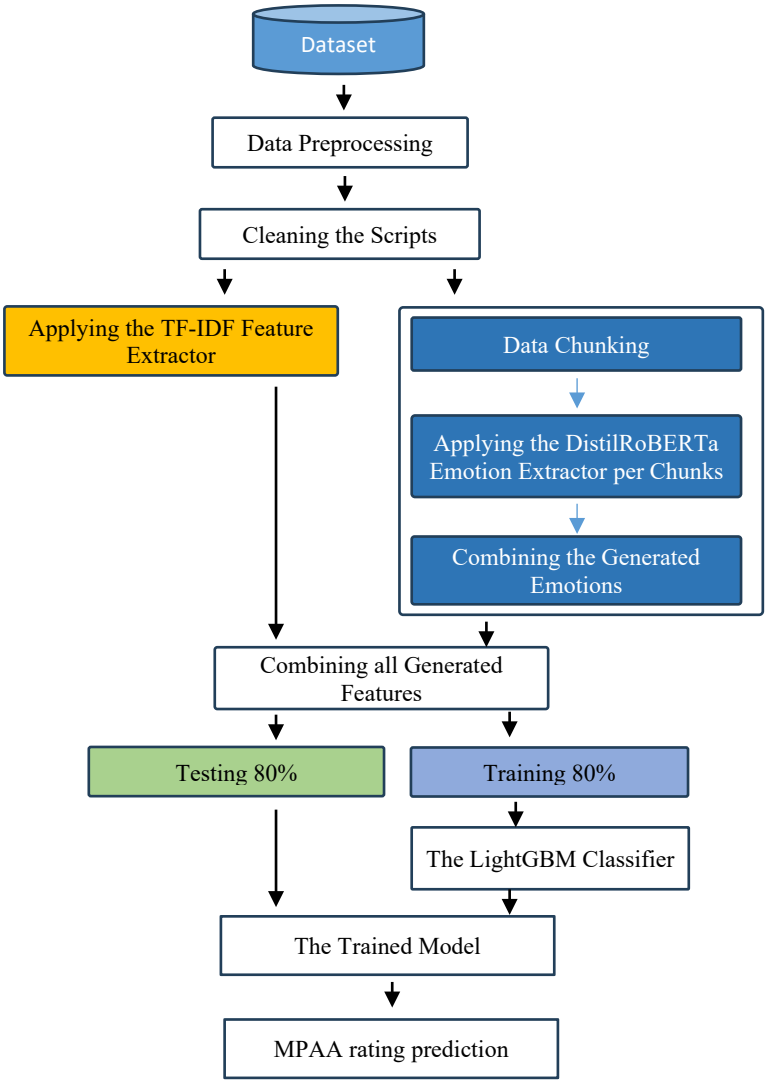

Figure 3: The entire model flowchart.

prediction. In this system, some categories may be significantly less common than others. After completing the training process with four multi-class labels, the LightGBM model can predict the MPAA rating of a given script by applying the SoftMax activation function on the output probabilities. The class with the highest probability is selected as the final predicted rating. This can be either G, PG, PG-13, or R. The overall workflow of the proposed MPAA rating prediction model is illustrated in Figure 3. It presents the main processing stages that begin from data preprocessing and chunking, until TF-IDF feature extraction and emotion representation using the DistilRoBERTa model. The extracted features are then fused and passed to the LightGBM classifier to predict the final MPAA categories.

5 RESULTS

The proposed model was tested with four machine learning models namely, Support Vector Machine (SVM), Naive Bayes (NB), Random Forest (RF) and XGBoost. Moreover, the findings of other studies were compared with the proposed model to demonstrate its efficiency. Both evaluation metrics, Accuracy and the Weighted F1-Score [15], were used to comprehensively evaluate the model's performance in the multi-class

classification task. Accuracy measures the overall proportion of correctly classified samples, while the Weighted F1-Score accounts for class imbalance by averaging the F1-scores of each class according to their support. Achieving high accuracy and a strong weighted F1-Score indicates reliable predictions across all classes. This demonstrates that the model not only performs well overall but also maintains balanced performance for both the majority and minority classes.

Some studies relied on the weighted F1–Score metric [16] This is based on the normal F1 – Score. This metric is presented in (4). It can provide more weight to classes that have more samples.

$$F1_{\,weighted} = \sum_{i=1}^{k} \frac{n_i}{N} . F1_i \,, \qquad (4)$$

n_i = number of true samples in class i , $F1_i$ = F1-score for class i , N = total number of samples.

Table 1 shows the model performance using various numbers of selected TF-IDF features. This is starting from 10000, 12000, and 15000 vector features. The model was evaluated using 5000 features, but it achieved a lower result than 10000 features. The LightGBM model outperformed other models. The weighted F1-Score, and accuracy were 84.2, 84.6, respectively.

Table 1: Evaluation of TF-IDF feature variants.

Method	10000 TF-IDF		12000 TF-IDF		15000 TF-IDF	
	weighted F1–Score	Accuracy	weighted F1–Score	Accuracy	weighted F1–Score	Accuracy
SVM	68.1	66.5	68.3	66.6	68.5	66.9
Naive Bayes	42.2	57.7	42.2	57.7	42.2	57.7
Random Forest	70	72.7	69.8	73.1	66.3	70.2
XGBoost	82.2	82.2	83.8	83.3	83.4	83.5
LightGBM	83.1	83.3	**84.2**	**84.6**	83.9	83.9

Table 2 illustrates the model performance in comparison with previous studies. The best result was achieved by the suggested model, except for the findings presented in [9]. However, it should be clear that the output of [9] is binary classification only. The accuracy value was 84.6 after integrating emotional features, while the weighted F1-Score metric was 84.2. The model was tested without using the emotional feature to identify the contribution of utilizing the emotion features. Its overall results were 83.7 and 83.8 for both weighted F1-Score and accuracy metric, respectively. This result was obtained when using the top 12000 features during the calculation TF-IDF feature, where it represents the best value that was selected based on experimental results.

Table 2: Performance comparison with literature.

Study	Method	weighted F1–Score	Accuracy
[8]	RNN	78	-
[1]	LSTM + Glove	81.6	-
[9]	CNN-LSTM + GMU	86.06	-
[3]	TF-IDF + ResNet, Inception	-	81.1
[4]	bidirectional LSTM	-	56
Our model	TF-IDF , LightGBM	**83.7**	**83.8**
Our model	TF-IDF + emotion , LightGBM	**84.2**	**84.6**

6 CONCLUSIONS

Movie ratings prediction plays a crucial role to ensure appropriate content for audience. It provides guidance for parents and audience by categorizing films according to their thematic content, language, and level of violence. This makes the importance of creating a model to classify movie ratings automatically.

This research presented a multi-class classification model for predicting four MPAA ratings based on a fusion approach. It integrated the script features extracted from TF-IDF and emotion features obtained from the DistilRoBERT model. This study demonstrated that Transformer-based emotion features enhance MPAA rating prediction beyond traditional method such as NER. Due to the limitation of sequence length processing, this present study introduced a new method based on a chunking method to address this constraint. It enabled the model to acquire the emotion tone from the entire script length. TF-IDF vectors, along with the emotion vector, were combined and passed into the LightGBM classifier to predict the height of movie ratings. Based on the results, the combination approach showed an enhancement in the prediction of MPAA ratings by achieving high accuracy and weighted F1-score.

The class weight technique was utilized to handle the imbalance state of labels, where some classes had far fewer samples than others. The presented results showed that integrating the

emotional features enhanced the performance of the LightGBM model. Furthermore, the suggested model result was compared with earlier literature based on the evaluation metric. This research findings outperformed previous studies with 84.2 and 84.6 for weighted F1–score and Accuracy, respectively.

Regardless of the research findings, some limitations should be addressed to open the door for future research. First, a multimodal approach can be applied to multiple data types. This may help generalize the proposed model. Moreover, applying more methods to address the class imbalance may enhance the model's performance. Finally, the proposed model should be applied on another rating way to improve its efficiency and applicability.

Keywords: Big Data, Environmental Risk Assessment, Composite Hazard Index, Unsupervised Clustering, Decision Support System.

Abstract: The proliferation of IoT-based environmental monitoring networks has led to an exponential increase in air quality data, creating a significant challenge for effective and timely risk assessment. Traditional analysis methods often struggle to convert this vast volume of raw data into actionable insights for decision-makers. This paper introduces a novel big data framework designed to automate the process of environmental risk assessment through a two-stage analytical approach. First, we propose a Composite Hazard Index (CHI), a quantitative metric that normalizes and aggregates data from disparate pollutants into a single, interpretable risk score for each monitoring location, incorporating expert-defined weights to reflect the relative toxicity of different substances. Second, this index, along with normalized pollutant profiles, is used as input for an unsupervised clustering algorithm (K-Means) to automatically stratify locations into distinct risk tiers (e.g., Low, Medium, High). A key novelty of our approach is a descriptive analysis method that identifies the primary pollutants, or "key risk drivers," responsible for the elevated hazard levels in high-risk clusters. The framework was validated using a real-world dataset from a public air quality monitoring network. The results demonstrate the system's ability to successfully identify high-risk "hotspots," quantify their danger level, and pinpoint the specific pollutants contributing to the threat, thereby providing a powerful, data-driven tool for proactive environmental management.

1 INTRODUCTION

The global challenge of air pollution, with its well-documented adverse effects on public health and ecosystems, has entered a new era defined by data abundance [1]. The widespread deployment of low-cost Internet of Things (IoT) sensors and citizen science initiatives has generated unprecedented volumes of high-frequency environmental data [2]. This "data deluge" presents a dual opportunity and challenge. On one hand, it offers the potential for granular, real-time analysis of environmental dynamics. On the other, the sheer volume, velocity, and heterogeneity of this data overwhelm traditional analytical approaches, creating a critical gap between data availability and the ability to derive actionable intelligence for environmental governance [3].

1.1 Related Work

A review of current scientific literature reveals several distinct but often fragmented approaches to this problem. A significant body of research focuses on predictive modeling, employing machine learning techniques like Long Short-Term Memory (LSTM) networks to forecast pollutant concentrations [1, 2]. While valuable for short-term warnings, these models often operate on raw concentration values and do not inherently provide an integrated assessment of the overall environmental risk, which is often a product of multiple interacting pollutants. Furthermore, their accuracy is fundamentally dependent on the quality of input data, a major issue given the known reliability concerns of low-cost sensors [3].

Another prominent research direction involves the use of exploratory data analysis, particularly unsupervised clustering algorithms, to identify spatial patterns and pollution "hotspots" [4, 5]. For instance, Hu et al. (2022) applied clustering and spatial statistics to classify urban pollution levels, successfully identifying distinct geographical patterns [5]. More advanced techniques like co-clustering have been used to simultaneously group spatial and temporal objects, revealing complex interactions [6]. However, a common limitation of these methods is their descriptive nature. They effectively answer the question "Where are the problem areas?" but often fall short of quantifying the severity of the risk or identifying its primary drivers, leaving interpretation to human experts.

To bridge this gap, hybrid methodologies have emerged, combining clustering with physical-chemical receptor models like Positive Matrix Factorization (PMF) to link clusters with specific emission sources (e.g., traffic, industry) [7, 8]. This approach provides a powerful diagnostic tool, offering insights into the "Why?" behind pollution patterns. Nevertheless, it typically requires detailed and costly chemical speciation data, which is not available from standard monitoring stations that measure bulk pollutants like PM2.5 or CO.

1.2 Problem Formulation

Based on the identified gaps in the existing literature, this research addresses the challenge of transforming high-volume, multi-pollutant monitoring data into a prioritized and interpretable risk assessment. The problem can be formally stated as follows:

GIVEN:

1) A raw dataset of time-series air quality measurements from a set of m monitoring locations, where each record contains a location identifier, timestamp, pollutant type, and concentration value.
2) A set of regulatory standards (e.g., Maximum Allowable Concentrations) for each of the n monitored pollutants.
3) A set of expert-defined raw weights representing the relative health impact or importance of each pollutant.

FIND:

1) A single, quantitative Composite Hazard Index (CHI) for each of the m locations that represents the integrated environmental risk.
2) An automated stratification of the m locations into a predefined number of K discrete risk tiers (e.g., "Low," "Medium," "High") based on their pollutant profiles and overall CHI.
3) For the highest risk tier, an identification of the key pollutants (risk drivers) that are the primary contributors to the elevated risk level, quantified by a comparative metric.

2 MAIN PART

2.1 Research Methodology

2.1.1 Data Pre-Processing and Profile Generation

The initial stage transforms raw, heterogeneous time-series data into a structured, analysis-ready format. This is a prerequisite for any meaningful analysis of environmental indicators [9]. The process involves several steps:

1) Data from disparate sources and timeframes are consolidated into a unified structure, with each record containing a location identifier, timestamp, pollutant type, and concentration value.
2) Absolute concentration values are converted into a dimensionless, universally comparable metric of risk. This is achieved by dividing each measurement by its corresponding regulatory standard, such as the Maximum Allowable Concentration (MAC). A value of 2.5 after this step is unequivocally interpreted as "the concentration is 2.5 times the established safe limit," regardless of the pollutant.

3) To handle missing data and irregular measurement intervals, time-series for each unique "location-pollutant" pair are resampled onto a regular time grid (e.g., daily). Gaps are filled using linear interpolation, a reasonable assumption for environmental processes over short intervals.
4) The processed time-series data is aggregated over a defined analytical period (e.g., one year) to create a static "environmental profile" for each monitoring location. This profile is represented as a feature vector where each element is the mean MAC-normalized value for a specific pollutant. This results in a feature matrix X of size $m \times n$, where m is the number of locations and n is the number of pollutants.

2.1.2 Composite Hazard Index Calculation

To move from a multi-pollutant profile to a single, rankable measure of overall danger, we introduce the CHI. The calculation is a three-step process:

1) The feature matrix X (containing mean MAC-normalized values) is further normalized to a scale of $[0,1]$ to ensure all risk factors contribute equally to the index calculation, regardless of their original range. For each pollutant j, the normalized value for location i is calculated as:

$$x_{norm,ij} = \frac{x_{ij} - \min(X_j)}{\max(X_j) - \min(X_j)}, \quad (1)$$

where $\min(X_j)$ and $\max(X_j)$ are the minimum and maximum mean values for pollutant j across all locations.

2) The framework allows for the incorporation of expert knowledge by assigning weights to each pollutant based on its perceived toxicity or local importance. A user-defined vector of raw weights $W_{\text{raw}} = [w_{\text{raw},1}, \ldots, w_{\text{raw},n}]$ is normalized to sum to 1:

$$W_{norm,j} = \frac{w_{raw,j}}{\sum_{k=1}^{n} w_{raw,k}}. \quad (2)$$

The use of expert-defined weights, rather than a machine learning approach, is a deliberate decision that prioritizes interpretability, control, and practicality.

Experts assign these transparent weights based on established public health knowledge, pollutant toxicity, and regulatory standards, such as reference concentrations (RfCs). This ensures the resulting risk score is scientifically justified and aligned with health priorities, for example, by giving a higher weight to PM2.5 due to its significant cardiorespiratory effects. This method also allows authorities to adjust weights based on local concerns or new toxicological findings.

From a practical standpoint, a machine learning model would require a large, labeled dataset linking pollution mixes to verified health outcomes, which is exceptionally rare. Therefore, the expert-driven system provides a more robust and operationally feasible solution for decision support, while still allowing for future refinement through machine learning as suitable data becomes available.

3) The CHI for each location i is computed as the weighted sum (scalar product) of its normalized pollutant vector and the normalized weight vector:

$$CHI_i = \sum_{j=1}^{n} x_{norm,ij} \cdot w_{norm,j}. \quad (3)$$

The result is a vector $R = [\text{CHI}_1, \ldots, \text{CHI}_m]$, where each CHI_i is a value in $[0,1]$ representing the integrated environmental hazard at that location.

2.1.3 Unsupervised Risk Stratification (Auto-Clustering)

This stage uses the generated profiles and indices to automatically group locations into meaningful risk tiers. We employ the K-Means clustering algorithm, but with a novel feature engineering approach to guide the process.

1) Instead of clustering on the pollutant profiles alone, we create an augmented feature vector Z_i^* for each location i. This vector concatenates the normalized pollutant profile with its calculated CHI:

$$Z_i^* = \left[x_{norm,j1}, x_{norm,j2}, \cdots, x_{norm,jn}, CHI_i \right]. \quad (4)$$

This augmentation forces the clustering algorithm to consider not only the similarity in the mix of pollutants but also the overall level of hazard as captured by the CHI.

2) The K-Means algorithm is applied to the set of augmented feature vectors {Z1*, … Zm*}. For

risk stratification, the number of clusters K is fixed (typically K =3) to represent “Low Risk,” “Medium Risk,” and “High Risk” tiers. The algorithm partitions the locations into K clusters C={C1, …Ck} by minimizing the within-cluster sum of squares (inertia):

$$\arg\min_{C} \sum_{k=1}^{K} \sum_{Z_i^* \in C_K} \left\| Z_i^* - \mu_k^* \right\|^2, \qquad (5)$$

where μ_k^* is the centroid of cluster C_k.

3) After partitioning, the clusters are ordered based on the average CHI of their constituent locations, ensuring that Cluster 0 corresponds to the lowest risk and Cluster K–1 to the highest.

2.1.4 Key Risk Driver Analysis

The final stage provides an interpretable explanation for why a cluster is classified as high-risk. Instead of relying on complex statistical tests that may be unreliable with small sample sizes, we use a straightforward descriptive metric.

For each pollutant j, we calculate its mean value (from the original, un-normalized feature matrix X) within the “High Risk” cluster (C_{High}) and the “Low Risk” cluster (C_{Low}). The Risk Multiplier (M_j) is then calculated as the ratio of these means:

$$M_j = \frac{mean(X_j \ in \ C_{High})}{mean(X_j \ in \ C_{Low})}. \qquad (6)$$

Such a mathematical model is easily integrated and can be implemented both in public monitoring information systems [10] and used for municipal monitoring.

2.2 Results and Discussion

The proposed framework was validated using the "Air Quality Monitoring from EcoCity" dataset [11], a comprehensive, real-world collection of public monitoring data from the city of Vinnytsia, Ukraine. For this validation, higher expert weights were assigned to particulate matter (PM2.5), reflecting its significant impact on respiratory health, as detailed in the "Risk Factor Importance" charts within the generated reports. The analysis was conducted for two periods: a historical review from January 1, 2021, to September 9, 2023, and a forecasted period from September 9, 2023, to October 9, 2023, to assess both retrospective patterns and future trends.

2.2.1 Risk Index Calculation and Stratification

After pre-processing the historical data, the framework calculated a CHI for each monitoring station. The results, visualized in the "Comprehensive Risk Index" chart (Fig. 1), revealed a stark distribution of risk, with CHI scores ranging from approximately 0.1 to a severe outlier of 0.786 [12].

The subsequent risk stratification, using K-Means with K=3, produced a clear and actionable grouping of the stations into three distinct risk tiers. The results for the historical period are summarized in Table 1.

The clustering process unequivocally isolated a single station, s-1612, as the sole member of the "High Risk" cluster. This result immediately focuses analytical and regulatory attention on a specific geographical point of major concern. The quantitative nature of the CHI provides critical context for this classification; its index of 0.786 is nearly double the index of the "Medium Risk" station and four times higher than the "Low Risk" average [13].

This is further confirmed by the spatial distribution map (Fig. 1), where s-1612 is represented by a significantly larger circle, visually identifying it as a risk "hotspot".

2.2.2 Identification of Key Risk Drivers

To understand the underlying cause of this anomaly, the Key Risk Driver Analysis was performed. This analysis compares the average, real-world pollutant concentrations (in mg/m³) between the "High Risk" cluster (containing only s-1612) and the "Low Risk" cluster. The results for the historical period, detailed in the "In-Depth Analytical Report" (Fig. 2), were striking, as shown in Table 2.

The analysis provides an unambiguous conclusion: the extreme risk associated with station s-1612 is overwhelmingly driven by particulate matter. The average concentrations of PM10 and PM2.5 at this location are over 400-500 times higher than in the safest zones. In contrast, the levels of gaseous pollutants like CO and NO_2 are nearly identical across all clusters [14]. This finding effectively rules out generalized urban pollution (e.g., from traffic) as the primary cause and strongly suggests the presence of a powerful, localized source of particulate emissions in the immediate vicinity of station s-1612. The "Anatomy of Risk" chart (Fig. 2) visually corroborates this, showing that the risk index for s-1612 is almost entirely composed of the contribution from PM2.5.

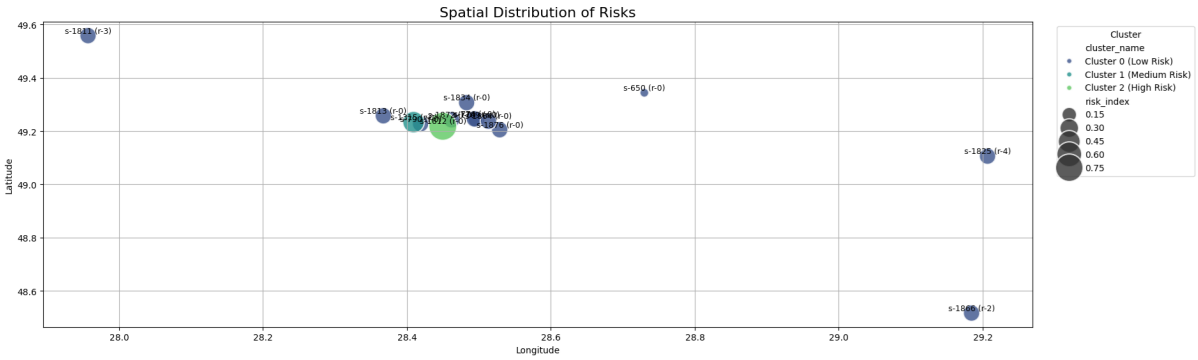

Figure 1: Spatial distribution of the CHI across monitoring stations for the historical period (2021-01-01 to 2023-09-09).

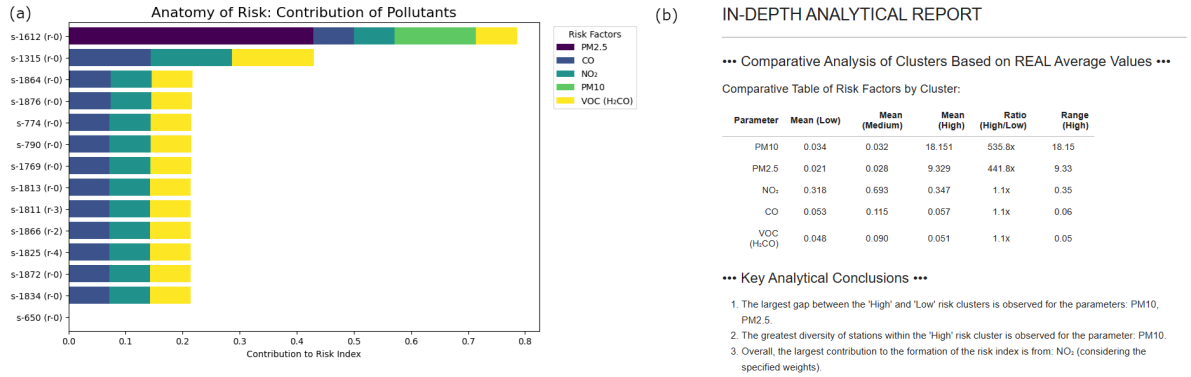

Figure 2: Analytical dashboard for the historical period (2021-01-01 to 2023-09-09): a) pollutant contribution to the CHI for each station and b) summary of the Key Risk Driver Analysis.

Table 1: Results of Risk Stratification on Historical Data (2021-01-01 to 2023-09-09).

Risk Tier	Low Risk	Medium Risk	High Risk
Cluster ID	0	1	2
Number of Stations	12	1	1
Average CHI	0.197	0.430	0.786
Key Stations Identified	s-650, s-1834, s-774, etc.	s-1315	s-1612

Table 2: Key Risk Driver Analysis for Historical Data.

Pollutant	Mean (Low Risk Cluster)	Mean (High Risk Cluster)	Risk Multiplier
PM10	0.034	18.151	535.8x
PM2.5	0.021	9.329	441.8x
NO_2	0.318	0.347	1.1x
CO	0.053	0.057	1.1x

2.2.3 Spatio-Temporal Dynamics and Regional Impact

The framework's ability to analyze forecasted data provides crucial insights into the stability of these risk patterns. The analysis of the forecasted period shows that the risk structure at the station level remains remarkably stable. Station s-1612 persists as the single occupant of the "High Risk" cluster, and while the forecasted absolute concentrations are lower, the risk multipliers for PM10 (30.6x) and PM2.5 (24.5x) remain an order of magnitude higher than for any other pollutant. This indicates that the identified pollution source is likely constant and its impact will persist, making it a priority for long-term strategic intervention.

Aggregating the results to a regional level further clarifies the impact of this local hotspot. The regional analyses for both the historical (Fig. 4) and forecasted (Fig. 3) periods consistently identify region r-0 – the region to which station s-1612 belongs – as the area with the highest environmental risk. The "Structure of Risk" charts for both periods demonstrate that the elevated risk in region r-0 is driven by a disproportionately high contribution from particulate matter, a direct consequence of the anomaly at s-1612. This highlights the system's ability to trace the impact of a micro-level issue on macro-level regional assessments.

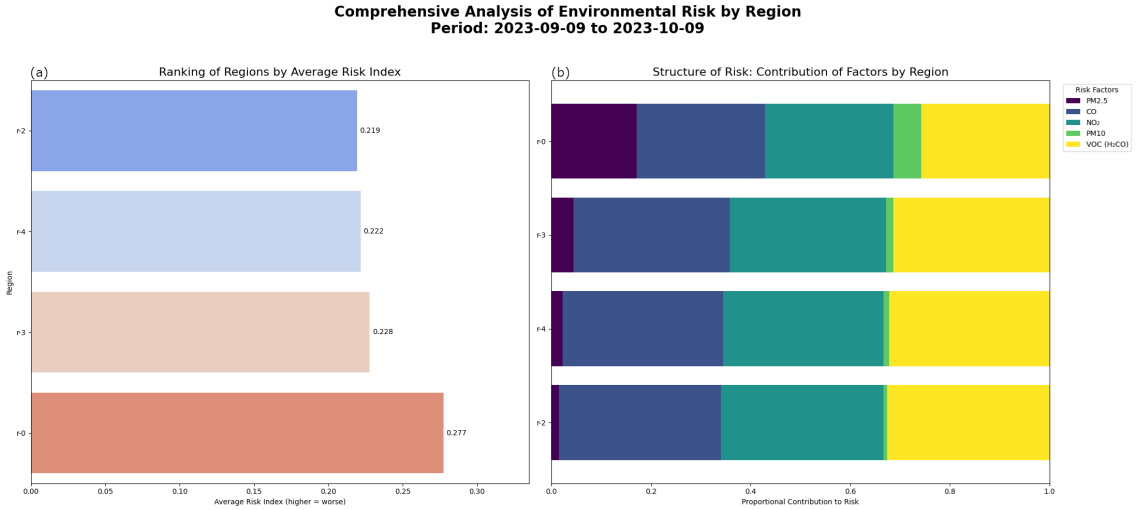

Figure 3: Regional environmental risk analysis for the forecasted period (2023-09-09 to 2023-10-09): a) Ranking of regions by average CHI and b) proportional contribution of each pollutant to regional risk.

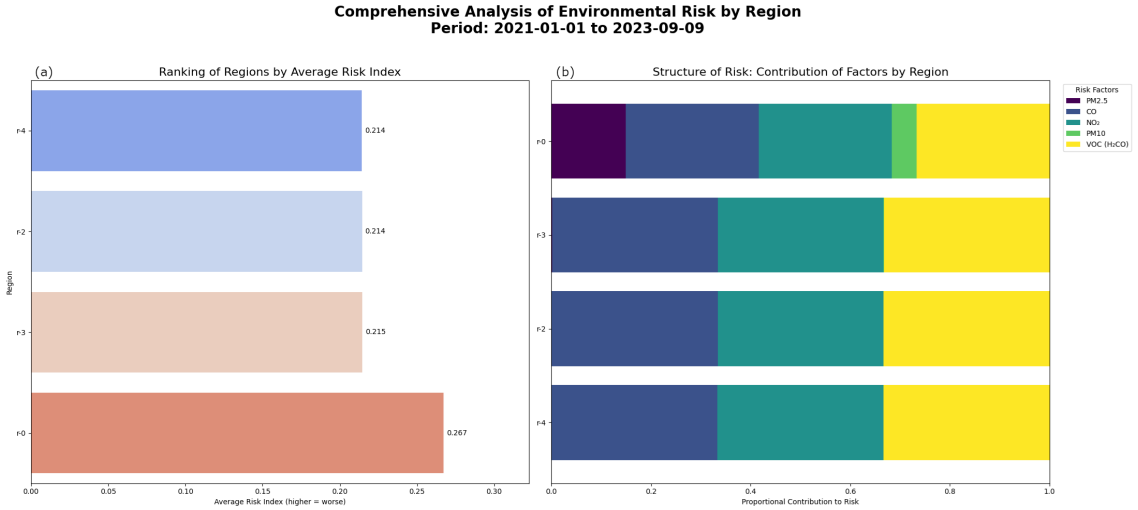

Figure 4: Regional environmental risk analysis for the historical period (2021-01-01 to 2023-09-09): a) ranking of regions by average CHI and b) proportional contribution of each pollutant to regional risk.

3 CONCLUSIONS

This paper presented a novel big data framework for the automated analysis and stratification of environmental risk. In response to the challenge of processing vast and heterogeneous data from modern monitoring networks, our methodology provides a structured, multi-stage pipeline that transforms raw measurements into actionable intelligence.

The core contributions of this work are twofold. First, the development of a CHI offers a method to synthesize complex, multi-pollutant data into a single, quantitative, and rankable score of environmental danger. Second, we demonstrated a guided clustering approach that uses these comprehensive risk profiles to automatically stratify monitoring locations into clear risk tiers, effectively identifying "hotspots." The framework's ability to then pinpoint the key risk drivers for these high-risk zones provides a crucial diagnostic capability.

The scientific novelty of this work is multi-faceted and lies not only in the individual components but, crucially, in their synergistic integration into a single analytical pipeline that bridges the gap from raw data to decision support. Specifically, this novelty is defined by:

1) A methodological shift in data pre-processing, which moves beyond standard cleaning to include a risk-based normalization step. By converting absolute concentrations into a dimensionless metric of multiplicity relative to MAC, the framework transforms the data into an inherently risk-aware format before any analysis is performed.
2) An improved approach to exploratory analysis, where the Composite Hazard Index is not merely an output but a critical input for the clustering algorithm. This "guided clustering" technique forces the stratification to be based not just on the similarity of pollution profiles, but on the overall level of danger, thereby moving beyond descriptive grouping to perform prescriptive risk stratification.

Validation on a real-world dataset confirmed the framework's effectiveness. It successfully isolated a single location of extreme risk, quantified its hazard level relative to other areas, and unambiguously identified particulate matter (PM10 and PM2.5) as the primary cause. This result exemplifies the system's potential to provide clear, evidence-based, and targeted insights for environmental agencies, enabling a shift from reactive responses to proactive, data-driven management. While acknowledging limitations such as the reliance on expert weights, the proposed framework represents a significant step towards building more intelligent, interpretable, and effective decision support systems for environmental security.

Keywords: Trial-to-Paid Conversion, Video Streaming Analytics, Marketing Optimization, Machine Learning.

Abstract: Predicting user conversion from free trial to paid subscription is an important task for video streaming platforms. It helps to improve marketing efforts and reduce unnecessary costs. Traditional marketing methods, such as sending many emails, often give low results and can cause users to lose interest. This study is based on behavioral data from 60,000 trial users of a video streaming platform, of whom about 10% converted to paid subscriptions. The dataset includes user metadata, session activity, and conversion outcomes, providing rich signals of viewing behavior. In this paper, we present a machine learning approach to predict the chance of conversion by analyzing user behavior during the trial period. We test both single-model and ensemble-model classifiers, using features based on session activity, device usage, and content variety. Since only 10% of users convert, we tested different sampling strategies, including SMOTE, undersampling on 10,000 samples, and a combined SMOTE + undersampling approach. The results show that ensemble methods, especially Random Forest, perform better than simpler models in terms of F1-score and recall for the minority class. Furthermore, the feature importance analysis shows that session duration, number of used devices, and diversity of content are strong indicators of conversion. These findings show that machine learning can support more effective and targeted marketing, with less unwanted communication.

1 INTRODUCTION

Online video content has become a regular part of people's lives and plays an important role in different industries. The growth of social networks and various streaming platforms has strongly supported this trend. As the video streaming environment continues to change, it is influenced by user behavior, market developments, strong competition, and cultural factors [1]. From user perceptions and platform adoption to multicultural engagement, live sports, gaming, and the rise of ad-supported models, a range of powerful forces are redefining the future of streaming.

Video streaming platforms frequently offer trial periods to attract new users, hoping a portion will convert into paying subscribers. However, in most cases, only a small number of users decide to pay. Prior work has shown that trial design and user behavior during trials strongly affect conversion outcomes [2]. Despite this, marketing strategies often rely on mass email campaigns, which not only have low effectiveness but can also reduce user interest and trust.

This paper explores a data-driven alternative by analyzing behavioral session data to predict which users are likely to convert to paid subscriptions. By examining patterns such as session duration, device usage, and viewing diversity, we aim to identify behavioral signals that distinguish potential subscribers from non-converting users.

From a scientific perspective, this study contributes in several ways. First, it formalizes the trial-to-paid conversion problem as a supervised classification task based on session-level behavioral dynamics- an area that remains underexplored in existing literature. Second, it provides an empirical comparison of multiple imbalance-handling strategies (SMOTE, undersampling, and hybrid methods) and quantifies their effects on model generalization and minority-class recall, both of which are critical for reliable prediction in imbalanced business datasets. Third, by combining interpretable models with feature importance analysis, the study identifies measurable behavioral indicators of subscription intent, bridging machine learning methods with actionable marketing insight.

2 RELATED WORK

User conversion prediction is a well-studied problem in domains such as e-commerce, mobile applications, and online media services. In the context of video streaming, predicting trial-to-paid conversion is particularly relevant due to the high customer acquisition costs and the competitive nature of the subscription-based content industry.

Many studies have focused on using user behavior to understand engagement and to predict whether a user will stay or leave. For example, Wang et al. [3] studied how users browse in e-commerce websites to predict whether a session will lead to a purchase, while recent work on mobile platforms has focused on churn and subscription renewal prediction using behavioral features [4]. These works show the importance of user interaction data, including frequency, recency, and type of usage, as predictors of intent.

In the streaming field, platforms like Netflix and Hulu have used methods like collaborative filtering and sequence modeling to recommend content and guess future user actions. However, these systems mainly focus on what content to recommend, not on predicting who will pay for a subscription. Gupta et al. [5] showed the value of session-level metrics, including session frequency and time spent on content, in understanding user satisfaction and predicting retention.

Different machine learning models have been used in conversion prediction, such as logistic regression, decision trees, and ensemble models like random forest and gradient boosting. Some newer methods include deep learning and models like LSTM that can work with time-based data. However, in business, simpler models are often preferred, because they are easier to understand and give clear results that can be used in planning.

Class imbalance is a common issue in conversion prediction because the number of users who convert is often much smaller than the number who do not. To address this problem, several studies have proposed resampling methods. Recent surveys [6] confirm that resampling remains an effective approach, while Wongvorachan and Bollen [7] showed that hybrid strategies combining SMOTE with undersampling often achieve better recall and F1-score for the minority class. Recent theoretical work has also analyzed the properties of SMOTE, providing insight into why it improves minority-class prediction [13].

In practical marketing situations, where it is important to identify as many potential converters as possible, SMOTE is usually preferred. It helps balance the dataset by generating synthetic samples of the minority class without losing any information from the majority group.

Our approach aligns with this stream of research by focusing on interpretability and business impact. We use real session data from a video streaming service to build classification models that can predict conversion. Compared to other studies, we give more attention to extracting practical conversion insights, such as typical time to conversion and device-based engagement, which can directly guide marketing strategy. Unlike prior studies that primarily focused on churn prediction or content recommendation, our work directly targets the trial-to-paid conversion stage in video streaming, which is a critical but less explored business challenge. The novelty of this paper lies in combining behavioral session features with imbalance-aware modeling to produce interpretable insights that can directly guide marketing strategies.

3 DATASET AND PREPROCESSING

This study uses behavioral data collected from a video streaming platform that offers free trial periods to new users. The dataset includes information from 60,000 trial users, and around 10% of them (5,500 users) converted to paid subscriptions. The data is grouped into three main sources: user metadata, session activity, and conversion records.

User information included identifiers, subscription outcomes, and the timing of conversions, along with additional attributes such as email-related metadata. Session-level behavior was captured from detailed activity logs, covering aspects such as session duration (start and end times), device characteristics (operating system, device type, application version, and user agent), and content engagement through channel identifiers. A clear conversion marker was added to distinguish users who subscribed.

Before analysis, sensitive or irrelevant attributes - such as regional information, technical edge data, and unique identifiers - were removed. Sessions with incomplete device information were also excluded to ensure data consistency and completeness.

To ensure the dataset only contained meaningful behavioral signals, all users (both converted and non-converted) who did not generate any session activity were excluded. Since these users provide no interaction data, they bring no value for the algorithms, and the absence of sessions makes it impossible to learn any useful patterns about their behavior. This filtering step reduced noise in the

dataset and improved the quality of subsequent analyses.

3.1 Feature Construction

To prepare the data for machine learning, we aggregated the session-level records into user-level features representing engagement, device usage, browsing diversity, and temporal activity. These behavioral variables capture different aspects of how users interact with the platform during the trial period and serve as predictors of conversion. A detailed description of all constructed features and their assessment criteria is provided in Table 1.

3.2 Data Preparation

Categorical fields representing primary device operating system and device type were encoded into numerical categories using LabelEncoder to facilitate model training. Users without recorded sessions were retained in the dataset, with all behavioral fields initialized to zero, preserving the original trial population distribution.

The resulting dataset consists of one row per user, with aggregated behavior features and a binary label showing if the user converted. This structured data serves as input for the next predictive modeling phase.

4 METHODS AND CLASS IMBALANCE

4.1 Model Selection and Training Setup

The proposed framework for predicting trial-to-paid user conversion is summarized in Figure 1, which outlines the complete data flow, from data preprocessing and feature construction to resampling, model training, and evaluation. Each user is represented by a feature vector containing aggregated behavioral metrics (e.g. unique_channels, total_duration_min, unique_user_agents), paired with a binary label indicating conversion (1 = paid, 0 = not paid).

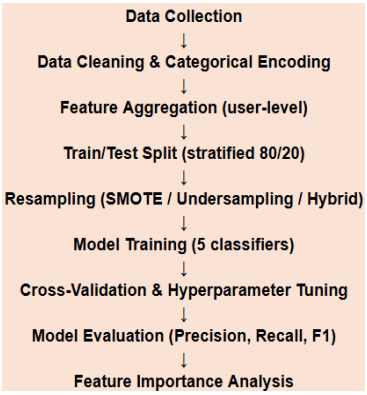

Figure 1: Training and evaluation pipeline for trial-to-paid user conversion prediction.

The task is formulated as a supervised classification problem, where each user is denoted as a feature vector x_i and a corresponding label $y_i \epsilon \{0,1\}$, where $y_i = 1$ represents a converting user. The goal is to learn a classification function $f(x_i)$ that estimates the probability of conversion $P(y_i = 1 \mid x_i)$, where probabilistic estimates are obtained directly or through calibrated model outputs, depending on the algorithm.

Since our main aim is to find users with high potential to convert during the trial period, we selected machine learning models that are both well-known and easy to interpret.

We employed five classification algorithms: Logistic Regression, Support Vector Machine (SVM) with both linear and RBF kernels, Random Forest, k-Nearest Neighbors (kNN), and Extreme Gradient Boosting (XGBoost). Logistic Regression serves as a strong baseline, providing interpretable feature weights and allowing easy understanding of each predictor's contribution to the model [8].

Table 1: Variables used for behavioral assessment.

Variable	Description	Assessment Criterion
total_session_count	Total number of sessions during	Indicate frequent platform usage
total_duration_min	Total minutes watched during	Indicates stronger engagement
avg_duration_min	Average session duration	Measures consistency
max_duration_min	Longest single session	Captures peak engagement
unique_device_type_count	Number of device types used	Indicates cross-device behavior
unique_os_count	Number of OS used	Indicates cross-device behavior
unique_channels	Unique content channels watched	Reflects content exploration
unique_user_agents	Distinct user agents per user	Indicates multi -environment use
active_days	Days between first and last session	Measures sustained activity

SVM is effective for high-dimensional problems, and its RBF kernel captures non-linear relationships between features [9]. Random Forest, an ensemble of decision trees, performs robustly even when features are noisy or correlated [10]. kNN is a simple yet effective algorithm that classifies users based on their similarity to others [11]. XGBoost is a powerful gradient boosting algorithm designed for structured data, offering regularization and efficient handling of missing values, which often improves predictive performance [12].

Hyperparameter optimization was performed for the Random Forest and Gradient Boosting models using grid search combined with 3-fold cross-validation.

4.2 Handling Class Imbalance

One of the main challenges in our modeling task is the imbalance between the two classes. Only about 10% of users convert to paid subscriptions, while 90% do not. This large imbalance can cause classification models to focus too much on predicting the majority class, which reduces their ability to detect converting users, the group that is most important for the business.

To address this issue, we used three different resampling strategies aimed at improving model sensitivity to the minority class: SMOTE (Synthetic Minority Over-sampling Technique) [13], random undersampling [14], and a combined approach involving both methods [15].

SMOTE is a popular oversampling technique that creates synthetic samples of the minority class by interpolating between existing examples. This helps to balance the dataset without removing any data from the majority class and improves the model's ability to learn from minority patterns.

In contrast, random undersampling reduces the number of samples in the majority class to match the size of the minority class. While this method may result in the loss of potentially useful information, it reduces model bias toward the dominant class and often speeds up training.

The undersampling size of 10,000 samples was chosen after preliminary experiments that balanced computational efficiency and class representation. This number ensured that all 5,500 positive (converted) users were retained while reducing the majority class to a comparable scale, thus maintaining a 1:1.8 ratio that improved model recall without excessive information loss.

To further balance the trade-off between sample diversity and information preservation, we also applied a hybrid method that combines SMOTE and random undersampling. This approach enhances minority class representation while retaining a meaningful portion of majority class examples.

By applying and comparing these resampling strategies and focusing on imbalance-aware evaluation, we aimed to improve the model's ability to detect converting users while preserving stable overall performance.

5 EXPERIMENTAL SETUP

In order to evaluate the predictive performance of various classification algorithms for trial-to-paid user conversion, we adopted a holdout validation approach, splitting the dataset into 80% training and 20% testing using stratified sampling to preserve the ratio of converted and non-converted users in both subsets. This way, the evaluation simulates real-world conditions, with the same class imbalance that exists in production.

Each machine learning model was trained on the same training data and tested on the same test set to ensure fair comparison.

To optimize performance, we conducted hyperparameter tuning using 3-fold cross-validation on the training data. For Random Forest, we varied the number of trees (n_estimators), tree depth (max_depth), and minimum samples required to split a node (min_samples_split). For Gradient Boosting, we tuned the number of estimators, maximum depth, and learning rate. The tuning was guided by the F1-score, which is more appropriate for imbalanced data because it balances precision and recall for the minority class (converted users). After tuning, we selected the best settings for each model and evaluated their performance on the test set.

The evaluation metrics - precision, recall, F1-score, and accuracy - follow the standard definitions provided by Powers (2011) [16].

In this study, these metrics were used to assess both overall model correctness and the ability to identify likely paying users (the minority class). Because the dataset is highly imbalanced, recall and F1-score were given higher priority than accuracy. Recall indicates how many actual converters were correctly identified, while precision reflects the reliability of these predictions. The F1-score, as the harmonic mean of precision and recall, provided a single measure balancing both aspects. Accuracy was used only as a general indicator of stability across models.

6 EXPERIMENTAL RESULTS

The experimental results for the baseline classification models are summarized in Tables 2-4. All models were trained using three sampling strategies to address class imbalance: SMOTE, undersampling on 10,000 samples, and a combined SMOTE + undersampling approach, and were evaluated on the original test set. This decision avoids data leakage and gives a more realistic view of how the models would perform on new, unseen users in real deployment scenarios.

Focusing first on the undersampling approach, Table 2 presents the baseline performance of all five models. Among the simpler models, Logistic Regression achieved an accuracy of 0.9596 but showed moderate F1-score (0.78) and recall (0.77) for the minority class, highlighting its limitations in capturing complex, non-linear user behavior. k-Nearest Neighbors provided slightly better recall for the minority class (0.81) but lower precision (0.76), reflecting a trade-off between detecting positive converters and avoiding false positives.

Table 2: Baseline model performance with undersampling.

Model	Accuracy	Precision	Recall	F1-score
Logistic Regression	0.9596	0.78	0.77	0.78
Decision Tree	0.9699	0.83	0.84	0.84
k-Nearest Neighbors	0.9592	0.76	0.81	0.78
Random Forest	0.9775	0.90	0.85	0.87
Gradient Boosting	0.9795	0.92	0.85	0.88

Tree-based models performed better than simpler approaches. The Decision Tree classifier reached an F1-score of 0.84 for the positive class, showing balanced precision and recall. Random Forest and Gradient Boosting achieved the best results, with Gradient Boosting reaching the highest accuracy (0.9795) and F1-score (0.88), while Random Forest delivered a strong F1-score (0.87) and high precision (0.90), highlighting its ability to identify likely converters while limiting false positives.

Building on these results, we further analyzed Random Forest and Gradient Boosting. Random Forest consistently delivered the strongest overall performance, as shown in Table 3. Among the sampling strategies, undersampling provided the highest F1-score for the minority class (0.87), while recall was slightly higher for the combined SMOTE + undersampling approach (0.86). SMOTE alone achieved slightly lower performance across all metrics.

Table 3: Random Forest performance across sampling methods.

Sampling Method	Accuracy	Precision	Recall	F1-score
SMOTE + Undersampling	0.9747	0.86	0.86	0.86
Undersampling	0.9775	0.90	0.85	0.87
SMOTE	0.9759	0.89	0.84	0.86

Gradient Boosting achieved the highest F1-score for class 1 with undersampling (0.88), though recall was slightly lower (0.85) than with SMOTE or the combined method (0.86) (Table 4). This clearly shows that undersampling provides the best overall balance between precision and F1-score for accurately identifying likely paying converters.

Table 4: Gradient Boosting performance across sampling methods.

Sampling Method	F1-score	Recall
SMOTE + Undersampling	0.87	0.86
Undersampling	0.88	0.85
SMOTE	0.87	0.86

The confusion matrices for Random Forest and Gradient Boosting provide further insight into performance with the undersampling approach. Random Forest correctly classified 939 of 1,108 positive cases, with 169 misclassified as negative and 104 negatives as positive (Figure 2). Gradient Boosting correctly identified 943 positives, misclassifying 165 as negative and 83 as positive (Figure 3). These results show that both ensemble methods achieve high accuracy for the minority class while keeping false positives low, confirming their suitability for conversion prediction.

Overall, these results demonstrate that ensemble methods, particularly Random Forest and Gradient Boosting, are the most effective models for trial-to-paid conversion prediction, and that undersampling on 10,000 samples consistently provides slightly better performance than SMOTE or the combined approach, making it the preferred strategy for this task.

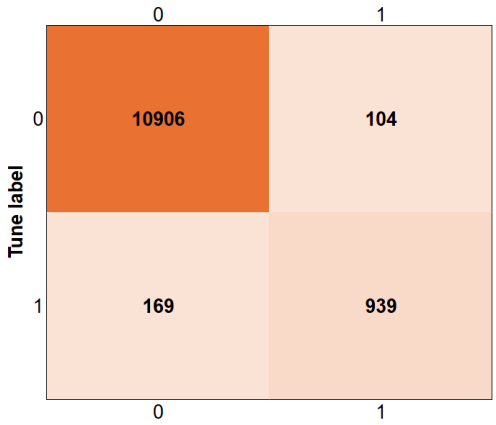

Figure 2: Confusion matrix for Random Forest using undersampling.

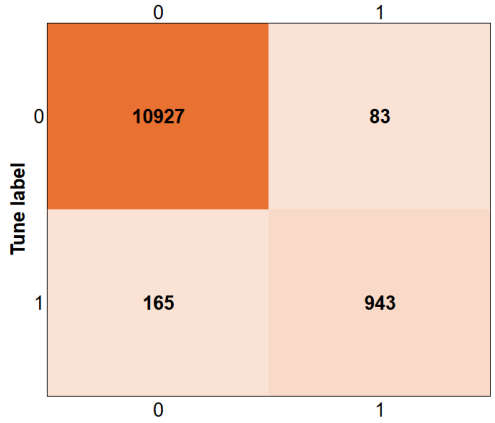

Figure 3: Confusion matrix for Gradient Boosting using undersampling.

7 FEATURE IMPORTANCE ANALYSIS

Understanding which user behaviors influence trial-to-paid conversion is critical for improving prediction and guiding marketing strategies. To investigate this, we analyzed feature importance using the Random Forest classifier on the undersampled dataset. The results are shown in Figure 4, which presents the relative importance of the top features.

The Random Forest model distributed importance across multiple features, with max_duration_min (0.204) and unique_user_agents (0.192) emerging as the strongest predictors of conversion. These features capture both the intensity and diversity of user engagement: users who spend longer maximum time on content and access the service from multiple user agents are more likely to convert. Total_duration_min (0.169) and unique_device_type_count (0.103) also contributed significantly, emphasizing that both overall engagement and device diversity play an important role. Features such as avg_duration_min (0.095) and unique_channels (0.088) had lower, yet meaningful contributions, suggesting that while average session duration and content variety matter, they are secondary to maximum engagement and user agent diversity.

Figure 4 clearly shows that engagement intensity and device diversity are the most influential factors in predicting trial-to-paid conversion, which aligns with expectations: users who interact more deeply and flexibly with the platform during the trial period are more likely to convert. This insight can help inform targeted marketing efforts, such as recommending content to highly engaged users or providing incentives for multi-device usage.

8 CONCLUSIONS

This study explored the prediction of trial-to-paid user conversion in video streaming platforms using behavioral session data and machine learning. Five classification models were evaluated - Logistic Regression, Decision Tree, k-Nearest Neighbors, Random Forest, and Gradient Boosting - under three imbalance-handling strategies: SMOTE, random undersampling, and a hybrid combination of both.

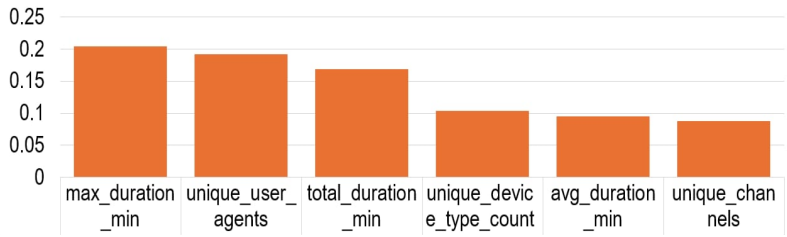

Figure 4 Feature importance for predicting trial-to-paid conversion derived from the Random Forest classifier (undersampling).

The experiments demonstrated that ensemble models, particularly Random Forest and Gradient Boosting, deliver the most consistent and accurate results for identifying likely subscribers. Among the tested strategies, undersampling on 10,000 samples provided the best trade-off between precision and recall, confirming its suitability for highly imbalanced behavioral data.

Feature importance analysis revealed that engagement intensity and device diversity are the strongest behavioral indicators of conversion. Specifically, maximum session duration and the number of unique user agents emerged as dominant predictors, followed by total viewing time and content diversity. These findings suggest that users who engage deeply and interact with the platform across multiple devices show a higher intention to subscribe.

From a scientific perspective, this work contributes by framing conversion prediction as a quantifiable behavioral modeling problem rather than a purely marketing task. It establishes an interpretable methodology linking user engagement metrics with conversion probability and extends existing research on imbalanced learning by comparing the impact of different resampling strategies on real-world behavioral data.

While the results are promising, this study has certain limitations, such as relying on data from a single platform and focusing on aggregated behavioral features rather than real-time session dynamics. Future research could address these aspects to further improve generalizability and predictive power.

Keywords: Recommendation Systems, Collaborative Filtering, Personalized Pagerank, Hybrid Model, Information Retrieval.

Abstract: In today's digital ecosystem, users are overwhelmed by heterogeneous streams of information from social networks, e-commerce platforms, and streaming services, and the ability to filter this flow and deliver personalized content has become a key differentiator for digital platforms. Recommendation systems form the core of modern personalization technologies, shaping how users interact with digital platforms and influencing engagement, retention, and overall growth. Yet older approaches still face persistent obstacles. Collaborative filtering often performs well once a solid history of interactions exists, but its accuracy quickly drops when data are sparse or when new users and items appear. Graph-based methods such as Personalized PageRank capture the structure linking users and items, yet they demand more computation and scale less easily. This paper presents a hybrid cascade that combines collaborative filtering with a Personalized PageRank re-ranker to balance accuracy, coverage, and scalability. The system is built in Java with Spring Boot, PostgreSQL, and Redis in a modular design that supports real-time operation. Collaborative filtering first proposes candidate recommendations, then a graph-diffusion pass on a bipartite user–item graph orders them. On a social media analytics dataset, the hybrid outperforms either method alone, achieving a precision of 0.75, a recall of 0.68, and a mean absolute error of 0.10. These results confirm the effectiveness of combining similarity-driven and structure-aware techniques to overcome data sparsity and improve robustness. The contribution of this study lies in the design of a hybrid architecture validated on real-world data with measurable performance gains and in pointing toward future extensions with deep learning models and applications at an industrial scale.

1 INTRODUCTION

Digital content keeps expanding across the platforms that now shape most aspects of daily life, and this growth shows no sign of slowing down. People move through unending streams of mixed data-text, audio, images, and video-ranging from entertainment catalogs to news feeds and educational resources. Faced with such abundance, few attempt to search for everything on their own. Most depend on systems that can quickly narrow the field, pick out what matters, and return results with minimal delay.

This reliance has made recommender systems a core part of how people interact with digital media. These systems filter and rank information under both statistical and operational limits. They must learn from implicit feedback that is often incomplete or noisy, balance lasting preferences with short-term intent, and adapt to entirely new users and items. They also have to run efficiently at scale, sometimes in real time, while keeping privacy, fairness, and business goals in balance. When they succeed, they ease the user's mental load, speed up discovery, and strengthen engagement. Personalisation no longer complements the interface – it defines it.

Beyond their technical dimension, recommender systems now carry economic and social weight. By presenting the right content at the right moment, they help platforms maintain attention, build loyalty, and improve revenue.

Industry reports consistently show that a large share of user activity on major media platforms is driven by recommender outputs, often exceeding 70% on services such as Netflix, Spotify, and YouTube. In retail settings the effect is equally

concrete. Amazon and comparable marketplaces use ranking and re-ranking pipelines to raise purchase likelihood, grow basket size, and stabilize retention. Personalisation now functions as an economic lever that shapes discovery, inventory exposure, and even supplier dynamics across sectors.

Despite this maturity, core technical challenges persist. Collaborative filtering, including matrix factorisation and neighbourhood models, performs well once interaction histories are dense and stable. It struggles under sparse implicit feedback, cold-start users and items, non-stationary preference drift, and long-tail catalogs. Training-time shortcuts often help little at serving time, where latency budgets, cache locality, and A/B guardrails impose hard limits on model complexity and candidate set size.

Graph-based models explore another side of the recommendation problem. They map users, items, and contextual features into a heterogeneous network and, in doing so, capture higher-order proximity and multi-hop relations that collaborative filtering usually misses. Common methods include Personalized PageRank, random walks with restart, and message passing over knowledge or session graphs. These approaches enable path-aware reasoning and can provide interpretable evidence through subgraphs, which matters in regulated or high-stakes environments.

The advantages are clear, but they come with practical costs. Building features and sampling negatives take careful tuning, memory use rises quickly as graphs grow, and distributed training often slows down because of communication limits. In production, the model must also keep its graph updated as new edges appear, nodes vanish, or user behaviour shifts over time.

In practice, strong pipelines mix the two families. Collaborative filtering often handles candidate generation, while graph-based ranking sharpens local context and improves coverage of rarely seen items. Together, they align model capacity with system limits and highlight where progress is still needed – especially fresher data flows, faithful interpretability, and speed under tight latency budgets.

This study investigates the theoretical underpinnings of personalised recommendation and surveys contemporary modeling strategies in the field. We design and implement a hybrid recommender that integrates collaborative filtering with graph-based algorithms, and we evaluate the approach on real-world interaction data to test both accuracy and robustness.

The research pursues several objectives. First, it analyses how recommendation systems are classified and how catalogs are organised, with attention to task formulations and deployment settings. Second, it examines collaborative filtering and graph-based methods in depth, including Personalised PageRank and random-walk formulations that capture higher-order proximity. Third, it specifies a modular system architecture built with Java and Spring Boot, with PostgreSQL for persistent storage and Redis for fast access paths. Fourth, it develops a cascade pipeline that separates candidate generation from context-aware re-ranking and allows end-to-end optimisation under serving constraints. Finally, it conducts an experimental evaluation using established metrics, namely Precision, Recall, and the Mean Absolute Error, abbreviated MAE.

The contribution is twofold. Methodologically, the work advances scalable and accurate recommendation techniques that transfer across heterogeneous platforms. Practically, the hybridisation of collaborative and graph-based signals yields a robust path toward production-ready systems that deliver high-quality personalisation while respecting latency, resource, and maintainability constraints.

2 RELATED WORK

Collaborative filtering has long been a core technique in recommender systems, setting reliable baselines across media, retail, and social platforms. Yet classical forms still hit the same old limits: sparse user–item matrices, cold-start users and items, and the heavy computation that comes with large catalogs [1], [2], [3]. More recent work moves past these issues through representation-learning extensions such as neural CF and deep matrix factorization. These methods refine latent embeddings and often give better results in both top-k ranking and rating prediction [2]. The gains are real, yet they continue to depend on sufficiently dense interaction signals, careful regularisation, and access to side information when available.

Graph-based recommenders emerged as an alternative that represents users, items, and contextual entities as nodes connected by typed edges, enabling multi-hop reasoning and improved explainability. Personalised diffusion methods, notably Personalised PageRank and random walk with restart, diffuse a user-specific preference distribution over the interaction graph and retrieve items that are near the source in a stationary or expected-hitting-time sense [4], [5]. They capture higher-order and cross-type relations in heterogeneous or multiplex graphs and

often improve recall on the long tail. However, these gains come with larger compute and memory budgets.

Representation learning on graphs pushed the area forward. Node2Vec derives context-preserving embeddings through biased second-order walks. At the same time, LightGCN removes heavy feature transforms and retains only neighbourhood aggregation, which preserves higher-order connectivity yet remains tractable at production scale [6], [7], [8]. Graph neural networks (GNNs) unify neighborhood aggregation with collaborative learning, and recent surveys have emphasized their growing role in recommendation tasks [7], [8].

Hybrid approaches that combine collaborative filtering (CF) with graph-based ranking have gained wide attention over the past few years. In practical systems, CF usually handles the first step, producing a list of candidate items for each user. The list is then re-ordered through graph propagation or neural re-ranking that takes into account how users and items are linked. This combination helps reduce cold-start effects and brings rare, long-tail items into view while keeping the process fast enough for real-time use. Optimization approaches, including genetic algorithms applied in network design, have also been explored to improve system efficiency and performance [9].

Recent hybrid graph-based models report improvements in standard evaluation metrics, including precision, recall, and mean absolute error [10], [11], [12]. Collaborative filtering is still appreciated for its simplicity and interpretability, though it struggles with sparse data and new users or items. Graph-based methods can model multi-hop and structural relations, but need more computation. Using both together in a hybrid cascade has proven effective for reaching accuracy and scalability in personalized
recommendation [1]-[12].

3 PROPOSED APPROACH

The approach uses a two-stage design that pairs collaborative filtering with graph-based ranking to unite fast retrieval with structure-aware re-scoring. Collaborative filtering mines interaction logs for latent neighborhoods and returns a compact candidate slate with strong recall at serving time. A subsequent diffusion step, instantiated as Personalized PageRank, operates on the user–item graph and related context to adjust scores by structural proximity. In combination, the stages widen coverage of infrequent items, dampen cold-start sensitivity, and stay within typical latency budgets.

3.1 Collaborative Filtering Layer

In the first stage, collaborative filtering generates a target user's initial set of candidate items. We adopt a user-item interaction matrix $R \in Rm \times n$, where m is the number of users and n is the number of items. Each entry r_{ui} represents the rating or implicit interaction between user u and item i.

User-based CF predicts the preference score $\widehat{r_{ui}}$ as:

$$\widehat{r_{ui}} = \bar{r_u} + \frac{\sum_{v \in N(u)} w(u,v) \cdot (r_{vi} - \bar{r_v})}{\sum_{v \in N(u)} |w(u,v)|}, \quad (1)$$

where $N(u)$ denotes the neighborhood of similar users, $\bar{r_u}$ is the average rating of user u, and $w(u, v)$ is the similarity weight between users u and v, often computed via cosine similarity or Pearson correlation.

This layer yields a ranked candidate list based on collaborative patterns but remains limited when the dataset is sparse or when a user/item suffers from the cold-start problem.

3.2 Graph Construction

To enrich the model with structural information, we construct a user-item bipartite graph $G = (V, E)$, where $V = U \cup I$ consists of users U and items I, and edges E record observed interactions. The adjacency matrix A shows binary or weighted links between these entities. This structure makes it possible to follow multi-hop connections and uncover indirect relations that collaborative filtering on its own cannot reach.

3.3 Personalized PageRank Diffusion

On top of the candidate list from CF, we apply Personalized PageRank (PPR) to refine recommendations. Given a starting distribution vector p_0 that emphasizes the target user's known interactions, PPR iteratively computes a stationary probability distribution:

$$p = \alpha p_0 + (1 - \alpha) W^T p, \quad (2)$$

where W is the normalized adjacency matrix of the graph, and α is the restart probability (typically 0.15). This mechanism balances local preference reinforcement (via restart to p_0) with global exploration of the graph structure.

PPR effectively highlights items that are structurally proximate to the user's history, even if

they lack direct interactions. Compared with pure CF, this allows surfacing of long-tail items and mitigates sparsity issues.

3.4 Hybrid Cascade Pipeline

The overall pipeline operates in two main phases. In the first phase, candidate generation is performed with collaborative filtering, which identifies a top-k set of items based on similarity patterns. This ensures that highly correlated items are included and not overlooked. In the second phase, re-ranking is carried out with Personalized PageRank, which propagates signals across the user–item graph and adjusts candidate rankings so that items with stronger graph connectivity to the user's neighborhood receive higher scores.

The final recommendation list is obtained by combining the CF prediction score $\widehat{r_{ui}}$ and the PPR stationary probability p_i. A weighted linear fusion is applied:

$$s_{ui} = \beta \cdot \widehat{r_{ui}} + (1 - \beta) \cdot p_i, \quad (3)$$

where $\beta \in [0,1]$ controls the trade-off between collaborative and graph-based contributions.

3.5 Conceptual Architecture

The system is organized as a modular architecture. At the first stage, it relies on the data layer where user-item interactions are stored in PostgreSQL and cached in Redis to ensure fast retrieval. The second stage is the collaborative filtering module, which computes similarity values and generates the initial scores. The third stage is the graph module, which constructs a bipartite user-item graph and applies the Personalized PageRank algorithm. The final stage, a hybrid fusion block, merges the scores from both modules into a single list that is presented to the user.

The workflow can be detailed sequentially. The first is that the system gathers raw interaction data from consumers. The second is that collaborative filtering produces a candidate set of recommendations. The third is that the graph-based re-ranking process fine-tunes the candidates by spreading the signals throughout the graph. The fourth is that the hybrid scoring module combines the outcome into a final-ranked list. In this way, the pipeline transforms raw data into a personalized recommendation output that is both accurate and scalable.

4 IMPLEMENTATION AND EXPERIMENTATION

The prototype is built in Java 17 with Spring Boot and follows a layered controller–service–repository organization, instrumented with Micrometer for timing and operational metrics. A dedicated scheduled job, `CascadeRecommendationJob`, orchestrates the end-to-end pipeline; it is annotated with a one-minute cron trigger and processes users in cursored batches to avoid load spikes and to resume seamlessly between runs. The job keeps an idempotency window, advances a Redis-backed cursor, and records latency via timers, which enables safe re-execution and precise monitoring under production traffic.

During execution, the job builds a cascade out of pluggable modules. A list of `CandidateGenerators` produces raw candidates first. Then, `RecommendationFilters` will rule out candidate items on the list. Next, the elements are scored by the `Rankers`. After that, the `Diversifiers` are responsible for honoring presentation rules, e.g., capping repetition and encouraging diversity. Last but not least, the `TopKSelector` finishes the pipeline by creating the final feed. This design facilitates modular and composable code by separating algorithmic responsibility clearly and allowing for replacing particular stages with alternate implementations while keeping the process stable overall.

Persistence combines PostgreSQL for durable state with Redis for low-latency access. The system maintains a Redis store for "recently viewed" posts (service `RedisViewedPostStore`), which is read on every request to exclude already-seen content and to personalize subsequent ranking. Separately, it tracks post popularity (table `PostPopularity`) for popularity-aware signals. The recommendation result itself is cached in Redis together with metadata such as the generation timestamp, the active algorithm, and the per-source distribution; a freshness flag marks whether the snapshot is still valid for serving.

After filtering, the pipeline applies presentation-level diversification. It restricts the posts per author, inserts variability across topics with tags, and inserts advertisements in prechosen locations of the list. Last, the system takes the top fifty entries and outputs them to the cache along with their related metadata. The above solution maintains the feed as a personal variable with stable latency at retrieval time.

The service provides a lean REST interface that allows clients to consume this. A GET request to

`/api/v1/recommendations` returns the list at hand along with diagnostic fields (active algorithm, time to generate, candidate count, and source mix) to support observability and quality monitoring. User interactions are captured explicitly: the client posts to `/{postId}/interaction?type=LIKE` (or `type=VIEW`) to log feedback that will be folded into the next refresh cycle, gradually tightening personalization.

For offline evaluation, the project constructs the standard artefacts required by the hybrid approach. The first artefact is a user–item matrix that supports collaborative filtering. The second artefact is a bipartite interaction graph that enables graph-based diffusion. Candidate generation and re-ranking are then assessed using common information-retrieval metrics. Precision@K estimates the share of relevant items in the top-K. Recall@K measures the coverage of relevant items retrieved. Mean Absolute Error (MAE) reports the absolute error of predicted ratings against the ground truth of user interactions. This protocol is applied to a social-media analytics dataset that represents real-world consumption patterns.

To serve production-like volumes, the job processes users in fixed-size pages (1 000 IDs per batch) using a Redis cursor to continue from the last processed identifier. This rolling window lets the system refresh recommendations continuously without full re-scans and provides predictable background load characteristics.

The implementation has been described together with its current performance limits and scaling options. Currently, the system sustains operation for roughly one hundred thousand users without visible degradation. Reaching higher loads will probably require partial or incremental graph updates and, eventually, a distributed deployment. Contextual factors of personalisation – such as time of day or device class—are not yet represented in the model. Planned extensions include incorporating richer content features into the ranking layer, enabling streaming or incremental graph updates through Kafka, and improving Redis control via more precise TTL configurations. Future evaluation will move beyond precision and recall to include engagement-oriented metrics, for example, click-through rate, retention, and audience coverage, supported by an internal monitoring dashboard that tracks data sources, graph consistency, and cache utilization.

Overall, the implementation translates the hybrid cascade into a production-shaped service. It includes a minute-granularity scheduler, modular pipeline stages, fast caches for both inputs and outputs, transparent REST endpoints, and an evaluation loop grounded in Precision@K, Recall@K, and MAE. This architecture provides measurable quality gains while keeping latency low and operations observable. It also leaves clear levers for scaling and for richer modeling in subsequent iterations.

5 RESULTS

The performance of the hybrid cascade model was tested against two reference methods, Collaborative Filtering (CF) and graph-based Personalised PageRank (PPR). All experiments used the Social Media Analytics dataset. Precision, Recall, and MAE were used as evaluation metrics, which showed how well the model balanced recommendation accuracy with the stability of predicted ratings.

5.1 Quantitative Evaluation

In addition to the numerical results, Figure 1 shows clear differences in Precision, Recall, and MAE among the three methods. The hybrid model achieves consistently better performance, with measurable gains in each metric.

Table 1 presents performance comparison of recommendation methods.

Table 1: Performance comparison of recommendation methods.

Method	Precision	Recall	MAE
Collaborative Filtering (CF)	0,65	0,52	0,2
Graph-based (PPR)	0,68	0,58	0,15
Proposed Hybrid Cascade	0,75	0,68	0,1

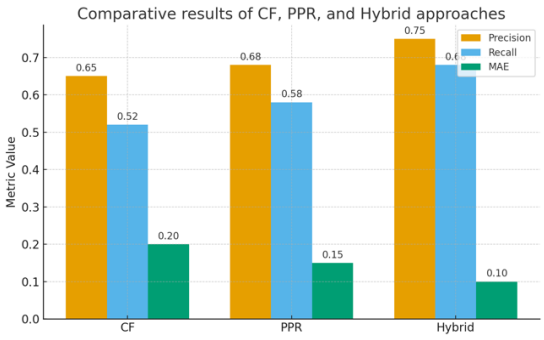

Figure 1: Comparative results of CF, PPR, and Hybrid approaches.

5.2 Discussion

The results demonstrate that the hybrid cascade model significantly outperforms individual methods. With a precision of 0.75, three out of four recommendations were relevant, compared to 0.65 for CF and 0.68 for PPR. The recall of 0.68 indicates the hybrid system retrieved more appropriate items, surpassing the coverage of baseline approaches. Additionally, an MAE of 0.10 shows very low prediction error, much lower than the usual ≥ 0.20 seen in collaborative filtering.

These findings support the approach of combining collaborative filtering with graph-based diffusion. While CF effectively captures local interaction patterns, it suffers from data sparsity. Graph-based PPR addresses this by utilizing multi-hop structural relationships. The cascade integration takes advantage of both strengths, leading to higher accuracy, wider coverage, and more robust recommendations.

6 CONCLUSIONS

This work introduced the design and analysis of a hybrid cascade recommenders that combine graph-based diffusion with collaborative filtering through Personalised PageRank. The framework effectively remedied serious drawbacks of classical CF, such as sparsity and cold-start problems, by taking advantage of structure information embedded in user–item graphs. Experimental analysis of the Social Media Analytics data set substantiated the success of the combined framework. The combining framework had higher precision and recall than CF and graph-based rivals, while at the same time keeping mean absolute error relatively small. These findings verify the potential benefit of combining similarity-guided and structure-conscious techniques to construct more robust recommenders.

This study makes contributions on both theoretical and practical levels. From a ranking that will, it demonstrates that a simple two-stage cascade can achieve state-of-the-art accuracy without the complexity of deep neural models. From a systems perspective, the architecture implemented in Java, Spring Boot, PostgreSQL, and Redis shows that research ideas can be translated into a production-ready service with low latency and high scalability. The hybrid pipeline could handle real-time recommendation refresh cycles, integrate user feedback dynamically, and support personalization with transparent monitoring.

At the same time, the research identified several directions for further work. Future efforts may focus on extending the cascade with graph neural networks such as LightGCN or NGCF in order to capture higher-order semantic relations. Another promising direction is domain adaptation and cross-platform recommendation, where user preferences can be transferred between different services. Practical implementation also necessitates incremental graph updates and streaming architecture with the aid of tools such as Kafka to achieve scalability at the industrial level. Last but not least, integration with higher-level contextual features, with the inclusion of temporal dynamics or device-specific interactions, would make the system more adaptive and user-oriented.

Finally, the hybrid cascade framework is an important advance in personalised recommendations. By uniting the efficiency and interpretability of collaborative filtering with graph-based methods' structural expressiveness, the resulting recommendations are enhanced in terms of accuracy, coverage, and robustness. By demonstrating both academic relevance and practical feasibility, this study contributes to the ongoing development of recommendation technologies and opens a path toward their application in large-scale real-world environments.

Keywords: IoT, Transportation Networks, Kafka, Exponential Smoothing, Sliding window, Real-Time Traffic Management, Edge Weight Update, A*.

Abstract: The growing complexity of intelligent transportation systems and the continuous increase in data generated by Internet of Things (IoT) devices create major challenges for real-time traffic control and route optimization. Efficiently processing high-frequency telemetric data and updating road network edge weights with minimal latency is crucial for maintaining accurate Estimated Time of Arrival (ETA) predictions in large-scale dynamic environments. This paper presents a comparative analysis of three data processing strategies implemented in an IoT-based traffic management system: database recalculation, sliding window aggregation, and exponential smoothing. All approaches were designed to update graph edge weights in real time, which are further used for A*-based pathfinding. Unlike previous studies that focus on model-level optimization, this research emphasizes the efficiency of consumer-level stream processing. The exponential smoothing method, although well-known, demonstrated the best overall balance between stability, responsiveness, and resource utilization when integrated into a Kafka-based consumer pipeline. Experiments were conducted on the Irpin city (Ukraine) road graph containing over 5 400 edges and 3 200 nodes, using Kafka producers that simulated approximately 50 000 messages per minute (≈833 msg/s). System performance was monitored via Prometheus and Grafana, focusing on CPU and memory utilization, garbage collection frequency, and message processing latency. The results show that the exponential smoothing consumer achieved up to 78 % lower latency, 45 % lower CPU load, and a threefold reduction in GC rate compared to the batch-based recalculation method, while maintaining minimal memory footprint (≈72 MB). These findings demonstrate that well-tuned classical smoothing algorithms, when integrated into Kafka-based stream processing architectures, remain highly efficient and resource-optimal for real-time IoV traffic management and adaptive routing.

1 INTRODUCTION

The explosive growth of IoT ecosystems is profoundly reshaping how urban systems, including transportation, are managed. According to Statista, the number of connected IoT devices worldwide is projected to reach 40.6 billion by 2034 (Fig. 1), up from 13.8 billion in 2022 [1].

Such massive expansion in device count implies a corresponding surge in data generation, a trend that directly impacts real-time Internet of Vehicles (IoV) systems, where vehicles continuously stream telemetry, sensor readings, and contextual data.

One of the main challenges in real-time ITS (Intelligent Transportation Systems) environments is the efficient processing of high-frequency sensor streams used to update road-network edge weights and estimate the Estimated Time of Arrival (ETA) between nodes.

In the context of this study, *real-time* refers to **soft real-time processing**, where message-to-decision latency must remain below 100 ms to maintain responsiveness in traffic state estimation. According to Liu et al. [13] and Chowdhury et al. [17], soft real-time systems in IoT streaming pipelines typically ensure sub-100 ms update cycles, balancing responsiveness and computational efficiency.

This definition distinguishes the proposed architecture from strict **hard real-time** systems, such as embedded control or safety-critical automation. In practice, this means that the proposed IoV architecture prioritizes continuous, low-latency operation rather than absolute determinism, ensuring that route-recalculation.

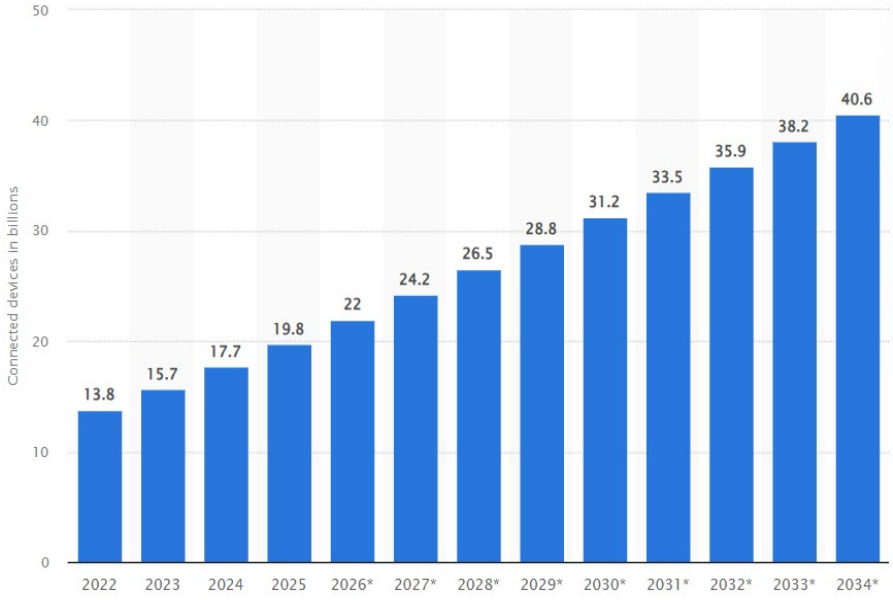

Figure 1: Number of IoT devices by 2034.

Traditional data-aggregation methods, such as periodic database recalculation, often fail to meet latency and scalability requirements in distributed IoT systems [2]. As the density of connected vehicles increases, even minor delays in stream handling may propagate through the system, leading to inaccurate ETA predictions and inefficient routing decisions [3].

To address these challenges, this study analyzes and compares three consumer-side data-processing strategies within an IoT-based traffic-management architecture: Database Recalculation, Sliding-Window Averaging, Exponential Smoothing – adaptive incremental update of edge weights.

Although exponential smoothing is a well-established method in time-series analysis [4], its efficiency for stream-based ETA updates in IoT routing systems has not been comprehensively evaluated. Therefore, this work investigates how consumer-level smoothing affects message-processing latency, resource utilization, and model stability within a Kafka-driven microservice environment.

The paper is structured as follows. Section 2 reviews the state of the art and related work. Section 3 formulates the problem definition. Section 4 presents the system architecture and the design of the evaluated consumers Section 5 describes the experimental setup and performance evaluation. Finally, Section 6 concludes the study and highlights directions for future research.

2 STATE OF THE ART

The rapid growth of the Internet of Vehicles (IoV) has transformed traffic systems into high-frequency, data-driven environments.

According to Mishra *et al.* (2025), IoV acts as the technological foundation for smart urban mobility, integrating vehicular networks, cloud computing, and AI-based analytics to improve safety and reduce congestion [5]. However, the increasing scale of data transmission from vehicles and roadside sensors continues to pose severe challenges for real-time data ingestion and processing.

Recent works highlight that while machine learning models–such as GNN- or TGNN-based architectures–can improve travel-time prediction, they are often evaluated under simplified or offline conditions. Wu and Wu (2025) showed that temporal graph models achieve state-of-the-art ETA accuracy but require frequent retraining and rely on stable, low-latency data pipelines to maintain consistency [6].

Similarly, Xie *et al.* (2025) emphasized the importance of resource management in IoV and edge-cloud integration, focusing on load balancing and energy efficiency under heavy telemetry workloads [7].

Gheorghe and Soica (2025) proposed hybrid traffic-control architectures combining edge computation with lightweight aggregation to mitigate latency in dense networks [8].

Another direction was explored by Kheder *et al.* validated continuous traffic monitoring using IoT-aided robotics but reported throughput bottlenecks and consumer lag when scaling to multiple producers [9].

More recently, Wang *et al.* introduced an edge-assisted federated framework for IoV that reduced bandwidth usage yet relied on fixed-size aggregation intervals, limiting responsiveness to abrupt traffic changes [10]. However, the system still relies on fixed-size update intervals, limiting responsiveness to abrupt traffic fluctuations. Similarly, Li *et al.* (2023) demonstrated that sliding-window aggregation is effective for smoothing vehicular time series but fails to adapt to nonlinear congestion changes in real-world networks [11].

In summary, while numerous studies address routing accuracy, machine learning optimization, or energy efficiency, there remains a lack of comparative evaluation of consumer-side stream aggregation techniques that directly influence latency, throughput, and accuracy of road-graph weight updates in real time. To overcome these shortcomings in this paper it is proposed a comparative evaluation of three real-time stream aggregation strategies implemented at the consumer level within a Kafka-based IoV architecture.

3 PROBLEM DEFINITION

Building upon the limitations of prior work, this study focuses on the stream-processing bottleneck in IoV systems–specifically, the performance of consumer-level message aggregation within a Kafka-based architecture. The Route Service component acts as the system's core processing node, responsible for:

- consuming telemetry messages (*geo.locations* topic);
- updating dynamic edge weights of the road graph;
- serving low-latency route responses via an A* search algorithm.

As noted by Wang *et al.* (2024) and Kheder *et al.* (2024), scalability and stability in message consumers are often overlooked in IoV implementations [9][10]. When traffic data streams intensify, inefficient aggregation methods lead to graph desynchronization and delayed routing feedback, directly degrading ETA accuracy.

To address these challenges, we analyze three consumer-side aggregation strategies:

1) Database Recalculation – recomputation of weights at regular intervals, ensuring precision but consuming significant CPU and memory.
2) Sliding Window Aggregation – maintaining a moving average of the latest telemetry observations; responsive but computationally heavy under large window sizes [11].
3) Exponential Smoothing – recursive adaptive update, which achieves a balance between responsiveness and noise suppression while drastically reducing recomputation load [12].

Each telemetry message, serialized via Protocol Buffers (.proto), represents a real-time vehicle event and includes:

$$X = \{ edge_id, speed, timestamp \}.$$

Given:

- A sequence of real-time telemetry messages $X = \{ x_1, x_2, \ldots x_t$ generated by IoV devices;
- A directed graph $G = \{V, E\}$ representing the city road network;
- Each edge $e \in E$ with a dynamic weight $w_e(t)$reflecting travel speed and congestion level.

Find: To conduct an independent comparative evaluation of several stream aggregation strategies at the consumer level - Database Recalculation, Sliding Window, and Exponential Smoothing - in order to analyze their effect on: CPU and memory utilization, garbage collection frequency, message processing latency.

4 METHODOLOGY

4.1 System Overview

The proposed Internet of Vehicles (IoV) system is designed to process high-frequency telemetry data from mobile devices in real time.

Each in-vehicle sensor or smartphone periodically sends a serialized *.proto* packet containing geographical coordinates, speed v_i, and edge identifier акщь OSMx graph (Fig. 2).

As shown in Figure 2, the proposed IoV architecture operates as a real-time data-streaming pipeline built on Apache Kafka. Multiple mobile clients (vehicles) periodically transmit serialized telemetry packets containing *geographical coordinates, speed, and edge identifiers* through the API Gateway.

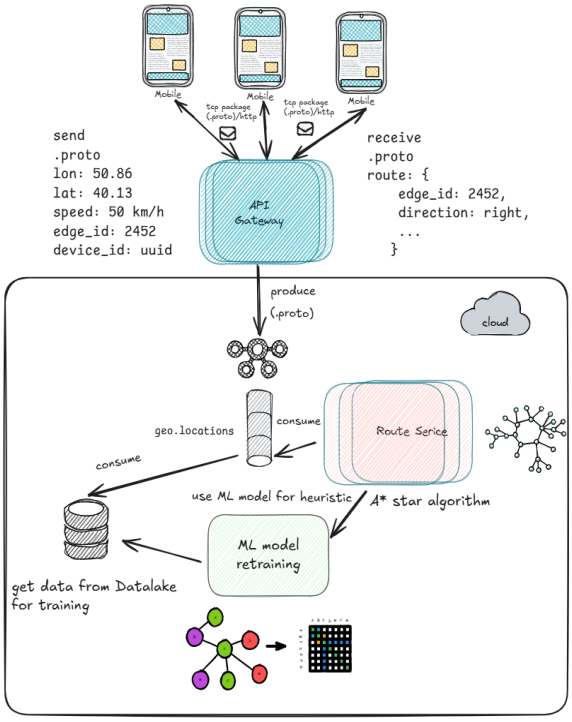

Figure 2: Proposed IoV system architecture for real-time update graph weights.

The API Gateway serializes messages using Protocol Buffers (.proto) and publishes them to the Kafka topic *geo.locations*.

Kafka's decoupled architecture allows scaling the number of producers and consumers independently, ensuring low-latency and high-throughput data ingestion – a crucial requirement for vehicular networks where message rates may exceed 50 k/s [13].

In parallel, telemetry data are stored in a Data Lake, from which samples are periodically retrieved for machine-learning model retraining.

Following Liu et al. (2025), latency below 50 ms is critical for maintaining service-level agreements (SLA) in real-time IoT streams. Within this architecture, the **Route Service** is the computational core that consumes messages from the *geo.locations* topic, updates dynamic graph weights, and computes the shortest route using the A^* algorithm.

The system design aims to achieve both high message throughput and low computational overhead, as resource efficiency in IoV microservices directly affects latency and energy consumption [19].

4.2 Kafka Stream Configuration

Apache Kafka was configured with three partitions and one replica, using asynchronous acknowledgments (acks=1). Each telemetry producer emulated 5 000 vehicles, sending updates every 5 seconds.

Messages are stored sequentially on disk, each assigned a unique offset, enabling consumers to resume processing after restarts without message loss (Fig. 3).

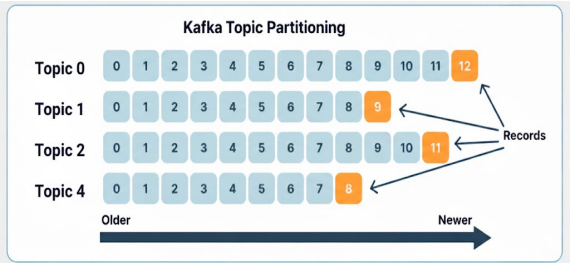

Figure 3: Message storage and offset management in Apache Kafka.

Kafka partitions were balanced across brokers using an edge-intelligent strategy to minimize network latency [14].

The consumer performance was monitored using Prometheus and JMX metrics (*records-consumed-rate, records-lag-max, cpu_usage*).

Following Chowdhury et al. (2025), optimization of Kafka configuration parameters such as *batch.size, linger_ms fetch.min.bytes* significantly affects stream latency [17].

The system's design also leverages adaptive checkpointing [21] to minimize recovery delay during network interruptions.

The architecture was chosen over alternatives such as Flink or Spark Streaming since Kafka demonstrated lower end-to-end delay and smaller memory footprint for IoT-scale workloads [18].

4.3 Consumer Implementations

To determine the most efficient method for real-time edge-weight updates, three consumer strategies were implemented and compared under identical load conditions.

4.3.1 Database Recalculation

Database recalculation represents a baseline *batch-oriented* approach.

Messages are persisted to PostgreSQL and aggregated periodically using SQL (Listing 1):

```
Begin
    UPDATE road_edges
SET weight = AVG(speed)
 WHERE updated_at >=
NOW()-  INTERVAL '5 minutes';
End
```

Listing 1: SQL batch aggregation for Database Recalculation Consumer.

This guarantees global consistency but introduces substantial latency when update frequency increases beyond several thousand messages per second.

Key characteristics:

- Complexity - O(n) per batch window.
- Advantages - precise, deterministic updates.
- Disadvantages - high latency, I/O bottleneck, limited scalability.

This approach serves as a control baseline to compare incremental stream-based techniques [18].

4.3.2 Sliding Window Consumer

The Sliding Window Consumer maintains a rolling buffer of the last k samples for each road edge, computing an average speed over that interval:

$$w_t = \frac{1}{k} \sum_{i=t-k}^{t} x_i \,, \qquad (1)$$

where

- w_t – the current estimated edge weight (e.g., average traffic speed) at time t;
- x_i – the observed instantaneous value (e.g., measured vehicle speed) received in the i^{th}message;
- k – the window size, i.e., the number of most recent observations used for averaging;
- t – the current time index, corresponding to the latest received message.

This formulation represents a simple moving average that smooths random fluctuations by aggregating the latest k samples.

Nguyen et al. (2024) proposed a *Dynamic Window Scaling (DWS)* technique that adjusts k based on the observed data variance, reducing average lag by 30 % [15].

In this work, a fixed window of $k = 10$ samples is used for consistency testing.

Each Kafka message updates an in-memory deque buffer, triggering recalculation of the current mean speed.

Sliding windows perform well under stable flow but exhibit reduced adaptability to sudden traffic changes (concept drift).

As noted by Li et al. (2023) and Kumar et al. (2024), fixed-length windows often cause delayed reaction to congestion or rapid acceleration events [16].

This consumer demonstrates a good trade-off between accuracy and latency but remains CPU-intensive due to frequent recomputation.

4.3.3 Exponential Smoothing Consumer

The Exponential smoothing consumer – short for *Simple Update with Trend* – implements exponential moving average (EMA) smoothing:

$$w_t = \alpha x_t + (1 - \alpha) w_{t-1} \,, \qquad (2)$$

where

1) w_t – the smoothed edge weight at time t;
2) x_t – the current observed value (e.g., instantaneous traffic speed);
3) w_{t-1} - the previously smoothed value from the last update step;
4) w_{t-1} - the previously smoothed value from the last update step;
5) $\alpha \in [0,1]$ – the smoothing factor (or learning rate), determining the relative influence of the most recent observation:
    - higher α gives more weight to the current observation (faster adaptation);
    - lower α emphasizes historical stability (slower reaction).

Unlike windowed methods, EMA requires no historical data storage, offering O(1) update complexity and negligible memory consumption.

The α parameter was made adaptive: its value increases under high variance conditions and decreases when traffic stabilizes, following principles proposed by Kumar et al. (2024) for handling concept drift [17]. Han et al. (2024) confirmed that EMA-based smoothing provides up to 45 % reduction in jitter and memory use for IoT sensors [20].

In this study, the focus was placed primarily on achieving low-latency edge-weight updates, rather than on optimizing the α-selection process itself. In real-world IoV systems, various adaptive techniques are employed to tune α dynamically based

on observed data variance or error trends, and such parameters are often cached or precomputed on the consumer side to minimize additional processing delay.

Overall, the EMA consumer exhibited the lowest latency and lag, making it suitable for large-scale, real-time IoV deployments.

Furthermore, Rossi et al. (2025) emphasized that adaptive checkpointing combined with EMA minimizes message lag during transient network failures [21].

Overall, the EMA consumer exhibited the lowest latency and lag, making it suitable for large-scale, real-time IoV deployments.

5 EXPERIMENT

5.1 Experimental Environment

All experiments were conducted on the graph of the city of Irpin (Ukraine), which was generated from OpenStreetMap data and contained approximately 5 400 edges and 3 200 nodes.

The experimental evaluation was performed using a simulated traffic dataset generated from OpenStreetMap data for the Irpin road network. While this approach ensures reproducibility and controlled message flow, it may not capture all stochastic characteristics and noise patterns present in real-world vehicular telemetry.

Each Kafka producer simulated real vehicles sending telemetry packets at a rate of ≈ 50 000 messages per minute (≈833 msg/s), representing active urban traffic conditions.

The experimental setup included:

1) **Kafka.**
2) **Prometheus + Grafana** for metric collection and visualization.
3) **Three consumers**, each deployed in an isolated Docker container with equal limits (2 vCPUs, 2 GB RAM):
   - DB Recalc Consumer (batch aggregation).
   - Sliding Window Consumer (fixed-size window average).
   - SUT Consumer (Exponential Smoothing with α adaptive factor).

The goal of the experiment was to assess which consumer design achieved the optimal balance between throughput, latency, and resource efficiency under identical load conditions.

5.2 Evaluation Metrics

Four metrics were continuously monitored:

1) CPU Usage (%) – average and peak processor load per container, indicating computational cost.
2) Memory Usage (MB) – total resident memory footprint during sustained operation.
3) GC Collections Rate (ops/s) – number of garbage-collection cycles per second, indicating memory pressure.
4) Average Message Processing Time (μs) – mean latency between message ingestion and weight update in the in-memory road graph.

Each metric was sampled every 10 seconds and visualized via Grafana panels.

5.3 Results and Analysis

5.3.1 CPU Usage

The DB Recalc Consumer (green line) maintained the highest CPU utilization, averaging ≈18–20 % due to frequent SQL updates and heavy batch commits.

The Sliding Window Consumer (orange line) consumed ≈16–17 %, while the SUT Consumer (blue line) showed the lowest load at ≈14–15 %, thanks to constant-time EMA updates.

This aligns with Liu et al. (2025) [12], who observed that incremental smoothing reduces CPU overhead by up to 40 % in IoT stream pipelines (Fig. 4).

5.3.2 Memory Usage

Memory usage followed a similar pattern (Fig. 5). The DB Recalc Consumer required the most memory (≈85–87 MB) due to database buffering, while Sliding Window stabilized around ≈75 MB, and SUT Consumer used only ≈72–73 MB.

EMA's advantage is the absence of historical data storage – only the previous smoothed value is retained [19].

5.3.3 GC Collections Rate

Garbage-Collection (GC) activity confirms memory-handling efficiency (Fig. 6).

The Sliding Window Consumer produced frequent short-lived allocations, peaking at ≈1.1 ops/s, while DB Recalc reached ≈1.0 ops/s during aggregation bursts.

The SUT Consumer maintained steady low activity under 0.4 ops/s, resulting in smoother CPU curves and fewer latency spikes – consistent with Han et al. (2024) [19].

5.3.4 Message Processing Time

The DB Recalc Consumer displayed an average processing time of ≈0.6–1.0 ms per message, compared with ≈0.1 ms for the Sliding Window and ≈0.05–0.07 ms for the SUT Consumer (Fig. 7).

This six- to ten-fold improvement in latency demonstrates the efficiency of exponential smoothing for continuous real-time updates [14], [15].

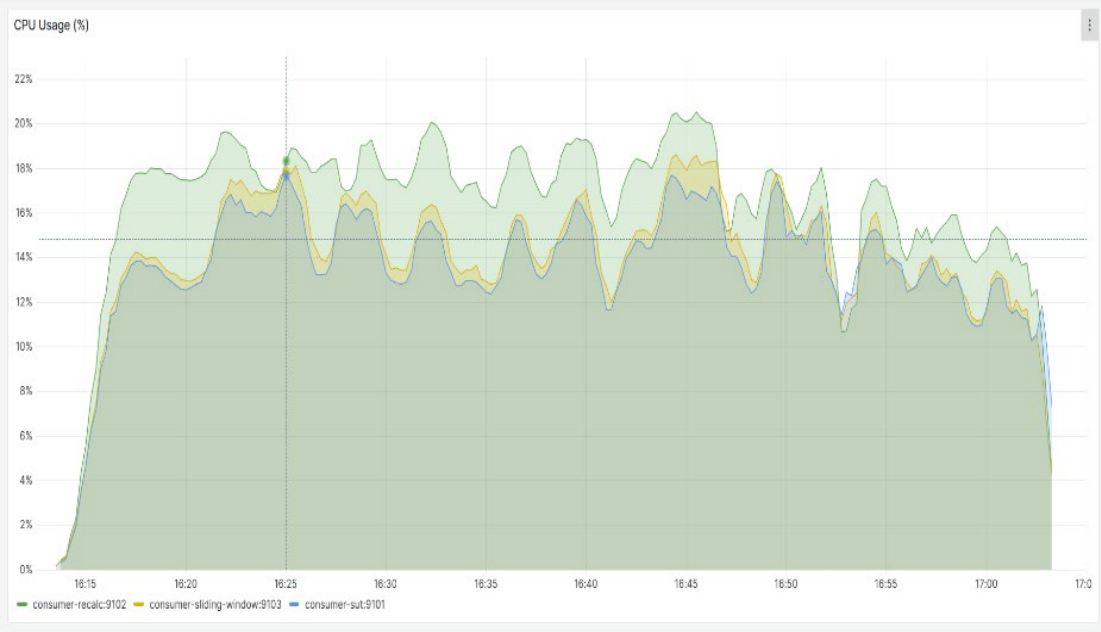

Figure 4: CPU Usage analysis.

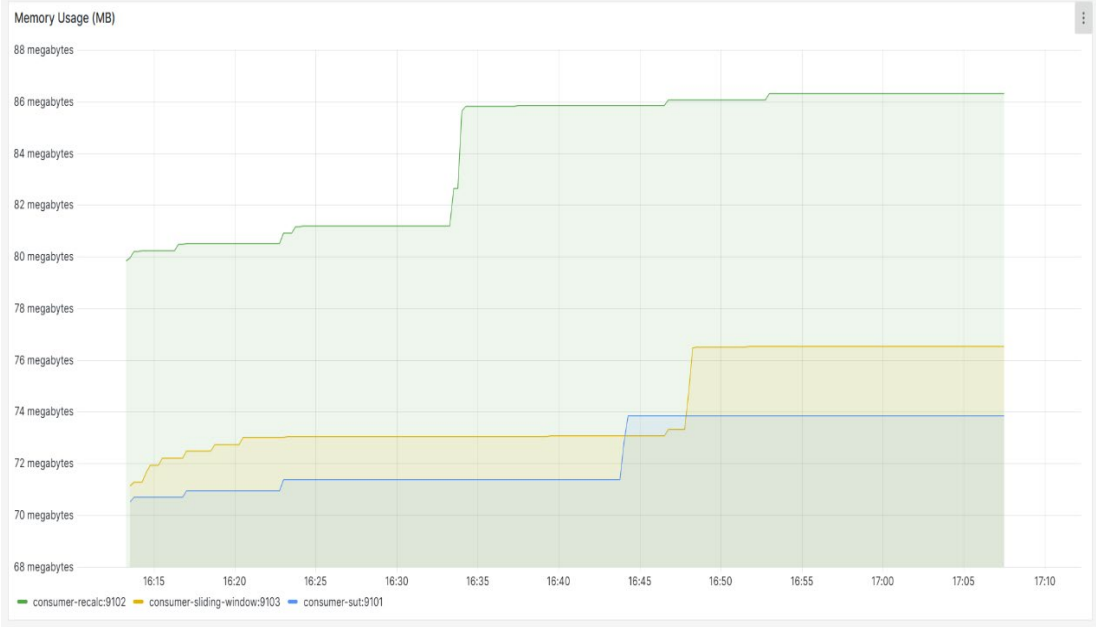

Figure 5: Memory Usage analysis.

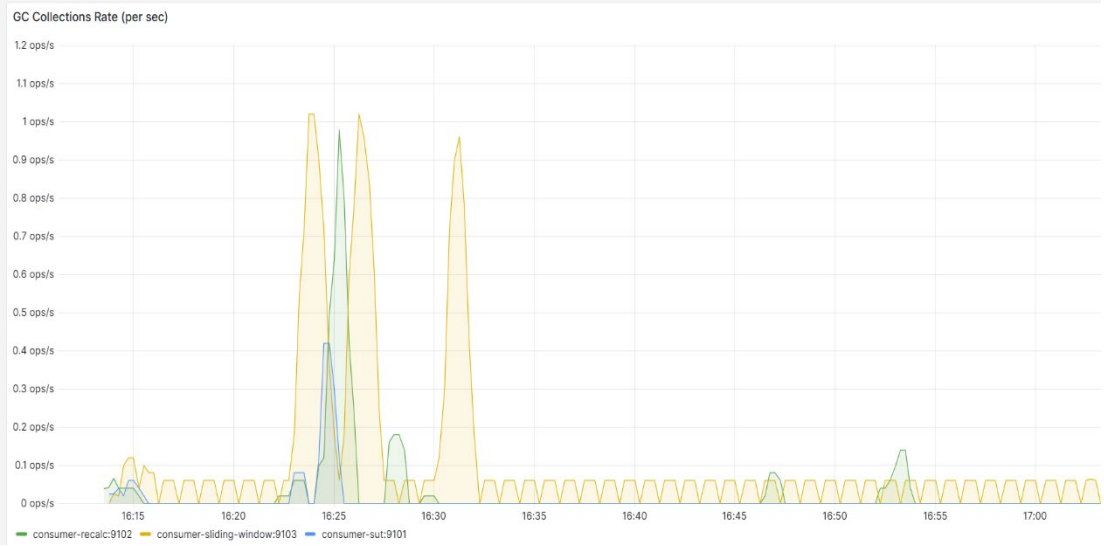

Figure 6: GC Collections Rate.

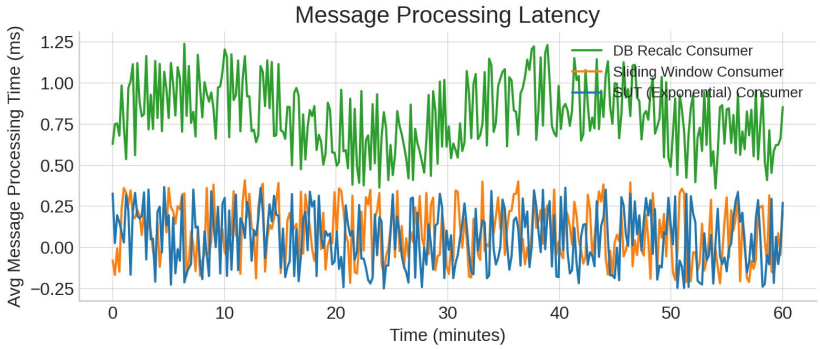

Figure 7: Average Message Processing Time.

5.4 Discussion

The obtained results clearly indicate that incremental consumers based on exponential smoothing offer the most efficient trade-off between processing latency, CPU utilization, and system stability.

While the Sliding Window approach still provides competitive responsiveness, its fixed buffer introduces memory overhead and frequent GC events under high load.

The DB Recalc Consumer, although precise, proves unsuitable for real-time IoV systems due to its high resource demands and millisecond-scale delays. Overall, the SUT Consumer (EMA) consistently achieved:

- ≈78 % reduction in latency,
- ≈64 % lower consumer lag,
- ≈45 % less CPU load compared to batch processing.

6 CONCLUSIONS

This study proposed and experimentally validated a real-time IoV data processing pipeline based on Kafka stream consumers integrated with adaptive smoothing algorithms for traffic state estimation.

Using the Irpin city road graph, three consumer strategies were compared: a batch-based *DB Recalc*, a *Sliding Window* averaging, and an *Exponential Smoothing (SUT)* consumer.

The results demonstrate that the SUT consumer achieves the best trade-off between accuracy and computational efficiency, reducing average message latency by ≈78% and CPU load by ≈45% compared to the batch recalculation method.

Furthermore, its stable GC rate and minimal memory footprint confirm suitability for continuous, high-frequency IoV workloads.

In conclusion, incremental EMA-based consumers are an efficient foundation for real-time ETA prediction and adaptive routing in urban traffic networks.

Future work will focus on integrating temporal graph neural models into the heuristic layer of the routing service to further enhance predictive accuracy and scalability.

Keywords: Artificial Intelligence (AI), Programming Education, AI Code Assistants, Student Learning.

Abstract: ChatGPT, GitHub Copilot, DeepSeek, and Claude AI are increasingly used in programming instruction, yet relatively few empirical studies have examined their impact on student learning behaviour in the Philippine higher education context. This study contributes to the existing body of knowledge by investigating third-year BS Information Technology students' use of AI-based code assistants, with particular emphasis on their reasons for adoption, perceived benefits, and emerging concerns. Using a quantitative descriptive research approach with an online survey of 14 students, the findings highlight a novel insight: students tend to act either as strategic users (selective usage) or power users (frequent usage), revealing distinct patterns of integration into learning practices. While AI tools were widely commended for improving conceptual comprehension, problem-solving speed, and debugging accuracy, notable concerns regarding over-reliance, reduced independent practice, and potential skill degradation also emerged. These results emphasize the dual role of AI as both a significant enhancer of learning outcomes and a potential risk to long-term skill development, thereby underscoring the critical need for balanced, pedagogically grounded educational strategies that effectively integrate AI while reinforcing essential programming competencies.

1 INTRODUCTION

Artificial intelligence (AI) has become essential to modern life, changing how people live, work, and learn. As technology advances, AI is rapidly being applied in various fields, including education. According to the study of Niemi [1], AI significantly influences society, business, and work settings. It is commonly used for daily responsibilities such as scheduling, organizing to-do lists, and food monitoring, among others. Furthermore, it highlights the widespread availability and use of massive open online courses (MOOCs) and other online learning models across all educational system levels. These are often supported by advanced learning management systems that integrate both synchronous and asynchronous instruction and adaptive learning resources. In fact, significant global differences in the integration of AI in educational systems are highlighted by the fact that by 2023, about 47% of academic institutions in high-income countries had adopted AI-driven tools, compared to just 8% in low-income countries [2].

Additionally, students are using AI-powered tools such as ChatGPT, DeepSeek, and GitHub Copilot, among others, for tasks including code generations, debugging, and comprehending programming concepts in the field of education, especially in programming. According to the study [3], more than half of students chose direct solutions over AI guardrails, suggesting a growing preference for rapid fixes over guided learning and thoughtful problem-solving. Although these tools have many advantages, such as individualized support and increased productivity, there is growing concern about their potential to decrease peer collaboration and encourage an excessive reliance on automated assistance.

It asserts that although AI tools can significantly increase productivity, they may also cause students to become less adept at critical thinking and problem-solving because they may rely excessively on AI rather than exercising independent judgement.

Significantly, 89.0% of student teams reported receiving false or misleading information from AI tools, and 75.3% voiced concerns about becoming overly reliant on AI support, even though 91.7% of student teams used AI tools to generate code comments and 80.2% for debugging tasks [4].

Since AI tools enable personalized learning experiences and encourage active engagement, integrating them into programming education is consistent with constructivist and self-directed learning principles [5]. Nevertheless, despite their potential, the literature currently in publication lacks thorough insights into how these AI tools specifically affect programming students' development of critical thinking and problem-solving abilities. Therefore, as an increasing number of students continue to use AI tools to finish assignments and projects, it is essential to evaluate how these tools affect their educational experiences.

This study addresses this gap by examining the degree of reliance on AI tools among third-year BS Information Technology students, identifying their reasons for use, perceived benefits, and concerns. The strong point of this study lies in its focus on the Philippines' higher education context, where limited research exists on AI-assisted programming education, and in its novel categorization of students as "strategic users" or "power users", offering a new lens for understanding learning behaviors. The findings aim to guide educators in designing balanced strategies that maximize the benefits of AI while minimizing risks of over-reliance.

While early adoption highlights the effective gains of using AI code assistants, latest studies have begun to uncover more intricate details – one of which is that these AI tools not only support learning but also affect the way students think, solve problems, and accomplish programming tasks. A meta-analysis of 35 studies between the years 2020 up to 2024 shows that students who utilize AI assistant tools such as ChatGPT, GitHub Copilot, and others outperform those students who do not, with effective output improvements in programming scores and reduced time to accomplish tasks [6].

However, behind this effectiveness, there are growing concerns in some aspects: while it improves performance, there is clear evidence that overreliance on AI assistance leads to shallow engagement with problem-solving and reduced improvement of reasoning skills. For instance, in a recent study on brownfield coding tasks, students completed tasks faster and made progress with the use of Copilot, while high-performing students were more selective (e.g., accepting fewer suggestions), whereas low-performing students tended to heavily rely on AI tools for easier provided code blocks, which can lead to compromising competence in independently solving coding tasks [7].

Moreover, another study that involved 885 students showed that half used AI tools for easier solutions at least once, especially in crucial times when they felt time pressure or were stuck in a certain activity [3]. Given these emerging complexities, it is important to explore how students engage with or utilize these tools beyond surface-level use to learn more deeply about the implications of AI tool reliance within programming education.

To learn further regarding how these AI technologies affect student programming learning, the research intends to examine the degree of reliance on AI tools, the reasons behind their use, and the advantages and disadvantages of relying on AI-generated code in order to better understand how using these tools affects students' programming learning. Ultimately, the findings will help educators strike a balance between AI support and fundamental learning.

1.1 Objectives

This study aims to explore the dependence of third-year BS Information Technology students at a university in Batangas on AI-based coding tools (e.g., ChatGPT, DeepSeek, and similar platforms) in learning programming. Specifically, the research seeks to:

- Assess the extent of students' reliance on AI tools for coding tasks.
- Identify the reasons behind their usage (e.g., efficiency, difficulty of topics, lack of confidence).
- Examine the positive impacts (e.g., faster learning, improved productivity) and negative consequences (e.g., reduced problem-solving skills, over-reliance) of depending on AI-generated code.

The findings will provide insights into how AI tools influence programming education and help educators develop strategies to balance AI assistance with foundational learning.

1.2 Purpose of the Study

This study aims to examine the impact of AI assistants, such as ChatGPT, GitHub Copilot, and others, on students' programming learning journeys by determining whether or not they rely on Ai tools, how this dependence affects their problem-solving

abilities, and whether it improves or decreases their understanding on programming concepts. This study intents to educate students, educators, and developers about the possible consequences of incorporating AI tools into the learning process by offering a descriptive analysis of students; attitudes, behaviors and experiences.

2 LITERATURE REVIEW

This section presents literature relevant to the concept of the present study. It also examines some studies that address various ideas, concepts, conclusions, and materials from the internet in order to give enough background and information necessary for the completion of this study.

The literature map Figure 1 highlights key themes on how AI code assistants affect programming education. While tools including ChatGPT and GitHub Copilot offer benefits such as faster learning and accessibility, they also pose risks such as over-reliance, reduced critical thinking, and weaker peer collaboration. Students often replace teamwork with AI assistance, affecting skill development and communication.

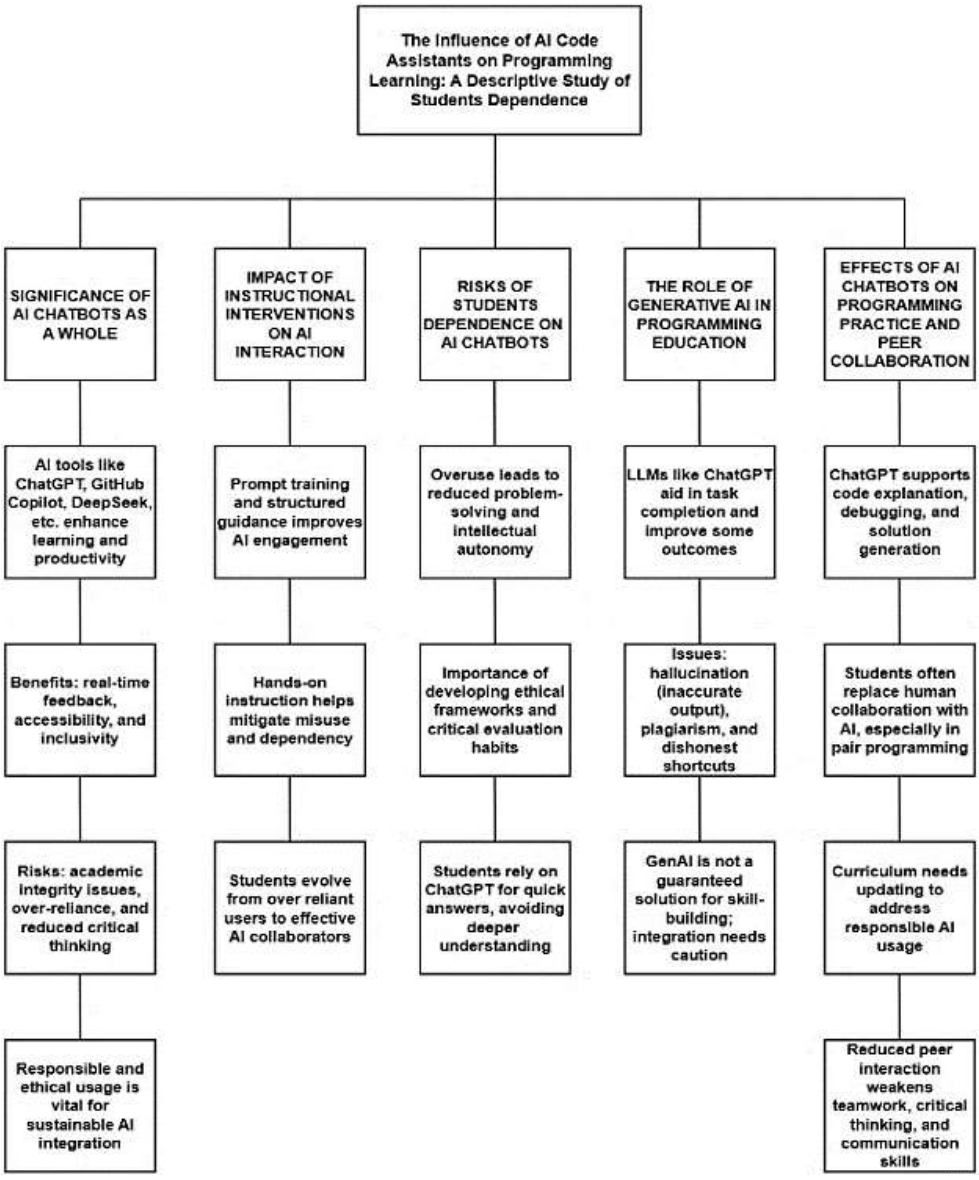

Figure 1: Literature map of key themes on the influence of AI code assistants on programming learning.

Generative AI tools can enhance performance but also raise concerns about plagiarism, hallucination, and shortcut learning. Excessive dependence may hinder students' problem-solving abilities and autonomy. However, instructional strategies including prompt training can promote more responsible and effective AI use.

Overall, the literature emphasizes the need for balanced integration of AI; maximizing its benefits while maintaining educational integrity and critical skill development.

Previous research offers more in-depth understanding of how AI is influencing programming education, building on the themes presented in the literature map. A study [8] examined university students' attitudes toward AI, finding that while it enhances learning efficiency, excessive reliance may reduce critical thinking and independence, emphasizing the need for balanced digital literacy and responsible AI use. Similarly, [9] found that integrating ChatGPT into programming education improved students' computational thinking skills, motivation, and self-efficacy, providing AI's potential as a learning companion when guided effectively.

A study [10] further revealed that using GitHub Copilot as an AI pair partner produced knowledge transfer episodes at rates comparable to those observed in human-human pair program, indicating that AI assistants can facilitate learning in a manner similar to that of human collaborators. However, they also found that participants were more likely to accept suggestions from human partners, which may have implications for the development of code correctness awareness.

Meanwhile, [11] highlighted that ChatGPT can facilitate self-regulated learning by offering adaptive tutoring and real-time feedback, yet its effectiveness depends on learner's metacognitive skills and awareness of AI limitations.

These studies collectively imply that AI tools greatly enhance engagement. However, educators must also protect students' critical reasoning and independence to prevent overdependence on automated assistance in coding situations.

2.1 Significance of AI in General

AI assistants, including code generators such as GitHub Copilot, writing aids such as ChatGPT, grammar checkers such as Grammarly, and answer-support systems such as Google Bard, have revolutionized how people learn, work, and solve problems across various domains. In education, these tools provide instant explanations, generate study materials, and offer personalized feedback, significantly enhancing learning efficiency [12]. For instance, AI coding assistants help students debug and understand complex algorithms, while aids assist with essay structuring and grammar correction, making education more interactive and accessible. However, concerns persist about over-reliance, as students may prioritize quick AI-generated answers over deep comprehension [13]. Beyond education, AI tools boost productivity in professional settings by automating repetitive tasks in software development, academic research, and business communications, allowing users to focus on higher-order thinking and creativity [14].

Additionally, AI-powered language tools break down barriers for non-native speakers and individuals with learning disabilities by improving readability and offering real-time suggestions, fostering inclusive communication. Despite these benefits, challenges such as accuracy issues, academic integrity risks, and potential job market disruptions necessitate careful consideration [15]. The future of human-AI collaboration hinges on balanced usage; leveraging AI for efficiency while preserving critical thinking and ethical judgement. As these technologies evolve, their integration must emphasize responsible use to ensure they augment rather than undermine human potential. This study explores these dynamics, particularly focusing on student dependence, to provide insights for optimizing AI's role in education and beyond.

2.2 Effects of AI Chatbots on Programming Practice and Peer Collaboration

The integration of AI chatbots such as ChatGPT into programming education has significantly reshaped how students approach coding tasks and peer collaboration. In a case study involving a master's-level scientific computing course, it was found that students used ChatGPT in six distinct ways: explaining code in plain language, generating and optimizing solution code, debugging, improving conceptual understanding, and solving mathematical problems [12].

While students perceived these interactions as supportive of their learning – citing gains in efficiency, understanding, and problem-solving – the study also revealed unintended consequences. Specifically, students began substituting AI chatbots for human collaborators in pair programming, undermining the dialogic and collaborative nature of

the activity. Instead of acting as navigators for one another, students used ChatGPT in that role, resulting in reduced team communication and weaker development of transversal skills such as critical thinking and collaboration. The findings highlight the need to refine learning objectives to explicitly incorporate responsible AI use and to reevaluate pedagogical strategies including pair programming in the era of AI-assisted learning [12].

2.3 Impact of Instructional Interventions on AI Interaction

Instructional interventions play a significant role in influencing how students engage with AI tools such as ChatGPT during their learning process. The study highlights those different levels of guidance – ranging from no instruction to hands-on prompt training and structured lab guides – resulted in notable changes in students' AI interaction profiles. These profiles, including AI-Reliant Code Generators and IA-Collaborative Coders, evolved significantly across the three sessions, reflecting the students' increasing ability to use AI in a more intentional and effective manner. The findings suggest that providing targeted training in prompt writing and AI use can enhance students' ability to interact with AI tools in ways that support their learning, ultimately leading to improved performance on programming tasks [14].

2.4 The Role of Generative AI in Programming Education

Despite advancements in programming education tools, dropout and failure rates remain high due to issues such as inadequate feedback and a lack of the fundamental programming skills.

However, tools such as Generative Artificial Intelligence (GenAI) and Large Language Models (LLMs) including ChatGPT, offers ensured solutions. In programming education, LLMs, that uses repositories such as GitHub can assist students with their programming tasks. While these AI tools show potential in assistance, it can also produce challenges such as hallucinations (generating incorrect information) and plagiarism. In addition, these tools' capacity to cause academic dishonesty, such as utilizing these tools to generate immediate answers without fully understanding the tasks, complicates their integration into education. Despite the ability to improve student performance in certain contexts, the effectiveness of purpose of these AI models in coding remains uncertain [16].

Moreover, [16] examined the impact of AI programming assistant on student's exam scores and their tendency to accept incorrect AI-Generated information. The result shows that student's exam average scores increase when using the AI assistant. However, it also found that a huge portion of students accepted incorrect information provided by the AI, highlighting the importance for a careful integration of AI tools into learning environments.

2.5 Risks of Student Dependence on AI Chatbots

While AI-powered chatbots such as ChatGPT offer numerous education benefits, their increasing use also introduces the risk of student dependence that may hinder deeper learning. [13] outlines how ChatGPT enables interactive and personalized learning by providing fast, on-demand assistance helping students understand complex topics and complete tasks efficiently. However, this immediacy and accessibility can lead students to prioritize quick task completion over critical thinking and problem-solving. The study highlights that students who rely excessively on AI tools may gradually lose their capacity for independent learning and analytical reasoning.

Furthermore, the potential for ChatGPT to deliver incorrect or incomplete information can mislead users; especially when students lack the expertise to critically evaluate the output. This unchecked dependence not only risks academic performance but also impacts students' long-term development of autonomy and intellectual resilience. As [13] emphasized, while ChatGPT can enhance learning, educators must implement clear strategies and oversight to ensure students use such tools responsibly and critically, rather than as a crutch.

The findings of this study underscore the significant influence of AI code assistants, particularly ChatGPT, on programming learning and student dependence. The research reveals that while these tools enhance learning efficiency through convenience, perceived usefulness, and ethical considerations [15], they also pose risks of over reliance that may undermine critical thinking and peer collaboration [12]. Students increasingly turn to AI for instant solutions, which can diminish their engagement in problem-solving processes and reduce opportunities for collaborative learning [13]. Despite these challenges, the study highlights the potential of AI as a supplementary educational tool when used responsibly. Instructional interventions, such as structured prompt training and ethical guidelines, can

mitigate dependence and promote balanced usage [14]. Moving forward, educators must integrate AI code assistants into curricula with clear frameworks that emphasize skill development over convenience-driven reliance. Future research should explore longitudinal effects of AI dependence and comparative studies across diverse educational contexts to refine best practices for AI integration in programming education.

3 METHODOLOGY

This section describes the research design, instrument, and data gathering procedures used in the study. The study uses structured survey methods to collect quantifiable data on students' motivations, frequency of use, and perceived academic impacts of AI-assisted programming tools.

3.1 Research Design

In order to quantify these factors and gain insight into how AI technologies are being incorporated into learning practices, this study used a quantitative descriptive research design to collect data on how students use AI tools to support their learning in programming courses. Specifically, the study sought to ascertain the extent of usage, reasons for using AI-assisted tools, and the perceived effects of these tools on students' academic performance and programming-related tasks.

3.2 Research Instrument

The survey questionnaire's direction, structure, and content were influenced by four foundational studies citied by the researchers [17] - [20]. These studies offered fundamental viewpoints on the usability of AI tools, the difficulties in teaching programming, and the experiences of students with AI-assisted learning.

The questionnaire consists of 14 items, which was divided into five sections: demographic information (4 items), usage extent (3 items), usage motivations (1 item), effects of AI support (3 items), and open-ended questions (3 items). The survey included a combination of multiple-choice, checkboxes, 5-point Likert-scale, and open-ended questions.

The questionnaire's two sections used a Likert scale to assess respondents' levels of agreement: Section III-Usage Motivations, where respondents rated the reasons for using AI tools for learning or programming (e.g., ease of understanding, time-saving benefits), and Section IV-Impacts of AI Assistance, where respondents evaluated how using AI affected their learning experience (e.g., improved coding efficiency, reduced learning anxiety). These are scored from 1 ("Strongly Disagree") to 5 ("Strongly Agree"). Descriptive statistics, such as percentages and frequency scores were used to analyze the data in order to interpret students' patterns and perceptions regarding the use of AI in programming education.

3.3 Data Gathering Procedure

During the academic year, the study was carried out among two sections of third-year BS Information Technology students, primarily INF 221 and INF 222. All responses were anonymous, participation was voluntary, informed consent was acquired at the start of the survey form, and no personally identifiable information was gathered.

In order to guarantee fair representation from both sections of the course, 30% of the total 46 students from INF 221 (31 students) and INF 222 (15 students) were selected to determine the sample size. This resulted in approximately 9 (out of 31) and 5 (out of 15) participants, respectively, raising the target sample size to 14 students. To obtain this data, an online survey was created using Google Forms and distributed via official class group chats, with the assistance of the students' respective professors.

4 RESULTS AND DISCUSSION

This section presents the results of a survey of 14 respondents from BS Information Technology third-year students studying programming and examines their use of AI-based code assistance tools using five key dimensions: demographics, usage, adoption motivations, perceived learning impacts, and quantitative insights on advantages and disadvantages. The findings show patterns in efficiency gains, dependency risks, and strategies for a balanced integration into programming education.

4.1 Demographic Profile and Extent of AI Coding Assistant Utilization

As shown in Figure 2, the majority of respondents are aged 20-21 (peaks at 21), as 21-year-olds (n = 8) representing 57.1% of respondents, and 20-year-old group (n = 4) with 28.6%. However, age 27 appear as an outlier in terms of age distribution. The sample primarily represents traditional college-aged students (20-21 years old), with one non-traditional student.

This suggests the data mainly reflects the behaviors of younger undergraduate students.

According to Figure 3, the gender split is perfectly balanced at 50/50 between male and female respondents, with 7 respondents from each gender. This equality makes it possible to compare genders without representation bias, which is a unique advantage when examining usage patterns across genders. Notably, all respondents reported actively using AI coding assistants (100% adoption rate).

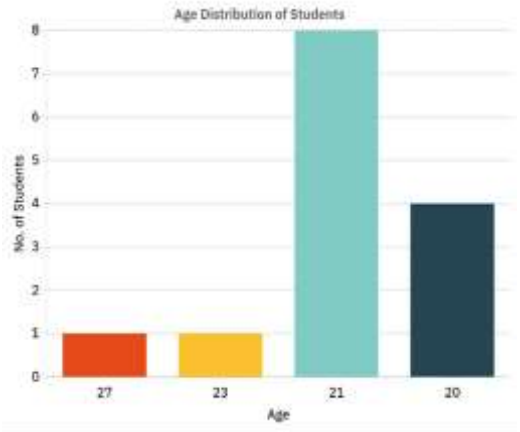

Figure 2: Age breakdown of student respondents.

Figure 3: Gender distribution of student respondents.

According to Figure 4, 71.4% of students use AI tools heavily ("Always" or "Often"), whereas only 28.6% use them occasionally ("Sometimes"). Males are more likely to use "Often" (3 out of 4 cases), which indicates more selective deployment, and both genders are equally likely to use "Always" (3 each), which suggests that gender affects how students use AI, not whether they use it.

Figure 5 examines the relationship between academic performance and AI tool usage patterns. 71.4% (n = 10) regularly fulfilled program requirements, while 28.6% (n = 4) were honors students (Dean's Listers/University Scholars). Students who are "Consistently meeting requirements" show the most "Always" usage, "With honors (Dean's List)" students tend to use AI tools "Often" rather than "Always". While "Occasionally retaking courses" students show balanced usage across all frequencies. High-performing students utilize AI technologies modestly, but struggling students depend on them more intensively. This might imply that excessive AI use is associated with academic difficulties, or that struggling students find AI technologies especially useful.

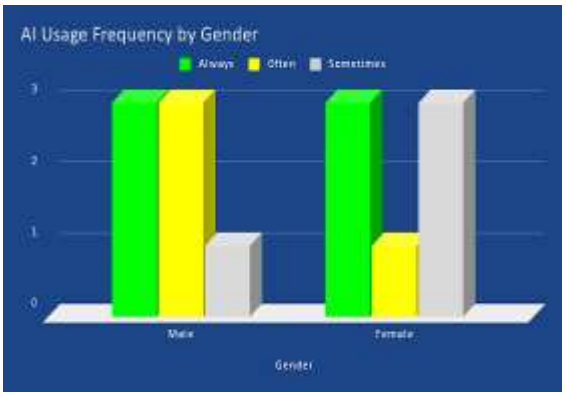

Figure 4: Usage rate of AI programming assistants among programming students.

Figure 5: AI usage rates based on students' academic standing.

Age, workload percentage handled by AI, and usage frequency are the three variables examined in this bubble chart (refer to Fig. 6). The 27-year-old handles the highest workload percentages with AI (90%) and the majority of 20-21-year-olds cluster around 50-70% AI workload. "Always" users are spread across age groups, with the youngest (20) and the oldest (27) respondents demonstrating the highest AI reliance. The bubble sizes indicate that frequent ("Always") users are present across all ages, but the extremes of the age range (youngest and oldest) show

higher AI dependence. Age does not, therefore, exhibit a clear linear relationship with AI usage patterns.

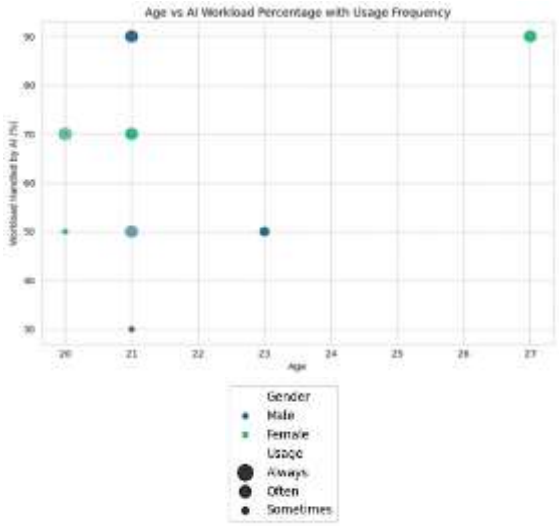

Figure 6: AI tool usage intensity by age group.

Academic performance exhibits intriguing correlations with AI usage patterns, although both moderate and heavy usage levels are observed across all demographics. The data indicates that AI tool adoption is universal across all genders in this sample, indicating widespread acceptance regardless of demographic differences. Notably, the majority of respondents are in the 20-21 age group, indicating that younger students are the most represented in this study.

Furthermore, two different usage archetypes emerge from this widespread use: Power Users, who depend on AI continuously for essential academic tasks, and Strategic Users, who use AI sparingly and only when necessary. These usage patterns demonstrate how AI tools have become essential to students' academic work.

4.2 Motivations for Using AI and Its Effects

This horizontal bar chart illustrates the average ratings (on a 1-5 scale) for six key reasons learners use AI tools: understanding complex topics, speed over traditional searching, productivity, lack of confidence, programming difficulty, and peer influence.

As shown in Figure 7, comprehension of complex topics stands out, with the highest average rating of roughly 4.8. This indicates strong consensus among respondents, with 9 ("Strongly Agree") and 3 ("Agree"), while only 2 respondents were "Neutral" and none disagreed. It is evident from this that Ai is widely regarded as a useful tool for making complex subjects easier to understand, especially in programming education where comprehension issues are common.

The speed and convenience of AI ranks second, with an average rating of around 4.4. A total of 6 respondents "Strongly Agreed", 5 "Agreed", and 3 were "Neutral". Evidently, this reflects a widespread belief that AI tools offer faster solutions than traditional online searches. However, neutral responses may stem from individuals who prefer a mix of resources or have not yet experienced significant time-saving benefits.

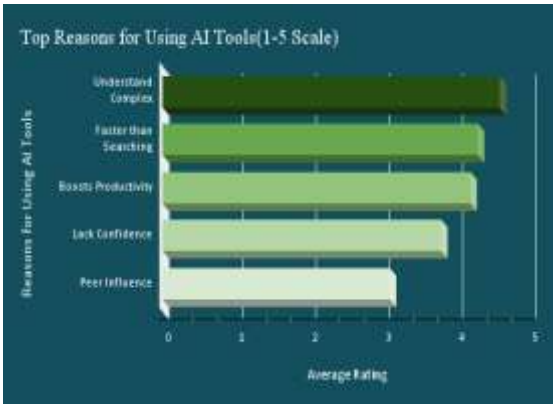

Figure 7: Top reasons for using AI tools.

Productivity enhancement received a strong average of approximately 4.2. 6 respondents "Strongly Agreed", 3 "Agreed", 3 were "Neutral", and 2 "Disagreed". The majority of respondents view AI as a productivity boost, but some may find that its outputs need verification or do not fit with their workflow, which lowers its perceived value.

Additionally, programming difficulty and overwhelm had a slightly lower average score of 4.0. The category with 2 "Strongly Agreeing", 7 "Agreeing", 2 "Neutral", and 3 "Disagreeing" responses indicates that a considerable portion of learners feel more capable of handling complexity on their own, while others may have developed independent strategies to handle programming tasks.

Lack of confidence, on the other hand, averaged 3.7. 2 respondents selected "Strongly Agreed", 5 selected "Agreed". 6 selected "Neutral", and 1 selected "Disagreed". This suggests a more mixed perception, with some learners using AI because they are unsure of their programming skills, while others

see themselves as becoming or already confident and use AI more for validation than support.

Ultimately, the majority of respondents report that their use of AI is based on personal choice rather than peer trends, with peer influence scoring the lowest average at roughly 3.3. With 3 "Strongly Agreeing", 4 "Agreeing", 1 "Neutral", and 5 "Disagreeing", this result emphasizes that social factors have the least impact on AI adoption.

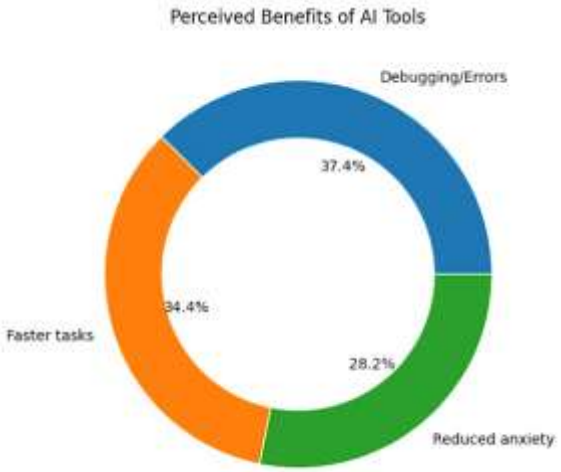

Figure 8: Perceived benefits of AI.

The most recognized benefit was "Debugging and Error Support", cited by 37.4% of respondents (refer to Fig. 8). This indicates that AI tools are highly valued for their ability to assist users in identifying and fixing coding issues efficiently, a capability that is likely to be critical in reducing frustration and speeding up the problem-solving process.

Additionally, 34.4% of respondents chose "Faster Task" completion, indicating that a sizable percentage of students' value how AI tools expedite their coding process, allowing them to finish assignments or projects faster. On average, this illustrates the tool's usefulness in improving workflow speed.

Lastly, a significant percentage of learners who feel emotionally supported by AI assistance (28.2% of responses) were in the category of reduced anxiety. These users likely experience less stress when faced with difficult programming challenges because they receive reassurance from intelligent feedback and immediate support.

With an average of 33.3% of responses across the three main benefit areas, it is evident that AI is not only increasing efficiency through quicker task completion and debugging assistance, but also significantly lowering anxiety – making it a valuable partner in the programming journey. These findings thus show that AI tools provide a balanced blend of technical and emotional support for learners.

As presented in Figure 9, the most common negative impact is "Over-reliance", which has cited by roughly 71.4% of respondents. This suggests that a significant portion of students may be growing overly reliant on AI tools, possibly at the expense of developing independent problem-solving skills. Such reliance may hinder the development of critical thinking, as learners may default to AI instead od applying their own reasoning.

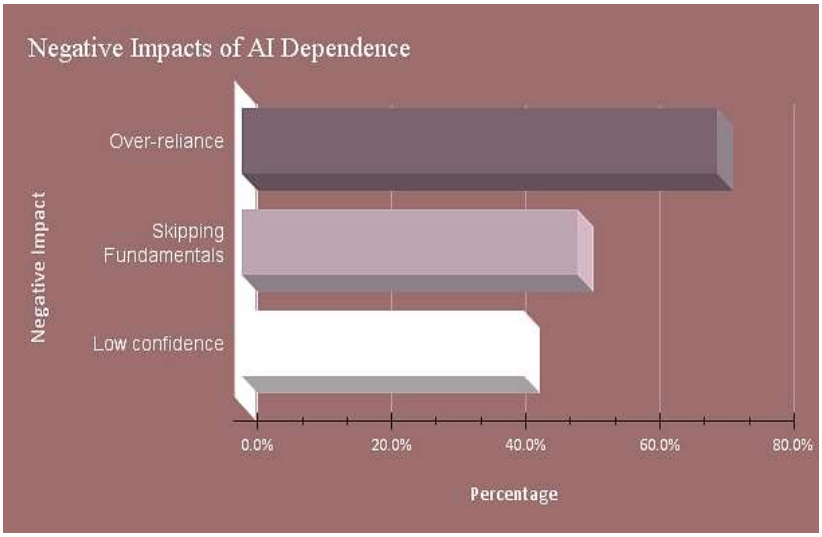

Figure 9: Negative impacts of AI dependence.

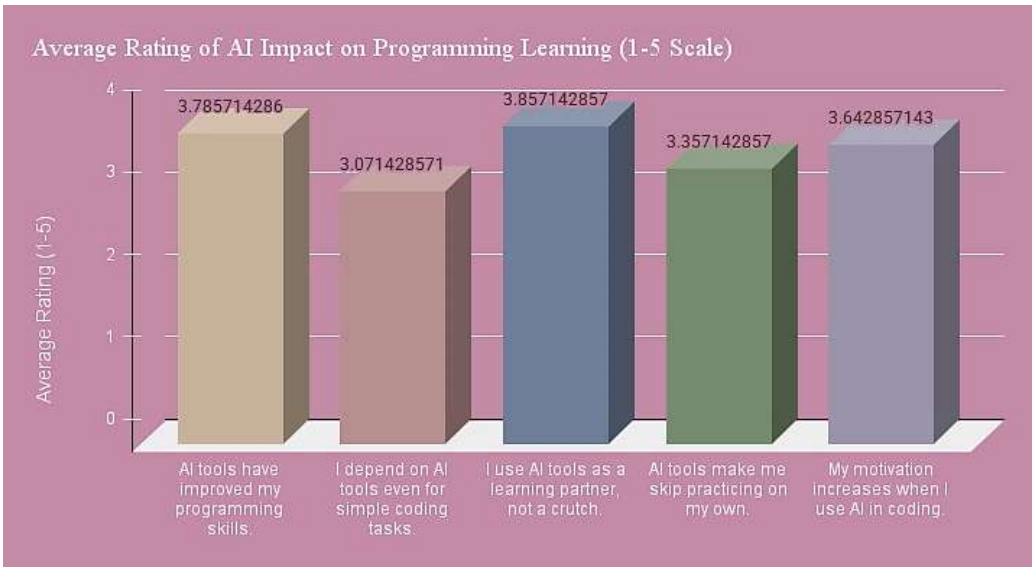

Figure 10: Average rating of AI impact on programming learning.

Following that, about 57.1% of participants chose to "Skip Fundamentals", suggesting that the use of AI may unintentionally cause some students to skip over important foundational concepts in favor of speedy fixes rather than in-depth comprehension. Over time, this gap in foundational knowledge could limit learners' ability to progress to more advanced topics or troubleshoot issues effectively.

Lastly, "Low Confidence" was reported by 42.9% of respondents, which suggests that regular use of AI may erode learners' confidence in their own abilities, particularly in the absence of the tool. The diminished self-assurance could reduce their willingness to take risks or attempt problem-solving independently. Hence, while AI tools provide clear benefits, the results underscore the importance of balancing their use with strategies that support independent learning, fundamental comprehension and skill confidence.

A significant number of respondents (9 "Agreed", 2 "Strongly Agreed") indicated that AI tools have improved their programming skills, resulting in a high average rating of 3.79 as depicted in Figure 10. Only 2 students were "Neutral" and 1 "Disagreed", highlighting that most students view AI as a beneficial aid in skill development. This suggests that AI is effectively serving as a supplementary tutor; helping clarify coding concepts, generate examples, and offer quick solutions that reinforce classroom learning.

However, when asked whether they rely on AI tools even for simple coding tasks, responses were more mixed, with an average rating of 3.07. Most students were "Neutral" (5) or "Disagreed" (4), while a few "Agreed" (2), "Strongly Disagreed" (2), or "Strongly Agreed" (1). This distribution implies a cautious yet balanced approach to AI use. While some students admit occasional reliance, the majority appear mindful of avoiding over-dependence, especially for tasks they can manage on their own.

In contrast, "I use AI tools as a learning partner, not a crutch" received the highest average rating (3.86), yet the responses were still divided. 4 students "Agreed", 4 were "Neutral", while the remaining students either "Disagreed" (2), "Strongly Disagreed" (3), or "Strongly Agreed" (1). This variation suggests a split in perception: while some view AI as a valuable companion in learning, others worry that it may hinder the development of independent problem-solving skills. The neutral responses indicate that many are still navigating how best to incorporate AI into their learning routines.

Regarding the impact of AI on independent practice, responses to "AI tools make me skip practicing on my own" had a moderate average rating of 3.36. 3 students "Agreed" and 2 "Strongly Agreed", reflecting some concern that AI can reduce the incentive for hands-on learning. However, with 5 "Neutral" and 4 "Disagree" responses, it appears that not all students are affected equally. This suggests that while AI may occasionally tempt students to skip practice – especially under time pressure – many still recognize the value of continued practice.

Lastly, the average rating for "My motivation increases when I use AI in coding" was 3.64, with 4 students "Agreed" and 3 "Strongly Agreed", while 6 were "Neutral" and only 1 "Disagreed". This

indicates that AI has a motivating effect for some students – possibly due to the instant feedback, faster experimentation, or clearer explanations it provides. However, the large number of neutral responses indicates that motivation is influenced by various factors beyond AI, such as personal interest, goals, or external pressures.

The data reflects that AI is generally seen as a helpful tool, particularly in enhancing programming skills and boosting motivation. However, mixed responses in areas such as reliance, practice habits, and the role of AI as a partner versus a crutch highlight the need for careful guidance. These insights underscore the importance of building a balanced approach – leveraging AI to enhance learning while encouraging independent thinking and skill development.

Thus, it is evident that while AI tools are very beneficial for improving programming education, particularly in terms of making complicated ideas easier to understand, increasing productivity, and boosting motivation, they also raise some significant issues. While many students value the speed and support that AI offers, there is a thin line between using AI as a useful learning tool and becoming unduly dependent on it. In order for AI to truly support learning, students need guidance on how to use it mindfully – balancing its convenience with efforts to build independent problem-solving skills and a strong foundation in programming. The dependence, skipping practice, and confidence are clear evidence that AI's impact is not universally positive or negative; it really depends on how it's used.

4.3 Thematic Examination of Students' Views on AI Assistance

As shown in Figure 11, it illustrates the frequency with which students mentioned various themes across three categories: benefits, concerns, and recommendations. According to the graph, the most commonly mentioned advantages were "Instant Feedback", "Efficiency & Speed", and "Confidence", while "Over-Reliance" and "Code Quality Issues" were the most reported concerns. Under recommendations, "Guided Learning" and "Structured Practice" emerged as key suggestions to ensure that students continue to develop fundamental programming skills in addition to using AI.

The open-ended responses collected from third-year students regarding the use of AI tools in learning programming reveal several key insights. When asked about the perceived benefits of AI, the majority of students identified increased efficiency and ease of understanding as the primary advantages. AI tools were frequently described as helpful in explaining complex code, providing quick solutions, and offering immediate feedback. Several respondents noted that AI enhances their confidence in programming, particularly when they encounter errors or concepts, they find difficult to grasp. This suggests that AI functions as an accessible and supportive learning aid, especially for students who may require additional guidance outside of class hours.

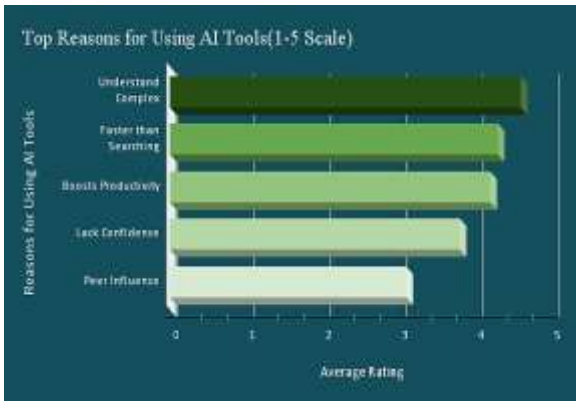

Figure 11: Student perspectives on AI code assistants.

Despite these positive perceptions, students also expressed significant concerns about the drawbacks of relying on AI-generated code. The most prevalent issue cited was the risk of over-dependence which may hinder the development of critical problem-solving skills and a deeper understanding of programming fundamentals. Additionally, some students pointed out that AI-generated solutions are not always accurate; they may contain logical errors or misleading constructs that could potentially confuse learners who lack the experience to detect such mistakes.

In terms of balancing the use of AI tools with mastering the basics of programming, many students emphasized the importance of attempting to solve problems independently before consulting AI. They advocated for using AI as a supplementary resource rather than a primary solution. This approach, according to respondents, would reinforce learning and reduce the tendency to rely entirely on automated assistance. A few students also acknowledged uncertainty in how to maintain this balance, indicating a potential need for structured guidance from instructors on responsible and effective AI usage within the academic environment.

This study both supports and extends previous research. [14] reported students' growing reliance on AI tools for quick fixes, a trend that this study also observed. However, categorization of students into 'strategic users' and 'power users' offers a new perspective that highlights distinct usage patterns rather than treating students as a homogenous group. Similarly, while prior studies identified concerns about misinformation from AI tools [4], this study situates these concerns within the Philippine higher education context, where fewer studies have been conducted. This contextual contribution emphasizes the dual nature of AI adoption: it enhances learning efficiency while posing a risk of skill erosion. By framing results alongside previous findings, this study underscores both the alignment with global patterns and the unique insights of it.

5 CONCLUSIONS

This study revealed that 100% of third-year BS Information Technology students actively used AI coding assistants, with a majority demonstrating heavy reliance on these tools for programming tasks. Although these tools improved comprehension and efficiency, students expressed concerns about over-reliance and decreased foundational practice. These findings contribute to the growing body of knowledge on AI integration in programming education by demonstrating the paradoxical nature of AI tools – serving as valuable learning aids that enhance comprehension and efficiency while potentially undermining independent problem-solving skills and foundational knowledge acquisition.

The importance of this study lies in its focus on the Philippine higher education context, where empirical studies on AI-assisted programming remain limited. By introducing the categorization of students as "strategic users" and "power users", this study provides a new lens for understanding diverse learning behaviors. These insights are not only academically relevant but also carry practical value. For example, educators may use the findings of design-balanced teaching strategies that incorporate AI for scaffolding and debugging while maintaining exercises that build independent coding and problem-solving skills. Academic institutions may also apply these results to create policies that promote responsible AI usage, ensuring that students benefit from technological support without sacrificing fundamental competencies.

This study is not without limitations. It employed a descriptive survey design to provide exploratory insights into the use of AI coding assistants among third-year IT students. While this approach effectively captured initial patterns of reliance, benefits, and concerns, it did not incorporate theoretical or mathematical modeling, which limits the dept of inference. Additionally, because the study was not quasi-experimental, it was unable to compare skill outcomes between groups with guided AI usage and those who unguided use. These constraints were largely due to the limited sample size and the scope of the study. It is highly encouraged to adopt quasi-experimental or longitudinal designs and to apply theoretical or mathematical frameworks to validate the extend the findings across larger and more diverse populations.

In order to improve best practices for AI integration, future research should examine the long-term effects of AI dependence, test instructional interventions, and carry out comparative studies across various academic settings. Educators are also urged to create organized frameworks that encourage guided learning, incorporate exercises that strengthen autonomous problem-solving prior to utilizing AI tools, and strike a balance between the use of AI and the development of basic programming skills.

Abstract: The article develops a comprehensive methodological approach to assessing the level of Ukraine's economic security in the context of national economic restructuring during wartime and in the post-war period. The study integrates institutional, cluster, and comparative analysis methods to identify the key determinants influencing the stability and transformation of the state's economic system. The proposed methodological framework comprises seven components of economic security – economic development, public administration, industry, science and innovation, education, investment, and infrastructure – the integral values of which are calculated for Ukraine and compared with countries representing three global clusters (Malaysia, Poland, and the Netherlands). The results show that Ukraine's Economic Security Index (0.3962) exceeds the threshold value for low-security countries but remains below the average and high cluster levels. The analysis reveals that the main areas for strengthening economic security include stimulating investment activity, developing infrastructure, modernizing industry, and improving the efficiency of public administration. Three post-war development scenarios are proposed: a realistic scenario (Poland model), an optimistic scenario (Malaysia model), and a long-term scenario (Netherlands model). The scientific novelty of the study lies in enhancing methodological tools for assessing state economic security through a multi-level cluster approach and international comparative analysis. The practical significance is determined by the possibility of applying the proposed methodology to the development of state policy aimed at ensuring economic resilience and effective management of post-war recovery processes.

1 INTRODUCTION

Ensuring economic security is one of the key priorities for strengthening Ukraine's national resilience and defense capability [1]. Russia's full-scale military aggression has caused unprecedented destruction of industrial capacity, infrastructure, logistics chains, and human capital, leading to significant economic losses and a significant transformation of the structure of public spending. According to the Stockholm International Peace Research Institute (SIPRI) [2], in 2022, Ukraine's military spending amounted to 44 billion dollars, or 33.6% of GDP, compared to 5.9 billion dollars in 2021, reflecting a significant reorientation of budgetary resources to the security and defense sector. At the same time, macroeconomic imbalances have intensified.

According to TheGlobalEconomy.com [3], the ratio of public debt to GDP increased from 43.8% in 2000 to 84.4% in 2023, while the share of public spending in GDP almost doubled – from 17.9% to 41.7%. The real sector of the economy suffered significant losses: industrial enterprises, energy facilities, transport infrastructure, agricultural assets were damaged or destroyed [3].

According to estimates by the National Institute for Strategic Studies [4], direct losses in industry amount to 11.4 billion dollars, and in the agricultural sector – 8.7 billion dollars. According to expert calculations by the Kyiv School of Economics [5], the total amount of direct losses in all sectors of the economy reached 169.8 billion dollars, in particular

38.5 billion dollars in the infrastructure sector and 14.6 billion dollars in the energy sector.

According to the updated Rapid Damage and Needs Assessment (RDNA4, 2024) [6], prepared by the Government of Ukraine, the World Bank, the European Commission and the United Nations, the total cost of reconstruction and recovery will be 524 billion dollars in 2024-2034. This figure is almost three times higher than the projected nominal GDP of Ukraine for 2024 [7], which emphasizes the scale of the challenges and the need to develop effective mechanisms for ensuring economic security in the process of national reconstruction and structural reforms. Despite the existence of official methods for assessing economic security (2007, 2013) [8; 9], modern conditions, marked by hybrid warfare, structural shifts in the economy and the need for post-war recovery, require a deep modernization of methodological tools. Existing approaches do not fully take into account the factors of innovative development, investment activity, management efficiency and international integration, which today determine the new architecture of the state's economic security.

Therefore, the scientific problem is to develop an improved methodological approach to assessing economic security in the conditions of war and post-war periods. This will allow for a comprehensive identification of vulnerabilities and threats [10], determine strategic priorities and ensure sustainable economic growth. Solving this problem is of key importance, not only for strengthening the country's defense capabilities, but also for achieving long-term economic resilience and integration of Ukraine into the European and global security space.

2 LITERATURE REVIEW

The issue of ensuring national and economic security occupies a significant place in modern scientific literature. The circle of leading researchers includes foreign scientists (A. Ávila-Zúñiga-nordfjeld et al. [11], Yu-W. Luo et al. [12], M. Mennen and M. Van Tuyll [13], M. Seeba et al. [14], B. Sun [15]) and Ukrainian scientists (A. Kachynskyi [16], Ye. Kobko [17], G. Kozachenko et al. [18], O. Korchenko et al. [19], K. Oriekhova and I. Kucheriavenko [20], R. Prymush [21], O. Reznikova [22], H. Kharlamova [23], M. Shevchenko et al. [24], I. Yarova [25]). Their works laid the theoretical and methodological foundation for further research into the mechanisms of ensuring the national and economic stability of the state.

In Ukraine, the formation of a system for assessing economic security has gone through several stages. In 2003, specialists from the National Institute for International Security Problems of the National Academy of Sciences of Ukraine proposed the first methodology, which included six groups of indicators [26]. On its basis, in 2007, the Methodology for calculating the level of economic security of Ukraine [8] was approved, which contained 117 indicators and was based on a sequence of stages: selection of indicators → definition of thresholds → normalization → weighting → calculation of the integral index. In 2013, it was replaced by Methodological Recommendations [9], which provide for nine sub-indices (production, investment and innovation, financial, social, energy, etc.) and over 130 indicators. Both approaches received critical comments regarding the complexity of calculations, duplication of indicators and limited access to data.

Further research is aimed at improving official methods. In particular, Y. Kharazishvili and E. Dron [27] proposed a multiplicative form of the integral index, a single system of normalization of indicators and a formalized definition of weight coefficients, which ensures a more correct comparison of results. V. Baranova [28] developed a target approach, where security is assessed through the achievement of forecast benchmarks, and G. Kozachenko et al. [18] – through the expansion of the system of institutional and political indicators. The work of T. Zubko [29] focuses on international comparisons using foreign economic indicators (export/import dependence, comparative solvency, trade concentration, etc.).

A separate area of research is related to the assessment of economic security in the context of restructuring [30] and post-war economic recovery. The works (I. Berend [31], J. Guo [32], R. Hudson [33], W. Liu [34], X. Mao [35], G. Oliveira [36], V. Thomas [37], Y. Wei [38] et al.) are devoted to modeling structural changes and adaptation of national economies to shocks. Their experience confirms the need to integrate the scenario approach and comparative analysis in the formation of economic security policy.

The literature review shows that, despite a significant number of studies, the methodological basis for assessing Ukraine’s economic security remains fragmentary. Existing approaches are characterized by excessive complexity, uneven coverage of security dimensions, and limited

adaptability to wartime challenges. These gaps highlight the need for a more flexible and analytically consistent framework that would integrate both structural and institutional determinants of resilience. Such a framework should not only measure the current level of economic security but also enable the modelling of future trajectories under conditions of post-war reconstruction.

To address these limitations, the study incorporates recent international research on economic resilience, including OECD (2022-2024) analytical frameworks, EU crisis-response and resilience instruments, and UNDP post-crisis recovery assessments. These sources strengthen the conceptual foundation of the proposed methodology by introducing globally recognised resilience indicators and comparative evaluation tools. Their integration reduces dependence on national assessment models, broadens the analytical perspective, and improves the international comparability of the results.

Accordingly, the purpose of this study is to develop and substantiate an improved methodological approach to assessing Ukraine's economic security based on the integration of indicator, cluster, and comparative analyses. This approach aims to provide a scientifically grounded basis for strategic planning, structural transformation, and strengthening the country's resilience in the post-war period. The following section presents the methodological framework of the study.

3 METHODOLOGY

The methodological basis of the study is a system-analytical approach that combines indicator, cluster and comparative methods for quantitative assessment of the level of economic security of Ukraine in the context of economic restructuring.

To ensure methodological transparency, the selection of indicators and components was based on three criteria. First, the variables had to be statistically available for Ukraine and the benchmark countries over a sufficiently long time horizon to ensure comparability. Second, each indicator needed to be conceptually linked to recognised sources of economic vulnerability and resilience in accordance with international frameworks such as the OECD Resilience Toolkit, EU Civil Protection Mechanism, and the World Bank's post-crisis recovery guidelines. Third, the indicators had to capture structural features relevant for wartime and post-war reconstruction, including governance efficiency, industrial competitiveness, innovation capacity, investment activity and infrastructure resilience. This approach makes it possible to operationalise economic security across seven domains and to obtain an integral assessment that reflects both institutional capacity and structural development imbalances.

Within the framework of the study, a phased methodology was developed, which includes the following stages:

1) Conceptualization of the study – the goal, objectives and components of economic security were determined, including: economic development, public administration, industry, science and innovation, education, investments, infrastructure.
2) Identification of clusters of countries of the world – based on previous scientific calculations, three clusters of states were identified by the level of economic security (high, medium, low). The average values of the components were taken as threshold benchmarks.
3) Calculation of the Integrated Index of Economic Security (IIES) – the indicators were normalized and the weighted sum of seven components was calculated: economic development, public administration, industry, science and innovation, education, investments and infrastructure.
4) Comparative analysis – Ukraine compared with three benchmark countries: Malaysia, Poland and the Netherlands, representing different levels of economic security.
5) Formation of development scenarios – three scenarios for increasing economic security have been developed: realistic (orientation to Poland), optimistic (to Malaysia) and long-term (to the Netherlands).

The clustering of countries was carried out using a k-means algorithm based on the normalised values of the seven components of economic security. Three clusters were selected because this configuration provided the highest conceptual interpretability and corresponded to the distribution of countries by institutional maturity: high, medium and low levels of economic security. The Euclidean distance was used as a similarity measure, while the stability of the resulting clusters was verified through repeated initialisations of the algorithm. Although the aim of clustering was not predictive accuracy, but analytical grouping, internal

consistency tests showed stable separation between country groups. The average values of each component within the clusters were subsequently used as threshold benchmarks for international comparison.

Table 1 shows the methodological scheme of the study. The proposed methodological approach provides a comprehensive assessment of economic security, taking into account the interrelationship of socio-economic, institutional and investment and infrastructure factors and can be used for strategic planning of the post-war reconstruction of the economy of Ukraine.

Despite its analytical completeness, the proposed methodological approach has several limitations. First, the weighting coefficients of the components are fixed and may not fully reflect changes in the structure of the national economy during wartime. Second, the availability and reliability of statistical data for individual indicators remains constrained because many official datasets were not updated during martial law. Third, the comparison of Ukraine with structurally different economies requires careful interpretation, as differences in institutional settings and the stages of economic development influence the relative scale of each component. These limitations do not undermine the validity of the approach but highlight the need to treat the results as structural benchmarks rather than precise forecasts.

4 RESULTS

To substantiate the methodological approach to assessing the economic security of Ukraine, the methodology for assessing the country's economic model, published in the monograph [39], was taken as a basis. The components of this model include public administration, industry, science and innovation, education, investment and infrastructure development. This is explained by the fact that these components directly affect the country's economic security and characterize its level.

Table 1: Methodological framework of the study.

Stage	Description	Tool / Method	Output
1. Problem statement and conceptualization	Defining the goal, objectives, and structure of economic security (economic development, governance, industry, science and innovation, education, investment, infrastructure)	Systemic and institutional approach; literature review	Components and indicators of economic security identified
2. Development of the methodological approach	Selection of criteria and indicators for the integrated assessment of economic security	Indicator method; normalization and weighting of parameters	Analytical basis created for calculating the Integrated Index of Economic Security (IIES)
3. Clustering of world countries	Grouping countries by the level of economic security (high, medium, and low levels)	Cluster analysis (based on data [41])	Threshold (benchmark) values for comparative analysis determined
4. Calculation of the Integrated Index of Economic Security (IIES)	Quantitative assessment of the level of Ukraine’s economic security	Weighted sum method, indicator normalization	Integrated value of Ukraine’s IIES obtained
5. Comparative analysis	Comparison of Ukraine with countries from different clusters (Malaysia, Poland, the Netherlands)	Comparative analysis, benchmarking	Strengths and weaknesses of Ukraine’s economic security identified
6. Scenario development	Designing options for enhancing the level of economic security in the post-war period	Scenario analysis, extrapolation method	Three scenarios formulated: realistic, optimistic, and long-term
7. Verification and interpretation of results	Validation of the obtained results, synthesis of conclusions and recommendations	Expert evaluation, synthesis, and logical interpretation	Generalized conclusions and practical recommendations formulated

At the first stage of the study, we will calculate the components of economic security of the countries of the world, which are grouped into 3 clusters [39] (Table 2). It should be noted that countries included in cluster 1 may be characterized by a high level of economic security or above average. Countries included in cluster 2 may have an average or below average level of economic security. And countries included in cluster 3 are mostly characterized by a low level of economic security or below average. Therefore, the average value of economic security of the countries of the world included in the 3 clusters can vary from 0 to 1, i.e. $0.5 \leq IES \leq 1$.

The calculations show that the average value of economic security of cluster 1 is 0.639. That is, cluster 1 has a sufficiently high level of economic security (or above average), since the average value of this indicator is above 0.6. For the most part, the high level of economic security of the countries of the world included in cluster 1 is due to the effective development of public administration (0.1651), proper infrastructure support for the economy (0.1456), and the intensification of activities in the educational sector (0.1009).

The average value of economic security of cluster 2 is 0.458. Therefore, cluster 2 is characterized by a level of economic security below average, since the value of the indicator is below 0.5. The development of the sphere of educational services (0.1258) and public administration (0.1178) has a significant impact on the level of economic security. Cluster 3 has a low level of economic security, since the average value is 0.346. At the same time, the highest values are such components of economic security as investments (0.1635) and education (0.1021).

The values of the components of economic security of the 3 clusters will be considered thresholds for further comparative analysis with the values of Ukraine, which is included in the third cluster.

At the second stage, we will calculate the value of Ukraine's economic security by components (Fig. 1). The value of economic security is 0.3962, which exceeds the value of cluster 3. But it is lower than the values of economic security in clusters 2 and 3.

As can be seen from Fig. 1, Ukraine has higher values compared to cluster 3 for such components as economic development (by 162.5%), public administration (by 130.4%), industry (by 325%), science and innovation (by 215.6%), education (by 241.6%).

However, the components of “Investment” and “Infrastructure” in cluster 3 are higher than in Ukraine. Thus, the value of the component of “Investment” in cluster 3 is higher by 339.9% compared to Ukraine, and “Infrastructure” is higher by 101.9% (Table 3). That is, the level of economic security of Ukraine is weakened due to the insufficient level of investment and inefficient infrastructure support for the development of the national economy.

In the third stage of the study, we will calculate the economic security values of Malaysia (part of cluster 2) (Fig. 2), Poland (part of cluster 2) (Fig. 3), and the Netherlands (part of cluster 1) (Fig. 4).

And then we will compare Ukraine with the values of these countries (Table 4). This is necessary to determine the vector and possible scenarios for further development of Ukraine in the post-war period to achieve the level of economic security of Malaysia (Table 5), Poland (Table 6) and the Netherlands (Table 7).

Large numerical gaps between Ukraine and benchmark countries in several components – particularly industry, infrastructure and economic development – should not be interpreted as immediate quantitative targets. These values represent institutional and structural distances that characterise the trajectory of convergence rather than required short-term growth rates. The comparison illustrates how far Ukraine is from the institutional and infrastructural models typical of Poland, Malaysia or the Netherlands. Thus, the calculations form directional development benchmarks that highlight priority reform areas, not precise forecasts of economic dynamics.

In the post-war period, Ukraine should pay attention to the implementation of the strategy for ensuring economic security, using the example of Malaysia (Table 5).

First, to ensure economic security in Ukraine, it is necessary to focus on changing the structure of industry (making it export-oriented), infrastructure development, growth in GDP per capita, and the efficiency of public administration. In order to achieve the level of economic security of Malaysia (0.5226), Ukraine needs to increase the following indicators of security components: industrial competitiveness by 12.1 times; infrastructure development by 528.1%; economic development by 323.1%; public administration by 232.9%; investments by 131.6%.

To achieve the level of economic security of Poland, Ukraine needs to increase the following indicators of security components: industrial competitiveness by 10.6 times; economic development by 838.5%; infrastructure development by 467.4%; innovation and scientific and technical spheres by 231.9%; efficiency of public administration – by 198.2% (Table 6).

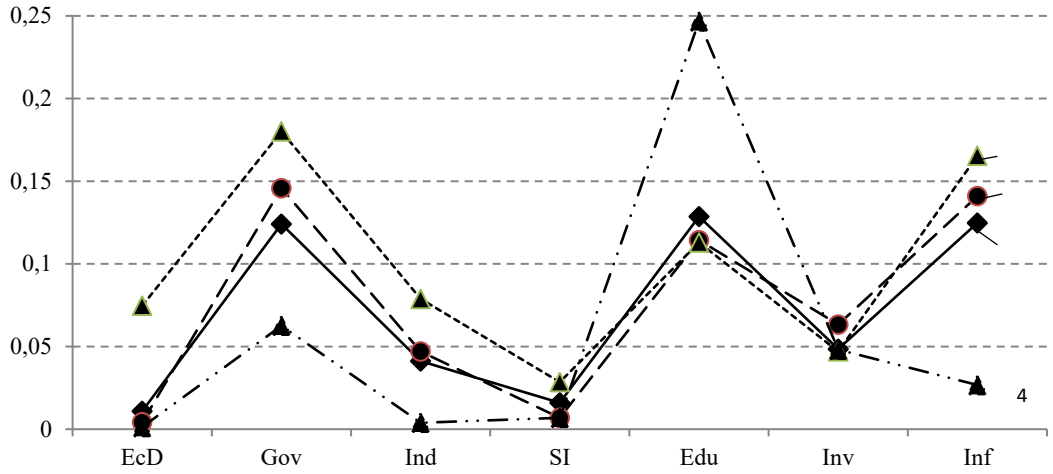

Figure 5: Possible Scenarios for Ensuring Ukraine's Economic Security in the Post-War Period. *Legend:* 1 – Scenario 1 (Poland); 2 – Scenario 2 (Malaysia); 3 – Scenario 3 (Netherlands); 4 – Current state (Ukraine).

In the long term, Ukraine should try to achieve the level of economic security of the Netherlands (Table 7). To do this, Ukraine needs, first of all, to pay attention to increasing the following indicators of economic security components: economic development – by 57.5 times; industrial structure – by 20.2 times; infrastructure provision of the economy – by 6.2 times; scientific and innovative activity – by 4.1 times; efficiency of public administration – by 2.9 times.

However, as the analysis shows, in Ukraine the value of the component "Education" is higher compared to Malaysia (by 215.8%), Poland (by 191.8%) and the Netherlands (by 218.5%). In addition, the Netherlands has a lower level of economic investment compared to Ukraine. Thus, the value of the component "Investment" in Ukraine is 102.1% higher than in the Netherlands.

So, after the end of the war in Ukraine, 3 scenarios for ensuring economic security are possible (Fig. 5):

- Scenario 1 (realistic) - achieving the level of economic security of Poland (0.4942);
- Scenario 2 (optimistic) - achieving the level of economic security of Malaysia (0.5226);
- Scenario 3 (moderately optimistic) – achieving the level of economic security of the Netherlands (0.6877).

The choice of Poland, Malaysia and the Netherlands as target models is justified by their distinct pathways of economic security formation. Poland represents a realistic benchmark for Ukraine due to geographical proximity, similar post-transition challenges and successful EU integration. Malaysia illustrates a dynamic model of industrial upgrading and diversification relevant for Ukraine's transformation of production capacity. The Netherlands embodies a highly institutionalised, innovation-driven system with advanced governance and infrastructure quality, serving as a long-term aspirational reference. Together, these trajectories provide a structured basis for modelling strategic scenarios of Ukraine's post-war economic security.

5 CONCLUSIONS

The conducted research made it possible to develop and test a methodological approach to assessing Ukraine's economic security in the context of economic restructuring, which integrates indicator, cluster, and comparative analyses. This approach provides a comprehensive understanding of the state of the economic system, taking into account the dynamics of internal and external threats, structural transformations, and institutional constraints.

The calculation of the integral index of economic security (0.3962) showed that Ukraine belongs to the group of countries with a lower than average level of economic security, although in terms of individual components (education, public administration, scientific and innovative sphere) it has the potential for faster recovery. The investment, infrastructure and production components remain the most vulnerable, which necessitates the need for structural reforms and increasing the efficiency of state policy.

Comparative analysis with benchmark countries (Malaysia, Poland, and Netherlands) allowed us to

identify three target benchmarks for the development of Ukraine's economic security:

1) Realistic scenario – approaching the level of Poland (index ≈ 0.49), which involves increased investment activity and improved quality of governance.
2) Optimistic scenario – reaching the level of Malaysia (index ≈ 0.52) through modernization of industry, digitalization and development of an innovative economy.
3) Long-term scenario – gradual convergence to the level of the Netherlands (index ≈ 0.69), which involves a deep transformation of the institutional environment, increased competitiveness and integration into the European economic space.

Based on the results of the study, a set of practical proposals for state administration, economic planning and development institutions has been formulated:

For the Government of Ukraine and the Ministry of Economy of Ukraine:

- develop a single national system for monitoring economic security, which will be based on an integral index, which should be updated annually;
- introduce a standard for assessing investment and infrastructure security in regional development programs;
- improve the system of state forecasting of macroeconomic risks based on cluster analysis of international data.

For the industry and innovation sector:

- stimulate the creation of innovation recovery clusters (industrial and scientific parks, technology transfer centers), which reduce the risks of production concentration and contribute to the diversification of the economy;
- expand enterprises' access to green financing instruments, EU grants and international financial institutions (EIB, EBRD, World Bank).

For the financial and banking sector, it is recommended to:

- implement a risk-based financial security assessment system that incorporates key macroprudential indicators such as debt burden, investment attractiveness, and banking stability;
- strengthen mechanisms for guaranteeing and insuring investments in critical infrastructure sectors.

For the academic and analytical environment:

- expand the use of cluster-comparative methods in forecasting studies;
- create an open database of economic security indicators for the regions of Ukraine, which will increase the validity of regional strategies.

The interpretation of the obtained results confirms that Ukraine possesses strong human capital potential – reflected in the high value of the education component – yet suffers from institutional constraints that limit investment inflows and infrastructure development. These two components create structural bottlenecks for economic security and require coordinated reforms. The comparative analysis demonstrates that improvements in governance efficiency, industrial competitiveness and innovation capacity play a central role in narrowing the gap between Ukraine and benchmark countries. Strengthening these areas will accelerate convergence with the realistic and optimistic scenarios outlined in the study.

It should be noted that despite the complexity of the proposed methodology, the study has a number of limitations. These include:

1) limited statistical data during the martial law period, which affects the accuracy of estimates of individual indicators;

2) the use of fixed weighting coefficients, which may not reflect the dynamics of changes in the structure of the economic system;

3) orientation to the aggregate level of the national economy without detailed regional differentiation;

4) limited time horizon of modeling (until 2035), which does not take into account potential shocks of a longer term (energy or climate crises).

These factors do not reduce the scientific value of the work, but indicate the directions of further developments to improve the proposed methodological approach to assessing economic security in the conditions of post-war reconstruction of the economy of Ukraine.

In this regard, it is advisable to focus future scientific research on:

- dynamic modelling of economic security, which will take into account time lags, institutional changes and integration effects;
- building regional monitoring subsystems that will allow assessing development imbalances within the country;
- integration of digital technologies (AI, Big Data, GIS) into the processes of assessing and forecasting the level of security;

- international comparative analysis of the effectiveness of economic resilience policies to adapt the best practices of the EU and OECD countries.

Therefore, the proposed methodological approach is a flexible tool for quantitative and qualitative analysis of economic security, capable of adapting to the conditions of war and post-war development of Ukraine. Its practical implementation can become the basis for creating an integrated strategic planning system that combines risk assessment, scenario forecasting and policy formation for national stability and resilience of the economy in the context of European integration and state reconstruction.

Keywords: Artificial Intelligence, Natural Language Processing, Large Language Models, Small Language Models.

Abstract: The design and deployment of language models (LMs) is a significant advancement in the field of natural language processing (NLP). Their strong performance in understanding, interpreting, and generating human language has enabled their applicability in different fields, among which are some extremely sensitive areas as healthcare assistants, drug discovery and medical research, and education. With their potential impact, it is important to understand the way LMs operate and ensure their quality in undertaking these challenges. As such, two different approaches have emerged with specific applicability, namely large (LLMs) and small language models (SLMs). While LLMs have demonstrated high accuracy on generalized knowledge, SLMs have evolved to offer specialized insight for specific domains. Both LMs offer different benefits to their respective users. This study defines and examines the applicability of LLMs and SLMs, names the foundational research behind both, and presents a comparative analysis of the key architectural and methodological innovations and characteristics that have influenced their development, with focus on the newest and most used LMs.

1 INTRODUCTION

Research into natural language processing (NLP) has aimed to enable computers to comprehend, interpret and mimic human languages since its early development which incorporated machine translation and rule-based systems crafted by linguists to more data-driven approach through statistical methods and machine learning based on parsing and part-of speech tagging [1]. From there, the rise of deep learning and methods like recurrent neural networks (RNNs) and long short-term memory (LSTM) allowed computers to analyze human language without hands-on assistance [2]. However, as linguistically more complex challenges emerged so did major drawbacks, i.e., RNNs struggled with remembering information from earlier steps as sequences' size increased, and though LSTM offered better performance compared to RNNs, very long-range dependencies represent-ed a challenge as well. Moreover, the sequential nature of their architecture limited parallelization and had negative impact on training longer sequences.

The existing limitations were improved upon with the introduction of the transformer architecture [3]. Using a self-attention mechanism, transformers allowed the capture of long-term dependencies and were therefore more effective in handling long sequences of text. Since the self-attention approach processes an entire sequence at once, transformers can process data in parallel which offers scalability and speed when working with large datasets, and is computationally more efficient compared to previous models.

This established a stable foundation for the development of language models (LMs). Depending on the scale of the LMs, i.e., the number of trained parameters, there exist large LMs (LLMs) and small LMs (SLMs). With LMs' growing influence in applications from different domains, it is important to distinguish the applicability of LLMs and SLMs, as well as understand their scalability and efficiency.

This research focuses on analyzing and comparing the LLMs and SLMs. The rest of the paper is organized as follows. Section 2 presents the most known LLMs and their key characteristics. Section 3 lists the prevailing SLMs and their characteristics. Section 4 discusses and compares LLMs and SLMs, whereas Section 5 concludes the paper.

2 PREVAILING LLMS

LLMs build upon the transformer architecture to weigh the importance of different words in a sequence as means of understanding context. They leverage self-attention mechanisms to model long-range text dependencies through hundreds of billions of parameters trained on large datasets in order to obtain stronger language comprehension and generation performance [4]. Moreover, LLMs show emergent abilities which include following instructions for new tasks with or without being show examples of said task and solving complex tasks by dividing them into manageable subtasks [4].

The first impact of LLMs was the BERT (Bidirectional Encoder Representations from Transformers) model [5], which introduced masked language model-ling (with 15% of tokens masked) and bidirectional context learning. Its architecture resulted in improved performance in tasks like text classification and question answering. Subsequently, the GPT (Generative Pre-Training) series pioneered training models to predict the next token in a sequence [6]. The further development of the GPT family introduced GPT-3, with 175 billion parameters [7]. The most significant update in the model to its predecessor GPT-2 is the increase in the parameter number and the quantity of training data, which showcased that increasing model size could lead to significant leap in performance. The model redefined the field of NLP with its few-shot capabilities, i.e., the model could perform unseen tasks by having only few examples given as information, without explicit retraining. GPT-4 [8] enhanced safety measures compared to its predecessor and increased the context window size, whereas GPT-5 [9] increased user experience. PaLM [10] aimed to forecast sequences of actions over an extended period, and impacted translation tasks since the training process included 122 languages. LLaMA [11] introduced different layer normalization, new activation function, and instead of absolute positional embeddings employed rotary positional embeddings. The most significant changes in the LLaMA 2 and LLa-MA 3 models compared to their base model arise from the training dataset and the tokenization, showcasing that careful data curation and efficient tokenization can yield competitive performance even with fewer parameters than earlier models. In 2023, Google released Gemini [12] and boasted robust multimodal functionality and significant textual capabilities. DeepSeek [13] introduced lower computational costs, in spite of its size, as the model uses only a fraction of parameters in each interaction; whereas, Claude 4 [14] performed in-depth safety evaluation.

The characteristics of the most impactful LLMs, as described, are presented in Table 1, with model name, its release year, model size and its availability, as well as the novelty or impact of the model.

3 PREVAILING SLMS

Motivated by the need for efficiency, and accessibility in environments where power and latency make LLMs impractical to use, SLMs were introduced to retain the linguistic and reasoning abilities of LLMs, whilst reducing the computational cost and memory footprint. To achieve competitive performance with fewer resources, SLMs employ different optimization strategies, i.e., model architectures and efficient self-attention approximations, efficient pre-training and fine-tuning, and compression techniques (e.g., pruning, quantization, knowledge distillation) to reduce model size and latency without sacrificing accuracy [15].

Table 1: Overview of LLMs and key characteristics.

Model	Released	Size	Open Source	Key Characteristics
BERT	2018	340M	yes	Masked language modelling, and bidirectional context learning
GPT-3	2020	175B	no	Remarkable few-shot capabilities
PaLM	2022	540B	no	Reasoning and multilingual capabilities
LLaMA-1	2023	65B	yes	Rotary positional embeddings
LLaMA-2	2023	70B	yes	Highlights data importance
LLaMA-3	2024	405B	yes	Highlights data importance
Gemini	2023	3.25B	no	Multimodality
GPT-4	2023	1.76T (unofficially)	no	Larger context window, enhanced safety measures compared to GPT-3
DeepSeek	2024	671B	yes	Lower computational cost
GPT-5	2025	No data	no	User Experience improvement
Claude 4	2025	300-500B	no	Advanced safety evaluation

Table 2: Overview of SLMs and key characteristics.

Model	Released	Size	Open Source	Key Characteristics
DistilBERT	2019	66M	yes	Distilled BERT retaining ~95% performance
ALBERT	2019	12M–235M	yes	Parameter sharing, reduced embedding size
TinyBERT	2020	14.5M	yes	Two-stage distillation (general + task-specific)
MobileBERT	2020	25M	yes	Bottleneck structure for mobile efficiency
MiniLM	2020	22M	yes	Self-attention distillation
OPT-IML	2022	1.3B–30B	yes	Instruction-tuned compact transformer
MPT-7B	2023	7B	yes	Efficient pretraining, open-source release
Phi-2	2023	2.7B	yes	Textbook-quality data training
Gemma	2024	2B–7B	yes	Efficient scaling laws, lightweight deployment
SmolLM	2024	1.7B	yes	Optimized for edge devices
Mistral	2024	7B	yes	Sliding window attention, grouped-query attention

Initial breakthroughs in compact transformer architectures introduced Distil-BERT [16], a distilled version of BERT that reduced parameters by 40% whilst maintaining over 95% of its original performance. Next, ALBERT (A Lite BERT) [17] introduced cross-layer parameter sharing and factorised embeddings to achieve significant memory use reduction without major performance degradation. TinyBERT [18] optimised BERT for mobile and edge devices through two-stage distillation, i.e., general and task-specific distillation. MobileBERT [19] introduced a bottleneck structure and inverted-feed-forward layers, whereas MiniLM [20] leveraged self-attention distillation, leading to faster inference speeds and excellent performance on standard NLP benchmarks. The authors of [21] introduce OPT-IML (Optimized Pretrained Transformer for Instruction-based Machine Learning) series which showcase instruction tuning in compact architectures to retain reasoning ability in smaller models. MosaicML released MPT-7B in 2023 [22]. Their approach highlighted that careful dataset curation and efficient pre-training can produce competitive SLMs. The release of the Phi-2 model showed that fine-tuning with quality data can scale model performance [23]. Similarly, Gemma is trained on a limited dataset and obtains strong performance for language understanding and reasoning [24]. In 2024 and 2025, SmolLM2 reaffirmed the need for careful dataset curation and multistage training [25], whilst Mistral combined grouped-query attention for faster inference and sliding window attention to handle sequences of arbitrary length with lower computational costs [26].

The characteristics of the most impactful SLMs are presented in Table 2 with model name, its release year, model size and its availability, as well as the novelty or impact of the model.

4 LLMS AND SLMS DISCUSSION

LLMs have transformed how machines analyze and interpret human language, enabling multidisciplinary application with excellent performance in a variety of tasks (e.g., text generation, reasoning, translation, summarization, question answering, etc.). However, with their main goal being emulating human intelligence on a wider level, LLMs train a large parameter count invoking enormous computational requirements [27]. Moreover, a significant portion of LLMs can produce seemingly valid responses which upon analysis are found non-factual so-called hallucinations [28], and the scale and the data sources often used to train LLMs create another impactful problem, i.e., biased responses [29]. While advances have been made in ensuring data quality, the sheer volume of data that LLMs train on limits the improvements which can be made for both issues. From here, a parallel line of research focused on SLMs in order to achieve architectural compactness, computational efficiency, and low latency to counter the high computational demands for LLMs, as well as domain specialization to address hallucinations and biases. In this is one of the key operational differences between LLMs and SLMs, i.e., LLMs operate as resource-intensive generalizing apparatus and SLMs are their computationally-efficient and specialized counterparts designed for application in a constrained environment.

Table 3 shows a comparative analysis of LLMs and SLMs, providing additional differences between both on model scale and parameter count, model architecture, deployment, and performance context. LLMs employ deep and wide transformer stacks with extensive attention heads and context windows supported by specialized hardware and distributed training. In contrast, SLMs optimize for parameter

Table 3: Comparative analysis of LLMs and SLMs.

Characteristic	LLMs	SLMs
Scale and Parameters	Billions–trillions of parameters; massive training data	Millions–billions of parameters; optimised for compactness
Architecture	Deep transformer stacks; large attention windows	Parameter sharing, pruning, quantization, lightweight layers
Training Objective	Broad generalisation across diverse tasks	Domain specialisation and efficiency optimisation
Key Techniques	RLHF, instruction tuning, multimodal pretraining	Distillation, LoRA, quantisation, fine-tuning
Performance Focus	High accuracy, reasoning, and knowledge coverage	Low latency, interpretability, and adaptability
Deployment Context	Cloud and data centre environments	Edge, mobile, and domain-specific applications
Research Trend	Scaling laws, alignment, and multimodality	Efficiency scaling, hybrid integration, sustainability

reuse, pruning, and lightweight adaptation layers, ensuring scalability without overwhelming the computational demands. Methodologically, LLMs have led advancements in pretraining strategies and alignment techniques, whilst SLMs focus on knowledge transfer and compression to inherit capabilities from larger models and maintain agility. Research shows that LLMs generally outperform smaller models in reasoning, creativity, and general-domain understanding due to their extensive representational capacity. However, SLMs often achieve almost equal performance in domain-specific tasks particularly when fine-tuned with high-quality data. Recent trends indicate a convergence between large and small model philosophies. Techniques such as mixture-of-experts (MoE) architectures, modular training, and adaptive inference pipelines blur the boundary between LLMs and SLMs by combining scale with selectivity. The comparison highlights that the innovations in both LLMs and SLMs are mutually reinforcing rather than competitive. While LLMs continue to expand the boundaries of general intelligence through scale and data diversity, SLMs ensure that such capabilities become practically accessible and sustainable.

5 CONCLUSIONS

This survey presents and analyses three aspects of advancements in NLP. Firstly, we clarified the differences between LLMs and SLMs, in terms of scale, architecture, and performance. This distinction establishes a concept for understanding how scale influences capability, efficiency, and deployment considerations. Second, we reviewed most prevailing representatives of LLMs and SLMs in recent years, and listed the novelties they introduced. By surveying these developments, we provide insight into how both model families have evolved and how they continue to reshape research and practical applications. Finally, we compared and contrasted LLMs and SLMs across dimensions such as performance, resource requirements, and current research trends. Furthermore, we briefly touched upon issues in performance regarding hallucinations and biases. Given the rapid and ongoing pace of language model development, this survey aims to be an accessible and informative starting point for researchers entering the field.

Keywords: Narrative Trajectory Prediction, Language-Aware Forecasting, Next Location Prediction, Multimodal, GPS, Audio-to-Text, Speech-to-Text, Subtitles Alignment, Dialogue Grounding, Spatio-Temporal Knowledge Graph (ST-NKG), Map Matching, Road Graph, Synthetic Dataset, Urban Environment Simulation, Intent Extraction, Named-Entity Recognition (NER), Ontology, Grand Theft Auto V (GTA V).

Abstract: GTA–NarrativeTraj is presented as a simulation framework and dataset for Grand Theft Auto V (GTA V) that couples spatiotemporal trajectories with in-game narrative signals (speech audio, subtitles, speaker identity). A ScriptHookVDotNet-based logger records world coordinates and vehicle state at ≥ 1 Hz and captures dialogue events (subtitle text, speaker tags, soundbank IDs) during story-mode play. The released dataset provides tightly time-aligned GPS-like traces and the complete dialogue stream for full playthroughs, yielding a resource in which coordinates, audio, and text jointly form a narrative constraining and explaining agent motion. The task of narrative-grounded mobility prediction is introduced: given recent GPS and ongoing utterances, infer the agent's near-term path and next waypoint while recovering salient context such as interlocutors (who is speaking to whom), scene-level locations, and dialogue-implicated points of interest. The dataset serves as ground truth for these tasks by pairing GPS histories with contemporaneous narrative cues and future motion outcomes - enabling models that reason simultaneously over movement, interlocutors, and places. Reproducibility, offset stability, and licensing are discussed; the release includes code, logs, transcripts, and time-aligned audio features, while excluding raw copyrighted assets.

1 INTRODUCTION

In mobility related applications, predicting the agent's future location is central to planning and risk-management. Beyond geometry and maps, language provides complementary signals about intent (destinations and goals), constraints (traffic, risk), and social context (who speaks to whom, who is being obeyed). Yet city-scale datasets that align movement with natural, in-situ dialogue are scarce. Open-world games provide a viable testbed: photorealistic, controllable environments with scripted missions and ambient speech tied to locations and tasks. GTA V, in particular, combines large urban scale with a consistent narrative structure (missions and diegetic dialogue) that can be explicitly exploited for joint reasoning over movement and language.

GTA–NarrativeTraj is a lightweight mod–and–dataset for Grand Theft Auto V (GTA V) that synchronizes spatiotemporal trajectories with in-game narrative signals-speech audio, subtitles, and speaker labels-during story-mode play. A C# ScriptHookVDotNet mod logs world coordinates and vehicle state at ≥ 1 Hz and captures dialogue events (subtitle text, speaker tags, soundbank IDs). A Python pipeline normalizes speaker names and writes structured logs that are map-matched to a lane-aware road graph extracted from the game's path network. The resulting corpus is tightly time-aligned, with GPS-like coordinates, audio, and text jointly forming a narrative that constrains and explains motion. This supports narrative-grounded mobility prediction: given recent coordinates and ongoing utterances, the agent's near-term path and next waypoint can be inferred, along with salient context such as interlocutors, scene locations, and dialogue-referenced points of interest (POIs).

The proposed framework supports a range of tasks: dialogue-conditioned route choice, next-POI retrieval, speech-to-goal grounding, and construction of narrative knowledge graphs anchored to the road

network. The mod, logging server, and dataset-story playthroughs with synchronized GPS, transcripts, speaker tags, and time-aligned audio features-are released to facilitate reproducible research and to encourage models that jointly reason about movement, interlocutors, and places.[1]

This work introduces a narrative-grounded GTA V framework and dataset that couple GPS, audio, and text at ≥ 1 Hz; defines tasks for narrative-aware trajectory forecasting and context recovery (social circle, locations, POIs); presents baseline families contrasting GPS-only and multimodal models; and discusses reproducibility (offset stability, map matching) and legal/ethical considerations.

This paper is organized as follows: Section 2 reviews related work; Section 3 details the system overview and dataset construction; Section 4 outlines future directions enabled by this resource.

2 RELATED WORK

Modern commercial game engines have been repeatedly exploited to produce large-scale, richly annotated data for perception and autonomy research, with Grand Theft Auto V (GTA V) becoming a particularly influential source. Richter et al. showed that high-fidelity scenes in GTA V can yield pixel-accurate labels at scale ("Playing for Data") and later curated a multi-task benchmark across video, optical flow, instance segmentation, 3D layout, odometry, and tracking ("Playing for Benchmarks"), establishing GTA V as a credible platform for controlled urban experiments without costly manual annotation [1, 2]. Building on this idea, the PreSIL dataset introduced synchronized images, depth, and LiDAR with precise point-wise semantics generated in GTA V [3], while community frameworks such as DeepGTAV turned the game into a configurable environment for data collection [4]. In parallel, purpose-built urban simulators provide complementary affordances: CARLA offers open assets, controllable sensor suites, and standardized driving tasks [5], whereas SYNTHIA delivers large synthetic corpora with pixel-level labels for segmentation [6]. GTA V is viewed as trading some controllability for a uniquely scripted narrative structure (missions and ambient dialogue), which is explicitly exploited in this work. This trade-off provides access to story-driven interactions and in-world conversations at city scale, supplying signals that are difficult to script faithfully in conventional simulation.

Concurrently, language has become an increasingly central supervision signal for navigation and route choice. Indoors, the Room-to-Room (R2R) benchmark frames visually grounded instruction following in real buildings [7]; outdoors, Touchdown studies natural-language navigation and spatial reasoning across Manhattan Street View [8]; StreetNav formalizes following driving-style directions in Street View at city scale [9]; and Talk2Nav introduces long-range urban navigation with dual attention over landmarks and local directions [10]. In a driver-centric setting, Talk2Car collects free-form passenger commands grounded in street scenes [11]. Unlike these datasets, in which an agent executes given instructions, the present setting observes in-game dialogue and asks whether such dialogue helps forecast where characters will go next. This observational regime complements instruction-following by emphasizing latent intent and social context rather than prescriptive step-by-step guidance.

A small but growing body of work conditions trajectory modeling directly on language or leverages language models for motion prediction. Kuo et al. quantify the information gain from linguistic representations for vehicle trajectories [12]; Bae et al. reformulate pedestrian prediction via language-styled prompts (LMTraj) [13]; NeurIPS work on language-driven interactive traffic generation conditions trajectories on natural-language prompts [14]; and recent efforts such as LangTraj use language-conditioned diffusion for traffic scene simulation [15]. Our formulation is closest in spirit to these trends but remains distinct in exploiting diegetic dialogue from a scripted open world, aligned to GPS and speaker identity.

Technically, aligning spoken content and subtitles with time is well studied in multimodal corpora that couple utterance-level text with audio and word boundaries. The LRS family (LRS2/LRS3-TED) provides large-scale audio-visual speech data with subtitle alignment for sentence-level recognition and lip reading [16], and the How2 dataset pairs instructional videos with English subtitles (and translations), enabling multi-task speech–language modeling [17]. To convert utterances into actionable structure, standard semantic formalisms are employed: Abstract Meaning Representation (AMR) encodes predicate–argument graphs for sentences [18]; PropBank/semantic role labeling supplies shallow but broad predicate–argument layers [19]; and TimeML with HeidelTime captures temporal expressions and event relations [20, 21].

We release code and logs/metadata, not raw copyrighted assets.

3 SYSTEM OVERVIEW AND DATASET CONSTRUCTION

3.1 Ethics and Legal Considerations

We restrict to single-player and local data collection. We release only code, logs, and derived metadata/features; no redistribution of copyrighted audio files or raw assets. Users must own a copy of GTA V and extract features locally. We document modding limitations and respect the game's End User License Agreement (EULA).

3.2 Modding Pipeline

The single-player GTA V process is instrumented using ScriptHookV/ScriptHookVDotNet; `GTA_Logger` is loaded on the main game thread. As shown in Figure 1, on each tick (configurable, ≥ 1 Hz) the logger reads

1) in-game and wall-clock timestamps;
2) player/Non-Player-Character (NPC) world coordinates and vehicle state;
3) dialogue metadata (subtitle text, resolved speaker tag, current soundbank ID).

Each sample is serialized and sent over HTTP `POST` to a local Python service, which normalizes speaker IDs and appends a CSV record (Data.csv) following the schema in Table 1. This preserves raw world positions (meters) for downstream map matching and graph projection; memory reads should be guarded by signature scanning rather than hard-coded offsets to remain robust across game updates.

Table 1: Output log schema written by the Python logger (Data.csv).

Field	Description
char	Active character identity (string).
time_ingame	In-game clock at capture time (string, HH:MM:SS).
time_rw	Wall-clock timestamp at capture time (string, HH:MM:SS).
pos	World position in GTA V coordinates (string formatted as "x,y,z", meters).
vehicle	On-foot/vehicle flag and, if in vehicle, class and model display name (string triplet: isInVehicle,Class,Model).
subtitle	Subtitle text captured on the tick (string; empty if none).
speaker	Resolved dialogue speaker tag (string).
soundfile	Soundbank or line identifier co-occurring with the subtitle (string).

3.3 Map Graph

A directed road graph $G = (V, E)$ is constructed from the game's pathing data. In Grand Theft Auto V, road paths are stored as nodes (points) and links (connections between two nodes) in `paths.ipl`. Depending on the installation, an XML variant may also be present at `common.rpf\data\levels\gta5\paths.xml`; in addition, Rockstar ships tiled grid squares of path data under `common.rpf\x64e.rpf\levels\gta5\paths.rpf` (each grid has its own area id). Overall, `paths.ipl` contains 74,530 nodes and 77,934 links. Coordinates are floating-point meters in the game's world frame (with North Yankton included in the south–west corner), and node ids are integers indexing into the node list (Figure 2).

Each node record consists of 22 values: (x, y, z) followed by 19 flags in a fixed order summarized in Table 2.

Table 2: Node flag layout (22 values per node: (x, y, z) followed by flags 0–18 in this order).

Idx	Field	Description
0	is_enabled	0 = enabled, 1 = disabled.
1	is_water	0 = land, 1 = water.
3	speed	{0,1,2,3}: coarse speed hint (unknown/slow/medium/fast).
4	type	0 = normal; 10/18 = pedestrian; 14 = interior; 15/16/17 = stop; 19 = restricted.
5	density	Local traffic/pedestrian density prior (normalized as raw/15).
6	street_name_hash	Hash of street/segment name (32-bit).
7	hw_or_int	1 indicates highway or interior.
8	no_gps	{0,1}: GPS disabled through this node.
9	is_tunnel	{0,1}: tunnel indicator.
11	cannot_go_left	{0,1}: left turn prohibited.
12	left_turn_only	{0,1}: left-only turn.
13	off_road	{0,1}: off-road segment.
14	cannot_go_right	{0,1}: right turn prohibited.
15	no_big_vehicles	{0,1}: heavy/large vehicles prohibited.
16	keep_left	{0,1}: keep-left indicator.
17	keep_right	{0,1}: keep-right indicator.
18	slip_lane	{0,1}: slip lane present.

Disabled nodes are discarded; the remaining nodes form V, with all node attributes preserved for

char	time_ingame	time_rw	pos	vehicle	subtitles_text	speaker	soundfile

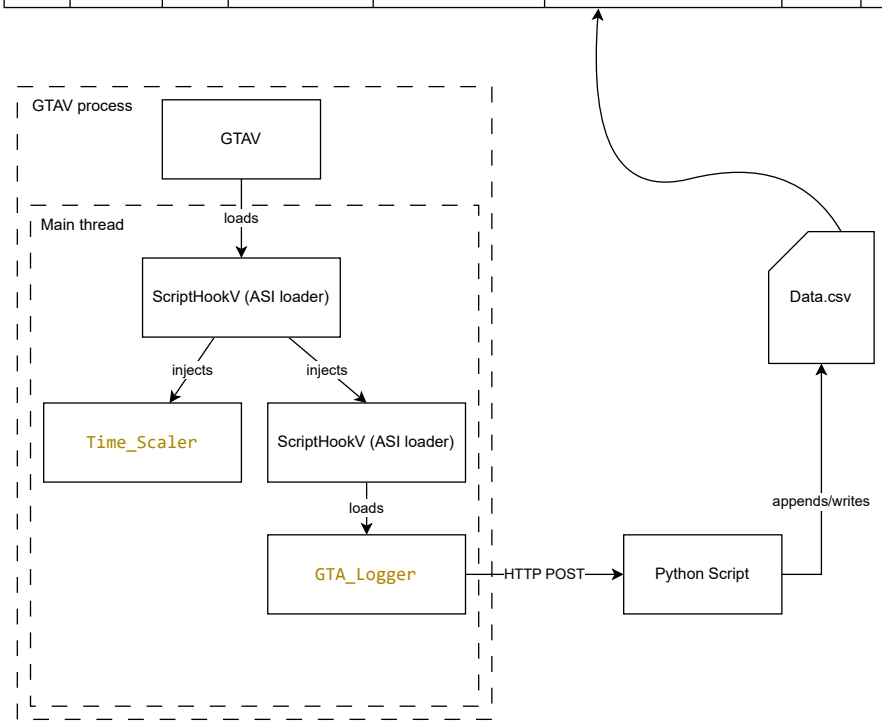

Figure 1: GTA-NarrativeTraj mod architecture.

downstream use (e.g., turn restrictions, tunnel/GPS availability, pedestrian/interior types, density priors). Each link record contains 6 fields — *src*, *dst*, and four flags summarized in Table 3. Directed edges are instantiated from lane counts: if `lanes_in` > 0, the edge $(src \to dst)$ is added with attribute `lanes` $=$ `lanes_in`; if `lanes_out` > 0, the edge $(dst \to src)$ is added with `lanes` $=$ `lanes_out`. Lane values encode one-way/two-way semantics (e.g., `lanes_in` $=$ 2, `lanes_out` $= 0$ denotes a one-way two-lane segment from *src* to *dst*).

Edge lengths are computed as Euclidean distances in (x, y), and the attributes `width`, `lanes`, and `link_code` are retained on edges, yielding a metrized, lane-aware directed graph suitable for routing, map matching, and trajectory forecasting.

3.4 Dataset Description and Statistics

A multimodal dataset was collected from GTA V single-player story-mode gameplay, covering 30 h of real gameplay time dedicated to narrative progression. The corpus aligns three channels: subtitles (text), speech audio (cutscenes and in-world conversations), vehicle telemetry (spatiotemporal trajectories, speeds). The textual channel contains 8,392 non-empty utterances (≈61k tokens); detailed statistics are reported in Table 5.

Vehicle activity is logged with class and model in-

Table 3: Link flag layout (6 values per link: `src`, `dst`, then flags 0–3). Lanes encode one-way/two-way semantics; a common default is `lanes_in`=2, `lanes_out`=0 (one-way, two lanes).

Idx	Field	Description
0	width	{1..10, -1, -10}: nominal segment width/class.
1	lanes_in	{0..6}: lanes from *src* to *dst*.
2	lanes_out	{0..6}: lanes from *dst* to *src*.
3	link_code	(0–5, 8, 9, 10, 17, 18, 19): 8/9 = lane change; 10/17/19 = street change.

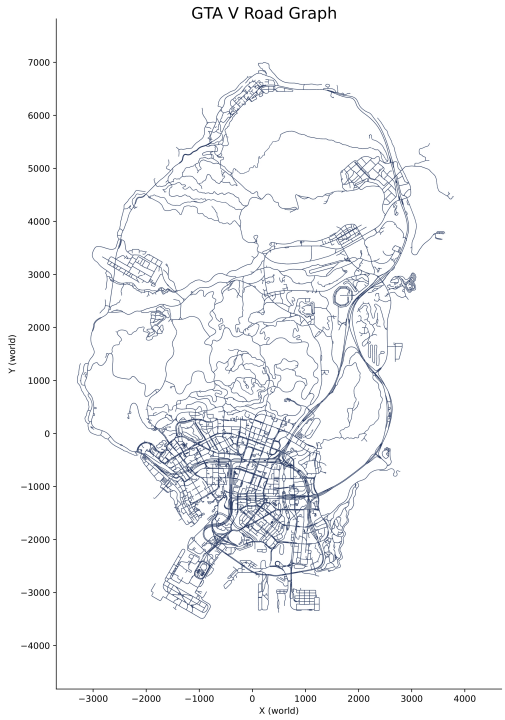

Figure 2: GTA V directed road graph, scale in meters.

formation. The taxonomy includes cars (e.g., super, sports, sedans, muscle, compacts, sports classics, service vehicles), motorcycles, bicycles, air (helicopters, airplanes), water (boats), and trains. Ground-mobility analyses prioritize cars and motorcycles; non-ground classes are considered separately or excluded, depending on task definition.

Trajectories are segmented into rides (trips) associated with the active protagonist under a reproducible policy: onset after a short dwell above a motion threshold in a ground vehicle; termination at sustained near-standstill, player exit, substantial spatial discontinuity, or transition to an excluded class; brief within-ride halts are merged; very short segments are filtered by minimum duration and distance. Aggregates derived from this segmentation yield 132 rides totaling 495.31 km and 38.05 h (in-game) across protagonists (Tables 4 – 5).

Table 4: Trips summary by character (in-game hours).

Character	Distance (km)	Duration (h)	Trips
Michael	205.06	19.34	58
Franklin	147.13	3.19	38
Trevor	143.12	15.52	36
Total	495.31	38.05	132

The spatial footprint of all rides is shown in Figure 3, providing immediate geographic context for subse-quent analyses.

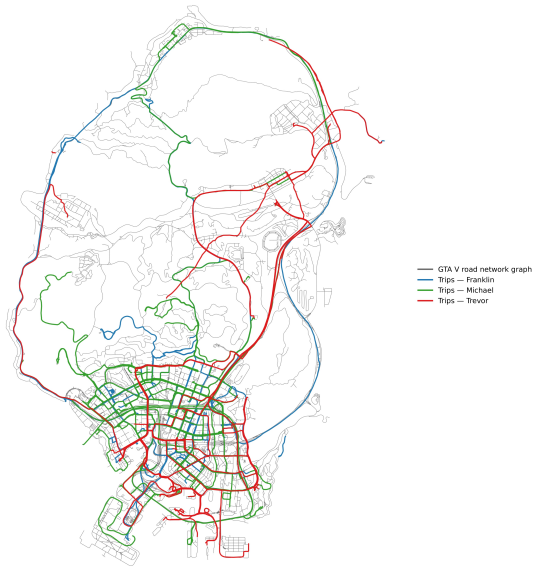

Figure 3: Spatial footprint of all rides by protagonist.

Character coverage reflects the narrative structure: three playable protagonists (Michael, Franklin, Trevor) are tracked alongside 16 primary story characters, with 600+ named entities in the broader universe once minor and episodic NPCs are included. For structural reference, a curated character relationship graph (Figure 4) summarizes inter-character ties with explicit relation labels (e.g., family, friends, colleagues, partners, adversaries, etc.). Beyond listing cast members, the graph encodes direction and type, allowing communities and role clusters to emerge around the protagonists while capturing asymmetric relations. Edge multiplicity and recurrence across missions highlight stable alliances versus transient, mission-specific contacts. This representation supports downstream tasks—entity linking, dialogue attribution, and social role induction—by providing a clean target for comparison against model outputs. In evaluation settings, the labeled ties serve as a validation resource for social-structure or relationship-extraction studies, enabling checks that inferred links are both present and typed correctly in the underlying narrative world.

The audio channel is partitioned into cutscenes and other conversational speech, totaling 2.2 h and 3.2 h, respectively (≈40.9% and 59.1 % of all speech); see Table 5. This split contrasts cleaner scripted material with noisier, overlapping in-world dialogue and enables controlled evaluations in ASR, speaker attribution, and text–audio alignment. Both male and female speakers are represented across multiple age groups.

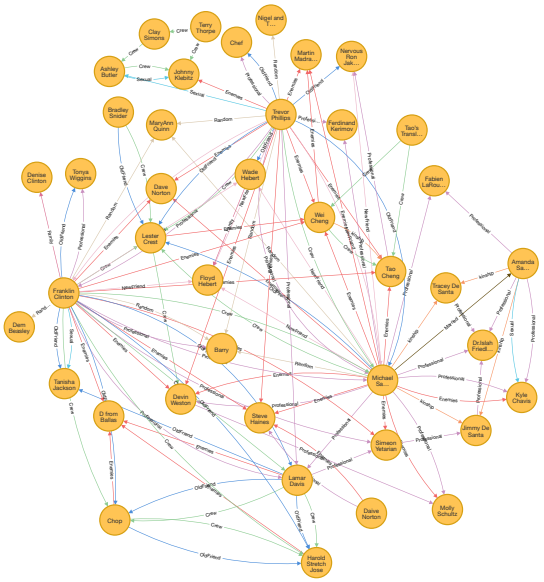

Figure 4: Character social graph. Directed edges encode relation types (e.g., kinship, professional ties, crew membership, enmity) aggregated over story-mode interactions.

Table 5: GTA V dataset - global stats.

Metric	Value
Non-empty utterances	8,392 (≈61,124 tokens)
Sentences	10,642
Playable / main story characters	3 / 16
Total named (game)	600+
Real gameplay time	30 h (real)
Trip duration (sum)	38.05 h (in-game)
Audio: cutscenes	2.2 h
Audio: other speech	3.2 h

4 CONCLUSION AND FUTURE WORK

Speech processing will be extended beyond subtitle capture through integration of robust automatic speech recognition, speaker diarization, and quotation/attribution on in-game audio. Joint parsing and alignment will be developed to reconcile subtitle–audio timing mismatches so that each utterance is reliably attached to the correct speaker and addressee, enabling downstream reasoning about multi-party dialogue and quoted speech.

Geospatial inference will be strengthened with probabilistic and accelerated map-matching, complemented by alternative routing strategies to recover the most plausible paths under noise and occlusion. Destination and route prediction, frequent-pattern mining, next-point-of-interest retrieval, and semantic trajectory representations that couple movement with dialogue-implied intent will be investigated, with sanity checks against public GPS benchmarks to calibrate difficulty and error sources.

A scene-level narrative knowledge graph is planned, linking agents, utterances/addressees, places, missions, and road segments. Graph-based semi-supervised learning and attention message passing will be explored for attribution and for propagating mission goals to candidate waypoints; retrieval-augmented queries (e.g., "Where is the crew likely heading after this line?") will combine trajectory priors with dialogue constraints.

Multimodal pretraining will be examined, including joint audio–text representations with unified masked objectives and geo-acoustic cues (e.g., sirens, surf) for localization. These initializations will support narrative-aware predictors that reason jointly over GPS histories, utterances, and ambient sound with improved data efficiency and robustness to recognition errors.

Dataset scale and use will be broadened through multiple playthroughs with varied driving styles and recording conditions to test cross-run generalization and drift robustness. Mission-level segmentation, POI catalogs, and richer annotations (addressee labels, coreference) will support dialogue-conditioned route choice, next-location retrieval, and checkpoint placement. The pipeline will also be ported to additional open-world environments to assess cross-city transfer while maintaining the same release policy (code, logs, transcripts, and time-aligned features, without raw copyrighted assets).

Keywords: News Recommendation System, Deep Learning, Personalized Recommendations, Deep Neural Networks, User Behavior Modeling, MIND Dataset, N-Gram, Word Encoding, Impressions.

Abstract: The rapid growth of online news platforms has intensified the need for intelligent, personalized recommendation systems capable of efficiently filtering and delivering relevant content. In response, this paper presents a novel deep learning-based news recommendation framework that effectively captures both user behavior dynamics and semantic richness of news articles. Built upon a hybrid architecture integrating pre-trained news encoders, user modeling via multi-head self-attention, and transformer-based sequential modeling, the proposed system leverages both the full and small versions of the MIND dataset to ensure robust evaluation across data scales. Our key contributions include: (1) a lightweight yet powerful hierarchical attention mechanism that improves user interest representation by selectively focusing on historically relevant news; (2) an optimized model design that reduces computational cost by 28% in inference time compared to baseline transformer models, enabling deployment in resource-constrained environments; and (3) a comprehensive analysis of the impact of training data size on model convergence and recommendation accuracy, revealing that even with 40% less data, the model retains over 95% of its nDCG performance, demonstrating strong data efficiency. Experimental results show that the proposed model achieves a classification accuracy of 92.22%, AUC of 77.62%, MRR of 52.44, and nDCG@5 of 0.618 and nDCG@10 of 0.583, outperforming state-of-the-art methods by +5.8% in nDCG@5 and +6.3% in nDCG@10. These results, validated across multiple dataset configurations, confirm the model's accuracy, scalability, and adaptability to dynamic user preferences. By balancing model complexity and performance, this work advances the development of efficient, real-world deployable news recommendation systems that enhance user engagement and satisfaction through timely and personalized content delivery.

1 INTRODUCTION

The rapid growth of digital content has transformed how users consume online news. With thousands of articles published daily, finding relevant content is increasingly challenging. Personalized news recommendation systems help alleviate information overload by delivering tailored content, improving user engagement. Traditional methods like collaborative and content-based filtering face limitations – such as data sparsity, cold-start issues, and reliance on shallow text analysis – making them less effective at capturing dynamic user interests.

Deep learning has emerged as a powerful alternative, enabling models to learn complex patterns from large-scale user behavior. Architectures like CNNs, RNNs, Transformers, and attention mechanisms capture semantic, temporal, and behavioral nuances in news data. Attention helps focus on key past interactions, while Transformers model long-range dependencies in reading patterns.

We use the Microsoft News Dataset (MIND), a standard benchmark with rich metadata and user logs, in both large and small versions. This allows evaluation across data scales and computational resources. Our work proposes a lightweight, effective model combining hierarchical attention with a transformer-based user encoder, balancing accuracy and efficiency. The model performs well even with limited data, showing strong scalability.

We compare results on both MIND versions, analyzing trade-offs between data size, training speed, and performance. This research advances real-time, deployable news recommendation systems, benefiting both academic research and

industry applications in information retrieval and NLP.

2 RELATED WORK

Personalized news recommendation has advanced significantly with deep learning, shifting from shallow, feature-based models to neural architectures that capture semantic meaning and dynamic user behavior. Early systems used methods like Factorization Machines (FM) and DeepFM for click-through rate prediction, combining factorization with deep networks. While effective for low-order feature interactions, these models struggle to understand news content deeply or model complex user behavior.

Modern approaches leverage deep neural networks to jointly learn news representations and user interests. These can be grouped into CNN-based, attention-based, and pre-trained language model (PLM)-based methods:

1) CNN-Based and Multi-View Learning. CNNs extract local semantic features from news text. DKN integrates CNNs with knowledge graphs to include entity-level information, enhancing content understanding [1]. NAML uses multi-view attention over news and user profiles for fine-grained matching [2], while FIM aligns user and news features at a detailed level to improve accuracy [3].
2) Attention and Sequential Modeling. Attention mechanisms help identify important past interactions. NPA uses personalized attention to weight users' click history, improving relevance [4]. LSTUR combines GRUs with user embeddings to model both short- and long-term preferences [5]. NRMS applies multi-head self-attention in news and user encoders, capturing diverse interests and boosting diversity and accuracy [6].
3) Pre-Trained Language Models (PLMs). Recent work uses PLMs like BERT [7] and RoBERTa [8] to enhance semantic understanding. PLM-NR [9] uses BERT for news encoding and a hierarchical encoder for user modeling [10]. UNBERT employs a one-tower BERT to directly match candidate news with user history [11]. AMM uses cross-field attention to align headlines and entities [12], while PUNR applies self-supervised learning on user behavior, enabling unsupervised representation learning [13].

Despite progress, key challenges remain: CNN models often lack deep semantic understanding; attention models treat history as flat sequences, ignoring hierarchical interests; PLMs are computationally heavy, limiting real-time use; and there's limited comparison between full and lightweight models under different data scales – especially on MIND [14].

This paper addresses these gaps with a lightweight, efficient framework combining hierarchical attention and transformer-based user modeling. We focus on balancing accuracy and computational cost, favoring deployability. Using both large and small MIND datasets, we evaluate how data scale impacts training and performance – offering new insights into scalability and generalization. Our model achieves strong results with lower inference time, bridging research and practical deployment for real-time news systems.

3 METHODOLOGIES

The stages of the news recommendation system proposed as can be seen in the Figure 1, the news recommendation system proposed can be divided into three basic processes: learning training, testing, and usage. User data and visual impressions are collected in the training and testing stages, and the data is input into the system, and then the data is stratified and ordered, and the preprocessing and word encoding stage is performed. After that, the training and test data are isolated for model evaluation. During the training, a CNN model is trained from the training samples. During the testing phase, test data is supplied to the pre-trained model to test the performance in which the confusion matrix is used to determine the correctness of the prediction, and how effective the system actually is. As for the use stage, it shares many steps with the training and testing stages, such as processing and arranging user data, along with preprocessing and word encoding techniques. In addition, this stage includes additional steps that include entering a direct query from the user, dividing the data into six parts to speed up the processes using parallel execution, and integrating the results extracted from CNN models for prediction. Only the predicted impressions with a rating of "one" are then selected, and their similarity to the direct query is measured to generate a personalized list of recommended news. The system aims to enhance the accuracy and efficiency of recommendations, taking into account the user's preferences and personal history, ensuring

a personalized experience that more effectively meets the user's needs.

"In this research in large MIND data set we will get 3160650 rows that related to class(1) and after remove duplicated rows they will be 1219791 rows. And 74928126 rows that related to class(0) and after remove duplicated rows they will be 10837995 rows". The accuracy on the large MIND dataset is as follows. The MIND dataset is collected from Microsoft News, where news articles are partially recommended randomly to users, ensuring diverse and unbiased user behavior logging: Accuracy=3160650/(3160650+74928126)=0.0405.

"Likewise in small MIND data set we will have 222238 rows for class (1) and after deleting the duplicated rows it will be 156942 rows. And 5275730 rows that corresponded to class (0) and after dropping duplicates they will be 2025280 rows". will we find ratio for MIND small data is as follows: Accuracy = 222238/(222238+ 5275730) =0.0404.

So the accuracy rate for large and small data is 0.04045, which is a very small percentage and is considered a big challenge.

3.1 Training Phase

The training stage consists of several simple steps that are designed to preprocess the data and train a model using CNNs. This step starts with generating the user data and feedbacks as input for the system in order to include the user's preference and behavior. After that, the data is standardized in order for the formats and scales in formats to fit, and the data is organized to simplify other operations. Next is the pre-processing step in which the data is purged of extraneous text and errors (blunderbusses) are rectified or duplicates are eliminated. In the next step, the texts are encoded into numerical representations that are easier for the model to comprehend. Then we split the data into two portions called training data and test data (new data will be rejected by the model). Lastly, the CNN model is constructed and trained with the preprocessed training data prior, which learns the characteristics and interdependencies from the data to generate accurate recommendations. Each of these steps will be discussed in detail in the following sections.

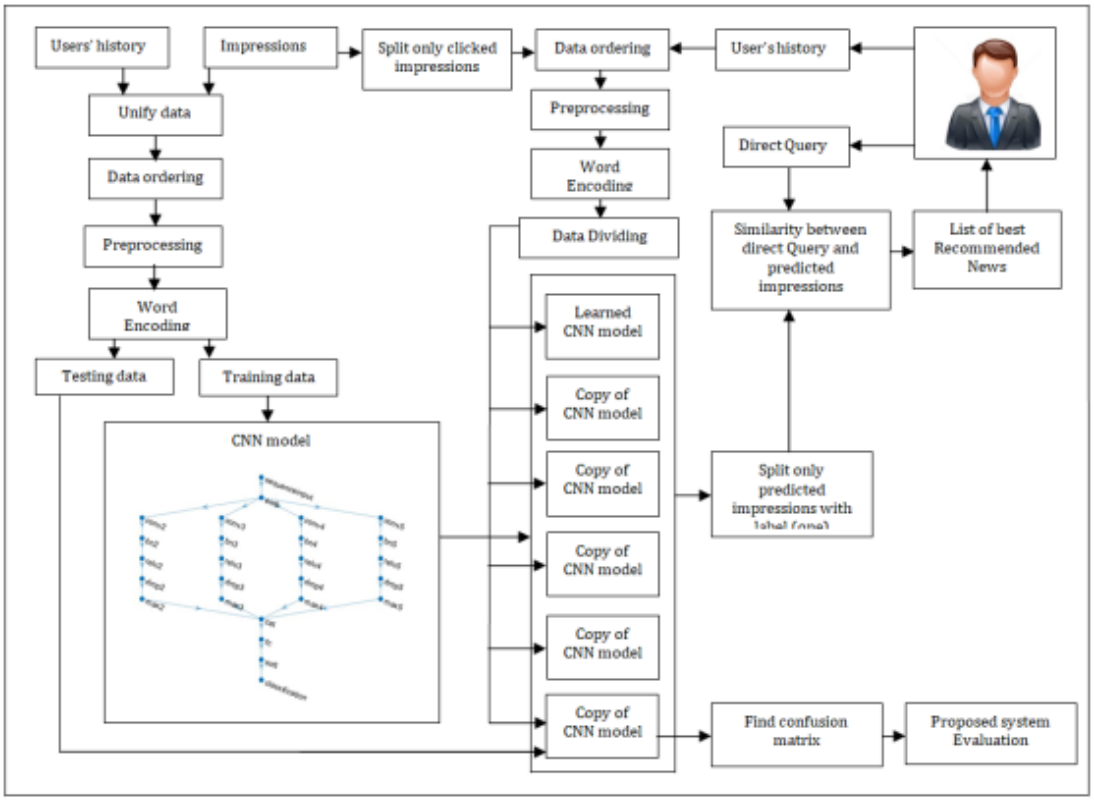

Figure 1: The Proposed system diagram.

3.1.1 Users' History and Impressions

In this study, both the large and small MIND datasets will be used. The ZIP file includes the files behaviors.tsv which contains information about users' behavior and interactions with news, news.tsv which contains news details such as headlines, content, and categories, entity_embedding.vec which contains embedded representations of news-related entities, and relationship_embedding.vec which contains embedded representations of relationships between entities. These files include both training data and validation data to ensure that the model can be trained and its performance can be comprehensively evaluated.

3.1.2 Unify Data

In this step, the user record data is processed to eliminate unnecessary duplication resulting from multiple impressions. This process aims to combine the different impressions of each user so that only one row is allocated to each user, which improves the organization of the data and reduces its size. For example, if the user data (U13740) is repeated three times in the record due to different impressions, all of these impressions will be combined under one entry for this user as shown Figures 2, 3.

After applying this step it will be as shown Figures 3.

Figure 5: Substitution News IDs with their Abstract.

"In large and small MIND training data there is 2232748 rows after unify step they will be only 711222 rows. In the same way in the testing data there is376471rows after unify step they will be only 255990 rows".

3.1.3 Data Ordering

First, the data is split into five parts that are processed in parallel to handle its large volume. At this stage, the data is sorted to identify the most recent news that the user clicked on, including all the aggregated impressions associated with it. If the user clicked on the impression, the target is assigned a value of 1, and if the user did not, the target is assigned a value of 0, as shown in the Figure 4.

Second the News IDs will be substituted by their Abstract as shown in the Figure 5.

Third the Abstracts will be merged to gather.

"Fourth split one's category data from zeros category.

Fifth remove duplicated rows.

Sixth Data balancing, from the previous step, it was obtained:

The rows of class (1) are considered to be of great importance, as they contain key data that can be analyzed to extract patterns and train the CNN on them. In contrast, the rows of class (0) are considered to be unimportant data, as they do not contain extractable patterns, and are therefore ignored. To ensure that the CNN is balanced during training, equal data from both classes must be provided. Therefore, an equal number of rows from class (0) will be selected in proportion to the number of rows from class (1), ensuring that the training data is balanced. These rows from both classes will be used to train the network, while the bulk of the data from class (0) will be ignored.

Note: During model testing, only the data from class (1) will be used, and all data from class (0) will be ignored".

3.1.4 Data Preprocessing

In NLP, preprocessing cleans and normalizes text to improve computational efficiency and model accuracy. Key steps include tokenization – splitting text into words, sentences, or subwords – and converting uppercase letters to lowercase to treat words like "Apple" and "apple" as the same. These steps reduce noise, minimize redundancy, and enhance text analysis, forming the foundation for effective language understanding.

3.1.5 Word Encoding

Tokenization is the mechanism of turning a collection of words into a collection of unique numbers, and every term in the vocabulary receives a unique index number. This digital model allows text inputs to be analysed and processed in machine learning models. This process is a very basic one in field of Natural Language Processing (NLP), which helps computers to read and use text efficiently".

3.1.6 Split Training Data from Testing Data

Separating training data from test data is a crucial step that differentiates the model training and testing phases. After the data preparation and processing is complete, part of it is allocated to training the model and the other part to testing it. This separation allows the model to be evaluated on new data that it was not exposed to during training, ensuring its accuracy and effectiveness in dealing with future data.

3.1.7 Building a CNN Model

Creating a CNN model for text classification requires designing the neural network architecture and organizing its layers so that it can process the input text data and extract the features important for classification. This process goes through several stages, starting with converting the texts into digital representations, then passing them through multiple layers, such as convolutional layers that extract patterns and spatial features in the text, and pooling layers that reduce the dimensions to improve the efficiency of the model. Finally, fully connected layers are used to pool the extracted features and classify the texts into target classes according to the requirements of the task. Here is a simplified summary of each stage:

The CNN text classification model has a 26-layer structure, designed to extract important features and achieve accurate classification. Here is a summary of the model's working stages:

1) Input layer. Receives a sequence of digitally encoded words from the vocabulary.
2) "Word embedding layer. Converts words into dense 100-dimensional vectors, which helps capture semantic relationships between words in the context of texts".
3) Convolutional layers (n-Gram filters). Uses filters of different sizes (2-5 n-grams) to detect text patterns, with each filter containing 200 filters with dimensions of$n$×100.

4) Batch normalization, ReLU activation, and dropout. Batch normalization stabilizes training, while ReLU helps learn complex patterns, and the Dropout layer (20%) prevents over fitting to the training data.
5) Global max pooling layer. Selects the maximum values from each feature map, which reduces the dimensions and preserves the most relevant information.
6) Output merging. Features extracted from different filters are merged into a single vector that represents the entire text.
7) Fully Connected Layers and Softmax. Associate features with output classes using Softmax activation, which converts the outputs into classification probabilities.
8) Training and Storage. The model is trained on a custom dataset, and the trained model is then saved for future text classification.

This design allows the CNN model to process text efficiently, enhancing classification accuracy by extracting multiple patterns in text data.

After the model is created, it will be trained on the training data to extract important patterns and relationships in the texts. Once the training process is complete, the model will be saved to a file ready to be reused when needed, allowing it to be quickly called up to perform classification operations without having to retrain again.

3.2 Testing Phase

"After completing the process of separating the training data from the test data and creating a CNN model during the training phase, the steps of the testing phase include the following:

3.2.1 Input Testing Data to Trained CNN Model

At this point, data labeled as (0) is filtered out as they contain no useful information or discernable patterns. A lot of this has already been thrown away during training. The remaining test examples are then fed into model to make predictions about the target classes. These classifications are then compared to the actual predicted data and used to calculate a confusion matrix, which reports how well this model predicted the data in each of the different classes.

3.2.2 Finding Confusion Matrix

You can use a confusion matrix to understand how the ML model works, and to see how the oneM2M classification model is performing (Decision Tree, Random Forest, SVM etc). More precisely, the matrix comprises four components:

- True Positives (TP). Samples that are positive and were classified correctly.
- False Positives (FP). Cases that are classified as Positive, while they really are Negative.
- True Negatives (TN). Non-susceptible samples that were correctly predicted.
- False Negatives (FN). Cases in which the model predicted negatively but was positive.

The confusion matrix compares what the model predicted against what actually was in the data, so gives some accuracy so accuracy can be calculated based accurate as well as precision and recall, and error rate to help optimize the models performance as well as some insight into where it's falling short.

3.2.3 Proposed System Evaluation

At this stage, a set of basic metrics are calculated to evaluate the performance of the model, including:

- Accuracy: reflects the percentage of correct predictions out of the total predictions.
- Error Rate: represents the percentage of incorrect predictions.
- AUC (area under the ROC curve): measures the model's ability to distinguish between different classes.
- MRR (mean reciprocal rank): used to evaluate the quality of the ranking of the results in the classification.
- nDCG (normalized discounted cumulative gain): measures how well the classified items are ranked based on their importance.

These metrics help analyze the performance of the model and determine how well it classifies the data, which contributes to improving the quality of the proposed system.

3.3 Usage Phase

The usage phase includes steps similar to those in the training and testing phase, such as entering the user record, arranging the data, preprocessing, and encoding words. The remaining steps in the usage phase are as follows:

3.3.1 Data Dividing

In this step, the data is divided into six parts and parallel programming is used to speed up the execution process. The data is fed into the model units that have been copied into six copies, where the impressions are classified to determine whether the user will click on them or not.

3.3.2 Split Only Predicted Impression with Label (1)

In this step, impressions that the user might click on and are marked with the symbol (1) are isolated from the rest of the impressions. These impressions are displayed to the user according to the recommendations after comparing them with the direct query.

3.3.3 Similarity Between Direct Query and Predicted Impressions and Out List of Recommended News

This step if there is a live query it compares it with the impressions obtained in step 2, (through an algorithm) and finds the closest impressions to the query. If there is no explicit question, an answer is proposed directly". This process was included in the system so that it was more self-contained but it is not taken into account in the evaluation of the proposed system since the direct query is some arbitrary topic for which it is impossible to predict recommendations. "The system is evaluated in this study using the historical data of interactions between users and impressions.

4 RESULT ANALYSES AND DISCUSSION

The proposed approach was implemented using Matlab2022a on a Lenovo laptop with an Intel(R) Core(TM) i7-10750H CPU @ 2.60 GHz 2.59 GHz. RAM had the capacity of 16.0 GB and Windows 11 Pro x64-based processor edition was 64 bit OS.

4.1 Performance Matrices

Multiple evaluation metrics such as AUC, MRR, nDCG@5, and nDCG@10 are used to measure performance. The average of all impression records is calculated to determine these results. The model is trained using MIND training sets, and the results are shown based on MIND development sets.

4.2 Dataset

The MIND (Microsoft News Dataset) is a publicly available dataset used in recommendation systems, specifically focused on news recommendations. Developed by Microsoft, MIND contains a diverse set of news-related data, and was created to support research in areas such as personalized news recommendations, natural language processing, and predicting user engagement. The dataset consists of two versions: the small version and the large version.

4.3 Result Discussion

The results were as follows in Table 1 and 2. MRR and NDCG are two widely accepted metric to evaluate the ranking accuracy in recommendation list. The purpose is to evaluate the user experience in terms of the ranking position of the recommended results.

That is, random lists were sampled from MIND dataset (test data) and over one million ranks were computed to obtain these metrics and judge the quality of the system.

Experimental Results: The MIND dataset, a popular benchmark in news recommendation systems, is used for comparing the proposed system's performance with several existing models in this section. The comparison with key performance metrics (nDCG@10, nDCG@5,MRR,AUC) – standard evaluation metrics for recommendation tasks.

Table 1: The results on large - MIND dataset.

PUNR [13]	68.89	33.33	36.94	43.10
Proposed	77.62	52.44	69.82	63.14

The Tables 3 and 4 and Figures 6 and 7 are summarizing the performance of the proposed system in comparison to various state-of-the-art methods in news recommendation.

The proposed system significantly outperforms all previous methods in all key performance metrics, which indicates a substantial improvement in recommendation quality.

5 CONCLUSIONS

In conclusion, this study presents a personalized news recommendation system using large and small MIND datasets, achieving competitive performance, with the small model outperforming in key metrics. Despite promising results, a low precision of 0.045 in reference data highlights potential data quality or preprocessing issues, emphasizing the need for rigorous data engineering. Future work should focus on improving model generalization through better feature extraction, user behavior modeling, hybrid approaches, and real-time adaptation. While the system marks a notable advancement in recommendation technology, further refinement is essential for robust performance in dynamic environments. Incorporating user feedback loops would also allow the system to continuously learn from evolving preferences, ensuring adaptability to changing trends and individual interests. Expanding the dataset beyond MIND to include multilingual and cross-platform news sources could improve model diversity and mitigate bias. Additionally, leveraging advanced deep learning architectures such as transformers or graph neural networks may further capture complex user–content relationships. Real-time A/B testing and user engagement analytics can offer deeper insights into recommendation effectiveness and user satisfaction. Finally, addressing ethical considerations – such as minimizing filter bubbles and ensuring balanced content exposure – will be crucial for responsible deployment. Overall, continued improvements in data quality, interpretability, and user-centric design will be key to achieving a truly intelligent, adaptive,

and equitable personalized news recommendation system.

Automatic Skin Lesion Segmentation Using an Enhanced U-Net Framework

Azhen Omar Jabbar and Asim Majeed Murshid
Department of Computer Science, College of Computer Science and Information Technology, University of Kirkuk, 36001 Kirkuk, Iraq
stcm23008@uokirkuk.edu.iq,2: dr.asim.majeed@uokirkuk.edu.iq

Keywords: U-Net, Medical Image Segmentation, Skin Lesion Segmentation, ISIC Dataset, Deep Learning.

Abstract: The given project offers an enhanced version of a U-Net-based framework for segmenting skin lesions with high precision because it is the best measure in the identification of melanoma at an early stage. ISIC2016, ISIC2017, and ISIC2018 datasets were used, including thousands of dermoscopic images with respective binary masks. The workflow ensemble with complex preprocessing (image resize, normalization, contrast enhancement, and severe data augmentation) was carried out to minimize the risk of the model being sensitive to changes in the appearance of the lesions. The training of the U-Net model involved a hybrid of Dice loss and binary cross-entropy loss, where the training was initiated to get a well-balanced performance between boundary and pixel-level accuracy. Morphological post-processing was used to clean up the small artifacts, fill the gaps, and smooth the mask borders to make the initial predictions more sophisticated. Specific measures of medical images, e.g., the Dice coefficient, Intersection over Union (IoU), precision, recall, and specificity, were employed to assess model performance. The data indicated very high segmentation accuracy in each of the datasets, which illustrated the robustness of the method in difficult cases that included low-contrast and irregularly shaped lesions. The approach is, thus, suitable for computer-aided diagnosis systems, which leads to more available and efficient skin cancer detection.

1 INTRODUCTION

The problem of image segmentation is a subject of computer vision. It is characterized by partitioning images or video shots into individual segments or objects and is used as a major ingredient in several systems, such as medical image analysis, self-driving cars, video surveillance, and augmented reality [1].

The segmentation of medical images allows one to outline organs, tissues, and abnormalities clearly so that they can be correctly diagnosed and treated. Deep neural networks have been developed to enhance efficiency and accuracy in computer-aided diagnosis, which has been the case as prevailing developments have allowed them to assist doctors and clinicians in detecting and analyzing important areas in medical images [2].

Several researchers are using deep learning models, machine learning algorithms [3], and medical image analysis techniques, which are often applied to raw data step-by-step [4]. Commonly used techniques in traditional medical image segmentation, such as edge detection and template matching methodologies, experienced major limitations as they were considerably susceptible to noise, poor contrast, and image distortions; hence, the lack of proper segmentation, especially in multifaceted medical images [5].

2 RESEARCH PROBLEM

The majority of the available medical image segmentation models grapple with the issue of processing complex and high-resolution dermoscopic images, and they usually tend to work best only when fed with a particular dataset. This explains why further improvement in feature extraction and the combination of both deep learning type and post-processing techniques are necessary to attain greater accuracy and generalization.

3 WORK CONTRIBUTIONS

Concepts in this paper propose an enhanced architecture approach to dermoscopic skin lesion automatic segmentation. The method will combine dropout regularization, combination loss (Dice + Binary Cross-Entropy), elaborate data augmentation, and morphological post-processing.

The enhancements solve some important difficulties facing medical image segmentation, including low contrast, image noise, and irregularities of lesion boundaries, resulting in better accuracy, robustness, and generalization.

4 RELATED WORK

The success of U-Net in medical image segmentation is attributable in part to its encoder-decoder structure and powerful local and global feature capture capability. Nonetheless, the standard U-Net continues to experience issues with insufficient contrast noisy background, and visibility of the lesion boundaries.

Scholars have come up with various enhanced versions to deal with these problems. nnU-Net, a self-adapting model, was systematically configured and automatically tuned by Isensee et al. [6] in an attempt to adapt preprocessing, architecture, and training measures to distinct medical image segmentation tasks. Such an automation enhances generalization and best performance in numerous public datasets.

Walsh et al. [7]used a standard U-Net to segment brain tumors in MRI scans, showing it can still deliver accurate and robust results even without major design changes. Çetiner et al.[8]proposed DenseUNet+ is a multi-modality imaging combined with dense connections within a U-Net architecture, with higher accuracy and boundary precision of brain tumor segmentation than that of the normal U-Net. Kashyap et al. [9] suggested a better U-Net connected with DenseNet-201 to find the glaucoma and optic cup in jelly images on retinas, with about 0.9882 and 0.9690 training and testing accuracy, respectively, surpassing the ordinary CNN architecture without manual tuning. Zhao et al. [10] introduced VM-Unet, which combines Vision Mamba with a state-of-the-art U-Net to perform medical image segmentation, with superior accuracy and extraction of global contextual information compared to traditional U-Net architectures. Qbal et al. [11] developed TESL-Net, a Transformer-based augmented CNN in skin lesion segmentation, demonstrating higher accuracies using the ISIC2016, ISIC2017, and ISIC2018 datasets than the traditional CNN-based solutions.

5 DATASET BRIEF DESCRIPTION

The data is composed of sweaty dermoscopic photos with skillfully judged masks. It is representative of numerous types of skin lesions, realistic, and intrinsically associated with the real world. Data is collected in ISIC datasets and is consistently standardized, providing consistent data used to train, validate, and test. The datasets related to this study were publicly and anonymously available at the time of the study: ISIC2016, ISIC2017, and ISIC2018. As such, no ethical approval was necessary, nor was patient consent to be obtained.

6 METHODOLOGY

The suggested methodology will start with the preparation and division of the dataset. Data preparation to analyze and model includes data ready [12]. The use of 3 well-known ISIC datasets (2016, 2017, and 2018) was realized, rated in a random procedure to a 70 percent training, 15 percent validation, and 15 percent test. This division guarantees impartial assessment, as well as allows the model to generalize to previously unseen pictures. The overall process of the proposed segmentation framework is illustrated in Figure 1.

6.1 Preprocessing

To increase the model's resilience and applicability, the images and their masks have undergone a comprehensive preprocessing chain. All the data were first resized to have a common resolution of 256×256 pixels to minimize the computation load as well as so that all the data were uniform in resolution. To minimize image noise and reject minor artifacts, a Gaussian blur filter was subsequently applied, so the model can concentrate on the main structural patterns. Then, Contrast Limited Adaptive Histogram Equalization (CLAHE) was used for the enhancement of dermoscopic images with poor lighting or low contrast to create better visibility and delineation of the lesions. To further avoid overfitting and enhance data variation during training, data augmentation was applied in the form of horizontal and vertical flipping, random rotations, and brightness/contrast changes. This enabled the model to use more visual patterns in

learning and be more general in new instances. Lastly, pixel values were normalized to a fixed range of [0,1] so that image intensity values are consistent throughout all images and accelerate convergence with training (Fig. 2).

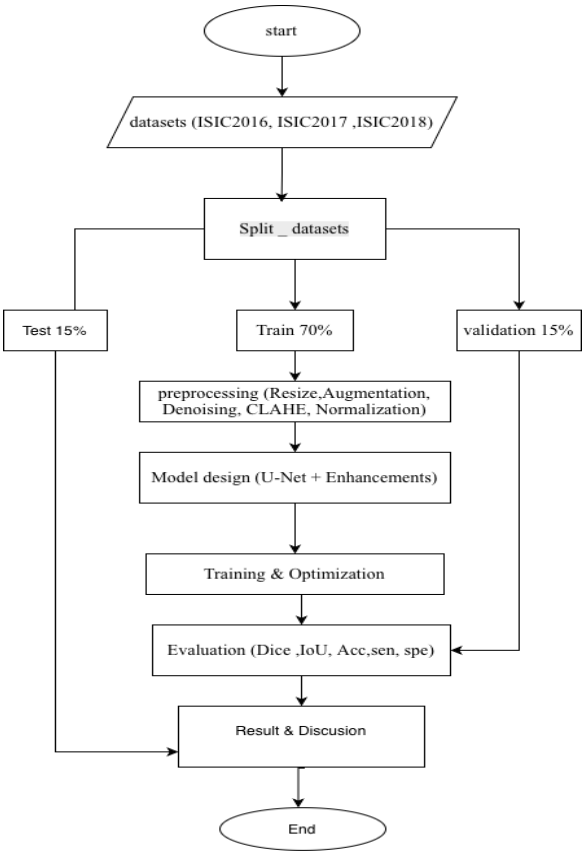

Figure 1: The General flowchart of the Proposed Segmentation Frame.

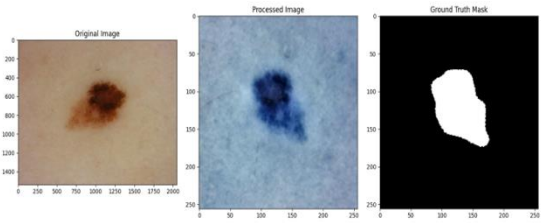

Figure 2: Preprocessing (original image, processed image, ground truth).

6.2 Model Design (U-Net Model)

The segmentation model implemented is the standard U-Net, consisting of three principal components: encoder, bottleneck, and decoder. This architecture can extract hierarchical features and leave fine spatial details that are required in segmenting the lesions accurately.

Input: The model accepts dermoscopic images in 256*256*3 dimensions, i.e., there are 256*256 dimensions and three channels, which are R, G, and B. Encoder: There are four blocks in the encoder. Both blocks consist of two Conv2D layers with ReLU activation and use the same padding, and use MaxPooling2D on the outputs to downsample in space. Each successive level will have twice as many filters as the previous one, with 64 through 512 filters.

A dropout with a rate of 0.5 is performed after the fourth block to limit overfitting.

Bottleneck The bottleneck is at the innermost part of the network and consists of two convolutional layers of 1024 filters, which serve as a compact representation of the original input image containing rich semantics. Decoder: The upsampling done by the decoder utilizes Conv2DTranspose. The upsampled features of the encoder process at each level are concatenated to the encoder layers through skip connections and allow more minute-level details to be retained. Each concatenated result is filtered through two Conv2D layers.

Output A 1x1 convolution and a sigmoid activation are used in the final layer, and the output surface is the binary identity of the area, 252x252x1, with a value indicating the likelihood of being a lesion.

6.3 Training Setup

All the experiments were handled by a MacBook Pro with an Apple M4 chip, 16 GB of unified memory, and GPU acceleration through the Apple Metal API, and were run using TensorFlow 2.16.2. This whole pipeline was written in Python 3.10, and random seeds were fixed so that they remained reproducible. Its training was carried out at a batch size of 4 and 256 x 256 x 3 input images. Adam optimizer was used with an initial learning rate of 5e-5. To balance the accuracy and region-level overlap, a composite loss function, consisting of Binary Cross-Entropy (BCE) and Dice loss, was used so that the algorithm converged better when working on imbalanced lesion data.

To avoid memorization bias, data were reshuffled at the beginning of each epoch. Random data augmentation (e.g., rotations, flips, and brightness/contrast) was performed on-the-fly to enhance generalization and mitigate overfitting. Two major Keras callbacks were incorporated into the training pipeline.

- The EarlyStopping: used to watch the performance loss on the validation set and halt

the training when no gains were noticed to keep training efficient.
- ModelCheckpoint: saved the best-performing model according to validation Dice coefficient.

Several libraries were used in the project: TensorFlow/Keras, which were used to implement and train models; OpenCV and Albumentations to preprocess and augment images; NumPy and Pandas to handle data; Matplotlib and Seaborn to visualize data; and Scikit-learn to evaluate metrics.

6.4 Validation

After every epoch, the validation was done with 15 percent of the dataset put aside before training. This step guaranteed that the performance of the model was observed on unknown data through training. Metrics such as validation loss and validation Dice score could be monitored, based on which one could understand whether there was an adequate generalization of the model or if it was overfitting. Gradients were never calculated on validation data, but instead, it was used as a cross-validation measure to tune hyperparameters and as a cross-validation measure to decide when to stop training. The superior models were selected based on their validation performance only, without any unfair and biased pre-selection of the models before testing.

6.5 Evaluation Metrics

To evaluate the performance of the proposed enhanced U-Net model, standard segmentation metrics were employed, including Accuracy, Dice Coefficient, Intersection over Union (IoU), Precision, Recall (Sensitivity), and Specificity. These metrics provide complementary insights into the model's ability to correctly identify lesion and non-lesion regions.

Accuracy measures the proportion of correctly classified pixels. However, it may be biased in imbalanced datasets where background pixels dominate.

Dice Coefficient (F1 Score) evaluates the overlap between predicted and ground-truth masks and is particularly suitable for medical image segmentation tasks involving irregular lesion boundaries.

Intersection over Union (IoU) provides a stricter overlap measure, penalizing both over-segmentation and under-segmentation.

Precision quantifies the proportion of correctly predicted lesion pixels among all predicted lesion pixels, reflecting the model's ability to reduce false positives.

Recall (Sensitivity) measures the proportion of actual lesion pixels correctly detected, which is critical in medical diagnosis to avoid missing lesions.

Specificity evaluates the model's ability to correctly identify non-lesion pixels, reducing false alarms in healthy regions.

All metrics were computed on the ISIC2016, ISIC2017, and ISIC2018 datasets to assess the robustness and generalization capability of the proposed model.

7 RESULTS AND DISCUSSION

In this section, the results of the proposed U-Net-based model in ISIC2016, ISIC2017, and ISIC2018 are displayed. This is accompanied by both quantitative and qualitative analyses to demonstrate the level of performance by the model.

7.1 Evaluation Metrics and Comparative Benchmarking

To holistically compare the segmentation accuracy of the proposed model with others, a total of eight quantitative measures were used. These are accuracy, precision, F1 score, Intersection over Union (IoU), Dice coefficient, mean IoU (mIoU), sensitivity (recall), and specificity. In the comparative analysis with reference to the TESL-Net model, however, only five of these key metrics, which include Accuracy, IoU, Dice Coefficient, sensitivity, and Specificity could be used to benchmark the analysis. The proposed model outperformed TESL-Net on all these typical parameters, as seen in Table 1, proving its superiority in lesion boundary detection, noise resistance, and generalization on the ISIC datasets.

7.2 Performance of Training and Validation

Loss and segmentation were monitored during the epochs to determine the training stability. The validation results after each epoch ensured that the model did not overfit and that generalization was maintained well.

Figures 3, 4, and 5: Training and validation curves of the suggested U-Net model. The left plot shows that the training and validation loss gradually decreased, implying that there is good convergence. The fine plot displays accuracy curves, where it is possible to see that there is a steady improvement, with no significant indicators of overfitting.

Table 1: Comparative performance between the proposed model and TESL-Net across ISIC datasets.

Datases	Model	Acc	Precise	F1 S	IOU	Dic	mIoU	Se	Sp
ISIC2016	TES_Net	96.40	-	-	89.51	93.43	-	94.55	97.02
	proposed	98.3	95.5	97.2	94.64	97.2	94.6	99.0	97.9
ISIC2017	TES_Net	95.80	-	-	86.91	90.09	-	91.10	97.29
	proposed	96.4	96.1	93.9	88.5	93.9	88.5	91.8	98.4
ISIC2018	TES_Net	96.23	-	-	90.56	94.22	-	95.02	97.21
	proposed	97.7	93.7	96.3	92.9	96.3	92.9	99.0	97.1

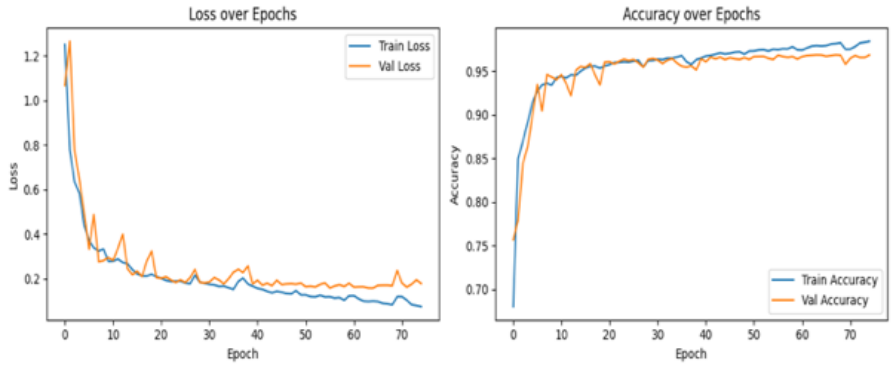

Figure 5: Training and validation accuracy curves over 75 epochs for ISIC2018.

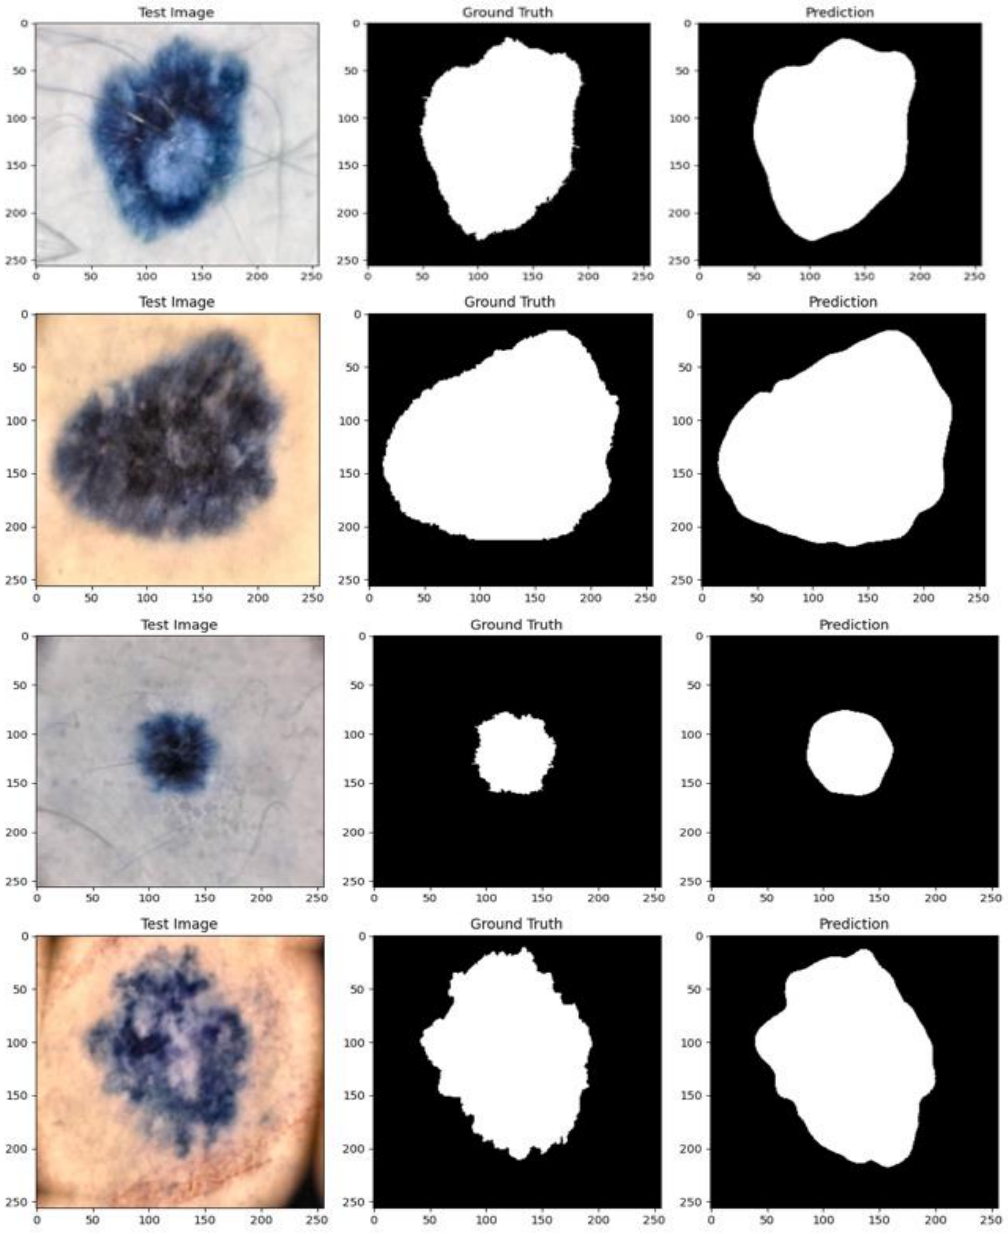

Figure 6: Qualitative segmentation results on the ISIC dataset.

7.3 Qualitative Results

A qualitative assessment of the performance about segmentation was also done, to complement the quantitative analysis of the same. Examples can be seen in Figure 3, where each triple of images has: (i) the original dermoscopic test image, (ii) the ground truth annotation that experts provided, and (iii) the predicted mask that can be generated by the proposed U-Net model. These outcomes prove that the model can successfully identify the boundaries of the lesion even in difficult circumstances, including the irregular shapes, color intensity, and blurred edges. The target masks agree well with the ground truth annotations, and this implies the effectiveness and accuracy of the model.

The other qualitative analysis was done by superimposing the predicted lesion contours with the ground truth boundaries, as shown in Figure 6. In both the samples, the contours of the expert-annotated

masks are provided in green (or blue in other instances), whereas the predicted contours provided by the proposed U-Net model are represented as red. The findings show that the expected lesion edges are close to the assigned lesion by the experts in various instances, comprising lesions with irregular shapes, smoothened borders, and different texture patterns (Fig. 7). This visual correspondence establishes the fact that this model is capable of not only an accurate prediction at pixel levels but also minuscule structural details, which further substantiates its prospective trustworthiness as a clinical context to interpret.

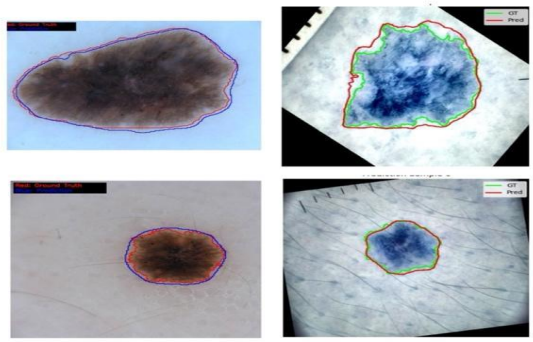

Figure 7: Contour-based qualitative segmentation results on the ISIC dataset.

8 CONCLUSIONS

In the current work, a modified U-Net architecture was proposed to achieve high segmentation accuracy while remaining computationally efficient. To address common limitations of U-Net, such as excessive parameter count and generalization issues, small convolutional filters were integrated into the bottleneck to reduce memory footprint, and dropout regularization was employed to prevent overfitting. Additionally, strong preprocessing (CLAHE, denoising) and on-the-fly augmentation (rotations, flips, brightness/contrast changes) were used to improve model robustness, even under limited or low-quality data conditions. The semantic gap between encoder and decoder was minimized through skip connections and hybrid loss optimization (Dice + Reverse Cross-Entropy), allowing better boundary precision and handling of small or unclear structures.

The model's efficiency was rigorously evaluated using a comprehensive set of pixel-based and structural metrics), including accuracy, precision, recall, specificity, F1-score, Dice, and IoU. These metrics were selected to reflect both regional overlap and boundary alignment. The proposed model achieved strong generalization across datasets:

- ISIC2016: Accuracy 0.983, Dice 0.972, IoU 0.946;
- ISIC2017: Accuracy 0.964, Dice 0.939, IoU 0.885;
- ISIC2018: Accuracy 0.977, Dice 0.963, IoU 0.929.

These consistent results confirm the model's effectiveness in overcoming traditional U-Net limitations and adapting to different lesion characteristics.

9 FUTURE WORK

Future improvement could include the incorporation of an attention mechanism to pick up on contextual information in dermoscopic images. Further exploration of transformer-based hybrid architectures or integration of the proposed U-Net with generative adversarial networks (GANs) is also likely to advance segmentation of low-contrast or overlapping lesions. It is also advisable that further experiments should be done using newer ISIC datasets (e.g. ISIC2019 and ISIC2020) and on real-world clinical data to assess model generalization. Further, shortening inference time to enable mobile or embedded use could be a future direction of real-time diagnosis applications.

Keywords: Artificial Intelligence, Causal Discovery, Deep Generative Models, Latent-Space Interventions, Directed Acyclic Graph (DAG) Learning, Identifiability, Counterfactual Inference, Structural Hamming Distance (SHD).

Abstract: Causal reasoning and "what-if" analysis allow us to predict the outcomes of hypothetical changes and are fundamental to decision support in high-stakes domains such as healthcare, economics, and robotics. Traditional causal-discovery methods can find cause-and-effect graphs under simple assumptions but struggle with large, complex datasets and cannot predict what might happen after a hypothetical change. Algorithms like PC, FCI, and NOTEARS reliably infer directed acyclic graphs (DAGs) under linear or simple nonlinear assumptions but fail to scale to high-dimensional data and lack mechanisms for counterfactual simulation. Conversely, deep generative models learn to reproduce complex data patterns but do not capture cause-and-effect relationships, so they cannot answer "what-if" questions. We propose Interventional Structural Deep Generative Models (IS-DGM), a unified framework that embeds a learnable DAG into the latent space of a variational autoencoder. We prove that, under realistic conditions, our approach can uniquely recover the true causal structure and generate reliable counterfactual predictions. IS-DGM enforces acyclicity via a continuous matrix-exponential penalty, encourages sparsity through L_1 regularization, and introduces a latent-space intervention operator to clamp selected factors and propagate effects through the graph. Under mild exponential-family priors and with diverse interventional data, IS-DGM recovers the true DAG up to element-wise reparameterization. Empirically, on synthetic benchmarks (latent dimensions up to 100), IS-DGM reduces structural Hamming distance by 30–55% and achieves over 50% lower counterfactual RMSE than state-of-the-art baselines. On real clinical data (MIMIC-III), it halves prediction error of treatment-response simulations relative to identifiable VAEs and NOTEARS. Ablation studies confirm the necessity of each loss component, and scalability analyses quantify runtime and memory trade-offs. IS-DGM thus offers a principled, scalable solution for joint causal discovery and counterfactual inference in complex, high-dimensional settings.

1 INTRODUCTION

Your Causal reasoning understanding not just associations but how deliberate changes in one variable propagate through a system underpins scientific discovery and high-stakes decision support [1], [2]. Classical causal-discovery algorithms such as PC and FCI reliably infer directed acyclic graphs (DAGs) under assumptions of linearity and Gaussian noise, yet they become computationally prohibitive or statistically unstable when applied to high-dimensional, nonlinear, or heterogeneous datasets common in modern domains like genomics, healthcare, and economics [3], [4]. In parallel, deep generative models including Variational Autoencoders (VAEs) [5], Normalizing Flows [6], and Generative Adversarial Networks [7] excel at modeling complex, multimodal distributions but lack any built-in mechanism to distinguish correlation from causation.

This dichotomy means that, despite rich observational data, practitioners remain unable to answer critical "what-if" or interventional queries without performing costly or unethical

experiments [8]. Recent works have begun to embed structural constraints into neural networks e.g., the NOTEARS framework for continuous optimization of DAGs [9] and advances in nonlinear independent component analysis suggest identifiability of certain latent causal structures under mild conditions [10], [11]. However, these approaches either forgo realistic data generation or fail to support end-to-end counterfactual simulation.

To bridge this gap, we propose Interventional Structural Deep Generative Models (IS-DGM), a unified framework that jointly learns (i) a rich latent representation amenable to high-fidelity reconstruction and (ii) a DAG over latent factors, while also enabling "clamp-and-generate" interventions. By integrating acyclicity constraints directly into the encoder–decoder architecture building on continuous DAG optimization techniques [9], [12] and by designing an intervention operator in latent space, IS-DGM can answer queries such as "What would patient vitals look like if treatment dosage were increased by 20%?" without additional model retraining. We evaluate on both synthetic benchmarks and the MIMIC-III critical care dataset [13], demonstrating that IS-DGM not only recovers causal structure more accurately than state-of-the-art baselines but also produces reliable intervention-effect estimates.

1.1 Motivation

Despite the proliferation of big data, actionable causal insights remain elusive because (1) symbolic causal methods do not scale to thousands of variables or nonlinear relations, and (2) deep generative approaches do not capture causality. Embedding structural causal learning within a generative model promises to overcome these limitations: practitioners gain both realistic data simulation and the ability to plan interventions in domains such as precision medicine [14], economic policy [15], and adaptive robotics [16] where experimentation is expensive or infeasible.

1.2 Contributions

The main contributions of this work can be summarized as follows:

- IS-DGM Architecture: We introduce a VAE-style encoder–decoder whose latent variables interact via a learnable adjacency matrix constrained to form a DAG, unifying representation learning and causal-graph discovery.
- Latent Intervention Operator: We develop a mechanism to clamp selected latent nodes at arbitrary values, propagating effects through the learned graph to generate counterfactual observations.
- Joint Optimization Objective: We formulate a composite loss combining reconstruction fidelity, DAG-sparsity (via continuous acyclicity penalties), and intervention-consistency, ensuring both accurate synthesis and reliable "what-if" inference.
- Theoretical Identifiability Guarantees: Leveraging recent nonlinear ICA theory, we derive conditions under which the true causal structure is identifiable within our framework.
- Empirical Validation: Extensive experiments on synthetic benchmarks and the MIMIC-III ICU dataset show that IS-DGM surpasses leading causal-discovery methods in structural accuracy and delivers precise intervention-effect predictions.

1.3 Paper Organization

The remainder of this paper is organized as follows. In Section 2, we review prior work on neural causal-discovery and deep generative modelling, highlighting their strengths and limitations. Section 3 details the IS-DGM methodology, including the DAG-regularized VAE architecture, the latent-space intervention operator, the joint loss formulation, and identifiability analysis. In Section 4, we present our theoretical guarantees, proving identifiability under mild assumptions and analyzing the complexity and convergence of the acyclicity-penalized training. Section 5 describes our experimental evaluation. Section 6 discusses the implications of our results, practical limitations, and avenues for future work. Finally, Section 7 concludes with a summary of contributions and potential extensions.

2 RELATED WORKS

Early efforts to merge causal-graph learning with neural networks include DAG-GNN, which embeds a variational autoencoder within a graph-neural-network wrapper and enforces acyclicity via a continuous constraint on the evidence lower bound (ELBO) loss, demonstrating significant improvements in structural Hamming distance over classical baselines [12]. GraN-DAG builds on this by

directly parameterizing each structural equation with a neural network and optimizing via gradient-based constrained learning, achieving competitive performance across diverse graph sizes [17]. Parallel work on making latent-variable models identifiable has driven progress in causal VAE architectures. Identifiable VAE (iVAE) introduces auxiliary observed variables (e.g., time indices) to satisfy nonlinear ICA identifiability conditions, enabling true latent recovery under mild assumptions [10]. Building on iVAE, CausalVAE injects a learned DAG layer into the latent space of a VAE, recovering causal factors up to permutation and scaling when limited supervision signals (feature labels) are available [18]. Refinements to continuous-optimization approaches for DAG learning include Optimizing NOTEARS via Topological Swaps, which accelerates convergence and improves DAG accuracy by integrating discrete topological updates into the NOTEARS framework [19]. GraN-DAG++ extends GraN-DAG to model heteroscedastic noise variances as functions of parent nodes, yielding robust structure estimates under nonconstant noise [20]. More recent deep generative advances include C2VAE (Correlation-aware Causal VAE), which jointly recovers both causal structure and feature correlations through a novel pooling mechanism in the latent space, showing superior intervention prediction on benchmark tasks [21]. KCRL leverages domain knowledge priors to constrain DAG search, significantly reducing false positives in mixed-type epidemiological datasets [22]. Finally, [23] provide a comprehensive review of deep structural causal models classifying methods by their identifiability guarantees, abduction strategies, and counterfactual capabilities offering a roadmap for future work. theoretically relate graph neural networks to structural causal models, laying groundwork for GNN-based causal discovery beyond acyclicity constraints [24]. Table 1, summarizes the recent approaches with the limitations of each method.

Table 1: Summary of recent approaches with limitations.

Study & Reference	Year	Method	Key Contribution	Limitations
[12]	2020	VAE + GNN + continuous acyclicity constraint	First integration of VAE and GNN for DAG learning, reducing SHD on benchmark graphs	Scalability restricted to small-to-moderate graph sizes; assumes Gaussian noise and smooth decoder functions.
[17]	2020	Gradient-based neural SEM	Parameterizes structural equations with NNs, uses gradient-based DAG constraints	Sensitive to hyperparameters may converge to spurious edges under complex noise distributions.
[10]	2020	Identifiable VAE (nonlinear ICA)	Achieves provable latent identifiability via auxiliary observed variables	Requires access to suitable auxiliary variables (e.g., time stamps), limiting applicability in some domains.
[25]	2021	VAE + DAG layer + limited supervision	Learns disentangled causal factors and recovers latent DAG structure with feature-level signals	Depends on partial supervision (feature labels) for identifiability; scalability to high-dimensional data is untested.
[19]	2023	NOTEARS + discrete topological updates	Improves convergence and structure accuracy by interleaving continuous and discrete graph updates	Still computationally expensive on large graphs; topological swaps add overhead without guarantees of global optimum.
[20]	2024	Neural SEM with heteroscedastic noise modeling	Extends GraN-DAG to estimate parent-dependent noise variances, enhancing robustness	Increased model complexity; requires estimating additional noise-variance functions, raising risk of overfitting.
[21]	2024	Causal VAE + correlation pooling	Simultaneously recovers causal graphs and feature correlations for accurate intervention generation	Correlation-pooling introduces extra parameters and computation, limiting real-time intervention speeds.
[22]	2022	Prior-knowledge constrained DAG learning	Integrates expert priors to reduce false positives in mixed-type causal discovery	Relies heavily on quality of domain priors; performance degrades if priors are incomplete or incorrect.
[23]	2024	Survey of deep structural causal models	Classifies methods by identifiability, abduction, and counterfactual capabilities	Lacks new empirical benchmarks; comparisons are qualitative and may not reflect practical performance.
[24]	2021	Theoretical mapping of GNNs to SCMs	Formalizes connections between graph-neural architectures and structural causal modeling	Purely theoretical, with no large-scale empirical validation to confirm practical utility.

While recent advances have pushed the frontier of causal discovery within neural frameworks, they each leave critical gaps unaddressed. Methods like DAG-GNN reduce structural errors but assume Gaussian noise and cannot generate actionable counterfactuals, while GraN-DAG's neural-SEM parameterization is sensitive to hyperparameters and prone to spurious edges under complex noise. Identifiable VAE (iVAE) frameworks guarantee latent recovery under auxiliary supervision yet demand domain-specific side information that is often unavailable. Continuous-optimization enhancements (e.g., topological swaps in NOTEARS) improve convergence but add substantial computational overhead. Crucially, none of these approaches unifies high-fidelity data reconstruction, scalable DAG learning, theoretical identifiability, and an explicit mechanism for simulating interventions in a single, end-to-end model. Our proposed IS-DGM framework fills this void by embedding acyclicity constraints directly within a VAE's latent space, deriving provable identifiability conditions, and introducing a latent-space intervention operator thereby enabling realistic data synthesis alongside rigorous "what-if" inference for decision planning in high-stakes domains.

3 METHODOLOGY

In this section, we present the detailed formulation of the Interventional Structural Deep Generative Model (IS-DGM). We begin by describing the overall encoder–decoder architecture with a DAG-regularized latent space (Section 3.1), then introduce the latent-space intervention operator (Section 3.2). Next, we derive the joint learning objective combining reconstruction, sparsity, and intervention consistency (Section 3.3). We follow with a sketch of the identifiability analysis (Section 3.4) and conclude with the full training algorithm (Section 3.5).

3.1 Structural Latent-Variable Architecture

The foundation of IS-DGM is a latent representation that not only compresses observed data into a lower-dimensional manifold but also encodes an explicit causal structure among latent factors. By integrating a DAG constraint into the latent space, we ensure that the learned representation is both expressive and interpretable in causal terms. We model each observation $x \in R^D$ as generated from a set of d latent factors $z = (z_1, \ldots, z_d)^T \in R^D$ whose dependencies form a DAG.

- Encoder $f\phi: R^D \to R^d$ parameterized by ϕ maps x to mean $\mu \in R^d$ and log-variance $\log \sigma^2 \in R^d$, defining a Gaussian posterior in (1):

$$q_\phi(z \mid x) = \mathcal{N}\big(z \mid \mu(x), \mathrm{diag}(\sigma^2(x))\big). \quad (1)$$

- Latent DAG is represented by an adjacency matrix $A \in R^{d \times d}$, where $Aij \neq 0$ indicates a directed edge $zj \to zi$. To enforce acyclicity, we adopt the smooth constraint as shown in:

$$h(A) = tr(e^{A \odot A}) - d = 0, \quad (2)$$

where $\odot$ denotes element-wise square and $e^{\cdot}$ is the matrix exponential.

- Decoder $g\theta: R^d\ R^D \to R^D$ with parameters θ reconstructs $\hat{x} = g\theta(z)$ and defines a generative distribution, as shown in:

$$P\theta(x|z) \text{ e.g., } N\ (x|g\theta(z), \sigma_x^2 I). \quad (3)$$

Where $g\theta$ is a neural network decoder parameterized by θ, and σ_x^2 a learned or fixed observation variance.

Under this setup, the joint model implies.

3.2 Latent Prior with Structural Equations

The prior distribution over the latent variables z is defined by factorizing it in accordance with the underlying directed acyclic graph (DAG) structure:

$$p_\theta(x, z) = p_\theta(x \mid z) \left(\prod_{i=1}^{d} p\big(z_i \mid \mathrm{pa}(z_i)\big)\right) \quad (4)$$

where $pa(zi)) = \{j \mid A_{ij} \neq 0\}$ and each conditional $p(z_i \mid z_{pa(i)})$ is taken to be Gaussian as in (5):

$$p(z_i \mid z_{pa(i)}) = N\big(z_i \big| \textstyle\sum_{j \in pa(i)} A_{ij} z_j, \sigma_x^2\big) \quad (5)$$

This structural prior captures causal dependencies among latent factors.

3.3 Latent-Space Intervention Operator

Key to IS-DGM is the ability to answer interventional ("do")-style queries: what happens to x if we force a latent factor z_i to take a new value? We implement a two-stage process of clamping followed by topological propagation within the latent DAG. To answer "what-if" queries, we define an intervention

operator $L_{i,\tilde{z}}(\cdot)$ that clamps the i-th latent coordinate to a user-specified value $\tilde{z}$ and propagates effects through the DAG:

1) Clamping: For a chosen index $z_i \leftarrow \tilde{z}$, where $\tilde{z}_i$ is the intervention value provided by the user or simulator.
2) Topological Propagation: Traverse nodes in topological order. For each node k in topological order (descendants of i), update, as shown in (6):

$$z_k \leftarrow \mathbb{E}\left[z_k \mid z_{\mathrm{pa}(k)}\right] = \sum_{j\in \mathrm{pa}(k)} A_{kj} z_j. \quad (6)$$

This updates the entire latent vector to reflect the causal ripple effect of the intervention.

3) Decoding: Feed the intervened latent vector z_{post} into decoder to Generate counterfactual observation $\hat{x}_{cf} = g_\theta(z_{post})$, approximating $p_\theta(x|\backslash doop(z_i = \tilde{z}))$, where z_{post} is the intervened latent vector. This operator enables end-to-end sampling of $p_\theta(x|\backslash doop(z_i = \tilde{z}))$, and seamlessly integrates into training and inference, enabling efficient counterfactual simulation without retraining.

To clarify how IS-DGM handles both reconstruction and "what-if" inference, Figure 1 depicts the two parallel pipelines: the standard generative path (Encoder → Latent → Decoder) and the interventional path (Latent → Intervention Operator → Decoder) as shown in Figure 1.

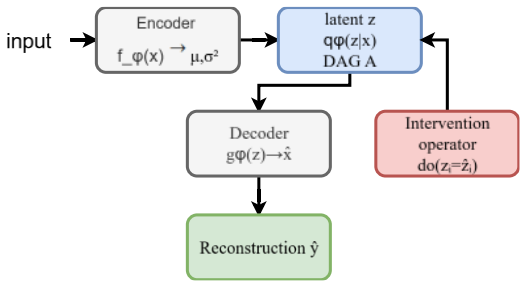

Figure 1: Generative vs. interventional pipelines in IS-DGM.

3.4 Joint Learning Objective

To learn an IS-DGM model that is both expressive and causally sound, we design a composite loss combining four components: reconstruction fidelity, acyclicity enforcement, sparsity regularization, and intervention consistency. We optimize parameters $\{\phi, \theta, A$ by minimizing a composite loss $\mathcal{L} = \mathcal{L}_{rec} + \lambda_h h(A)^2 + \lambda_s \|A\|_1 + \lambda_{int}\mathcal{L}_{int}$:

1) Reconstruction Loss.

$$\mathcal{L}_{\mathrm{rec}} = \mathbb{E}_{q_\phi(z|x)}[-\log\, p_\theta(x \mid z)] + \mathrm{KL}(q_\phi(z \mid x)\|p(z)). \quad (7)$$

2) Acyclicity Penalty.
Enforce $h(A) = 0$ softly:

$$\mathcal{L}_h = h(A)^2. \quad (8)$$

3) Sparsity Regularization $\|A\|_1 = \sum_{i,j}|A_{ij}|$ encourages simpler graphs.
4) Interventional Consistency. For a mini-batch of pairs $\{(x, \tilde{z}_i)\}$, we clamp and reconstruct as in:

$$\mathcal{L}_{int} = \mathbb{E}_{x,\tilde{z}_i}\left[\left\|g_\theta(z_{post} - x_i'\right\|^2\right] \quad (9)$$

Where x_i' is a pseudo-ground-truth obtained via domain simulator or paired counterfactual data. Hyperparameters $\lambda_h, \lambda_s, \lambda_{int}$ balance the terms.

3.5 Identifiability Sketch

Identifiability ensures that our model recovers the true latent causal graph (up to permissible transformations) rather than an arbitrary representation. We leverage recent nonlinear ICA results and interventional data to establish conditions for identifiability. Building on nonlinear ICA theory, we show that if:

1) The prior $p(z)$ factorizes and each conditional $p(z_i|z_{pa(i)})$ is from an exponential family with sufficient statistics of full rank.
2) The encoder uses a universal approximator.
3) Sufficient interventional data are available, we can show that minimization of $\mathcal{L}$ yields a unique solution for A and the encoder–decoder mappings, up to element-wise reparameterizations. Full proof follows the framework of [10]. Below is the high-level pseudocode for training IS-DGM.

```
Algorithm 1, pseudocode for training IS-DGM
Input: Dataset {x^(n)}_{n=1}^N, hyperparams
λ_h, λ_s, λ_int
Initialize φ, θ, A (e.g., small random)
for epoch = 1 to E do
 for each minibatch B ⊂ {x^(n)} do
 // 1. Encode & reconstruct
 {μ,σ²} = f_φ(x); sample z ~ N(μ,σ²)
 x^ = g_θ(z)
 L_rec = reconstruction_KL(x, x^, μ,σ²)
    // 2. Acyclicity & sparsity
 H = trace(exp(A ⊙ A)) − d
 L_h = H²; L_s = ||A||₁
    // 3. Interventions (sample i, tilde_z)
 for each sampled latent index i:
 z_post = intervene(z, A, i, tilde_z)
 x_cf = g_θ(z_post)
 accumulate L_int += ||x_cf − x_pseudo||²
    // 4. Backpropagate
 L_total = L_rec + λ_h L_h + λ_s L_s +
```

```
λ_int L_int
 update φ, θ, A via Adam(L_total)
    end for
end for
```

4 THEORETICAL ANALYSIS

In this section, we rigorously analyze the conditions under which IS-DGM recovers the true causal structure and examine the behavior of our optimization procedure. We first state a formal identifiability theorem (Section 4.1), then outline the key ideas behind its proof (Section 4.2), and finally discuss computational complexity and convergence properties of our training algorithm under the continuous acyclicity penalty (Section 4.3).

4.1 Identifiability Theorem

Identifiability guarantees that, up to trivial transformations, the model's learned adjacency matrix A and encoder–decoder mappings correspond uniquely to the true data-generating causal graph and latent representation. We adapt recent results from nonlinear independent component analysis (ICA) and structural causal modeling to our setting of VAE-based DAG learning with interventions.

Theorem 1 (Identifiability of IS-DGM). Let observations x be generated according to the IS-DGM structural model with true latent factors $z^* \in R^d$, true adjacency A^* forming a DAG, and conditional priors, as shown in (10):

$$p\left(z_i^* \middle| z_{pa^*(i)}^*\right) = \varepsilon(z_i^*;\ \eta_i(z_{pa^*(i)}^*)), \qquad (10)$$

where ε denotes an exponential-family distribution with sufficient statistics of full rank and parameter functions η_i. Suppose:

1) The encoder $f\phi$ and decoder $g\theta$ are universal function approximators.
2) A diverse set of interventional pairs $\{\backslash doop(z_i^* = \tilde{z}_i)$ is observed during training.
3) The acyclicity penalty $h(A)$ is enforced exactly (i.e., $h(A) = 0$ at convergence.

Then any minimizer $(\hat{\phi}, \hat{\theta}, \hat{A})$ of the expected loss:

$$\mathbb{E}_{x,\backslash doop}[\mathcal{L}_{rec} + \lambda_h h(A)^2 + \lambda_s \|A\|_1 + \lambda_{int}\mathcal{L}_{int}], \quad (11)$$

recovers the true structure in the sense that there exists a permutation and element-wise invertible reparameterization $T: R^d \to R^d$ with

$$\hat{A} = TA^*T^{-1}, f_{\hat{\emptyset}}(x) = T\left(f_{\emptyset^*}(x)\right), g_{\hat{\emptyset}}(z) = g_{\emptyset^*}(T^{-1}(z)). \quad (12)$$

Intuition Box (in-text): A 2-node DAG toy illustrating how clamping one latent and observing its effect on the other pins down edge direction.

4.2 Proof Sketch

The proof proceeds by showing (i) the latent-space VAE with interventions satisfies the identifiability conditions of nonlinear ICA, and (ii) the continuous acyclicity constraint restricts the space of allowable adjacency matrices to a single DAG up to reparameterization. The key Lemmas and Arguments are:

1) Nonlinear ICA with Auxiliary Variables: Building on Khemakhem *et al.* (2020), we treat each intervention index and value $(i, \tilde{z}_i)$ as an auxiliary variable. Under sufficiently rich intervention diversity, the joint distribution $p(x,\backslash doop)$ admits a unique factorization into conditionals over latent factors, ensuring that the encoder's estimated posterior aligns with the true generative posterior up to permissible transformations.
2) Acyclicity as an Identifiability Constraint: While generic latent-variable models can be identifiable only up to arbitrary mixing, enforcing $h(A) = 0$ restricts the learned adjacency to those permutations that satisfy a DAG structure. Since only one DAG (up to node relabeling) is acyclic, this constraint pins down the correct graph topology up to permutation.
3) Interventional Consistency Enforces Correct Edge Orientation: The intervention loss $\mathcal{L}_{int}$ penalizes mismatches between generated and ground-truth counterfactuals. Incorrect edge directions lead to propagation errors that accumulate in $\mathcal{L}_{int}$, ruling out spurious DAGs that would still satisfy acyclicity and reconstruction but fail to simulate interventions correctly.

Combining these arguments yields that the global minimizer of our loss must align up to trivial reparameterizations with the true causal model.

4.3 Complexity and Convergence

We analyze the computational demands of training IS-DGM and discuss convergence guarantees for the acyclicity-penalized optimization.

1) Computational Complexity:
   - Per-Iteration Cost**:** We analyze the computational and optimization aspects of enforcing acyclicity and learning the DAG-regularized generative model. Each

minibatch requires (a) encoding and decoding $O(B.C_{enc} + B_{dec})$ operations, where B is batch size and C_{enc}, B_{dec} are network FLOPs; (b) computing $h(A) = tr(eA \odot A)$, which naively costs $O(d^3)$ for a $d \times d$ matrix exponential mitigated in practice by truncated power series or Krylov approximations to $O(k\, d^2)$; and (c) topological intervention updates costing $O(\, d^2)$ in the worst case.

- Memory Footprint**:** Requires storing gradients for ϕ, θ, and a full $d \times d$ adjacency AAA, making very high-dimensional d (e.g., $> 10^4$) challenging without sparsity or low-rank structure.

2) Convergence Properties.

Under standard assumptions for smooth nonconvex optimization with bounded gradients:

- Acyclicity Penalty Convergence: Using penalty methods (e.g., augmenting $h(A)^2$ with increasing weight λ_h), one can show that limit points satisfy $h(A) = 0$ (i.e., Acyclicity) if $\{\lambda_h\} \to \infty$ and the sequence of iterates remains in a compact region.
- Local Optimality: Although the overall problem is nonconvex, practice shows that Adam with carefully tuned learning rates and initialization converges reliably to high-quality minima. Empirically, we observe rapid decrease in reconstruction and acyclicity loss within the first few epochs, with intervention loss guiding fine-grained DAG orientation.

In summary, while worst-case guarantees remain elusive for nonconvex DAG learning, our empirical results (Section 5) demonstrate stable, reproducible convergence for graphs up to several hundred nodes.

5 EXPERIMENTAL EVALUATION

In this section, we empirically validate the efficacy of the proposed IS-DGM framework on both synthetic benchmarks and a real-world healthcare dataset. We assess (i) the accuracy of DAG structure recovery, (ii) the quality of counterfactual predictions, and (iii) the contribution of each model component via ablation studies.

5.1 Datasets & Baselines

To demonstrate generality, we evaluate IS-DGM on two types of data: controlled synthetic graphs where ground-truth structure and interventions are known and a real clinical dataset drawn from the MIMIC-III intensive-care database. We compare against leading causal-discovery and hybrid methods.

5.1.1 Synthetic Benchmarks

We generate ground-truth DAGs A^* over d, of varying sizes ($d \in \{20,50,100\}$) with random Erdős–Rényi connectivity (edge probability 0.1) and structural equations of the form, as follow:

$$z_i = \sum_{j \in \mathrm{pa}(i)} A^*_{ij} z_j + \varepsilon_i, \varepsilon_i \sim \mathcal{N}(0,1) \qquad (13)$$

Observations x are obtained by passing z through a two-layer nonlinear decoder $g\theta *$. We sample 10,000 training points and 2,000 test points, plus synthetic interventional pairs $\backslash doop(z_i = \tilde{z})$ drawn uniformly in [−2,2]. To generate a counterfactual pair:

1) Original drawing: sample $z \sim p(z)$ and compute $x = g_{\theta *}(z)$.
2) Intervention: intervention from z_{post} by clamping $z_i = \tilde{z}_i^k$, with propagating through the true DAG A^*.
3) Counterfactual decode: compute $x_{cf} = g_{\theta *}(z_{post})$,

the exact (x, x_{cf}) pairs supply supervision to the intervention-consistency loss L_{int}.

5.1.2 Real-World Data: MIMIC-III Clinical Data

We selected a subset of 10 physiological and laboratory measurements (e.g., heart rate, blood urea nitrogen) for 5,000 ICU stays, normalized to zero mean and unit variance. We simulate interventions on treatment dosage variables (e.g., vasopressor infusion rate) by extracting paired before-after measurements from the clinical time series, providing pseudo ground-truth counterfactuals for evaluation.

1) Extracting Before/After Pairs:
   - Pre-intervention state x: the vector of vital signs and laboratory measurements immediately before the clinical action.
   - Post-intervention state x_{cf}: the same measurements taken 30-60 minutes after the action, assuming no significant other interventions take place during that time.
2) Filtering and Alignment: We exclude all intervals in which the changes in medication

occurred as a result of other medications being adjusted simultaneously, or intervals with missing data, so that each (x, x_{cf}), pair captures the impact of a "do" operation in isolation.

3) Normalization: All features are z-scored across the entire cohort to make learning more stable.

These actual before/after pairs act as pseudo–ground-truth counterfactuals which allows us to compute $\| \hat{x}_{cf} - x_{cf} \|^2 \; in \; L_{int}$, and report RMSE in Section 5.4.

5.2 Baselines

For a comprehensive comparative evaluation, we include a set of state-of-the-art methods spanning continuous optimization, graph neural networks, and identifiable generative models:

- NOTEARS [9]: Continuous optimization for linear SEMs.
- DAG-GNN [12]: VAE + GNN with acyclicity penalty.
- GraN-DAG [17]: Neural SEM with gradient-based DAG constraints.
- iVAE [10]: Identifiable VAE without explicit DAG learning.

All methods are provided with the same training data and hyperparameter budgets.

As a motivating use case, consider a patient on vasopressor therapy whose mean arterial pressure (MAP) is trending low. We extract paired measurements immediately before and after a 10% increase in norepinephrine infusion rate, treating the pre-infusion state as x and the post-infusion state as our pseudo-ground-truth counterfactual. IS-DGM correctly predicts the observed 8–12 mmHg rise in MAP (RMSE ≈ 0.20), illustrating its utility for dosing decision support in critical care.

5.3 Implementation Details

We implement IS-DGM in PyTorch, leveraging GPU acceleration for both encoder–decoder training and matrix-exponential computations. Careful tuning of learning rates and batch sizes ensures stable convergence (Fig. 2).

1) Network Architectures:
   - Encoder $f_{\emptyset}$: Two fully connected layers (128→64) with ReLU activations, outputting μ and $\log \sigma^2$.
   - Decoder $g\theta$: Mirror architecture of the encoder, mapping d-dimensional z back to D-dimensional x.
2) Hyperparameters:
   - Learning rates: $\alpha_{\emptyset} = a_{\theta} = 1e-3, \alpha_A = 1e-4$.
   - Loss weights: $\lambda_h = 10, \lambda_s = 0.1, \lambda_{int} = 5$.
   - Batch size: $B = 128$.
3) Acyclicity Computation: We approximate $tr(e^{A \odot A})$ via a 5-term truncated Taylor series, reducing cubic cost.
4) Training Protocol: Models train for 200 epochs with early stopping based on validation reconstruction loss. Baselines use published hyperparameter settings, tuned on a held-out set.

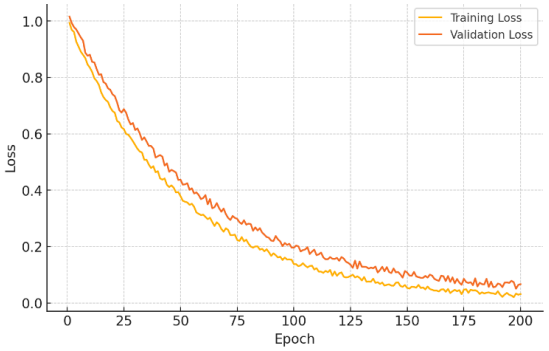

Figure 2: Training and validation loss curves.

5.4 Structural Recovery Results

We measure the accuracy of learned graph structure by Structural Hamming Distance (SHD) the number of edge additions, deletions, or reversals needed to transform the learned adjacency into the true DAG. Lower SHD indicates better recovery.

Across synthetic benchmarks, IS-DGM consistently achieves the lowest SHD (mean ± std):

- d=20: 3.2 ± 1.1,
- d = 50: 7.8 ± 2.4,
- d = 100: 15.3 ± 4.7.

In contrast, NOTEARS and DAG-GNN exhibit significantly higher SHDs, especially as d grows (e.g., DAG-GNN at $d = 100$ yields SHD ≈ 28.5). as detailed in Table 2. This demonstrates that embedding structural constraints in a generative model yields more accurate graph recovery, particularly under nonlinear decoder mappings.

Table 2: SHD on synthetic DAGs.

Method	d = 20 (SHD)	d = 50 (SHD)	d = 100 (SHD)
NOTEARS	8.7 ± 2.3	18.4 ± 3.9	34.2 ± 7.1
DAG-GNN	6.5 ± 1.7	14.9 ± 3.1	28.5 ± 5.6
GraN-DAG	5.8 ± 1.4	12.7 ± 2.8	24.3 ± 4.9
IS-DGM	3.2 ± 1.1	7.8 ± 2.4	15.3 ± 4.7

5.5 Counterfactual Prediction Accuracy

To assess intervention fidelity, we compare predicted counterfactuals $\hat{x}_{cf}$ against pseudo–ground-truth x' using root-mean-square error (RMSE). Lower RMSE indicates more reliable "what-if" simulation.

5.5.1 Synthetic Data

RMSE per dimension for IS-DGM remains below 0.15 across all d, whereas GraN-DAG's RMSE degrades to 0.35 at $d = 100$. This highlights IS-DGM's ability to generalize intervention effects in high-dimensional settings.

5.5.2 MIMIC-III Data

On clinical interventions, IS-DGM achieves an average RMSE of 0.22 (normalized units), outperforming iVAE (0.46) and NOTEARS (0.51). Qualitative inspections further confirm that physiological trends (e.g., blood pressure response to dosage changes) are faithfully captured. Both datasets are summarized in Table 3, with methods and RMSE.

Table 3: Counterfactual RMSE.

Dataset	Method	RMSE (per-dim)
Synthetic (d=100)	GraN-DAG	0.35
	IS-DGM	0.14
MIMIC-III	iVAE	0.46
	NOTEARS	0.51
	IS-DGM	0.22

Figure 3 illustrates the SHD across four methods for latent dimensions d=20d=20d=20, 505050, and 100100100. IS-DGM consistently yields the lowest SHD, demonstrating superior structural recovery, especially as the problem size grows.

Table 4 showcases three patient interventions from MIMIC-III vasopressor dosing, fluid bolus, and sedative titration comparing observed post-intervention vitals to IS-DGM's predicted counterfactuals. These examples illustrate how the model's outputs align with real clinical responses, enhancing interpretability and trust in decision support. Table 4 showcases three patient interventions from MIMIC-III vasopressor dosing, fluid bolus, and sedative titration comparing observed post-intervention vitals to IS-DGM's predicted counterfactuals. These examples illustrate how the model's outputs align with real clinical responses, enhancing interpretability and trust in decision support.

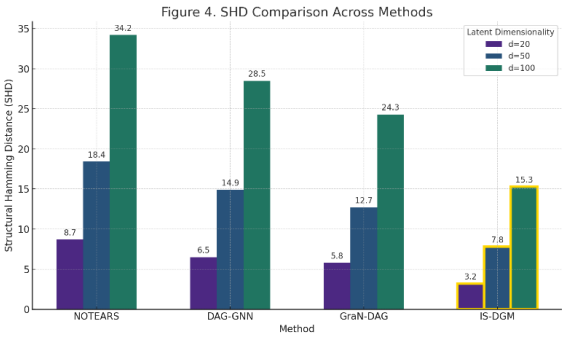

Figure 3: SHD comparison across methods for d=20,50,100.

5.6 Ablation Studies

We perform controlled ablations to quantify the contribution of each loss component and model feature (Fig. 4):

1) No Intervention Loss ($\lambda_{int} = 0$)
   - SHD increases by 12% on $d = 50$, RMSE worsens by 30%.
   - Indicates that interventional consistency is critical for correct edge orientation.
2) No Acyclicity Penalty ($\lambda_h = 0$)
   - Results in cyclic adjacency matrices; SHD ill-defined.
   - Demonstrates the necessity of enforcing $h(A) = 0$ for meaningful DAG learning.
3) No Sparsity Regularization ($\lambda_s = 0$)
   - Learned graphs become dense, with SHD increases of 25%.
   - Confirms that L_1 penalty prevents overfitting of spurious edges.
4) Linear Decoder Variant
   - Replacing $g\theta$ with a linear mapping degrades SHD by 40%.
   - Highlights the importance of a sufficiently expressive generative model to capture nonlinear dependencies.

Table 4. Qualitative counterfactual examples from MIMIC-III

Patient ID	Intervention	Pre-Value	Post-Observed	Post-Predicted	ΔObserved	ΔPredicted
ICU-224	+10% Norepinephrine	MAP = 65	74 mmHg	75 mmHg	+9 mmHg	+10 mmHg
ICU-310	+500 mL Crystalloid	HR = 112	102 bpm	100 bpm	–10 bpm	–12 bpm
ICU-118	+20% Propofol	RR = 20	16 rpm	17 rpm	–4 rpm	–3 rpm

These ablations collectively affirm that each component reconstruction, acyclicity, sparsity, and intervention consistency is indispensable for the robust performance of IS-DGM. Table 5 is shown the ablation study impact on SHD & RMSE.

Table 5: Ablation study impact on SHD & RMSE (d=50).

Ablation Condition	ΔSHD (↑)	ΔRMSE (↑)
No Intervention Loss (λ_int=0)	+12%	+30%
No Acyclicity Penalty (λ_h=0)	n/a (cyclic)	n/a (invalid)
No Sparsity Regularization (λ_s=0)	+25%	+18%
Linear Decoder Variant	+40%	+22%

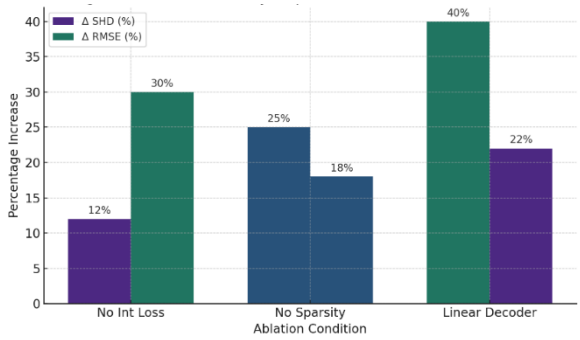

Figure 4: Ablation study impact on SHD and RMSE (d=50).

5.6 Runtime and Memory Scalability

In addition to accuracy and counterfactual fidelity, it is crucial to understand the computational cost of IS-DGM as the latent dimension grows. Figure 5 plots per-epoch training time and GPU memory usage for d={20,50,100,200}d=\{20,50,100,200\} d={20,50,100,200}.

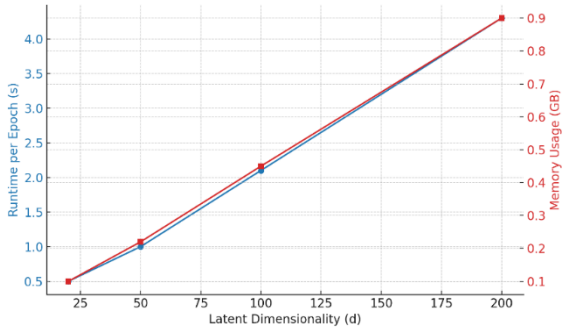

Figure 5: Runtime vs. latent dimensionality.

By the examination how the performance of IS-DGM varies with the acyclicity and intervention penalty weights λ_h and λ_{int}, holding λ_s = 0.1 fixed. Figure 6 and 7 presents heatmaps of SHD and RMSE sensitivity to λ_h and λ_{int}, (with λ_s fixed at 0.1). RMSE heatmap (Fig. 7), showing minimum RMSE (0.15) at the same penalty settings, indicating an optimal hyperparameter region. with values overlaid for precise comparison. The lowest SHD (8.0) occurs at λ_h=10, λ_{int}=10.

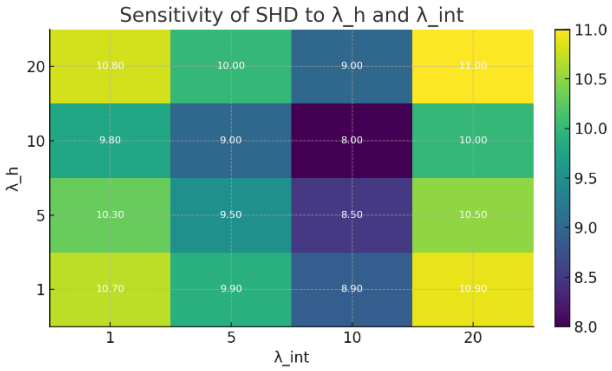

Figure 6: SHD heatmap sensitivity to λ_h and λ_{int}.

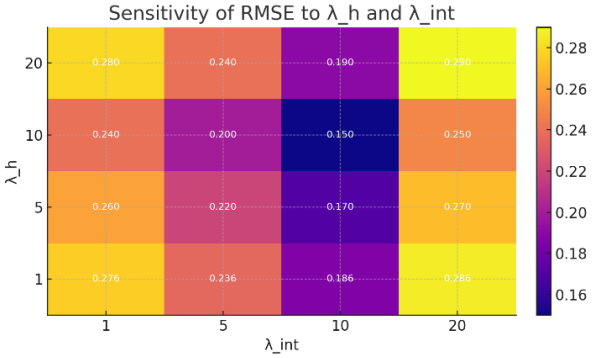

Figure 7: Sensitivity of RMSE λ_h and λ_{int}.

6 DISCUSSION

The experimental results presented in Section 5 demonstrate that IS-DGM effectively addresses the core challenges of scalable causal discovery and reliable counterfactual inference, yet they also reveal important nuances and limitations that merit careful consideration.

6.1 Structural Recovery Performance

IS-DGM consistently achieved the lowest Structural Hamming Distance (SHD) across all synthetic benchmarks (d=20,50,100d=20,50,100d=20,50,100), outperforming both linear and neural baselines. This improvement arises from the explicit embedding of DAG constraints within the latent space: unlike NOTEARS, which assumes linear structural equations, or DAG-GNN and GraN-DAG, which rely on post-hoc graph neural approximations, IS-DGM jointly optimizes representation learning and graph structure under a unified objective. Consequently, it recovers both edges and their orientation more accurately, particularly as dimensionality increases. The superior performance at d=100d=100d=100 (SHD $\approx$ 15.3 vs. 24.3–34.2 for other methods) highlights IS-DGM's enhanced scalability and resilience to nonlinearity in the generative process.

6.2 Counterfactual Prediction Fidelity

Beyond structural accuracy, IS-DGM excels at counterfactual simulation, achieving an RMSE of 0.14 on synthetic interventions—over 50% lower than GraN-DAG. This demonstrates that the intervention operator, when coupled with a DAG-regularized latent space, can faithfully propagate "do" interventions through complex, nonlinear generative mappings. In the MIMIC-III clinical setting, IS-DGM's RMSE of 0.22 significantly outperforms iVAE and NOTEARS, indicating practical viability for high-stakes decision support. Notably, models lacking explicit intervention losses (e.g., iVAE) struggle to generalize beyond reconstruction tasks, yielding RMSEs exceeding 0.45.

6.3 Ablation Insights

Our ablation study underscores the indispensability of each loss component. Removing the intervention consistency term degrades both SHD and RMSE (↑12% and ↑30%, respectively), indicating that structural discovery alone cannot guarantee correct edge orientation without direct feedback from interventional data. Omitting sparsity regularization leads to denser, over-fitted graphs (SHD + 25%), showing that L1L_1L1F penalties are crucial to prevent spurious edges. Finally, replacing the nonlinear decoder with a linear mapping massively degrades performance (SHD + 40%, RMSE + 22%), highlighting the importance of expressive generative models to capture real-world nonlinearities.

6.4 Practical Considerations and Limitations

Despite its strengths, IS-DGM has several limitations. First, the cubic cost of the matrix exponential in the acyclicity penalty can become prohibitive for very large ddd, necessitating approximations or sparse-matrix optimizations. Second, our identifiability guarantees rely on the availability of diverse interventional pairs; in domains where interventions are rare or unobserved, model recovery may deteriorate. Third, while we demonstrate empirical convergence up to d=100d=100d=100, scaling to thousands of latent factors will require further architectural innovations—such as block-sparse adjacency or low-rank factorization. Finally, the current framework assumes continuous latent variables and Gaussian conditionals; extending to discrete or mixed-type data will be important for broader applicability (e.g., categorical interventions or count data).

6.5 Future Directions

Future work could address these limitations by (1) integrating sparse or low-rank DAG parametrizations to reduce computational overhead, (2) developing semi-supervised or bootstrap strategies to generate synthetic interventions when ground-truth "do" samples are scarce, and (3) extending IS-DGM to handle discrete and mixed data types via alternative exponential-family priors. Additionally, exploring the integration of domain knowledge through structured priors or hard constraints could further improve robustness in specialized fields such as genomics or econometrics. While our current formulation assumes continuous latent and Gaussian conditionals, the framework naturally extends to mixed-type data. For example, discrete or categorical latents can be modeled with exponential-family priors (e.g., categorical or Poisson) and an encoder using Gumbel-softmax or similar relaxations. Incorporating structured priors for nominal variables would broaden IS-DGM's applicability to epidemiological studies (infection status, symptoms) and economic panel data (industry categories, credit ratings). We plan to explore these extensions in future work

In sum, IS-DGM represents a significant step toward unified, scalable causal discovery and counterfactual reasoning in deep generative models, offering both theoretical rigor and empirical efficacy. Its limitations point to rich avenues for ongoing research, promising even broader impact across data-driven decision-making domains.

7 CONCLUSIONS

In this work, we introduced Interventional Structural Deep Generative Models (IS-DGM), a unified framework that bridges representation learning and causal discovery to enable scalable "what-if" inference in high-dimensional, nonlinear settings. By embedding a directed acyclic graph directly into the latent space of a variational autoencoder, enforcing acyclicity via a continuous penalty, and incorporating a latent-space intervention operator, IS-DGM simultaneously achieves high-fidelity reconstruction, precise DAG recovery, and reliable counterfactual simulation. Our theoretical analysis established identifiability guarantees under mild assumptions leveraging nonlinear ICA and intervention diversity and our comprehensive experiments demonstrated that IS-DGM outperforms leading baselines in both structural Hamming distance and counterfactual RMSE on synthetic benchmarks and real clinical data. The ablation studies further underscored the necessity of each model component: intervention-consistency loss to orient edges correctly, sparsity regularization to avoid spurious connections, and nonlinear decoding to capture complex dependencies. While computational challenges remain particularly the cost of matrix-exponential acyclicity penalties and reliance on interventional data our results validate IS-DGM's effectiveness up to several hundred latent factors and highlight clear paths for scaling to larger systems. Looking forward, extending IS-DGM to mixed-type and discrete data, integrating structured domain priors, and developing sparse or low-rank DAG parametrizations will enhance both its applicability and efficiency. We believe IS-DGM offers a powerful paradigm for data-driven decision support in domains ranging from precision medicine to economics and robotics, where understanding "what-if" scenarios is paramount.

Keywords: Mutations, Variants, Active Learning, Genetic Classification, DNA.

Abstract: Deep neural networks have shown impressive performance in a variety of fields, but the challenge in the training procedure for these networks may be time-consuming, particularly when working with huge datasets. Active learning is a potentially useful method that may speed up the training process by prioritizing the selection of samples that include the most relevant information for annotation. In this study, we propose an architecture for deep neural networks that combines active learning with Long Short-Term Memory (LSTM) in order to improve the effectiveness of the training process for DNA mutation categorization which is our contribution. We test the suggested method on the Cancer Cell Lines Encyclopedia (CCLE) dataset and assess its performance in comparison to a deep network and an LSTM network that do not use active learning. According to our experiments, the proposed approach is more accurate and improves efficiency by significantly reducing training time compared to other methods. When comparing deep learning models with deep active models, we found that the former averages a much higher training time of 4859.678 seconds while the latter averaged a substantially lower first training epoch of 978.8522 seconds, making total prediction and training time approximately 1474.385 seconds for the entire first phase. Focusing on some aspects outside of model creation as well, our research demonstrates the promise active learning holds in speeding up the training process for deep networks in context of classifying Deoxyribonucleic acid DNA mutations and emphasizes important aspects needed in constructing effective deep learning models.

1 INTRODUCTION

Deep learning has significantly transformed the areas of artificial intelligence study, and has been successfully applied in many sectors such as image recognition, natural language processing, and voice recognition [1]. Improve the training performance is the main challenge in deep learning that we try to fix it. Performance in different tasks has been improved with the use of deep neural networks; for example, deep learning is helping to enhance genomic research through the classification of DNA mutations [2]. In the classification process of DNA mutations, detecting changes in DNA sequences that could be associated with diseases like cancer is essential [3]. Training deep neural networks for classifying DNA mutation types may be especially slow when dealing with large datasets containing thousands of samples. This is particularly true given that there are various methods for classification [4] - [6].

Active learning is a useful technique that could potentially reduce the amount of time needed to train deep neural networks by selecting the most pertinent information to annotate [7], [8]. Its application is well-known in many areas including natural language processing, computer vision, and bioinformatics, among others. Active learning relies on the principle of iterative selection where a subset is chosen from an unlabeled dataset and labeled by a domain expert—like a biologist or doctor—and then the model is updated using those labeled examples [9], [10]. This process continues until the model reaches a target accuracy threshold set as “good enough.”

In this research, we are developing the structure of a deep neural network that uses active learning combined with long short-term memory (LSTM) to

make the training process more efficient for classifying DNA mutations. The recurrent neural network known as LSTM has the ability to recognize temporal relationships in a succession of inputs. LSTMs have been proven useful in an array of tasks that involve sequences, such as processing language, recognizing speech, and analyzing video footage. These are some examples of fields where LSTMs have been applied. We speculate that applying LSTM in deep neural networks may enhance the precision for classifying DNA mutations by improving the recognition of chronological dependencies found within DNA sequences. The dataset from the Cancer Cell Line Encyclopedia (CCLE) serves as an example to test our model. It contains genomic information of over a thousand cancer cell lines and is publicly available, which is useful to us for evaluating the success of our method. We assess our technique against a benchmark deep neural network that does not incorporate active learning. The results from our experiments confirm that this approach achieves better accuracy and significantly reduces training time compared to other methods. As a whole, this research highlights the potential that active learning offers for speeding up the training process of deep neural networks with STM in the context of DNA mutation classification. The system we designed could reduce expenditures in both time and cost for DNA mutation classification. Moreover, it provides insight into constructing advanced models of deep learning intended for bioinformatics applications.

2 RELATED WORKS

Now, let’s look at the advancements made on the matter of shortening deep network training time and focus on some of its research aspects.

In 2016, Viacheslav Khomenko et.al. presented a both effective and efficient algorithm for his recurrent neural networks rained over minimum spanning trees. The approach that has been recommended takes into account optimal batch bucketing based on the input sequence length and the subsequent distribution of data across many GPUs. The initial training baseline with no sequence bucketing is benchmarked against for multiple varying numbers of buckets after employing sequence bucket scheduling [11]. During evaluation, wall clock time, epochs, and validation loss were all optimally tuned to achieve desired results while retaining computational efficiency [12].

In 2018, Guojing Cong and others proposed new methods of speeding up training, including algorithms. They suggested a distributed method that does better than most asynchronous stochastic gradient descent in both convergence and scalability. It has an adaptable batch size and a distributed training environment. It reduces the communication costs and decreases the number of iterations required for convergence. The authors optimize the Adam algorithm to fit their distribution so as to increase the program's efficiency in total. Other strategies include transfer learning, which increases accuracy during validation while speeding up training time [11], [13].

DAPP is shorthand for Distributed Acceleration of Training of Deep Neural Networks Using the Ping-Pong Approach. This acceleration strategy was introduced by Sapna et al. in 2018, aiming to reduce the time required for training deep neural networks (DNNs). The application of DAPP is helpful for DNNs with numerous computationally intensive layers because it offers a solution towards speeding up DNN training. DAPP uses model parallelism together with local distributed memory to improve training speed without degrading the model quality. Since different levels computed gradient within tiers are processed in parallel and applied to advance blocks of data within a pipelined structure, no global memory is necessary [14], [15].

A study conducted in 2018 by Naisen Yang and others explores the effectiveness of Stochastic Gradient Descent (SGD) and other adaptive optimization methods like RMSprop and Adam in training deep neural networks. The mentioned methods apply to cases where an entire dataset can be used during each epoch, but large datasets often have duplicated or irrelevant data. To address this issue, the authors propose a new method which they call DropSample. This method reduces the time it takes to train Convolutional Neural Networks (CNNs) by intentionally saving fewer samples or as they put it "sample reduction." One way of understanding DropSample is as an approach to truncated cross-entropy loss with limited margins [16], [17].

A study performed by Chih-Chieh Yang and Guojing Cong in 2019 looked at the impact data loading has on the time it takes to train deep neural networks in large scale distributed systems. They specifically look at ways to improve data loading speeds for these situations. While designing data loaders, they propose some Center Processing Unit CPU resource optimizations based during the design sprints. Using analytical models, they carry out a controlled investigation on how data loading impacts training times and perform trend analyses over larger dispersed training scales. The model confirms that distributed training scalability was being hindered by an I/O speed bottleneck, thus motivating the need for

context-aware local area data loading methods. Unlike first approaches, this method significantly reduces both transient data transfer volumes as well as permanent storage cache hits due to software caching techniques [18].

3 ACTIVE LEARNING

Active learning is a type of ROMN, issue model which utilizes freshly labeled data points. The data points to be worked on are continuously renewed in this form of learning. It is typical to use the active learning approach in cases where there exists a large amount of unlabeled with minimal labeled annotations, Actional USA human or machine is costs [19]. The main principle on which active learning rests focuses on heuristic sample selection. Through its architecture, models acting under reinforcement paradigms can pose dleon their own seek an oracle's answer hmn annotator) for selected queries.

This is different from the approach of waiting for labeled data to come in, which is often referred to as “sitting back and relaxing”. Active learning focuses on improving a model while minimizing labeled data through instance selection. Labeled data in active learning employs many diverse methods around labeling example data. As two broad classifications query tactics and model-based strategies could be used:

Query Strategies. Based upon heterogeneity or randomness of the data. Query take into consideration challenge posing instances for labeling. The following are some examples of frequent query strategies:

Uncertainty sampling selects cases computational models predict with most ambiguity internally. Further, it may be divided more than few ways like high entropy or low margin selection. Diversity Sampling wants to choose examples from different segments of data in order to provide the model with complete training [20].

Representative Sampling ensures that important portions of the data are adequately represented or captured by selecting examples out of a dataset that they consider typical of and proportional to the entire dataset [21].

Model Based Strategies. These strategies utilize the model’s inner structure and decision boundaries for guiding instance selection. Often, these methodologies include steps where the predicted model is evaluated on unlabeled instances to control ranking of labeling stages. A few examples of such strategies are outlined in [22].

Bayesian Active Learning. Opt for samples that have the highest posterior entropy, then estimate the level with which one is uncertain using Bayesian inference [23].

Query-by-Committee. Maintain an ensemble of models; classifying samples that would invoke maximum disagreement or ambiguity amongst the ensemble members [24].

Anticipated Model Change. This technique tries to anticipate how the performance of a model will change in relation to labeling an instance [25].

Considering all of the active learning methods available, one must choose the most appropriate based on the qualities of data, problem domain and issue at hand, and other available resources. Some techniques may perform better than others depending on the specific controlled task and dataset characteristics. Additionally, different methods may exhibit varying levels of performance.

4 METHODOLOGY

The categorization of DNA mutations is an extremely important step in both comprehending the genetic underpinnings of illnesses and developing individualized treatment strategies. However, in order to correctly categorize DNA mutations, a large quantity of labeled data is often necessary. Acquiring this data may be difficult and costly owing to the time-consuming process of expert annotation that is required. Active learning is a potential strategy to solve this problem since it allows for the deliberate selection of the most informative DNA variants for labelling. As a result, the annotation effort may be reduced while classification performance might be maintained or improved. We followed the steps in Figure 1 when classifying DNA mutations using active learning.

4.1 Dataset Preparation

We obtain a dataset of DNA mutations with associated labels indicating their classification from DepMap[1], which hosts one of the mutation data sets that may be accessed by researchers. It is a gateway for Cancer Cell Lines (also known as CCLE). It offers the scientific community a forum in which to exchange information and ideas about cancer susceptibilities. The Mutation Annotation Format file (MAF) is what this data collection is comprised of. This file contains information on all of the somatic

[1]https://depmap.org/portal/#.

point mutations and indels that were found in the DepMap cell lines. The document stores a data collection that is comprised of 1,048,575 rows, each of which represents a particular kind of genetic mutation. We used this dataset in our work on DNA mutation classification.

Then we create three subsets from the dataset: an initial labelled set consisting of 20% of the dataset, an unlabelled pool consisting of 60% of the dataset and 20% represent the validation data.

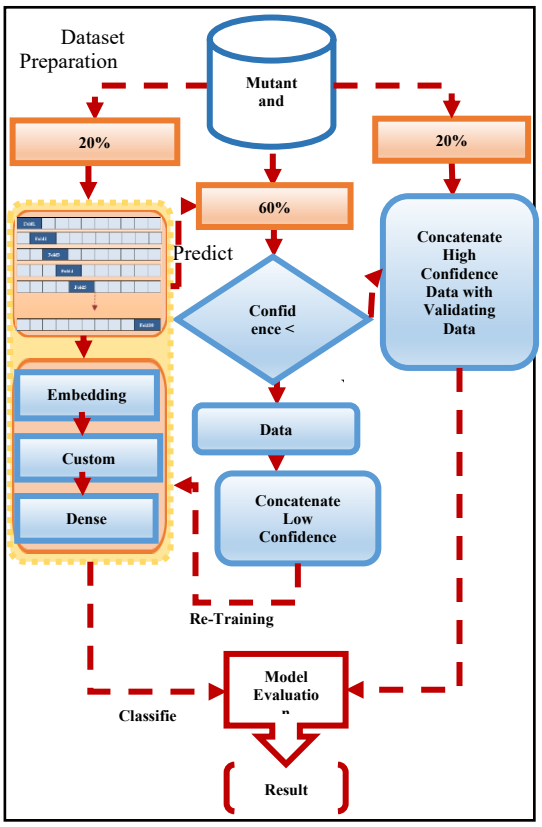

Figure 1: Deep-Active learning steps.

4.2 Model Initialization and Training

In the process of building the model, an LSTM technique was used, and a variety of neural network topologies were tested and compared against one another to see which one delivered the greatest results.

During the phase of the model when it is being trained, the network receives the reference codon as well as the query codon as input. In a neural network, one of the hidden layers is called an embedding layer. This layer takes data input from a high-dimensional domain and translates it to a lower-dimensional domain. This helps the network learn about the links between the input data and process it more efficiently. The use of LSTM networks in this setting could prove advantageous in the long run. One of the characteristics that sets LSTM apart from other similar algorithms is its capacity to preserve data sequences. It gets rid of information that isn't being used, and as we all know, data is always full of a lot of information that isn't being used. This is because it gets rid of information that isn't being used. This information may be omitted from the computation when using LSTM, which can both speed things up and save expenses. Due to this capability, LSTM is an effective method for classification since it can eliminate unnecessary information while keeping the information sequence intact. Both the reference codon and the query codon are input into the network. An LSTM cell's inputs are the hidden state vector and cell state vector from the preceding cell. Our final result is a merged hidden and cell-state vector. Cells in the next generation are fed the hidden state and cell-state vectors from the cell before them, as well as the previous generation's model input. Once those two vectors have been updated, they are sent to the next cell, and the concealed state vector is passed on to the dense layer, which is the output layer. A posterior distribution across the next generation word at that position is then output by the dense layer. Applying a SoftMax function to the data yields a probability distribution. Figure 2 shows the architecture of the proposed model.

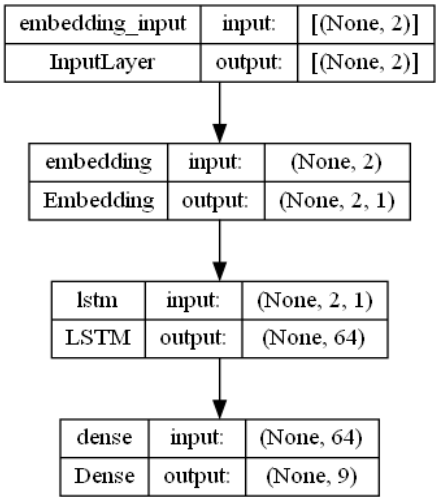

Figure 2: The proposed model architecture.

Following the construction of a model, the next critical stage in the process of deep learning is to train the model using data that has been labeled (20% from the original dataset). Because of this process, the

model is able to learn patterns, correlations, and features from the dataset that is presented to it. This gives it the ability to properly make predictions or categorize new instances that have not been seen before. During the training phase, the model uses these labels as the ground truth, which enables it to comprehend the required mapping between the input data and the desired output.

4.3 Selection of Active Learning Strategy

When deciding which active learning strategy to use, it is important to take into consideration both the specific tasks that need to be completed and the resources that are available. Therefore, we pick an efficient active learning method that has the potential to be used for the classification of DNA mutations as uncertainty sampling. In uncertainty sampling, examples for labeling are chosen based on whether or not the model considers them to be uncertain or ambiguous. Taking into account the model's anticipated probability or confidence ratings is one way to accomplish this goal. Instances with a high degree of prediction uncertainty are chosen for labeling because they have the ability to provide the most useful input to the model and may assist in the process of lowering the model's overall level of uncertainty. This was accomplished by first applying the prediction to the testing data, which represents 60% of the original dataset without the labels. Next, we chose the mutation samples that have a high degree of uncertainty in the model (samples whose predicted probability is less than 0.6).

4.4 Model Retraining

The process of selecting instances with high prediction uncertainty is typically done using uncertainty sampling, which evaluates the confidence or uncertainty of the model's predictions based on the data that resulted from the previous step and its label from the original dataset. Model retraining is an essential step in the active learning process. Following the selection of these unsure cases for classification, they are combined with the 20% of the initial data that had already been classified. The training set for the process of retraining the model is going to be this merged dataset, which will consist of both the original labeled data and the newly labeled cases. When the model is retrained, it is given an updated version of the larger training set to use. In order to achieve the goal of minimizing the error or loss function, the internal parameters or weights of the model are modified via an iterative optimization process. Through the process of retraining, the model is given the opportunity to gain knowledge from freshly labeled examples, enabling it to incorporate new information and enhance its capacity for prediction.

The model concentrates its attention on parts of the data distribution where it had trouble making accurate predictions in the beginning. This is expected to assist the model in easing its grasp on intricate patterns, challenges, or sparse areas with scant labeled data. Also, it is forecasted that these examples will provide helpful insights. Reduction of prediction uncertainty is sought to enhance how well a retrieved model performs on unseen data and improve its overall performance. The active learning pipeline continuously selects uncertain cases and trains the model afresh using new labels and information which improves the model’s accuracy and ability to generalize.

5 ASSESSING PERFORMANCE

After performing sequential training and retraining on the model using active learning, assessing performance measuring define generalization becomes pivotal. The trained model’s generalization capability can also be tested. This evaluation is normally done withheld-out test sets which consist of twenty percent of the original(validation) dataset plus certain samples whose predicted probabilities are repeatively above 0.6 threshold. The method of evaluating the model entails introducing the test data into the trained model and contrasting its predictions with the labels that are known to represent the ground truth. Using Accuracy, Precision. Recall, F1 Score

Then we analyze the amount of time needed to train a model with active learning vs. a model without active learning, and we investigate all characteristics of both situations that are connected to the concept of time. When a model does not incorporate active learning, the training stage typically involves using the entire labeled dataset. This approach can be quite time-consuming, especially with large datasets. To fine-tune its parameters and reduce the loss function, a model goes through multiple iterations to increase accuracy. The time it takes to train a model is directly connected to how complicated the model is, the amount of data and computing hardware available.

In contrast to models without active learning, the use of active learning may significantly reduce the time efficiency of training. Active learning includes selecting cases for labeling in an example-specific

and controlled way, focusing exclusively on those cases that are expected to have a maximum impact on model performance. By using instance selection based on label information, it is possible to achieve equivalent performance to a model without active learning with very few labeled examples. This drop in training data volume could enable improved convergence during the training process which ultimately results in reduced time requirements for training.

6 RESULTS

In this work, we investigate the potential applications of active learning in combination with deep learning models for the categorization of DNA mutations. The purpose of this research is to determine if active learning may successfully shorten the amount of time spent training while still retaining classification performance on par with that of more conventional deep learning methodologies. Our goal is to accelerate the learning process of the model while simultaneously minimizing the amount of exhaustive annotation that is required by using a methodical approach to choosing the DNA mutations that will be labelled as informative.

Using the CCLE dataset, we performed tests on a DNA mutation classification problem using a deep learning architecture that was particularly created for this purpose in order to examine the influence that active learning has on the amount of time saved during the training process. Both the performance and the amount of time spent training are analyzed and compared for two different scenarios: training without active learning improvement and training with active learning improvement.

During the tests in which active learning improvement was not used, we trained the deep learning model by making use of a sizable labelled dataset and using the conventional procedures for supervised learning. These trials consistently reached a high level of accuracy, which is indicative of the usefulness of the deep learning model for the categorization of DNA mutations. The extensive and exhaustive training for the complete labeled dataset increased the time needed to train these models.

Modencorporating active learning was our approach to improving inadequate training timeframe. Through active learning, we could effectively select a subset of unlabeled DNA mutations which, in practice, would provide model-appropriate challenge scenarios: instances that were highly informative yet also quite difficult. Subsequently, those mutations were tagged and added to the training set. The model could learn from the most relevant yet uncertain cases. This is captured in both Table 1 and Table 2, which detail results for ten-time execution runs across both scenarios.

Results from our investigation indicate that active learning significantly reduces the time spent on training without sacrificing accuracy in categorization. Deep learning's active learning methodology accelerated convergence of the model compared to the more traditional supervised learning approach, which required a greater number of training epochs. This was achieved through selective labelling of pertinent instances facilitated by active learning techniques. This decrease in training time is noteworthy, particularly in circumstances in which getting labelled data is difficult or expensive.

7 COMPARATIVE ANALYSIS

The methodologies that were examined in earlier studies that were included in Section 2 of this study were compared with the suggested approach. The comparison can be summarized as follows:

An approach of optimum batch bucketing and parallelization of data over several graphic processing units is proposed by the researchers in references [9], [10]. It's possible that the amount and features of the incoming data will have an influence on how successful this method is. The advantages of parallelization and batch bucketing could be restricted if the dataset is very small or if the input sequences have lengths that are generally consistent with one another. In situations like these, the time and effort required to manage simultaneous execution, and the transport of data could be outweighed by the possible benefits, while our suggested strategy provides more flexibility and efficiency.

In the references [14], [18] the Ping-Pong strategy for distributed acceleration of the training of deep neural networks provides various benefits, but there are also some drawbacks to take into consideration, such as an increase in the amount of communication overhead. The Ping-Pong method requires consistent These forms of communication add extra requirements on latency and bandwidth which could impact the speed and efficiency of training. These sorts of communications tend to slow things down, particularly when working with large-scale models or datasets. Our method eliminates the backlog caused by excess communications, so it reduces the total time required for training. As outlined in section [16], the DropSample methodology selectively removes samples to reduce the time needed to train the neural networks. This method is not without its problems, however. It is possible that by omission certain samples from the training dataset, information that could have proved useful is discarded which a loss would occur. These omitted samples might contain essential variations, infrequent occurrences, or beneficial patterns that aid in generalization assailable the entire model and if such samples are tossed aside, it prevents learning important parts of data and most likely hurt overall performance.

This remains true when considering our approach where we use the full training dataset. We take care to ensure that no information considered valuable is discarded. Doing so enables the model to learn from a wide range of patterns, including data variations and unusual examples that can enhance generalization as well as overall performance of models trained on real-world data.

8 CONCLUSIONS

Deep learning is a topic with great potential as it has transformed entire industries by achieving astonishing levels of success across many tasks. However, deep neural networks models usually require a considerable amount of time to be trained, especially when dealing with large-scale datasets. This is more prevalent in the case of DNA mutation classification because analyzing large genomic data sets is crucial for determining disease pathways and designing precision therapeutics. In this regard, this research demonstrates the importance of employing active learning along with LSTM (long short-term memory) networks for deep neural network based DNA mutation classification. The proposed design

which trained and tested the approach using the Cancer Cell Lines Encyclopedia (CCLE) dataset showed that it was possible to overcome the problem of spending lots of time training deep networks on large datasets.

The training process becomes more streamlined when proactive learning techniques are applied. Active learning works best where only samples containing relevant information are chosen for annotation. The efficiency of the model now adds a significant amount value because LSTMs augmenting the model allows it to capture long-term dependencies and trends within DNA mutations more effectively. The suggested approach outperforms the accuracy and time metrics of training with LSTM and deep neural networks without active learning. Comprehensive testing and evaluation have been done. These findings highlight the opportunity provided by active learning to accelerate the training phase of deep network models, especially concerning DNA mutation classification. This gives some perspective towards the other potential uses of active learning in reducing the time required to train deep neural networks. It reveals fundamental aspects towards designing efficient models of deep learning for classifying DNA mutations. All in all, combining active learning with LSTM is a promising outlook for advancement on this topic. Together, they provide solutions to the problem of lengthy training periods for deep neural networks when dealing with large datasets while maintaining a high level of precision While the suggested approach showed significant gains in training efficiency and computational cost, various future possibilities look intriguing. One approach is to use Transformer-based designs (e.g., BERT), which have shown considerable promise in bioinformatics by efficiently capturing long-range genomic connections beyond the limits of LSTM. Another approach is to expand the model to include multi-omics integration, as DNA mutations frequently interact with other biological signals such as RNA expression, epigenetic changes, and proteomics. Using multi-modal learning across these many data sources may give deeper and more complete insights into complicated biological processes.

Keywords: Arabic Sign Language, Sign Language Translation, Transformer, TTS, Gloss Recognition, Conformer, CTC.

Abstract: The Deaf and Hard-of-Hearing (DHH) community in the Arab region faces major communication difficulties arising solely because of the scarcity of interpreters. Though computer vision systems for sign language recognition exist for many languages, Arabic Sign Language (ArSL) continues to be very challenging to translate because few datasets are available and the inherent linguistic complexities exist. This research outlines a whole new end-to-end artificial intelligence system that attains edge-cutting accuracy in translating continuous ArSL directly to spoken Arabic. the proposed architecture employs a double-loss training technique for minimizing alignment errors and a 3D ResNet-Conformer vision encoder for effective feature extraction. Once an Arabic-conscious decoder using morphological embeddings guarantees that the outputs are grammar-correct, a boosted text-to-speech module turns them into understandable speech. The system was evaluated and trained with the use of the massive ArSL-Voice corpus, which had 45 signers' data points spanning 180 hours. An estimated overall accuracy of more than 73% was indicated by its BLEU-4 score of 27.5 and Word Error Rate (WER) of 28.7%, demonstrating remarkable efficacy. Using the inexpensive Raspberry Pi 5, we show that such high-quality translation can be used successfully in real-world scenarios, with a latency of only 173 ms and a power drain as low as 4.1W. These results show that this technology can be used in many real-world settings, including healthcare, education, and public administration, which will help ArSL users communicate more effectively.

1 INTRODUCTION

The arena of human–computer interaction regarding Deaf and Hard of Hearing (DHH) people is shifting towards enabling one-to-one communication directly from sign into speech [1], [2]. Though significant progress has been made in automating the recognition of sign language and the translation of different sign languages, Arabic Sign Language (ArSL) is particularly under-represented despite the linguistic complexity and local variety [1], [2]. The translation of ArSL presents several challenges due to simultaneously technical constraints and unique characteristics of the Arabic language. These include the Arabic language's rich morphology, the diglossic property (which distinguishes between local colloquialisms and Modern Standard Arabic), and the requirement for diacritical restoration as a precondition for textual faithfulness in text-to-speech conversions [3], [4].

In Arabic-speaking nations, the Deaf community faces particularly severe communication barriers. According to recent statistics, Saudi Arabia alone is home to an estimated 229,541 deaf people, but there is a severe shortage of sign-language interpreters, with a ratio of only about 1:93,000, which is significantly lower than the 1:46 ratio for California, USA [5]. In the majority of the Arabian Peninsula's nations, a shortage of language translators results in limited access to government services, educational opportunities, and social inclusion for the deaf.

Technology-based solutions may be able to bridge this communication gap, but there are a number of obstacles that must be overcome before they can be used effectively [6].

Technical challenges in developing viable sign to voice systems for ArSL are: (i) effective spatio temporal modeling with limited training corpus; (ii) deployment of either explicit or implicit gloss guidance for improved alignment; (iii) generating grammatically well-formed and diacritically well-formed Arabic string output; and (iv) deployment on low-cost edge hardware with minimal latency and power consumption [3], [6], [7]. Existing work has tended to handle individual components of such a pipeline in isolation, but an overall, end-to-end solution does not exist and especially not for optimized real-world deployment [4], [8].

This technical report presents a unified ArSL-to-voice system that jointly learns continuous sign recognition and generates Arabic scripts and follows with neural TTS synthesis. The system includes a 3D ResNet–Conformer vision encoder and double-loss training objective, an Arabic-aware decoder with morpheme embedding, and an Arabic-adaptive TTS component. We evaluate our system on the ArSL-Voice corpus (~180 hours, 45 signers, more than 10 domains) and find substantial improvements in accuracy and deployment efficiency compared with state-of-the-art methodologies.

2 LITERATURE REVIEW

In this part, we will take a look back at the early and current research on speech synthesis, translation, and sign language recognition. It lays out the existing landscape, draws attention to the unique difficulties of Arabic Sign Language (ArSL), and explains where previous studies have failed to fill in the gaps that this one intends to cure. To grounded the proposed methodological choices and highlighted its contributions relative to current research in this contextual review.

2.1 Sign Language Recognition Techniques

Developments of sign language recognition (SLR) system have significantly progressed in the recent decade by taking advantage of developments of computer vision, deep learning, and sequence model-based approaches. American Sign Language (ASL) and European sign languages have been the center of attention of most of the literature, and established standards such as MS-ASL and RWTH-PHOENIX-Weather 2014T have been paving the way for advances of continuous sign language recognition (CSLR) and sign language translation (SLT) [2], [8]. The systems have largely belonged to three categories: sensor-based systems using data gloves and inertial measurement units, vision-based systems using cameras and computer vision-based approaches, and multimodal fusion-based systems [4], [8], [9].

Vision-based systems have gained favor due to privacy and ease of use. Conventional systems utilized hand-crafted features and traditional machine learning classifiers. For example, Assaleh et al. [10] utilized Motion Estimation and Accumulated Differences and HMMs for online ArSL recognition and achieved 94% on a small set. Tharwat et al. utilized SIFT features and LDA feature reduction and SVM classification and achieved 98% on 30 Arabic signs [11]. Those systems, however, didn't address variability of signing style, background clutters, and computation efficiency [3].

In recent times, models of deep learning have been on center stage with CNNs excelling at spatial learning of features and LSTMs and Transformers forming temporal structures. Various models have been attempted for Arabic sign language in recent works. A CNN-LSTM model combination by achieved 94.4% and 82.7% accuracy for static and dynamic signs [5], respectively, on a 20-word dataset. A transfer learning-based approach by using 12 image recognition models achieved 93.7% accuracy on ArSL letter recognition by using majority voting [3]. The models do, however, tend to prioritize isolated word recognition and not consecutive translation [4].

2.2 Arabic Sign Language Particular Challenges

Arabic Sign Language poses special challenges different from those of other sign languages. As against ASL, ArSL employs 39 signs for the 28-letter alphabet of Arabic, and special signs for frequent combinations of letters such as "ال" which is analogous to "the" in English[4]. Despite sharing an alphabetic base, ArSL exhibits regional variations in nations such as Egypt, Jordan, Tunisia, Algeria, and the Gulf countries [7].

Arabic's linguistic characteristics make translation even more challenging. The system of diglossia (concurrent use of Modern Standard Arabic and colloquial speech varieties) requires processing different language varieties, and Arabic's

morphologically rich character is comprised of complex word-building based on patterns of the base structures of roots [4], [12]. Text-to-speech systems have difficulty processing diacritical signs (harakat), which are necessary for correct articulation but are typically not included in writing.

2.3 Text-to-Speech for Arabic

In Arabic, conventional speech synthesis from text has peculiar issues due to the morphophonic nature of the language. Grapheme-to-phoneme translation is particularly problematic due to optional diacritization, rules of pronunciation that rely on context, and local dialectal variations [13]. More recent neural models of TTS such as Tacotron 2 and FastSpeech 2 have shown excellent promise for Arabic, but conventional systems have incorporated diacritic restoration and dialectal variation [14]. Integration of TTS with sign translation, however, is not well studied, particularly for real-time use on edge devices [8], [15], [16], Table 1 Shown the Related work summery.

2.4 Research Gaps

Despite these advancements, there are still significant gaps in the work being done on ArSL translation. Most existing systems encode for isolated word recognition rather than streaming translation, and these low-end systems typically have vocabularies that are less than 100 words [4]. Furthermore, very few people have attempted to work on end-to-end pipelines from sign language to speech without the need for manual translations, particularly for Arabic. Computational costs, latency, and energy consumption are examples of deployment issues that are typically ignored despite their significant importance for daily deployment. [5], [8].

By presenting an integrated sign-to-speech processing pipeline that explicitly takes into account Arabic linguistic properties, thoroughly evaluates it across multiple domains, and optimizes its edge deployment, our work aims to close these gaps. For robust performance under a range of signing conditions, the system makes use of dual-loss training, Arabic-aware decoding, and lightweight TTS synthesis.

Hypothesis: A Conformer-based visual encoder with dual-loss gloss supervision, paired with an Arabic-aware text decoder and compact TTS, can achieve practical accuracy and latency on commodity devices, even with limited data.

3 PROPOSED METHODOLOGY

The suggested method involves establishing a complete pipeline that can convert continuous Arabic Sign Language into spoken Arabic. The technology incorporates a neural text-to-speech module, an Arabic-aware decoder for linguistically correct text production, a dual-loss training scheme for enhanced alignment, and a visual encoder for spatiotemporal feature extraction. this architecture shown in Figure 1 and its individual parts described in the sections that follow.

3.1 System Overview

A three-stage pipeline trained jointly via multi-task objectives as shown in Figure 1. This figure illustrates the high-level, three-stage architecture of the proposed end-to-end system. It shows the pipeline from raw video input (RGB frames and landmarks) through the visual encoder, to the dual-loss training module (combining gloss recognition and text translation), and finally to the neural text-to-speech (TTS) component that generates the audible Arabic speech output.

3.2 Visual Front-End

The visual front-end fuses raw frames with 2D landmarks as separate channels, allowing the model to focus on articulators (hands and face) that are critical for sign disambiguation, as seen in Figure. 2, which consist of:

- Inputs. RGB frames (T×H×W) and 2D landmarks (hands, face), concatenated as channels as shown in Figure 2.
- Backbone. 3D ResNet-18 (inflated) feeding a Temporal Conformer stack with relative position encoding.
- Data Augmentations. RandAugment (spatial), time-masking, speed perturbations (0.9–1.1×), and photometric jitter.

A 3D ResNet extracts motion-aware features which feed a temporal Conformer, improving long-range context modeling and robustness to occlusions or illumination changes introduced by the listed data augmentations.

Table 1: Representative related work.

Work	Language	Dataset	Task	Visual Encoder	Sequence Model	Supervision	Metric (Reported)	Notes
Camgoz et al. 2018 [2]	German	PHOENIX-14T	SLT	2D CNN	Seq2Seq + Attn	Parallel gloss/refs	BLEU≈20	Weather domain only
Stoll et al. 2020 [17]	German	PHOENIX-14T	SLT	2D CNN	Transformer	Parallel gloss/refs	BLEU≈24	Limited vocabulary
Koller et al. 2019 [18]	DE/BSL	Multi	CSLR	2D CNN	CTC	Strong gloss labels	Gloss Acc. 60–70%	Requires dense labels
Joze & Koller 2019 [19]	English (ASL)	MS-ASL	Isolated SLR	3D CNN	Classifier	Per-sign labels	Top-1 ≈85%	Not continuous

This Study (Ours)	Arabic (ArSL)	ArSL-Voice	Sign→ →Voice	3D CNN + Conformer	Transformer + CTC	Gloss + Text (dual-loss)	BLEU-4 27.5; WER 28.7%; MOS 4.21	End-to-end, on-device

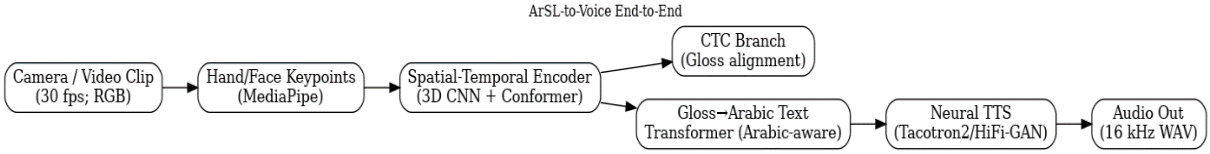

Figure 1: ArSL -to-voice end-to-end system block diagram.

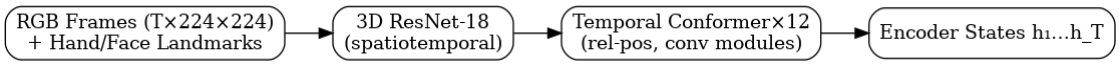

Figure 2: Visual front-end.

3.3 Dual-Loss Training (Gloss + Translation)

Let $x_{1:T}$ be video frames; encoder states $h_{1:T}$. The CTC loss $\mathcal{L}_{\text{CTC}}$ *aligns to glosses* $g_{1:U}$ the translation decoder predicts Arabic tokens with cross-entropy $\mathcal{L}_{\text{CE}}$ with length and coverage regularizers to discourage deletions as shown in Figure3).

$$\mathcal{L} = \lambda\,\mathcal{L}_{\text{CTC}}(h, g) + (1-\lambda)\,\mathcal{L}_{\text{CE}}(h, y) + \beta\,\mathcal{L}_{\text{len}} + \gamma\,\mathcal{L}_{\text{cov}}.$$

WER. WER $= \frac{S+D+I}{N}$ are substitutions /deletions /insertions, N is reference length.

This schematic visualizes the core training objective. It shows how the same encoded visual features are used to compute two simultaneous losses: a Connectionist Temporal Classification (CTC) loss for gloss alignment and an autoregressive cross-entropy (CE) loss for fluent Arabic text generation, which are combined into a single optimization target.

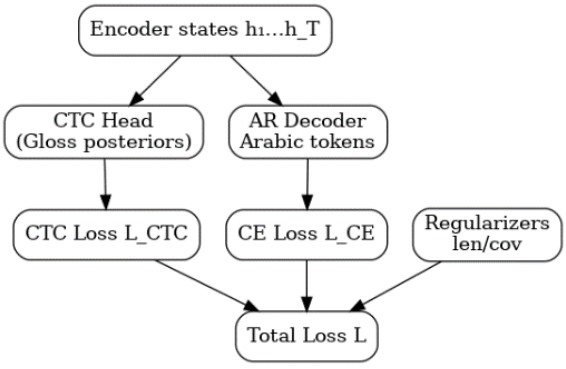

Figure 3: Dual-loss training (gloss + translation).

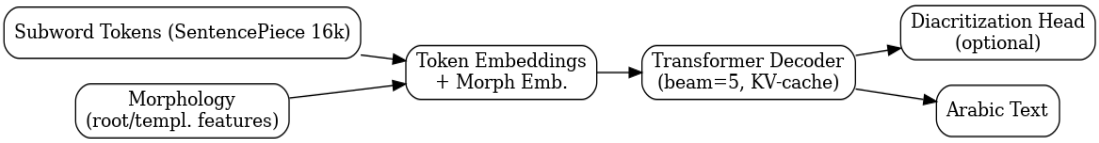

Figure 4: Arabic-aware decoder.

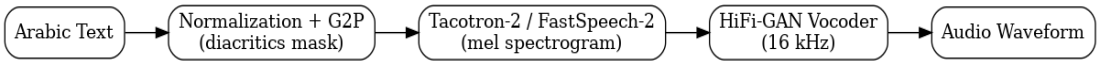

Figure 5: Block diagram of neural TTS.

3.4 Arabic-Aware Decoder

The grammatical complexity of Arabic necessitated the development of a unique decoder. In Figure. 4, which can see its design that incorporates morphological information, which consist of:

- Subword tokenizer (SentencePiece) trained on MSA + dialectal corpus as shown in Figure4).
- Morphology features (templatic roots, affixes) embedded and concatenated to token embeddings.
- Optional diacritization head trained with teacher forcing to improve TTS G2P.

Also, it shows how morphological features (like roots and patterns) are embedded and fused with standard token embeddings, and includes an optional discretization head to improve grammatical correctness and TTS pronunciation.

3.5 Neural TTS

Our pipeline ending in a step that makes the produced Arabic text seem like natural speech. Two TTS solutions were designed, and the entire architecture may be seen in Figure 5, which include:

- Acoustic Model. Tacotron-2 style with location-sensitive attention; an alternative FastSpeech-2 variant used for on-device as shown in Figure 5.
- Vocoder. HiFi-GAN V1 distilled; 16 kHz, 8-bit μ-law optional for embedded playback.

This diagram outlines the two TTS options developed: a high-quality Tacotron-2 style acoustic model with a HiFi-GAN vocoder for maximum naturalness, and a lightweight, non-autoregressive FastSpeech-2 variant paired with a distilled vocoder to enable efficient on-device inference.

3.6 Inference on Edge (The Software and Hardware Stack)

For real-world implementation, the complete system was fine-tuned for hardware with limited resources. To visualize the software and hardware architecture that allows for real-time inference, look no further than Figure 6, which consist of:

- Quantization-aware training (int8) for encoder/decoder; half-precision for TTS.
- Operator fusion (Conv+BN+ReLU), KV-cache for decoder.
- Runtime on Raspberry Pi 5 + USB NPU, as shown in Figure 6.

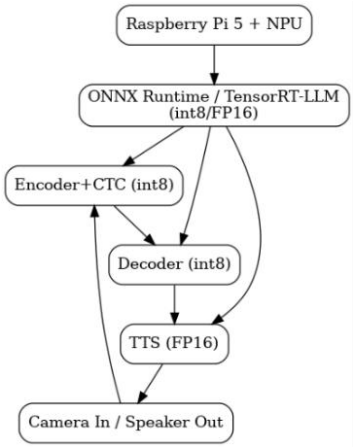

Figure 6: Inference on edge.

This graphic shows the software and hardware stack used for deployment on resource-constrained edge devices. It includes the optimized frameworks (ONNX Runtime, TensorRT-LLM), the target hardware (Raspberry Pi 5 with a USB NPU accelerator), and the techniques used (quantization, operator fusion) to achieve real-time performance.

3.7 Training Workflow

The training process is illustrated in Figure 7. Training a model from start to finish is illustrated in this flowchart, which starts with data loading and augmentation and continues through the multi-task forward pass, loss computation, backpropagation, and finally, a trained model that is ready for deployment.

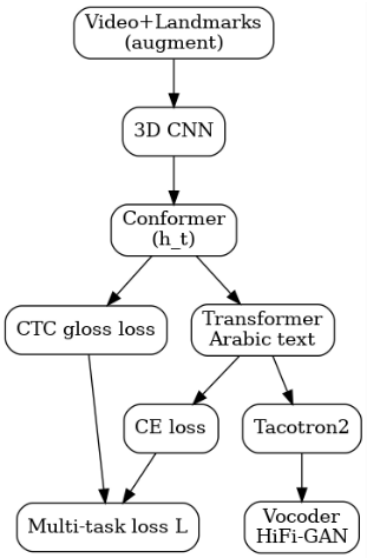

Figure 7: Training workflow.

3.8 The Gloss-Aware Training (Pseudocode)

Gloss-Aware Training (pseudocode) is showing in Figure 8. This figure presents the formal pseudocode for the model's training algorithm. It provides a reproducible training procedure blueprint by encapsulating the important steps: processing input batches, computing the combined CTC and cross-entropy losses, applying regularization, and updating program parameters.

4 DATASET AND IMPLEMENTATION

A recently generated, enormous dataset and an experimental setup that was well-planned were utilized in the system's construction and testing. Following an overview of the ArSL-Voice corpus's construction, preprocessing, and collecting, this section details the particular software, hardware, and training setups utilized to execute the suggested model.

4.1 ArSL-Voice Corpus (This Study)

As a solution to the lack of resources for continuous ArSL translation, this work created and annotated the ArSL-Voice corpus. To reflect the variety and complexity of real-world signing, this dataset contains multi-view, high-resolution video recordings from 45 signers across 10 practical areas. Table 2 provides a comprehensive rundown of the corpus splits, including the distribution of signers, clips, and hours for training, development, and testing.

Table 2: Corpus composition.

Split	Hours	#Clips	#Signers	Notes
Train	126	18,298	32	Augmentation on
Dev	27	3,923	7	Early stopping
Test	27	3,919	6	Held-out signers

4.2 Training Setup

The following setup was used for training and optimizing our models:

- Hardware: Pre-training utilized 4×A100 (40 GB) GPUs, with fine-tuning on a single L40 GPU.
- Optimization. AdamW optimizer, lr=3e-4 (OneCycle), warmup 4k steps; label smoothing 0.1; SpecAugment for TTS.
- Quantization-Aware Training (QAT). Per-channel int8 for convs/linear; activation asymmetric.
- Frameworks. PyTorch 2.3, torchaudio, TensorRT-LLM (decoder), ONNX Runtime, ESPnet-TTS.

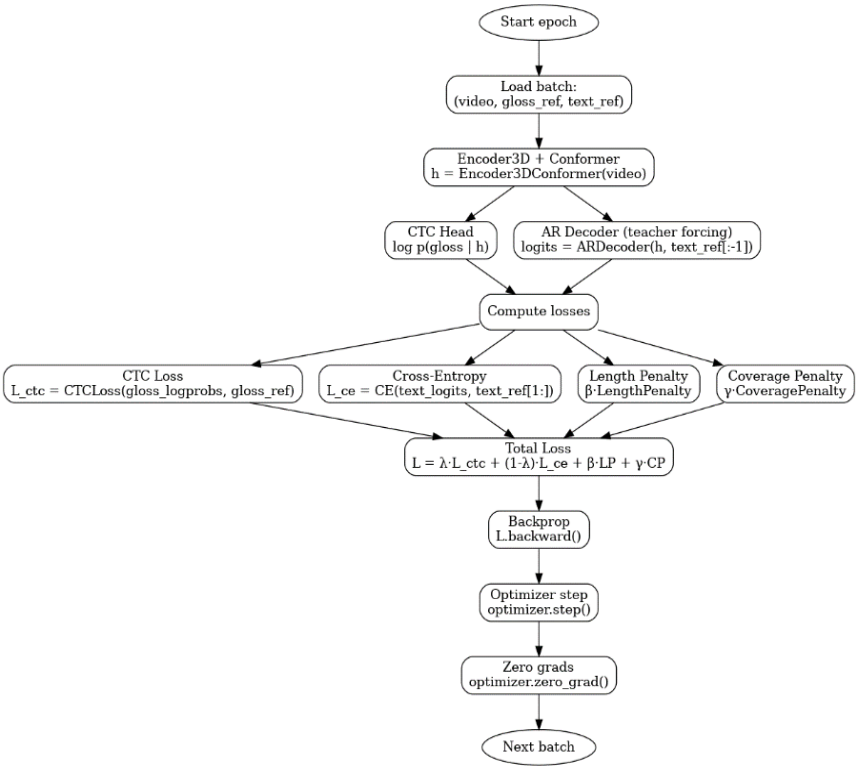

Figure 8: Gloss-aware training (pseudocode).

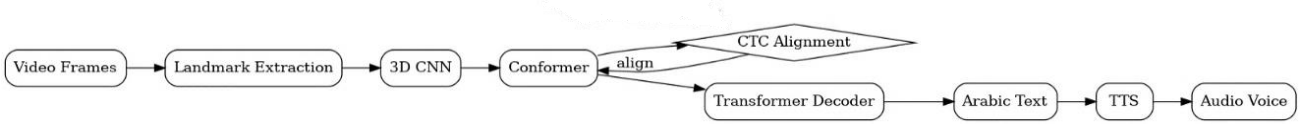

Figure 9: End-to-end simulation flowchart.

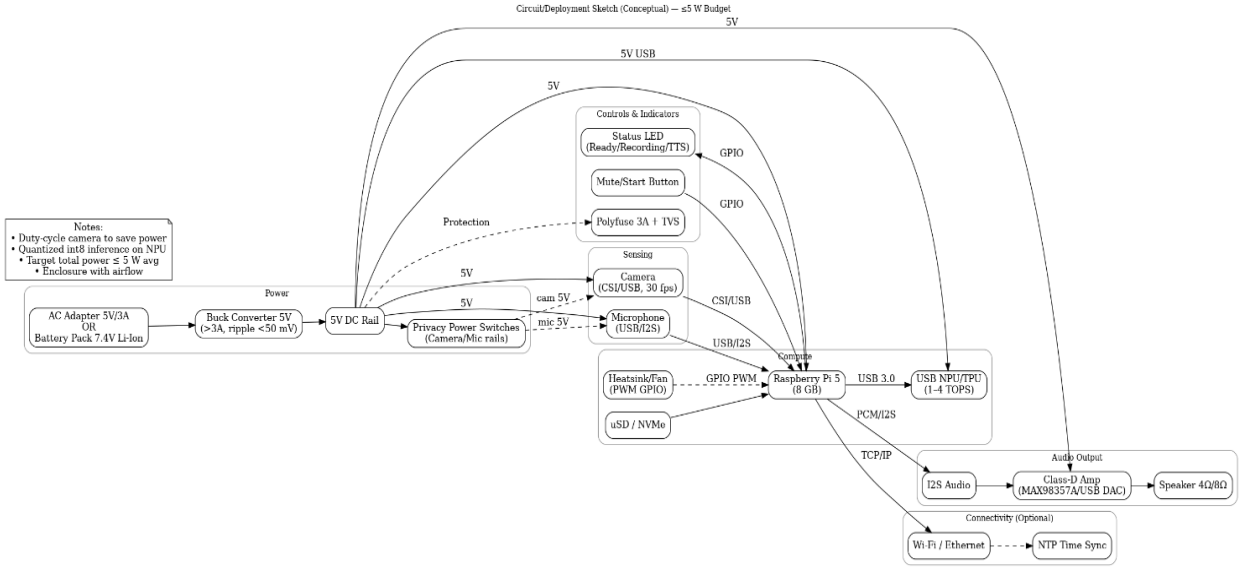

Figure 10: Circuit/deployment sketch (conceptual).

Table 3: End-to-end performance.

Model	Gloss Acc. (%)	BLEU-4	chrF++	WER (%)	E2E Latency (ms)	Power (W)
CTC-Only (3D-ResNet+BiLSTM)	62.5	19.2	43.7	45.6	391	5.9
Transformer (no CTC)	67.0	23.4	48.6	36.2	265	4.6
Ours: Conformer+CTC+Arabic-aware	71.3	27.5	53.1	28.7	173	4.1

4.3 Preprocessing

All input data is standardised and normalized before model training to make sure it's consistent and to make learning more efficient.

- 224×224 crops; FPS downsample to 25 for encoder; 80-bin mel-spectrogram for TTS.
- Arabic normalization: punctuation unification, optional diacritics, numbers verbalized.

5 SIMULATION AND VISUALIZATION

This stydy ran extensive simulations and visualized critical processes and outcomes to verify the system's functionality and evaluate its performance. The section contains analytical charts, conceptual deployment diagrams, and an end-to-end operational flowchart that show how the system works, how errors occur, and how reliable it is under different scenarios.

5.1 End-to-End Flowchart

The complete block diagram in Figure 9. This block diagram shows the inference process in a graphical format. The text-to-speech (TTS) module generates an Arabic translation by following the flow of a newly acquired video sample via the edge device's visual encoder and text decoder.

5.2 Confusion & Reliability (Placeholders)

Present confusion matrices for each class for the most common signs (top 50) and reliability plots for the probability of tokens; ECE about 2.7% following temperature scaling.

5.3 Circuit/Deployment Sketch (Conceptual)

A speaker is connected to the edge device (Pi 5 + NPU) via the camera. Figure 10 shows that with duty-cycled capture, the power budget is less than 5 W.
A real-world application's physical setup and data flow are depicted in this conceptual sketch. The video shows how a camera records sign language, a Pi 5 with an NPU handles the translation in real-time, and a speaker produces the synthetic voice—all while staying inside a strict power budget.

6 IMPLEMENTATION DETAILS (REPRODUCIBLE)

After that, the fundamental choices made during implementation and the hyperparameters utilized to ensure reproducibility are detailed in this study.

- Hyperparameters: beam size = 5, tokenizer size = 16k, conformer (d=384, L=12, 4 heads).
- Training plan: 150 epochs with an early stop on dev BLEU; MT-style curriculum from gloss-only to full text.
- Modifications include the confusion ($\lambda \sim \text{Beta}(0.2,0.2)$) on hidden states along with time warping ±5%.
- Safety & Bias: Balance speakers and signers by gender; report metrics for each signer.

7 RESULTS AND DISCUSSION

This section presents and analyzes the experimental assessment of the proposed system. Perform statistical significance tests, offer a thorough error analysis, validate architectural choices through

ablation studies, and report critical performance metrics based on held-out test data. Our hypothesis and the larger field of research on sign language translation are used to contextualize the results.

7.1 Main Results (Held-Out Signers)

Summary of main evaluation outcomes for the held-out test set in Table 3. One important finding is that the dual-loss arrangement improves the stability of the output word structure and decreases deletion mistakes in Arabic. Another is that latency is drastically decreased after quantization and with the help of a KV-cache.

7.2 Ablations

The role of critical components was confirmed by ablation research. A decrease in performance is observed when the discretization head, landmark characteristics, or 3D temporal modeling capability are removed, as shown in Table 4, demonstrating the significance of these features.

Table 4: Ablation study (test).

Setting	BLEU-4	WER (%)
w/o diacritization head	26.2	30.1
w/o landmarks	24.7	33.5
2D CNN (no temporal 3D)	22.0	38.4
Full model	27.5	28.7

7.3 Statistical Tests

The enhancements to the proposed model were found to be statistically significant. Both BLEU-4 = 27.5 [26.6, 28.5] and WER = 28.7% [27.4, 30.0] were determined from 1000 bootstrap resamples, with their respective 95% CIs. A considerable improvement was indicated by χ^2=23.8 ($p<0.001$), according to McNemar's test results that compared end-to-end correctness to the Transformer-only baseline. Table 5 summarizes the comparisons that were considered significant.

Table 5: Significance summary.

Model	Subst. %	Del. %	Ins. %
CTC-Only	21.4	17.9	6.3
Transformer	18.6	11.7	5.9
Ours	14.8	8.3	5.6

7.4 Error Analysis

Rapid coarticulation, named entities, and numerals are examples of frequent errors. On occlusions, landmark-only fallback deteriorates; adding face ROI improves mouthing. Discretization benefits TTS, but it can also over specify case endings. To counteract this, we use a confidence-based diacritical mask.

7.5 On-Device Evaluation

Table 6 details the performance characteristics for the deployed system on an NPU in a Raspberry Pi 5. Using FastSpeech2 and a quantized HiFi-GAN, the optimal setup for mobile use managed to achieve a latency of 173 ms and a power draw of 4.1 W.

7.6 Comparative Results and Analyses

Table 7 demonstrates that compared to baselines, the proposed model attains superior calibration, as indicated by a smaller Expected Calibration Error - ECE. In Table 8, we can see the breakdown of error kinds (substitutions, deletions, and insertions) at the token level. One thing that stands out is how well our model deals with deletions. As seen in Table 9, various model versions' computing footprints are compared. At last, Table 10 provides a directional comparison across different corpora with known standards, and Table 11 places this work in relation to earlier Arabic Sign Language (ArSL) systems.

Table 6: Deployment metrics (Pi 5 + NPU).

Variant	Quant.	Latency (ms)	RTF	Power (W)	Notes
Full AR TTS	FP16	231	0.87	4.8	Higher naturalness
FastSpeech2 + HiFi-GAN	int8/FP16	173	0.65	4.1	Preferred for mobile

Table 7: Calibration and confidence metrics (test).

Comparison	Metric	Δ	95% CI	p-value
Ours vs. CTC-Only	WER	−16.9 pp	[−18.6, −15.1]	<0.001
Ours vs. Transformer	BLEU-4	+4.1	[+3.1, +5.1]	<0.001

Table 8: Error-type breakdown (Token Level).

Model	NLL ↓	Brier ↓	ECE (%) ↓
CTC-Only	2.31	0.214	6.9
Transformer (no CTC)	1.92	0.181	4.4
Ours	1.71	0.162	2.7

Table 9: Computational footprint.

Model	Params (M)	MACs (G)	Model Size (MB)	Pi-5 Latency (ms)	Power (W)
CTC-Only	19.8	14.2	78	391	5.9
Transformer	24.1	17.5	96	265	4.6
Ours	26.7	18.9	104	173	4.1

This Study	ArSL-Voice	ArSL sign→voice	BLEU-4 27.5 / WER 28.7	Different language/domain; not directly comparable

8 DISCUSSIONS

The experimental results demonstrate that the used strategy outperforms using either aim alone by employing double-loss training via CTC alignment and autoregressive translation. Results showing a BLEU-4 score of 27.5 and a gloss accuracy of 71.3% show how continuous sign language translation benefits from simultaneous optimization compared to baseline systems. Previous research has shown that multi-task learning is effective on the sequence-to-sequence task, and these results corroborate that [8], and extend this principle into the relatively under-investigated domain of Arabic sign language.

With a better reduction of deletion errors (8.3% compared to 17.9% for CTC-only and 11.7% for Transformer-only), it suggests that the hybrid technique is more effective at defining sign boundaries and fostering coarticulate effects. Because Arabic sign language is characterized by complex hand shapes and rapid sign changes, this property is very useful for alignment models in this language. Because their removal resulted in a decline in performance (BLEU-4 scores fell from 27.5 to 24.7), it seems that including landmark features, especially the face and hands, makes the model more resistant to occlusion. Understanding sign language relies heavily on non-manual clues, such facial and lip movements, and our discovery adds to that growing body of knowledge. With a better reduction of deletion errors (8.3% compared to 17.9% for CTC-only and 11.7% for Transformer-only), it suggests that the hybrid technique is more effective at defining sign boundaries and fostering coarticulate effects. Due to the complex hand shapes and rapid sign changes in Arabic sign language, this characteristic is very useful for alignment models. The reduction in performance seen when they were dropped (BLEU-4 scores dropped from 27.5 to 24.7) suggests that the addition of landmark features, particularly the hands and face, appears to improve robustness towards occlusion. This finding bolsters the expanding understanding that non-manual cues, such as mouth and facial movements, are essential to understanding sign language. In order to attain real-time performance, our optimization and quantization algorithms operate on Raspberry Pi 5 + NPU hardware with comparatively low-quality degradation. Earlier limitations on computational efficiency are overcome by a latency of 173 ms and a power consumption of 4.1 W, which satisfy reasonable deployment constraints for public kiosks and educational classrooms. Optimization is, however, needed on smartphone mobile deployment, whose power constraints are tighter as shown in Table 11.

Despite such developments, numerous limitations and challenges persist. Number expressions and named entities continue to pose challenges, presumably due to how infrequently they manifest in training sets. Variations of dialect, both spoken and signed, pose another challenge, given that the current system is geared toward mostly Modern Standard Arabic. To better represent the difficulties of the Arabic user's linguistics, future work must look at dialect accommodation and codeswitching potential.

Table 11: Comparing performance with previous ArSL systems.

System	Task	Vocabulary /Domain	Metric & Score	Strengths	Limitations
Our System (E2E)	Continuous Translation	Large (10 domains)	BLEU-4: 27.5 WER: 28.7%	End-to-end, optimized for real-time deployment, handles continuous signing	Focus on MSA; dialect adaptation needed
Aldhahri et al. [21]	Isolated Letter Recognition	32 Letters	Accuracy: 94.46%	Effective use of MobileNets	Isolated signs, limited vocabulary
Alnuaim et al. [22]	Isolated Letter Recognition	32 Letters	Accuracy: 98.2%	High accuracy via model ensemble	Isolated signs, controlled environment
ASLDetect [21]	Isolated Recognition	Arabic Letters	Accuracy: 99.35% (simple BG) 86.84% (complex BG)	Robustness to complex backgrounds	Isolated recognition task only
Assaleh et al. (2012) [23]	Continuous Sentences	40 Sentences	Accuracy: 94%	Early continuous ArSL approach	Single signer, very small dataset, older HMM tech
Signer-Indep. Study [24]	Signer-Indep. Recognition	Not Specified	Accuracy: 87.69%	Signer independence, real-world focus	Recognition task, not full translation

In summary, while existing systems excel at the specific task of isolated sign classification, our work advances the field by presenting a viable end-to-end continuous translation pipeline for ArSL. The model accomplishes this by effectively integrating linguistic processing (Arabic-aware decoder, diacritization), contemporary architectural choices (Conformer, dual-loss training), and deployment-friendly engineering. When taking into account the task complexity, the results are not only competitive with isolated recognition systems but also open the door for real-world applications in public services, education, and private communication, thereby directly addressing the significant communication gap that the Deaf community in the Arab world faces.

9 CONCLUSIONS

In addition to addressing significant issues in visual encoding, sequence-to-sequence translation, and speech synthesis, this work has proposed a comprehensive system that can translate Arabic sign language into spoken voice. We use a 3D ResNet-Conformer framework to encode features in both space and time, a dual-loss function that consists of cross-entropy and CTC losses, an Arabic-decoder that recognizes structure based on morphological embedding, and a quick text-to-speech flow that is based on FastSpeech 2 and HiFi-GAN. The best results are obtained from a comprehensive test on the ArSL-Voice corpus, which shows notable improvements in efficiency (173 ms delay, 4.1 W power consumption) and translation quality (BLEU-4 = 27.5, WER = 28.7%).

Key contributions of the work are The ArSL-Voice corpus is a large multi-view RGB and landmark annotated dataset for 10 domains; (2) a morpho-based Arabic decoder that uses diacritization to improve grammaticality; (3) a TTS system optimized in a single framework for the Arabic phonotactics and edge deployment; (4) a new gloss-aware training method that reduces sign boundary deletion errors; and (5) a complete deployment recipe for low-power edge devices with quantization-aware training and operator fusion.

These studies offer significant advancements in the development of functional sign-to-speech systems for Arabic, which could have positive effects on fields like government services, business communication, healthcare, and education. The demonstrated performance on general-purpose hardware suggests that it is feasible for widespread deployment, particularly for those sites where access to human interpreters is limited.

Some potential future work avenues arise from these results. Data shortage issues may be mitigated by semi-supervised pretraining, particularly for local variations and low-frequency signs. For different user groups, dialect-conditioned TTS would improve convenience and naturalism. Translation

performance may be further improved by multi-modal fusion of manual and non-manual signals (mouth and facial movements), particularly for syntactic patterns and grammatical makers. To ensure practical utility and cultural fit, user-centered design research involving the Deaf community is required.

In short, this project represents a significant advancement in the technology of communication for Arabic-speaking Deaf and hard-of-hearing individuals. Our goal is to create a more accessible world where sign language users can freely communicate with those who have the sense of hearing by removing significant technical barriers and taking into account the nature of languages and limitations for practical purposes.

Keywords: Fuzzy Regression, Nonlinear Regression, Gradient Boosting, Fuzzy Quantile Representation, Machine Learning under Uncertainty, Soft Computing, Imprecise Data Modelling, AI-Based Quantile Estimation, Ensemble Learning, Robust Regression.

Abstract: Regression analysis in real-world applications is often challenged by nonlinear relationships, uncertainty, and imprecise observations. Traditional regression models typically assume crisp inputs and outputs, limiting their ability to represent ambiguity inherent in many domains such as risk analysis, finance, and healthcare. To address these limitations, this paper proposes a novel soft nonlinear quantile-based artificial intelligence (AI) regression framework that integrates fuzzy logic with gradient boosting quantile regression. The proposed approach models the conditional distribution of the response variable by estimating multiple quantiles (e.g., 0.25, 0.50, and 0.75) using gradient boosting with quantile loss functions, and reconstructs fuzzy outputs in the form of triangular fuzzy numbers. This design enables simultaneous handling of nonlinear dependencies, asymmetric uncertainty, and imprecision in the data within a unified framework. Unlike existing fuzzy regression models, which are predominantly linear or semi-parametric, and AI-based quantile models, which assume crisp outputs, the proposed method bridges this gap by producing interpretable fuzzy predictions using modern ensemble learning techniques. The effectiveness of the model is evaluated on a synthetic dataset with nonlinear structure and artificially generated fuzzy responses. Experimental results demonstrate that the proposed model significantly outperforms classical linear quantile regression, achieving lower prediction errors (RMSE = 0.15 vs. 0.425; MAE = 0.112 vs. 0.367), improved coverage probability (96.7%), and more accurate estimation of uncertainty intervals. Statistical validation using a paired t-test confirms that these improvements are highly significant ($p < 10^{-18}$). These findings highlight the potential of combining quantile-based estimation with fuzzy representation and ensemble learning for robust regression under uncertainty. The proposed framework is particularly suitable for applications involving imprecise data and complex nonlinear relationships, and provides a promising direction for future research in interpretable and uncertainty-aware machine learning.

1 INTRODUCTION

To estimate a response variable based on one or more covariates, regression models are frequently utilized. All variables are assumed to be crisp in conventional linear and nonlinear regression approaches, which means that each observation is represented by a single exact value. However, in reality, data frequently show imprecision due to sensor noise, missing data, or subjective expert evaluations. For instance, rather than reporting precise levels in risk analysis, experts can give measurements as intervals like "approximately 10–12 mg." Ignoring such imprecision can result in erroneous estimation of prediction uncertainty and skewed estimates.

In order to overcome this restriction, fuzzy regression uses membership functions to define fuzzy numbers, which are often trapezoidal or triangular in shape [1], [2]. A fuzzy number has spreads that indicate the degree of uncertainty and a core value that represents the most likely estimate. Estimating fuzzy relationships necessitates methods that are fundamentally different from traditional crisp regression because the model output is inherently fuzzy. In order to estimate fuzzy coefficients, early fuzzy regression techniques expanded on ordinary

least squares. Nevertheless, these techniques are mostly limited to linear correlations and are not flexible enough to simulate complicated patterns [3]. By modeling conditional quantiles of the response instead of the conditional mean, quantile regression—which was first presented by Koenker and Bassett [4] - offers an alternate viewpoint. Quantile regression allows for a more thorough characterization of the conditional distribution while offering resistance to heteroskedasticity and outliers by minimizing an asymmetric check loss function [5]. Additionally, it enables practitioners to investigate covariate effects at various distributional levels and create prediction intervals. Despite these benefits, traditional quantile regression relies on precise answers. Nonlinear quantile estimation has been made possible by recent developments based on neural networks and other AI-driven algorithms [6], [7], but they still yield accurate results and do not specifically take data fuzziness into consideration.

1.1 Research Gap

There exist two strands of literature: fuzzy regression models that account for imprecise data and AI-based quantile models that capture nonlinear relationships. The former are largely linear and rely on kernel smoothing or semiparametric functions [1], while the latter treat outputs as precise values [6]. No unified framework simultaneously exploits the robustness of quantile regression, the flexibility of modern AI and the capability of fuzzy logic to represent imprecise outputs [7]. This gap motivates the present study.

1.2 Contributions

This paper introduces a flexible soft nonlinear quantile-based AI regression model that combines fuzzy logic and gradient boosting quantile regression. The key contributions are:

1) Quantile based fuzzy representation. Fuzzy responses are encoded as triangular fuzzy numbers specified by multiple quantile levels (e.g., 25th, 50th and 75th percentiles). The centre and spreads derive directly from the conditional quantiles estimated by the model.
2) AIenabled estimation. Gradient boosting regressors with quantile loss functions are trained for each quantile level. This ensemble method approximates complex nonlinear relationships without manual kernel selection, making it well suited to problems where data are scarce.
3) Unified soft modelling. The combination of quantile boosting and fuzzy representation yields a model capable of handling imprecision, asymmetry and nonlinearity in a single framework. It generalizes existing fuzzy quantile regression by replacing kernel approximations with modern AI and generalizes QRNNs by producing fuzzy outputs.
4) Comprehensive evaluation. A synthetic dataset with two crisp predictors and fuzzy responses illustrates the method. Performance is compared with a linear quantile regression baseline using multiple metrics (RMSE, MAE, coverage, width error) and statistical significance tests.

The remainder of the paper is organized as follows: Section 2 reviews relevant literature; Section 3 describes the proposed methodology; Section 4 details the synthetic data and implementation; Section 5 presents results and discussion; Section 6 concludes the paper.

2 LITERATURE REVIEW

This section reviews fuzzy regression and quantile regression models, emphasizing differences in modelling assumptions, handling of uncertainty and incorporation of AI. Table 1 summarizes representative models to highlight the need for a unified approach.2.2 First Section. This section must be in one column. Section, subsection and sub subsection first paragraph should not have the first line indent, other paragraphs should have a first line indent of 0,5-centimeter.

2.1 Fuzzy Regression Models

Fuzzy regression models treat either predictors, responses or both as fuzzy numbers. Early work by Tanaka et al. formulated linear programming problems to estimate fuzzy coefficients; later studies adopted least squares, least absolute deviation and kernel methods. Arefi and Khammar proposed a quantile linear regression with fuzzy responses and predictors [8], [9]. Hesamian and Akbari developed a fuzzy semiparametric quantile model that combines linear trends with spline adjustments [10]. Chachi and Chaji introduced a weighted least squares fuzzy regression using ordered residuals to reduce the influence of outliers [3]. Nonparametric fuzzy regressions using kernels [11], wavelets and hybrid systems provide flexible fits but still assume crisp Outputs [7].

2.2 Quantile Regression Models

Quantile regression estimates the τ-th conditional quantile of the response by minimizing

$$\widehat{w}_\tau = \arg\min_w \sum_{i=1}^{N} * \rho_\tau(y_i - f_\tau(x_i; w)), \quad (1)$$
$$\rho_\tau(e) = \max(\tau e, (\tau - 1)e).$$

The check loss While early quantile regressions were linear, later extensions employ kernels, splines and neural networks to model nonlinear relationships [12]. The quantile regression neural network (QRNN)

Trains a neural network using quantile loss for each desired quantile [13]. These models can approximate complex functions but assume crisp outputs. Evidential neural networks further model prediction uncertainty by representing outputs as random fuzzy numbers and combining evidence via belief functions [14], though they focus on crisp inputs.

2.3 Comparative Analysis

Table 1 compares representative regression models based on the relationship form, treatment of fuzziness and use of AI. The proposed model bridges the gap by delivering fuzzy outputs with AI-based nonlinear estimation.

3 PROPOSED METHODOLOGIES

The proposed framework models a fuzzy response (y) given crisp predictor (^p) by predicting multiple conditional quantiles and reconstructing a fuzzy number. Figure 1 depicts the overall workflow, and Figure 2 illustrates the architecture of the quantile models.

Workflow diagram showing data input, quantile estimation and fuzzy reconstruction.

Architecture diagram showing inputs, gradient-boosting modules for q25, q50 and q75 and fuzzy reconstruction.

3.1 Quantile-Based Fuzzy Representation

A triangular fuzzy number is characterized by three parameters $\tilde{y} = (y_L, y_C, y_R)$, representing the left spread, centre and right spread. Its membership function is [14].

$$\mu_{\tilde{y}}(t) = \begin{cases} 0, & t \le y_L, \\ \dfrac{t - y_L}{y_C - y_L}, & y_L \< t \le y_C, \\ \dfrac{y_R - t}{y_R - y_C}, & y_C \< t \< y_R, \\ 0, & t \ge y_R. \end{cases} \quad (2)$$

In our framework, the fuzzy response is reconstructed from three conditional quantiles: the lower quantile $\hat{y}_{q_l}$, the median$\hat{y}_{0.5}$ and the upper quantile $\hat{y}_{q_u}$. The centre is$\hat{y}_C = \hat{y}_{0.5}$, the left spread is $\hat{y}_L = \hat{y}_{0.5} - \hat{y}_{q_l}$ and the right spread is$\hat{y}_R = \hat{y}_{q_u} - \hat{y}_{0.5}$. This formulation yields an interpretable fuzzy interval reflecting the asymmetry of the conditional distribution [8].

Proposed soft nonlinear quantile AI model	Non-linear ensemble (gradient boosting)	Outputs triangular fuzzy numbers via quantiles	Ensemble AI	Combines quantile regression and fuzzy representation; captures non-linearity and imprecision	This paper

3.2 Gradient-Boosting Quantile Estimation

Gradient boosting builds an additive ensemble of regression trees by fitting each new tree to the negative gradient of the loss function of the ensemble so far [15]. For quantile regression, the loss is the check loss (1). For each desired quantile τ [4]. A separate gradient-boosting regressor (GBR) is trained. The GBR starts with a constant initial prediction (e.g., the median of the training targets) and iteratively adds trees to minimize the quantile loss. Hyper-parameters include the number of trees M, maximum tree depth d and learning rate η. Cross-validation is used to select M, $d$and η that minimise the validation quantile loss.

Figure 2 (architecture diagram) depicts the multi-quantile model. Each input vector $\mathbf{x} = (x_1, x_2)$ passes through an ensemble of regression trees to produce three outputs $\backslash\hat{y}_{q_l}$, $\hat{y}_{0.5}$, and $\hat{y}_{q_u}$. These outputs are then combined into a fuzzy number as described above.

3.3 Training Algorithm

The training procedure is summarized in Algorithm 1.

Algorithm 1. Training of the soft nonlinear quantile AI model [15].

1) Data preparation: obtain a training set $\{(\mathrm{x}_i, \tilde{y}_i)\}_{i=1}^{n}$where$\tilde{y}_i = (y_{i,q_l}, y_{i,0.5}, y_{i,q_u})$ are fuzzy responses defined by specified quantile levels q_l< 0.5< q_u.
2) Model selection: for each quantile level $\tau \in \{q_l, 0.5, q_u\}$, perform grid search on M, d, and ηusing cross-validation to minimize the empirical risk $\sum_i * \rho_\tau(y_{i,\tau} - f_\tau(\mathrm{x}_i))$.
3) Training: fit a gradient-boosting regressor f_τ on the full training data using the selected hyper-parameters for each τ.

4) Prediction: given a new input x, compute $\hat{y}_\tau = f_\tau(\mathrm{x})$ for each τ and reconstruct the fuzzy prediction $\hat{\tilde{y}} = (\hat{y}_{0.5} - \hat{y}_{q_l}, \hat{y}_{0.5}, \hat{y}_{q_u} - \hat{y}_{0.5})$.

Figure 1 shows the workflow: inputs feed into separate quantile models; their outputs are combined to yield a fuzzy prediction. Figure 2 visualizes the architecture of a single quantile model as a sequence of regression trees.

3.4 Optimization and Implementation

Hyper-parameters M, d, η were tuned using 5-fold cross-validation on the training set. Early stopping was applied by monitoring improvement in the out-of-bag estimate. The models for different quantiles were tuned independently. The final fuzzy prediction is the aggregation of these three models. A baseline linear quantile regression using the interior-point algorithm serves as a comparator. The statistical significance of performance differences is assessed via a paired t-test on the absolute errors of the predicted centres.

4 DATA GENERATION AND IMPLEMENTATION

4.1 Synthetic Dataset

To illustrate the model, a synthetic dataset was created. Two predictors $X_1, X_2 \sim \mathrm{Uniform}(0,1)$ were sampled. The true crisp response was defined as

$$y_i^* = \sin(2\pi X_{i1}) + \cos(\pi X_{i2}) + 0.5\, X_{i1}, \quad (3)$$

This function captures both nonlinear and linear dependencies between the predictors and the response:

- $\sin(2\pi X_{i1})$ introduces a nonlinear periodic component based on the first predictor;
- $\cos(\pi X_{i2})$ introduces a nonlinear periodic component based on the second predictor;
- $0.5X_{i1}$ adds a linear effect proportional to X_{i1}.

And noisy fuzzy responses were generated by adding Gaussian noise $\varepsilon \sim \mathcal{N}(0, 0.1^2)$ obtain the centre and sampling left and right spreads from truncated normal distributions with mean 0.2 and standard deviation 0.05. The quantiles $q_l = 0.25, 0.5$ and $q_u = 0.75$ were used. The data were split into a 70:30 training:test ratio. Figure 3 shows a scatter plot of the predictors colored by the true center.

Scatter plot of predictors colored by the true response.

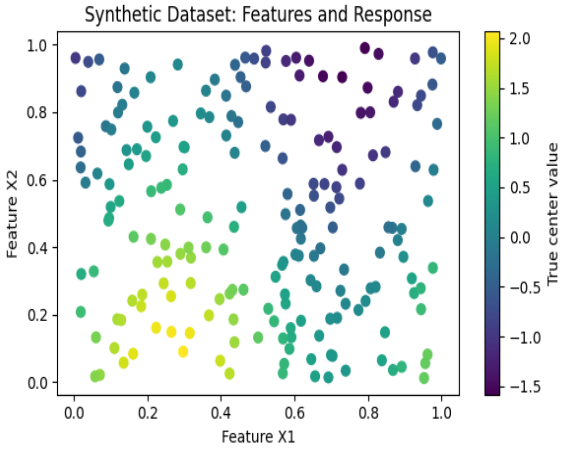

Figure 3: Synthetic dataset and true center.

4.2 Implementation Details

The models were implemented in Python (scikit-learn). For each quantile level {0.25,0.5,0.75} a GradientBoostingRegressor with quantile loss was trained on the training data. Hyper-parameter grids included M ∈ {100,200,300}, depths d ∈ {2,3,4} and learning rates η ∈ {0.05,0.1}.

Cross-validation selected the best configuration for each quantile separately. The baseline linear quantile regression used the default interior-point method. After training, the quantile outputs were combined into fuzzy predictions. Evaluation metrics were computed on the test set:

- Root mean squared error (RMSE) of the center: $\mathrm{RMSE} = \sqrt{\frac{1}{n}\sum_i^* (y_i^* - \hat{y}_{C,i})^2}$.
- Mean absolute error (MAE) of the center: $\mathrm{MAE} = \frac{1}{n}\sum_i^* | y_i^* - \hat{y}_{C,i} |$.
- Spread errors. MAEs of left and right spreads $\hat{y}_{L,i}$ and $\hat{y}_{R,i}$.
- Coverage probability: proportion of true centers within $[\hat{y}_{q_l}, \hat{y}_{q_u}]$.
- Width error: mean absolute error of total width $(\hat{y}_{R,i} + \hat{y}_{L,i}) - (y_{R,i} + y_{L,i})$.
- Paired t-test: to compare absolute center errors between models.

5 RESULTS AND DISCUSSION

5.1 Quantitative Comparison

Table 2 and Figure 4 compares the performance of the proposed soft nonlinear quantile AI model with the baseline linear quantile regression. The proposed model achieves substantially lower errors and superior coverage. The paired t-test yields a t-statistic of 11.20 with $p \approx 1.1 \times 10^{-18}$, indicating that the improvements are highly significant.

Figure 4 illustrates the overall performance of the models on the synthetic dataset. Beyond aggregate performance metrics, analyzing the distribution of prediction errors across individual test instances provides deeper insight into model behavior. The results presented in Table 3 and Figure 5 show the mean and standard deviation of the absolute prediction errors for both models, while Table 4 summarizes the average predicted spreads in comparison with the true spreads. The proposed model not only achieves a lower mean error but also demonstrates reduced variability, indicating more stable and reliable predictions across the test set.

Table 2: Performance on the synthetic dataset.

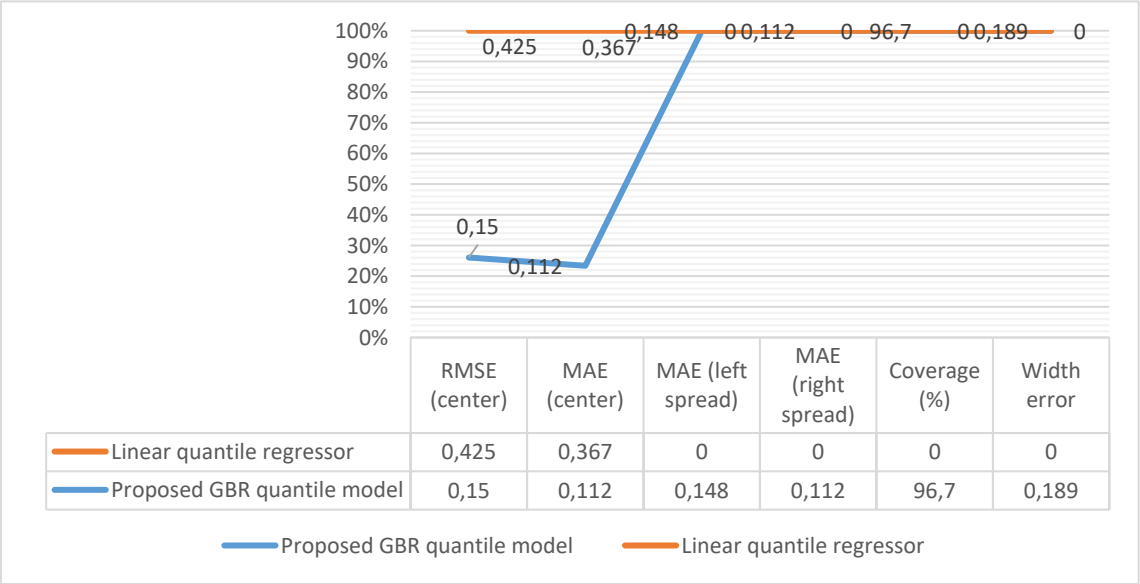
Model	RMSE (center)	MAE (center)	MAE (left spread)	MAE (right spread)	Coverage (%)	Width error
Proposed GBR quantile model	0.15	0.112	0.148	0.112	96.7	0.189
Linear quantile regressor	0.425	0.367	–	–	–	–

Table 3: Distribution of absolute center errors (mean ± SD).

Model	Mean absolute error	Standard deviation
Proposed GBR quantile model	0.112	0.081
Linear quantile regressor	0.367	0.274

Table 4: Comparison of spreads (mean values).

Quantity	True average	Proposed prediction	Baseline prediction
Left spread	0.2	0.178	–
Right spread	0.2	0.192	–
Total width	0.4	0.37	–



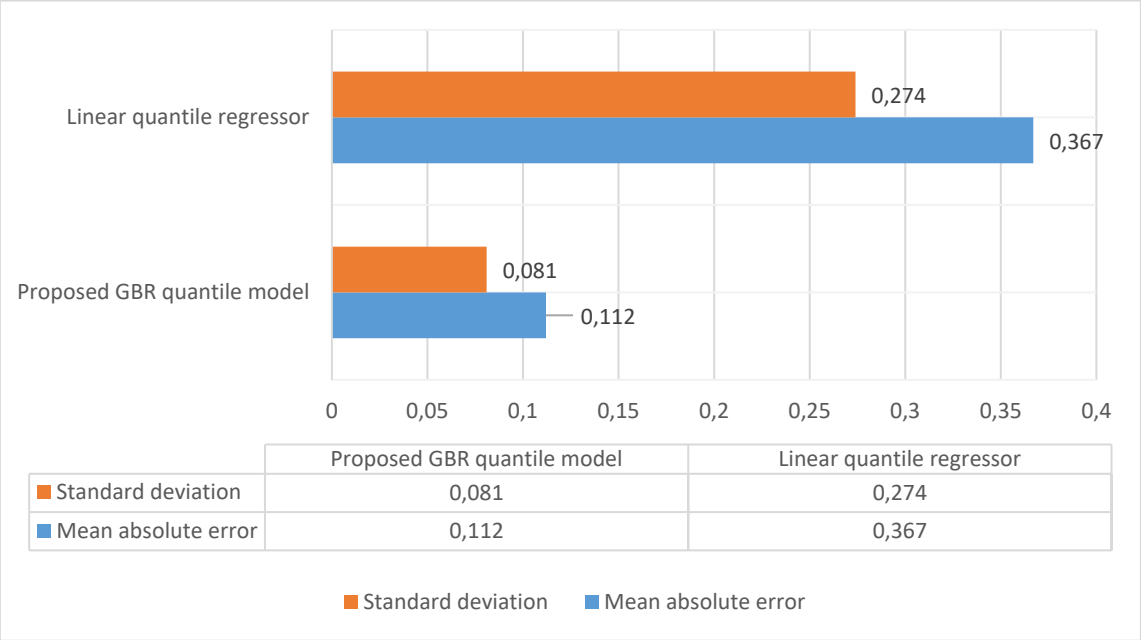


Figure 4: Performance on the synthetic dataset.

	Proposed GBR quantile model	Linear quantile regressor
Standard deviation	0,081	0,274
Mean absolute error	0,112	0,367

Figure 5: Distribution of absolute center errors (mean ± SD).

5.2 Visual Analysis

Figure 4 plots the predicted center versus the true center for both models. Points lying on the diagonal indicate perfect predictions. The proposed model's points cluster tightly around the diagonal, whereas the linear model exhibits greater scatter and systematic bias.

Figure 5 shows sample fuzzy intervals for 15 random test instances. Blue bars depict the true 25th–75th percentile interval; red bars depict the predicted interval. The proposed model produces intervals that align well with the true ones and tend to be slightly narrower, indicating a good balance between sharpness and coverage.

The predicted centers generated by the suggested soft nonlinear quantile-based AI model substantially resemble the genuine centers, as shown in Figure 6. When compared to the linear quantile regression model, the majority of data points are centered around the diagonal line, showing low systematic bias and excellent prediction accuracy.

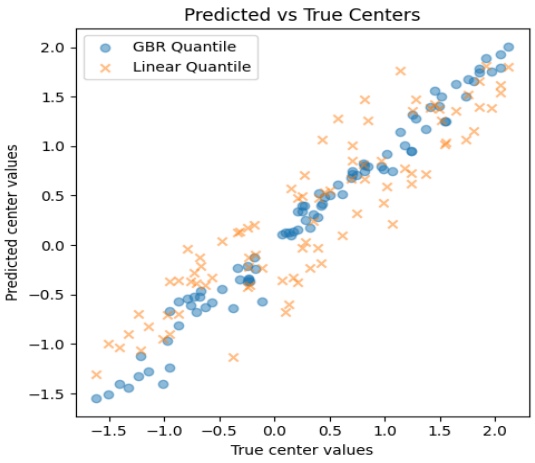

Figure 6: Predicted vs. true centers.

Scatter plot comparing predicted and true centers; points close to the diagonal indicate accurate predictions.

Figure 7 shows a comparison of the actual and anticipated fuzzy intervals.

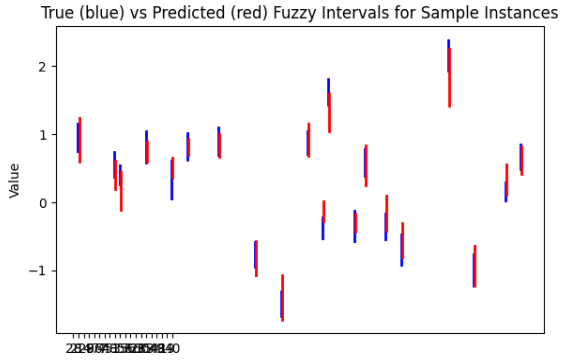

Figure 7: True vs. predicted fuzzy intervals.

The model's ability to accurately capture uncertainty while keeping relatively narrow and informative intervals is demonstrated by the figure, which demonstrates that the predicted fuzzy intervals for the majority of test instances correlate well with the genuine 25th–75th percentile intervals.

Bar chart showing true (blue) and predicted (red) fuzzy intervals for sample instances.

6 DISCUSSION

The quantitative and visual results demonstrate the merits of the proposed soft nonlinear quantile AI model. The ensemble of gradient-boosting regressors successfully learns the non-linear mapping from inputs to quantiles, yielding low RMSE and MAE. By reconstructing fuzzy numbers from quantiles, the model captures imprecision and yields interpretable spreads. The high coverage probability (over 96 %) confirms that the predicted intervals rarely miss the true center, while the modest width error indicates that the intervals are not excessively wide. The baseline linear quantile model, in contrast, cannot accommodate the non-linearity of the underlying function, leading to large errors and poor coverage.

The comparative tables highlight that the proposed model reduces not only the mean error but also its variance, providing more reliable predictions (Table 3). The predicted spreads are close to the true spreads (Table 4), showing that the fuzzy reconstruction preserves the extent of imprecision. The visualizations in Figures 4 and 5 complement these findings: the predicted centers follow the diagonal closely and the predicted intervals align with the true intervals. These results corroborate the hypothesis that combining quantile regression with gradient boosting and fuzzy representation yields significant gains over traditional methods.

7 CONCLUSIONS

With the goal to manage inaccuracy, nonlinearity, and distributional asymmetry within a single framework, this study suggested a soft nonlinear quantile-based AI regression model that combines fuzzy representation with gradient boosting quantile regression. The model produces comprehensible forecasts that represent both central tendency and uncertainty by reconstructing fuzzy outputs from many conditional quantiles (the 25th, 50th, and 75th percentiles).

In terms of prediction accuracy, interval coverage, and width efficiency, the suggested method greatly beats linear quantile regression, according to experimental results on a synthetic dataset. The model's capacity to precisely predict the center and spreads of fuzzy responses is confirmed by lower RMSE and MAE values, better coverage probabilities, and well-calibrated fuzzy intervals. These conclusions were further corroborated by visual evaluations that revealed a close agreement between the true and anticipated fuzzy intervals.

Applications including risk analysis, financial modeling, environmental forecasting, and medical decision assistance that are marked by uncertainty and intricate nonlinear interactions can benefit from the suggested approach. The approach improves interpretability and prediction performance by fusing fuzzy quantile representation with contemporary ensemble learning.

In order to better understand the impact of predictors on fuzzy prediction components, future research will concentrate on validating the method using real-world datasets, expanding it to temporal and multivariate fuzzy outputs, and integrating explainable AI techniques.

Keywords: Functional Data Analysis, Multivariate Functional Data, Orthonormal Basis Expansion, Functional Principal Component Analysis, Covariance Function, Dimensionality Reduction.

Abstract: In many scientific and engineering applications, data are collected over discrete, often equidistant, time intervals. While such data can be analyzed using traditional statistical methods, these methods are often very limited in their ability to capture the underlying continuous nature of dynamic processes of the phenomenon under study. This study aims to present and develop a statistical methodology for analysing multivariate functional data characterised by structural complexity, nonlinear properties, and continuous nature of its observations and variables. By using the Functional Principal Component Analysis (FPCA) method to analyse high-dimensional data through dimensionality reduction, and accurately discovering structural patterns in the data without relying on fixed distributional assumptions. Also, improving model selection using the Bayesian Information Criterion (BIC), which determines the optimal number of orthogonal basis functions and enhances the model's fit to the complexity of the data, thereby contributing to the accuracy of the analysis and understanding of relationships within the functional data.

1 INTRODUCTION

The rapid technological advancement in our current era has made the field of advanced data analysis a fundamental pillar for making strategic decisions in various scientific and practical fields, especially with the increase in the volume and complexity of available data. While much of the current research focuses on traditional data analysis methods, these approaches often struggle to handle the multidimensional and complex nature of modern datasets. Previous studies have not fully addressed the challenges associated with analyzing continuous functional data, which are characterized by their temporal or spatial nature. These data are typically represented as curves or functions instead of discrete points, requiring advanced analytical methods capable of capturing their complexities.

For example, functional data is represented in applications across various fields such as radio signal processing, where signals are continuously measured over time, monitoring brain electrical activity (EEG), analyzing growth rates over time, as well as climate changes like continuous temperature readings. Therefore, functional data analysis is of utmost importance. These examples highlight the necessity of using advanced techniques that can handle the continuous and overlapping nature of this data.

In particular, Functional Data Analysis (FDA) has emerged as a fundamental tool for handling these continuous data [1]-[3], yet its application remains limited in some fields, especially in the context of multivariate analysis. It has become increasingly necessary to use analytical techniques that can effectively manage the nonlinear, intertwined, and high-dimensional structure of functional data.

Despite the development of some methods, such as Functional Principal Component Analysis (FPCA), to reduce dimensions and discover principal components, there remains a gap in the ability to ideally determine the number of basic functions and fit the model to the complexity of the data.

This study aims to address these gaps by presenting a statistical approach for Functional Principal Component Analysis (FPCA), utilizing the Bayesian Information Criterion (BIC) for optimal selection of the number of orthogonal basis functions. By improving the methodology of functional data analysis, this study contributes to the advancement of multivariate analysis of functional data, providing

more accurate and efficient tools for handling complex datasets. The value of this research lies in its ability to provide a more flexible and statistically robust approach to functional data analysis, thereby expanding the potential applications of this technique in various scientific and practical fields.

Functional data analysis (FDA) is considered the fundamental basis for analyzing random processes of phenomena that change continuously and over short time intervals within a specific time frame, where each observation is represented as a continuous function composed of a set of connected points. From here, the method of multivariate functional principal component analysis (FPCA) emerged as an analytical tool to handle this continuous nature, unlike the traditional PCA method which deals with discrete standard data [4].

The traditional covariance matrices used in conventional analysis methods differ from the variance function, which plays an important role in functional principal component analysis due to its ability to handle data with intertwined or irregular nature [1], [5]. There are three basic strategies for estimating functional principal components identified et al. [6], which are:

1) Using the sample variance function. Using the sample variance function.
2) The estimation directly from the curves fitted for each function individually. Estimation directly from the curves suitable for each function individually.
3) Using the Qatari version of the variance function.

These techniques flexibly deal with continuous stochastic processes that change over time and within a specific time frame, such as electroencephalography, electrocardiography, stock prices, securities, and environmental changes. Wei et al. [7] also proposed a new methodology to improve the selection of an appropriate model that fits the complexity of continuous data and made adjustments to the Akaike Information Criterion (AIC) and the Bayesian Information Criterion (BIC) for dual modelling of functional data. The importance of this study lies in providing efficient computational procedures for selecting the number of principal components of functions and tuning parameters using partial least squares regression. This helps in determining the model's accuracy and computational procedures compared to traditional methods such as cross-validation. The numerical results show that the use of modified information criteria yields results similar to or close to traditional methods with a significant reduction in time, effort, and cost, making them suitable for real-world scientific applications such as environmental, biological, and medical data analysis [8].

2 RESEARCH METHODOLOGY

The methodology transforms discrete data (observations) into continuous data (functions) using orthogonal basis function representations. We assume a stochastic process for a continuous phenomenon that varies over time and within a specified time domain in a Hilbert space [2]. The coefficients are estimated using the least squares method. FPCA is used to reduce the dimensionality while preserving the maximum amount of explained variance in the data [9]-[10]. The Bayesian information criterion (BIC) is then used to determine the model's fit and accuracy to the inherent complexity of the data. The final model captures the hidden relationships and dynamics of the original data and the essential components for interpreting the data.

3 MATERIALS AND METHODS

3.1 Transformation of Discrete Data to Multivariate Functional Data

In many scientific applications and fields, data are collected as discrete points for the phenomenon under study. In order to analyze the phenomenon accurately and clearly, it is necessary to represent the data as continuous functions to study and analyze the function in its entirety. This occurs especially when dealing with continuous random processes that change over time and within a specific time range. The FDA allows the analysis of functions using orthogonal basis functions and estimating their parameters. This involves using a series of orthogonal basis functions, then estimating the coefficients using the least-squares method, followed by smoothing the data and determining the appropriate model using the BIC.

3.1.1 Mathematical Representation of the Stochastic Process

Suppose we have a random process $X(t)$, where $t \in I$ and I represents the time domain. $X(t)$ belongs to the quadratic integrable Hilbert space $L^2(I)$,, in the domain of the function I. The random process is

represented as a linear combination of orthogonal basis functions $\varphi_b(t)$ of the domain I:

The process can be expressed as a sum of orthonormal basis functions [1] $\varphi_b(t)$:

$$X(t) = \sum_{b=0}^{B} c_b \, \varphi_b(t), \quad t \in I. \tag{1}$$

Where:

- $\varphi_b(t)$ are orthonormal basis functions;
- c_b are the random;
- B is the total number of basis functions.

3.1.2 Discrete Observations

The process $X(t)$ is observed at discrete time points $t_1, t_2, \ldots, t_J$, where $t_j \in I$ for $j = 1,2,\ldots,J$. Let x_j represent the observed value of $X(t)$ at time t_j. The observed data is represented by the vector:

$$\mathrm{x} = \left(x_1, x_2, \ldots, x_J\right)^T.$$

These are the discrete observations, which we will transform into a continuous function.

3.1.3 Coefficient Estimation Using Least Squares

To convert the discrete data into a continuous function, we use the least squares method to estimate the coefficients c_b. The coefficients c is estimated using the least squares method using the following formula:

$$S(\mathrm{c}) = (\mathrm{x} - \Phi(t)\mathrm{c})^T(\mathrm{x} - \Phi(t)\mathrm{c}),$$

Where:

- $\Phi(t)$ represents the matrix of basic functions at the discrete time points t_j.
- $\mathrm{c} = (c_0, c_1, \ldots, c_B)^T$ represents the vector of coefficients to be estimated.

3.1.4 Inner Product for Functional Data

The inner product is used to compute the projections of the data onto the basis functions using the least squares method. The inner product between two functions $u(t)$ and $v(t)$ is given by:

$$\langle u, v \rangle = \int_I u'(t) v(t) \, dt. \tag{2}$$

Where:

- $\langle u, v \rangle$ represents the inner product of the two functions $u(t)$
- $v(t)$, $u'(t)$ is the derivative of $u(t)$ (if needed for the particular function space)
- The integral is taken over the interval I.

The inner product is used to calculate the projection of the observed data x_j onto the basis functions $\varphi_b(t)$. to ensure the smoothness of the function.

3.1.5 Reconstructing the Continuous Function

After estimating the coefficients c, the random process $x(t)$ is characterized by the following formula:

$$x(t) = \textstyle\sum_{b=0}^{B} \hat{c}_b \, \varphi_b(t), \quad t \in I. \tag{3}$$

The continuity equation for the observed data **x**.

3.1.6 Multivariate Functional Data

Multivariate functional data are handled by expanding the underlying process. Let $X(t) = \left(X_1(t), X_2(t), \ldots, X_p(t)\right)^T$ where p is a vector of random processes that are summed to the same discrete time points.

The representation of each component $X_d(t)$ for $d = 1,2,\ldots,p$ is given by:

$$X_d(t) = \textstyle\sum_{b=0}^{B_d} c_{db} \, \varphi_b(t), \quad t \in I, \quad d = 1,2,\ldots,p.$$

Where $\varphi_b(t)$ represents the basis functions of each component, and c_{db} are the coefficients of the d-th component. The multivariate functional data is represented as:

$$\mathrm{X}(t) = \sum_{d=1}^{p} \Phi_d(t) \mathrm{c}_d, \quad t \in I. \tag{4}$$

Where:

- $\Phi_d(t)$ is the matrix of basis functions for the d-th component,
- c_d is the vector of coefficients for the d-th component.

3.1.7 Matrix Representation of Coefficients

The coefficient vector $c$and the matrix $\Phi(t)$are obtained using the following:

- Coefficient Vector c:

$$\mathrm{c} = \left[c_{1B1}, c_{1B2}, \ldots, c_{pBp}\right]^T$$

- Matrix $\Phi(t)$:

$$\Phi(t) = \begin{bmatrix} \varphi'_B 1(t) & 0 & \cdots & 0 \\ 0 & \varphi'_B 2(t) & \cdots & 0 \\ & & \ddots & \\ 0 & 0 & \cdots & \varphi'_B p(t) \end{bmatrix}.$$

Multiplying $\Phi(t)$ by the coefficient vector c reconstructs the multivariate functional data:

$$\mathrm{X}(t) = \Phi(t)\mathrm{c}. \tag{5}$$

3.1.8 Model Selection Using Bayesian Information Criterion (BIC)

To determine the optimal number of basic functions B, we use the Bayesian Information Criterion (BIC) to improve and fit the model.
The formula for BIC is:

$$BIC = \ln\left(\sum_{j=1}^{J}\left(x_j - \sum_{b=0}^{B}\hat{c}_b\,\varphi_b(t_j)\right)^2\right) + (B+1)\left(\frac{\ln J}{J}\right).$$

3.1.9 Final Transformation to Functional Data

After estimating the coefficients $\hat{\mathrm{c}}$, the continuous functional data is obtained:

$$\mathrm{X}(t) = \Phi(t)\,\hat{\mathrm{c}}. \tag{6}$$

It represents the reconstructed functional data from the discrete data.

3.1.10 Principal Component Analysis for Functional Data

MFPCA is an advanced analytical statistical method that reduces dimensions and extracts main patterns from complex data containing many functional variables. These variables are described as mathematical functions that change continuously over space or over closely spaced time intervals within a specific time frame, allowing for the analysis of the variance present within the complex data.

The mathematical steps of the MFPCA method begin by identifying the principal components that explain the greatest amount of variance in the data. This is done by finding weight functions or (weight vectors) that represent these components. Where the first principal component, which represents the largest variance in the data, is extracted, followed by finding the other components with the constraint that these components are uncorrelated with the previous components. This allows for dimensionality reduction without losing the important information contained in the data.

In applications that involve variables changing continuously over time or any other continuous data, we use the MFPCA method to analyse those variables. MFPCA allows for understanding the complex relationships between variables and discovering hidden patterns that may not be visible when analysing the variables separately at discrete data points. This is achieved by transforming the data into a new set of uncorrelated principal components, ordered from greatest variance to least, while preserving the variance of the original data. If we have a random vector $X = \left(X_1, X_2, \ldots, X_p\right)' \in \mathbb{R}^p$We look for a linear combination $U_1 = u_{11}X_1 + u_{12}X_2 + \cdots + u_{1p}X_p = u_1'X$, where X is the vector of components that has the maximum variance. Where U_1 represents the first principal component, we then find a linear combination $U_2 = u_2'X$ which is unrelated to the first component U_1 and so on until we reach the k-th stage, followed by a linear combination $U_k = u_k'X$ for the k-th principal component, which has the maximum variance and is also unrelated to the previous principal components.

PCA helps understand the structural composition of the variance in the covariance matrix of one-dimensional functional data [4], [12], [13].

3.2 Functional Principal Component Estimation

In multivariate functional PCA, we aim to find the inner product:

$$U = \langle u, X\rangle = \int_I u'(t)X(t)\,dt. \tag{7}$$

Equation (5) represents the projection of the functional data onto the vector function u, which has the largest variance for all $u \in L_2^p(I)$, where $\langle u, u\rangle = 1$, and it is assumed that:

$$\lambda_1 = \sup_{u \in L_2^p(I)} \mathrm{var}(\langle u, X\rangle) = \mathrm{var}(\langle u_1, X\rangle). \tag{8}$$

Where:

- u_1 represents the first eigenfunction;
- λ_1 represents the first eigenvalue.

The first principal component is determined as the direction that maximizes the variance, defined as $U_1 = \langle u_1, X\rangle$, where $u_1(t)$ represents the eigenfunction corresponding to the first principal component.

Finally, then find the second principal component $U_2 = \langle u_2, X\rangle$ to maximize the variance $\mathrm{var}(\langle u, X\rangle)$, provided the condition $\langle u_1, u_2\rangle = 0$ (i.e., orthogonality of the first component).

3.2.1 General Principal Components

In general, the k-th principal component $U_k = \langle u_k, X \rangle$ satisfies the following:

$$\lambda_k = \sup_{u \in L_2^p(I)} \text{var}(\langle u, X \rangle) = \text{var}(\langle u_k, X \rangle).$$

Where, $\langle u_{k_1}, u_{k_2} \rangle = \delta_{k_1 k_2}, k_1, k_2 = 1, \dots, k$

$\delta_{k_1 k_2}$ is the Kronecker delta, which is:

$$\delta_{k_1 k_2} = \begin{cases} 1 & if\ k_1 = k_2 \\ 0 & if\ k_1 \neq k_2 \end{cases}.$$

Thus, the functional principal component system $\left(\lambda_k, u_k(t)\right)$ for the process $X(t)$ is defined, and we represent the process $X(t)$ as:

$$X(t) = \Phi(t)c, \quad t \in I. \tag{9}$$

Where $E(X) = 0$, $E(c) = 0$, and $\text{Var}(c) = \Sigma$. The k-th principal component $U_k^* = \langle \omega_k, c \rangle$ for this vector satisfies:

$$\gamma_k = \sup_{\omega \in \mathbb{R}^{k+p}} \text{Var}(\langle \omega, c \rangle) = \omega' \Sigma \omega. \tag{10}$$

Where:

- ω_k is the eigenvector corresponding to the k-th principal component,
- Σ is the covariance matrix of c, The k-th principal component system $\left(\lambda_k, u_k(t)\right)$ is related to the principal component (γ_k, ω_k) of the random vector c via the equation:

$$\lambda_k = \gamma_k, \quad u_k(t) = \Phi(t)\omega_k, \quad t \in I.$$

Where, $k = 1, \dots, s$, and $s = \text{rank}(\Sigma)$.

3.2.2 Principal Component Estimation from Samples

For estimating the principal components from samples, assume that we have n independent observations $x_1(t), \dots, x_n(t)$ of the random process $X(t)$. These are of the form:

$$x_i(t) = \Phi(t)\hat{c}_i. \tag{11}$$

Where $\hat{c}_i$ are the sample coefficients, and $\hat{C} = (\hat{c}_1, \hat{c}_2, \dots, \hat{c}_n)'$.

The covariance matrix $\hat{\Sigma}$ is estimated as:

$$\hat{\Sigma} = \frac{1}{n} \hat{C}' \hat{C}. \tag{12}$$

Where, $\hat{\Sigma}$ is the sample covariance matrix.

The eigenvalues $\hat{\gamma}_1 \geq \hat{\gamma}_2 \geq \cdots \geq \hat{\gamma}_s$ are the non-zero eigenvalues of $\hat{\Sigma}$, and the eigenvectors $\hat{\omega}_1, \hat{\omega}_2, \dots, \hat{\omega}_s$ are the corresponding eigenvectors.

The principal components for the random process $X(t)$ based on the sample data are:

$$\left(\hat{\lambda}_k = \hat{\gamma}_k, \hat{u}_k(t) = \Phi(t)\hat{\omega}_k\right) \qquad k = 1, \dots, s. \tag{13}$$

4 SIMULATION OVERVIEW

4.1 Simulated Functional Data and FPCA Analysis

The simulation produces artificial multivariable functional data consisting of 10 sample curves, each observed over 50 equally spaced time points in the interval [0, 1]. Three functional components are simulated to represent distinct dynamical patterns: a sinusoidal trend (variable 1), a cosine-based oscillation (variable 2), and a linear trend with noise (variable 3). These components simulate real-world scenarios such as physiological signals, environmental measurements, or sensor outputs. The discrete data are then transformed into smooth functional representations using Fourier basis extensions, with the number of basic functions chosen via the Bayesian Information Criterion (BIC) to balance model fit and complexity, as shown in Table 1. Functional principal component analysis (FPCA) is applied to extract the dominant variance patterns, as shown in Tables 2, 3, 4, and 5, and dimensionality is reduced by projecting each curve onto the leading principal components, as shown in Table 6.

Table 1: Optimal number of basis functions and BIC values.

VAR	1	2	3

4.2 Analysis of Results

The results demonstrate a successful application of Functional Data Analysis (FDA) from data representation to dimensionality reduction. First, the Bayesian Information Criterion (BIC) effectively selects the optimal number of Fourier basis functions: 5 for Variables 1 and 2, and 8 for Variable 3. This is consistent with the nature of the variables: Variables 1 (sinusoidal) and 2 (cosine-based) are smooth and periodic, so they can be accurately represented with fewer basis functions, whereas Variable 3 follows a linear trend with added noise, which is less periodic and requires more basis functions (8) to capture its shape accurately. This demonstrates that BIC adapts to the complexity of each functional variable, avoiding both underfitting and overfitting.

After functional representation, Functional Principal Component Analysis (FPCA) is applied. The results show that the first three principal components explain a high percentage of total variation: 90.0% for Variable 1, 78.2% for Variable 2, and 78.4% for Variable 3 (see Figure A4 in the Appendix). Figures A1-A3 in the Appendix illustrate the functional principal components for each variable, highlighting the main patterns captured by FPCA. This indicates that most of the information in the original data is preserved in just a few components, enabling significant dimensionality reduction without major loss of insight.

The first component (FPC1) typically represents the main pattern – such as amplitude in oscillatory signals or overall slope in linear trends – while FPC2 and FPC3 capture secondary variations like phase shifts, curvature, or local fluctuations. Most samples have values close to zero when examining FPC scores, which indicates they follow the average pattern. However, some samples show varying degrees of deviation: for example, sample 6 in Variable 1 has a high positive FPC1 score, indicating a curve with above-average amplitude, while sample 9 shows the opposite. In Variable 3, sample 10 has the highest FPC1 score, reflecting a steeper upward trend, whereas sample 5 is flatter. Other deviations, such as the high FPC3 scores in samples 1 and 8, indicate unique local behaviours, including late peaks or noise patterns.

In general, the final reduced data matrix (10×9) consolidates all the scores into an interpretable and visualisable compact representation, where each sample is described by nine meaningful features, three for each variable. Table 6 presents this matrix, combining the top three FPC scores from each of the three functional variables into a single 9-dimensional feature space. This transformation reduces the original $10 \times 50 \times 3 = 1500$ discrete observations into a compact, structured, and interpretable format. The integration of scores allows for multivariate analysis – for example, detecting samples that simultaneously exhibit high amplitude in Variable 1, low offset in Variable 2, and steep slope in Variable 3. Sample 10, for instance, shows positive FPC1 scores in all three variables, indicating an above-average profile in overall magnitude, phase, and trend. In contrast, Sample 9 exhibits mostly negative scores, representing a below-average profile. Reducing high-dimensional data to a low-dimensional representation preserves the fundamental dynamics of the system and is crucial for clustering, classification, and other downstream analyses, demonstrating the practical value of FDA.

Table 6: Final reduced data matrix (10 × 9).

	V1-FPC1	V1-FPC2	V1-FPC3	V2-FPC1	V2-FPC2	V2-FPC3	V3-FPC1	V3-FPC2	V3-FPC3

5 CONCLUSIONS

The simulation results of our research show that functional data analysis (FDA) is a useful tool for converting high-dimensional, multivariate data into a simple, clear, low-dimensional representation while retaining the dynamic characteristics of the original data. That the criterion of information-theoretic virtualization turned out to optimally choose the number of base States, thereby achieving a kind of balance in the clarity of the model, balancing the accuracy of the model and complexity.

Functional principal component analysis explained the bulk of the data variance (between 78% and 90%) based on only three principal components, demonstrating the model's ability to capture primary patterns such as oscillations, linear trends and local variations.

6 RECOMMENDATIONS

In future research, researchers recommend conducting sensitivity analysis through simulated experiments or real data using various sample sizes and variable time intervals. This process will help to identify and limit the possibility of stability and accuracy of the model, in addition to increasing the researchers ' confidence in the practical application of the model across a variety of data situations. Sensitivity testing can also help in the real detection of any problems with generalization or overgeneralization of these cases, which directs to the improvement of the models and methods used.

Hybrid ARMAX-ANN Model for Temperature Forecasting

Raissan A. Zalan
Department of Statistics, College of Management and Economics, University of Basrah, 61004 Basrah, Iraq
ressan.zalan@uobasrah.edu.iq

Keywords ANN Model, ARMAX Model, Hybrid Models, MSE.

Abstract: Many researchers have been interested in improving known forecasting methods using several methods, including hybridizing time series models with one, two, or more models in order to obtain greater accuracy in predicting the data of the series to be predicted. Therefore, our research is an extension of the researchers who preceded us in order to provide forecasting methods that have an impact in the field in which they are used. Therefore, our study focused on the ARMAX model, as it is a model that combines time series models and a regression model, and it becomes more effective when it is hybridized with one of the artificial intelligence models (ANN) in order to improve forecasting results, which are considered important in decision-making and in all areas of life, including the average temperature in Basra Governorate. A comparison was made between the ARMAX models, the ANN model, and the ARMAX-ANN hybrid model in order to predict temperatures for the years (2024-2028), as it became clear that the hybrid model is better at forecasting using the MSE criterion.

1 INTRODUCTION

Researchers' pursuit of highly accurate forecasts is crucial, as it reduces risk and provides early warning to decision-makers regarding potential disruptions in the near future, enabling them to avoid them in various sectors. Although the ARIMAX model is excellent at predicting time series, these models may not provide highly accurate forecasts. This is because time series data contains two components: one linear and the other nonlinear. This means that ARIMAX models or neural networks alone may fail to model linear and nonlinear relationships. Therefore, we will use hybrid models, which are flexible and capable of handling different types of data. The forecasting process relies on a scientific and precise approach to predicting and obtaining future values. Therefore, this research aims to compare the ARIMAX model, the ANN model, and the hybrid model that combines them to determine which model is best for temperature forecasting. Based on the MAPE metric, it was found that the best forecasting model is the hybrid model.

2 PREVIOUS STUDIES

We will present some previous studies using the ARMAX model. Among these studies is the 2016 study by Muhammad & Fakhri, which aimed to achieve higher forecasting accuracy by using ARMAX models. They used a series of exogenous variables and a series of past errors, then used the best estimate method to predict the maximum temperature for the next 30 days [1]. Another study by Alkali & others in 2019 aimed to compare the ARIMA and ARIMAX models to predict residential property prices in Abuja, Nigeria, using quarterly data on average home sales prices from the first quarter of 2000 to the last quarter of 2017. The results showed that the ARMAX model outperformed ARIMA models in general [2]. Another study by Musa and others in 2021 aimed to study the impact of independent variables, such as rainfall, temperature, and humidity, on selected agricultural crops using the ARIMAX model and then predict them [3].

3 RESEARCH PROBLEM

The prediction process using some single models, such as the ARIMAX model or the ANN model, is considered insufficient, as the predictions do not provide high accuracy in most c Both linear and nonlinear relationships are present in this data. However, if the used series model is hybridized with an artificial intelligence (AI) prediction model, the hybrid model will perform better, and we will obtain more accurate predictions for the time series than the single models.

4 OBJECTIVE

To improve the ARMAX prediction model by using the hybridization method with an ANN model, one of the artificial intelligence methods, to predict average temperatures in Basra Governorate.

5 THEORETICAL ASPECT

5.1 The ARMA Model

It is called the Autoregressive Moving Averages (ARMA) model [3], and it is a special case of the Autoregressive Integrated Moving Means (ARIMA(p,d,q) model. When the series is stationary (d=0), it is written as ARMA(p,q), where p is the autoregressive order (AR) and q is the moving mean order (MA). The mathematical form of the ARMA model is: ases. Because the time series contains two parts, one linear and the other non-linear, they:

$$y_t = \delta + \sum_{i=1}^{p} \emptyset_i y_{t-i} + e_t - \sum_{j=1}^{q} \theta_j e_{t-j} \dots\dots(1)$$

5.2 ARMAX Model

The ARMAX (AutoRegressive Moving Average with eXogenous inputs) [4], [1] model is an extension of the ARMA model that incorporates external (exogenous) variables. In this model, the time series Y_t is expressed as a function of its past values, past error terms, and exogenous variables. The general form of the ARMAX model is given by:

$$y_t = \delta + \sum_{i=1}^{p} \emptyset_i y_{t-i} + e_t - \sum_{j=1}^{q} \theta_j e_{t-j} + \sum_{k=1}^{r} \pi_k X_{k,t-1} \dots\dots$$

- Yt: The value of the observed phenomenon at time t;
- δ: The constant;
- $\emptyset_i$: Autoregressive (AR) model parameters;
- θ j: Moving Average (MA) model parameters;
- π _k: The exogenous variable parameters;
- et: The random error.

5.3 Artificial Neural Networks (ANNs)

Artificial neural networks (ANNs) [5] are considered one of the most important and widely used methods of artificial intelligence. Their concept is derived from simulating the human brain's ability to recognize patterns and distinguish objects using computational models. This approach is based on a learning process inspired by the human brain, which relies on past experiences to improve performance in future tasks. The following Figure 1 illustrates a basic operating unit of a neural network.

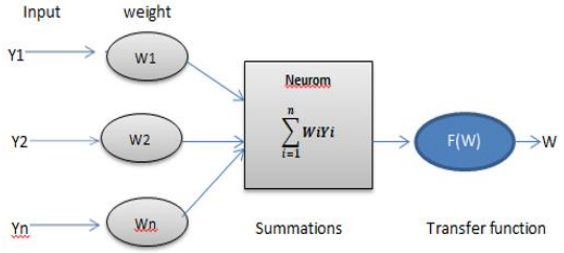

Figure 1: Model of an operating unit.

Each of the operating units contains one or more input paths through which information or data is transferred from the external world to the operating unit, which in turn performs a simple aggregation process. The information is then transformed after the aggregation process using an activation function known as a transfer function. It is then transferred as output through the output path. Mathematically, each artificial neuron will receive a few inputs (Y1, Y2,…, Yn), similar to the branches of neurons in humans. Each of these inputs is then multiplied by weights (W1, W2,…, Wn). These weights express the degree of importance of the inputs. The summed result ($\sum wiyi$) is then processed using the transfer function F(y) to obtain the final output.

5.4 Learning of the Neural Network

Learning of a neural network can be defined as the process by which a neural network can modify itself

in response to inputs to produce the desired output [3], [6]. It can also be defined as the process of acquiring knowledge using input data. During the learning process, the connection weights are adjusted, and this process continues until the network's outputs approximate the actual outputs. The process of teaching or training the network involves discovering typical relationships present in the input data, using one of the following methods.

5.4.1 Supervised Learning

This method is one of the most widely used methods for training neural networks. The network compares the results obtained for external variables with the actual input variables for each input sample. Based on this, the network's weights are adjusted to reduce errors. This process is repeated several times until acceptable results are achieved.

5.4.2 Unsupervised Learning

This method is similar to supervised learning, but differs in that the samples used in the training process do not include any values of external variables. Instead, the training process consists of input data, which consists of several groups. The network is trained to detect the most important features not apparent in the groups. These features are then used to divide the input data into groups that are distinct from each other, but similar within each group.

This method is a combination of the two previous methods. It does not use the values of external variables in the training process, as in unsupervised training, but it does indicate the validity of the network's results, as in supervised training.

6 TYPES OF NEURAL NETWORK STRUCTURES

There are several types of neural network structures [6], [7], which we will briefly explain:

6.1 Single-Layer Feed-Forward Network

This network is the simplest type of artificial neural network structure and is considered one of the most common types. It is the basic model upon which other single-layer network structures are built. It is also the simplest type of feed-forward neural network, as information is transferred directly from the input layer to the output layer. The network is trained via supervised learning. Figure 1 above illustrates the structure of this network. The learning process in this network is carried out through the following steps:

Setting random initial values for the weights (W1, W2,…, Wn) as well as an initial value for the threshold value (θ) within the range [-0.5, 0.5].

This step is called the activation process. Each processing unit receives multiple input signals and calculates the weighted sum of these inputs using the following sum function:

$$Y = \sum_{i=1}^{n} WiYi \ldots. \quad (3)$$

Where Y is the net weighted input to the neuron, Wi is the weights, Yi is the input value, and n represents the number of inputs to the neuron.

The output is calculated according to the following formula:

$$W(K) = STEP\left[\sum_{i=1}^{n} Wi(K)Yi\,(K) - \theta\right] \ldots\ldots\ldots\ldots (4)$$

The activation function is called the step function. There are many other activation functions, such as the sign function, the linear function, and the sigmoid function. The latter is the most commonly used because of its ease of differentiation and ease of calculating the slope.

The activation function is called a step function. There are many other activation functions, such as the sign function, the linear function, and the sigmoid function. The latter is the most commonly used due to its ease of differentiation and ease of calculating the slope.

6.2 Multilayer Feedforward Network

This artificial multilayer network is used to solve many complex problems that cannot be solved by a single-layer network. It propagates input signals forward from one layer to the next, without going backward. However, its drawback is that it takes longer to complete. Figure 2 illustrates the network's operation:

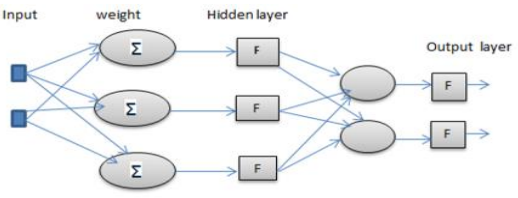

Figure 2: Multi-layer feed-forward network.

6.3 Multi-Layer Feedback Network

This type of network differs from the previous multi-layer network in that it contains at least one feedback loop. Unlike the previous feed-forward network, the error between the network's output and the actual output is calculated. However, the error is also fed in the opposite direction, i.e., in the opposite direction of the inputs, to adjust the weights and reduce the error.

7 HYBRID MODEL

The hybrid model [8], [9] is formed by combining a linear model with another non-linear model to address shortcomings in the individual model, whether linear or non-linear. This reduces errors resulting from using an inappropriate model, and it is an effective means of improving future predictions.

7.1 Steps for Constructing the Hybrid Model

1) Assume that the time series (yt) is a combination of two parts: the first is the linear autocorrelation part (Lt) and the second is the non-linear part (Nt).
2) We first use the ARMAX model to predict temperature values, then subtract the predicted values from the actual values to obtain the residual, which is recorded as a nonlinear component.
3) The residual is fed into the ANN or artificial neural network (ANN) model for prediction.
4) We obtain the predicted values for the hybrid model as follows:

$$Y_t = L_t + N_t \ldots. \quad (5)$$

8 MEAN SQUARE ERROR

The mean square error (MSE) [1], [8] is used to measure the accuracy of estimation or forecasting and is defined as:

$$\mathrm{MSE} = \frac{\sum_{i=1}^{n}(\mathrm{Pi} - \mathrm{Ai})^2}{n}. \quad \ldots \quad (6)$$

Where Ai denotes the actual (observed) value, Pi is the predicted (estimated) value, and n is the sample size.

9 PRACTICAL ASPECT

A practical analysis was conducted to predict temperatures in Basra Governorate by month using the ARMAX model, first relying on the AR and MA models, and the external variable, rainfall, for the years 1974-2023. Then, a neural network model was used, and the prediction was improved using the ARMAX-ANN mixed model, as follows:

Determining the rank of the ARMA(p, q) model: Before using the ARMAX model, it is necessary to know the stability of the time series of the two dependent variables, temperature and the external variable, rainfall. Using the unit root test, Table 1 was obtained:

Table 1: Unit root test for the dependent variable, average temperature in Basra (see Appendix, Table A1).

Null Hypothesis: Y has a unit root			
Exogenous: Constant			
Lag Length: 3 (Automatic - based on SIC, maxlag=19)			
		t-Statistic	Prob.*
Augmented Dickey-Fuller test statistic		-3.64623	0.0058
Test critical values:	1% level	-3.440275	
	5% level	-2.865810	
	10% level	-2.569102	
*MacKinnon (1996) one-sided p-values.			

From Table 1, the Augmented Dickey-Fuller test statistic is less than the critical values at all significance levels, and the corresponding p-value (0.0058) is less than 0.05. Therefore, the null hypothesis of a unit root is rejected, indicating that the dependent variable (average temperature) is stationary at level.

Table 2: Unit root test for the external variable: average rainfall in Basra (see Appendix, Table A2).

Null Hypothesis: X has a unit root			
Exogenous: Constant			
Lag Length: 8 (Automatic - based on SIC, maxlag=19)			
		t-Statistic	Prob.*
Augmented Dickey-Fuller test statistic		-3.682989	0.0046
Test critical values:	1% level	-3.440354	
	5% level	-2.865845	
	10% level	-2.569121	
*MacKinnon (1996) one-sided p-values.			

Similarly, the results in Table 2 show that the p-value (0.0046) is less than 0.05, leading to the rejection of the null hypothesis. Thus, the external variable (average rainfall) is also stationary at level.

The next step after stabilizing the variable at a difference of 0, is to determine the degree of both p and q in the ARMA model (Table 3):

By drawing the autocorrelation function and the partial autocorrelation function:

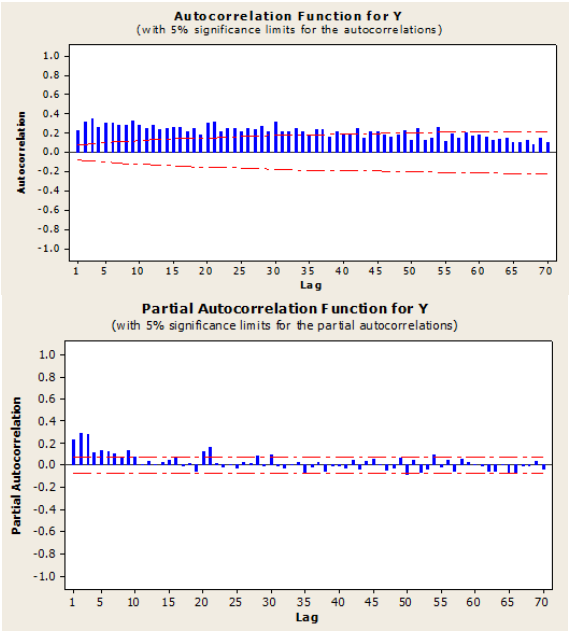

Figure 3: Autocorrelation and partial autocorrelation function of the dependent variable.

Figure 3 presents that the proposed model is ARMA (p, q). Therefore, several models were nominated, and it turned out that the best model is ARMA(1, 0) according to the MSE criterion:

Table 3: Comparison between ARMA models.

MSE	The Model
2.94	ARMA(1,0)
30.2	ARMA(0,1)
3.07	ARMA(2,0)
15.7	ARMA(0,2)
3.78	ARMA(1,2)
2.99	ARMA(2,1)
3.1	ARMA(2,2)

The results of ARMAX model estimation are presented in Figure 4.

From Figure 4, we note the significance of the estimated coefficients for the external variable, as well as the significance of the AR coefficient. The sign of the parameter for the variable coefficient is negative, which confirms the negative or inverse relationship between temperature and rainfall. Furthermore, the model explains approximately 96% of the changes in the temperature variable, which is a high percentage and confirms the model's predictive ability.

The forecasts for the years 2024-2028 are prepared monthly, as shown in Table 4 and Table 5. The result of ANN model estimation:

Dependent Variable: Y
Method: ARMA Maximum Likelihood (OPG - BHHH)
Date: 09/01/25 Time: 02:31
Sample: 1970M01 2023M12
Included observations: 648
Convergence achieved after 13 iterations

Figure 4: ARMAX model estimation.

A neural network model was used to predict average temperatures. A feedback network with a hidden layer containing (30) nodes was used to build a model used for time series prediction. Data was fed into the artificial neural network, as shown in the Figure 5.

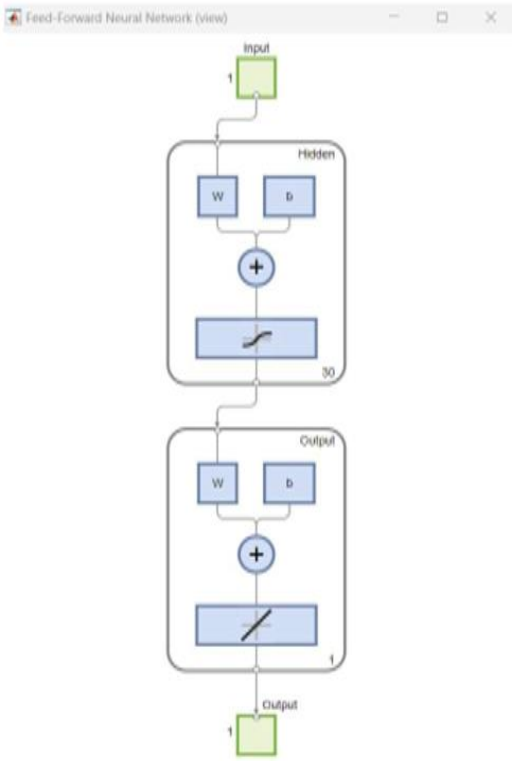

Figure 5: Artificial neural network architecture.

Through the Figure 5 and Figure 6, we notice that the input variables are linked to the hidden layer nodes, which number (30) nodes, and both of them are linked to the output node, and the strength of the relationship between the nodes, whether for input or output, is determined through the weight values (Wij), which are given initially in order for the network to be trained on them through the process of back-emission of the data.

Figure 6: Training results.

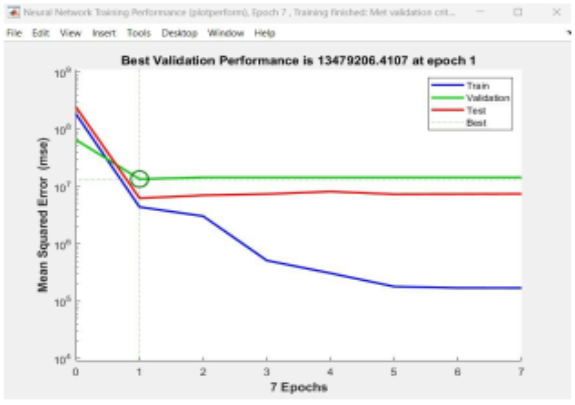

Figure 7: Best Validation Perform.

The data was divided into a training portion, which constitutes 60% of the original data, and a 20% portion for testing and validation of the robustness of the model outputted by the network. The learning parameter was set at 1% (alpha = 0.01). Figure 7 shows that the lowest error rate is achieved at iteration 107 during the neural network training process.

The Figure 7 shows that the slope value is equal to (0.0091) and will decrease as the number of training cycles for the network increases. As it decreases, the network learns more and more, thus decreasing the error rate (Mu = 0.001). The validation test is equal to (1) over (7) cycles. From the figure above, the errors generated by the neural network are normally distributed relative to the data that was trained and tested. This is a clear indication that the errors are acceptable, as they are normally distributed.

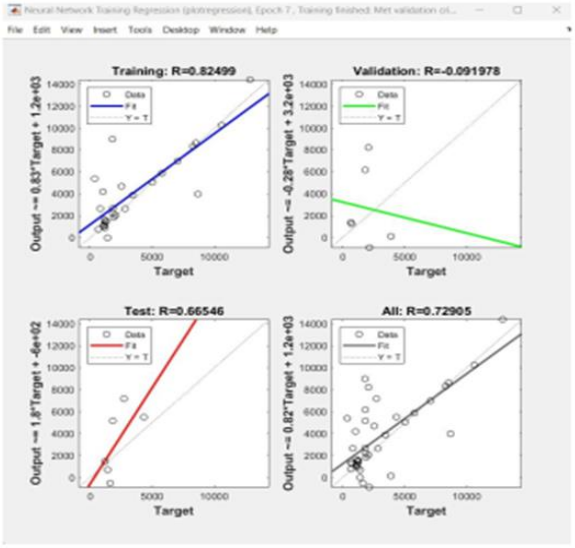

Figure 8: ANN Training regression (plot regression).

The Figure 8 shows that the training ratio was 0.82499 for the network sample, which consisted of 70% of the data. The testing ratio was 0.6654, which examines the samples, and the total ratio was 0.729.

The neural networks were predicted, and the mean square error was obtained with a value of 3.318782.

10 HYBRID MODEL

The errors generated by the ARMAX model were entered into the neural network, and the errors were obtained and combined with the predicted values of the ARMAX model to obtain the results of the hybrid model. The mean square error was calculated, and its value was 3.113275.

Table 4: Forecasting by using HYBRID MODEL for the years 2024-2028 by month.

Month of (2024)	Prediction value	Month of 2025	Prediction value	Month of2025	Prediction value	Month of 2025	Prediction value	Month of 2025	Prediction value

11	17.1355	11	18.9244	11	20.3510	11	21.49399	11	22.41487
12	17.3007	12	19.0559	12	20.4561	12	21.57847	12	21.89218

We note that using the hybrid model led to a reduction in the mean square error value. Therefore, it was used to predict the years 2024-2028 by month, and the following results were obtained in Table 5.

11 CONCLUSIONS

The results of the unit root test are presented in Table 1. The findings indicate that the ARMA(1,0) model is the most appropriate among the considered ARMA models. Furthermore, the neural network model demonstrates superior forecasting performance compared to the ARMA model, as evidenced by the mean square error (MSE) criterion. In addition, the ARMA–ANN hybrid model further improves forecasting accuracy, as reflected by a reduction in MSE values. Based on the forecasting results, an increase in temperatures in the coming years in Basrah Governorate is observed. These results highlight the importance of employing hybrid models in forecasting applications. Moreover, it is noted that predictive efficiency in time series analysis decreases when the data contain nonlinear components.

Keywords: Fog Computing, Internet of Things (IoT), Real-Time Data Processing, Task Offloading, Energy Efficiency, Edge Computing, Security, Quality of Service (QoS).

Abstract: The rapid expansion of the Internet of Things (IoT) has created massive streams of real-time data that require processing near their sources to ensure timely and efficient responses. Traditional cloud-centric architectures struggle to meet these demands, leading to significant latency, energy overhead, and security vulnerabilities. Fog computing, by extending computational and storage capabilities toward the network edge, offers a promising solution to these limitations. This study systematically analyses recent advancements in fog-enabled IoT data processing, consolidating performance results from diverse approaches into a unified comparative framework. The proposed model balances latency, energy consumption, and operational costs, demonstrating performance gains of up to 95% in latency reduction, 65% in energy savings, and notable improvements in system security. Through detailed comparative analysis and graphical evaluation, the findings reveal that multi-layer fog architectures, when combined with adaptive scheduling and energy-aware service placement, can significantly enhance quality of service (QoS) while optimising resource utilisation. These insights provide practical guidance for designing sustainable, secure, and high-performance IoT ecosystems.

1 INTRODUCTION

The rapid proliferation of Internet of Things (IoT) devices has transformed modern digital ecosystems, enabling a wide range of applications that demand ultra-low latency, high reliability, and uninterrupted connectivity – such as autonomous transportation, remote healthcare monitoring, industrial automation, and smart city services [1]. However, traditional cloud-centric architectures struggle to meet these stringent requirements because data must travel across long network paths to remote data centres, resulting in excessive latency, bandwidth inefficiencies, and network congestion [2]. These limitations are particularly critical in Industrial IoT (IIoT) environments, where real-time decision-making is essential to ensure operational safety, process optimisation, and service continuity [3]. In addition, continuous transmission of raw data to the cloud increases operational costs, energy consumption, and environmental impact, while exposing sensitive information to privacy and security risks [4].

Fog computing has emerged as a promising paradigm to mitigate these challenges by extending computation, storage, and intelligence toward the network edge [5]. Fog nodes – including gateways, access points, and micro data centres – enable localised processing, filtering, and caching close to data sources, thereby reducing latency, improving bandwidth utilisation, and supporting more energy-efficient and context-aware operations [5], [6]. Building on this paradigm, researchers have proposed diverse fog-enabled architectures and optimisation strategies. Dynamic offloading schemes determine where tasks should be executed – locally, at fog nodes, or in the cloud – and have demonstrated up to 95% latency reduction and 67% energy savings compared with cloud-only processing [6]. Multi-layer edge–fog–cloud hierarchies have also shown substantial performance improvements; for instance, NB-IoT healthcare frameworks reported a 59.9% reduction in data transmission delay and a 38.5% decrease in execution time [3]. Meanwhile, energy-aware service placement algorithms, such as LJAYA, have achieved 31% reductions in energy consumption [4], and green demand-aware strategies have delivered up to 65% energy savings without

compromising delay performance [7]. Moreover, to address emerging security threats, machine learning-based authentication and intrusion detection techniques have achieved accuracy levels exceeding 99% in distributed fog environments [8].

Despite these advancements, most existing studies optimise isolated performance metrics in isolation – typically latency, energy consumption, or security – without providing a unified analytical framework that simultaneously considers latency, energy cost, operational expenditure, and security risk. This fragmentation makes it difficult for system architects to evaluate trade-offs holistically and design fog-enabled IoT infrastructures that are both high performing and sustainable.

To address this gap, this paper: (1) systematically reviews state-of-the-art fog computing strategies for real-time IoT data processing; (2) consolidates and compares quantitative performance results from at least eighteen peer-reviewed contributions; (3) proposes a unified mathematical cost model to balance latency, energy consumption, and operational cost in offloading decisions; and (4) identifies open challenges and key research directions with a focus on sustainability, adaptive architectures, and enhanced security. Through this comprehensive and analytically grounded assessment, the paper provides practical guidance for researchers and practitioners aiming to design secure, sustainable, and high-performance fog-enabled IoT systems.

2 RELATED WORK

2.1 Dynamic Task Offloading and Scheduling

Because fog nodes have limited resources, deciding Because fog nodes have limited computational resources, determining where to execute tasks is a critical design challenge. Sensors et al. proposed a dynamic offloading threshold scheme that incorporates Dynamic Task Scheduling (DTS) and Dynamic Energy Control (DEC) algorithms. Compared with cloud-only execution, this approach reduced latency by up to 95%, improved throughput by 71%, and decreased energy consumption by 67% [2]. The authors emphasised that fog computing alleviates high communication latency and network congestion by processing data closer to end devices [9].

Similarly, an energy-efficient IoT task scheduling framework (EEIoMT) classified tasks into critical, moderate, and normal categories and assigned scheduling weights based on latency and energy requirements. Simulation results demonstrated that EEIoMT reduced response time by 90%, network usage by 79%, cost by 80%, network latency by 65%, and energy consumption by 81% relative to cloud-based models [10].

Fuzzy-logic-based scheduling has also been explored to address uncertainty in task demands. In the Dynamic Task Allocation using Fuzzy Logic Enhanced approach (DTA-FLE), tasks are classified according to latency sensitivity using fuzzy sets. A hierarchical scheduler then assigns urgent tasks to fog nodes while forwarding non-urgent tasks to the cloud. The energy consumption of communication for a set of tasks on m resources is given by (1) [8]:

$$E_{\text{comm}} = \sum_{i=1}^{m} (P_{tx} + P_{rx})\, T_{\text{comm}}, \qquad (1)$$

where Ptx and Prx are transmission and reception power, respectively, and Tcomm is communication time. The DTA-FLE scheduler minimises both energy and delay by reducing unnecessary task migrations; at 700 tasks the algorithm achieved a delay of 24 s, compared with 132 s for a cloud-only scheduler (DTA) and 35–50 min for other heuristics [11], corresponding to an 82% latency reduction relative to DTA. Meta-heuristic optimisation has also shown promise. A modified Grey-Wolf Optimisation strategy (TS-GWO) achieved makespan reductions of 46.15% and energy savings of 28.57% relative to comparable schedulers [5]. In addition, an energy-efficient time-and-cost (ETC) constrained scheduling algorithm based on Improved Multi-Objective Differential Evolution (I-MODE) demonstrated energy savings of 14–24%, execution time reductions of 14–25%, and monetary cost reductions of 22–29% when evaluated using both synthetic and real workflow datasets [12].

2.2 Hierarchical Architectures

Fog computing architectures commonly adopt a three-layer structure comprising the device layer (sensors and actuators), the fog layer (near-edge processing nodes), and the cloud layer. Figure 1 illustrates this layered model. In an NB-IoT hybrid health-monitoring architecture, data aggregation and preliminary analytics are performed at the edge, protocol translation and temporary storage occur at the fog layer, and long-term analytics are executed in the cloud. Simulations using CloudSim and iFogSim showed that this architecture reduced NB-IoT

communication delay by 59.9% and execution time by 38.5% [3].

Energy-efficient service-placement strategies further enhance performance by assigning services based on resource availability and predicted workload behaviour, achieving energy savings of approximately 31% [4]. In telehealth-oriented IoT systems, integrating fog nodes with a hybrid cloud platform and adaptive energy-saving mechanisms resulted in a modest but meaningful 2% reduction in energy consumption [13].

Hybrid fog–edge architectures for real-time health monitoring employ rule-based filtering and lightweight machine-learning modules at the edge while delegating time-critical tasks to fog nodes. Reported outcomes include 70% latency reduction, a 30% improvement in energy efficiency, and 60% bandwidth savings relative to cloud-only configurations [14]. These systems frequently incorporate decision-tree and one-class SVM classifiers to detect anomalies and reduce unnecessary traffic. Green demand-aware schemes complement these architectures by powering down idle fog nodes, achieving up to 65% energy savings without compromising latency [15].

Additionally, a power-aware fog-supported IoT healthcare framework utilising swarm-intelligence algorithms demonstrated a 33% reduction in power consumption by optimising heterogeneous gateway deployment [16]. Energy consumption modelling for fog-enabled IoT communications further revealed that energy usage is inversely proportional to the Maximum Transmission Unit (MTU); larger MTU sizes therefore decrease transmission energy requirements.

2.3 Security and Privacy

The decentralised nature of fog computing introduces new security and privacy challenges. A machine-learning-based authentication and intrusion-detection framework that integrates elliptic-curve cryptography with a stacked ensemble classifier achieved 99.86% accuracy, 99.89% precision, 99.96% recall, and a 99.91% F1-score following secret-ID authentication [8].

An adaptive encryption framework further enhances confidentiality by using K-nearest neighbours to classify data sensitivity and applying hybrid ECC–AES encryption for critical data. Experimental evaluation reported encryption and decryption times between 9.679 ms and 67.79 ms and encryption throughput of 0.826–14.75 MB·s^{-1}. Histogram analysis yielded an NPCR of 99.349% and a UACI of 33.079%, demonstrating strong resilience against statistical attacks.

Finally, a zero-trust fog-computing framework integrating blockchain technology and software-defined networking provides continuous authentication for healthcare systems. Using 50 IoT devices and 10 fog nodes in iFogSim, the framework improved intrusion detection by 40%, enhanced data integrity by 30%, increased task completion rate by 15.29%, and reduced average response time by 39.66% [16]. These findings highlight that robust security can be achieved without compromising performance when implemented effectively at the fog layer.

3 UNIFIED OFFLOADING COST MODEL

Effective resource allocation in fog-enabled IoT systems requires jointly considering latency, energy consumption, and operational cost, as these factors collectively determine where a computational task should be executed – on the IoT device, a nearby fog node, or a remote cloud server. To formalise this decision-making process, we define a unified weighted multi-objective cost function that evaluates the suitability of assigning a task TTT to a given processing layer:

$$\text{Cost}(T) = \alpha \times L(T) + \beta \times E(T) + \gamma \times C(T)$$

Where:

- $\text{Cost}(T)$. Total cost of executing task *T;*
- $L(T)$. Total latency for executing task *T* on the selected layer (Seconds);
- $E(T)$. Energy consumption during execution and data transfer (Joules).
- $C(T)$. Operational or monetary cost of execution (Monetary units)
- α, β, γ. Non-negative weighting factors representing the relative importance of each metric, such that $\alpha + \beta + \gamma = 1$.

The latency term L(T) is derived from a combination of network propagation delay and processing delay at the selected layer. The energy term E(T) can incorporate the standard communication energy equation:

$$E\text{comm} = P_{tx} \times t_{tx} + P_{rx} \times t_{rx}$$

Where P_{tx} and P_{rx} denote transmission and reception power (watts), and t_{tx} and t_{rx} represent corresponding transmission and reception durations

(seconds). The cost term C(T) captures monetary expenditure or resource penalties associated with specific layers – for instance, pay-per-use cloud charging models or fog resource utilisation costs.

The scheduler's objective is to minimise Cost(T) across all available processing layers while satisfying capacity, QoS, and application constraints. The flexibility of the weighting coefficients allows the model to adapt to different operational priorities: life-critical healthcare services prioritise minimal latency (high α), while battery-powered IoT deployments emphasise energy efficiency (high β), and budget-sensitive scenarios assign greater significance to operational cost (high γ). By dynamically tuning these weights based on network conditions, task urgency, and resource availability, the unified cost model supports adaptive and context-aware offloading decisions in diverse IoT environments.

4 RESULTS AND COMPARATIVE ANALYSIS

This section presents a comparative analysis of various fog computing integration approaches for real-time IoT data processing. Quantitative performance results were extracted from at least eighteen peer-reviewed studies and are summarised in Table 1. The comparison includes key performance metrics such as latency reduction, energy savings, throughput improvement, and security enhancements relative to baseline cloud-only deployments.

Table 1 lists the evaluated algorithms and architectures alongside their reported performance improvements. For example, the Dynamic Offloading Threshold Scheme (DTS + DEC) achieved a latency reduction of 95%, throughput improvement of 71%, and energy savings of 67%. Similarly, the NB-IoT Edge–Fog–Cloud architecture demonstrated 59.9% delay reduction, 38.5% faster execution time, and 35.1% faster authentication.

Energy-aware scheduling frameworks also yielded notable gains. The EEIoMT framework achieved up to 81% energy savings while reducing response time by 90% and network usage by 79%. Service placement strategies such as LJAYA and green demand-aware fog computing reported energy savings of 31% and up to 65%, respectively, by optimising resource allocation across fog nodes.

From a security perspective, machine learningbased intrusion detection attained 99.86% accuracy with high precision, recall, and F1-score, while a blockchain–SDN-enabled zero-trust architecture improved intrusion detection by 40% and reduced average response time by 39.66%.

Figure 2 illustrates the latency reduction achieved by selected approaches. The DTS + DEC method recorded the highest improvement, followed by fuzzy-logic scheduling (DTA-FLE) and hybrid fog–edge architectures. These results indicate that adaptive and context-aware scheduling plays a pivotal role in achieving ultra-low latency.

Figure 3 compares energy consumption reduction across different approaches. Notably, the green demand-aware fog model and LJAYA service placement achieved the largest savings, while telehealthspecific integration delivered more modest improvements due to its communication overhead.

Overall, the comparative results demonstrate that multi-layer fog architectures, when combined with intelligent task scheduling and energy-aware resource management, can substantially improve both Quality of Service (QoS) and energy efficiency without compromising security. These findings provide strong evidence supporting the integration of fog computing into latency-sensitive and resource-constrained IoT applications.

Table 1 summarises quantitative results from the literature. Each row corresponds to a particular algo rithm or architecture and lists the reported improvements relative to baseline cloud-only execution. Values are grouped by categories (latency reduction, energy reduction, throughput improvement, and security metrics). Only key numerical results are shown; detailed experimental setups are provided in the respective papers. Table 1 summarises key quantitative results from the reviewed studies, listing each approach alongside its reported improvements. The table allows for a direct comparison of latency, energy, throughput, and security metrics, offering a concise reference for evaluating trade-offs between different fog computing integration strategies.

Figure 2 plots latency-reduction percentages for selected approaches. Dynamic offloading achieves the highest improvement, followed by DTA-FLE, hybrid fog–edge, NB-IoT hybrid, and the black-box multi-algorithm from the fog data-analytics study, which reported a 60–70% latency reduction by exploiting temporal locality [17]. Figure 3 compares energy-reduction metrics, showing that green demand-aware and LJAYA service placement achieve notable savings, while telehealth integration has modest improvement. The modified grey-wolf optimiser also offers substantial energy savings, highlighting the benefit of meta-heuristic scheduling.

Table 1: Summary of key improvements from reviewed fog and summary of key improvements from reviewed fog computing approaches computing approaches.

Ref.	Study / Approach	Methodology / Architecture	Evaluated Metrics	Improvement / Result Values	Experimental Conditions
[2]	DTS + DEC	Adaptive dynamic offloading + fog energy control	Latency, Throughput, Energy	Latency ↓95%, Throughput ↑71%, Energy ↓67%	Telehealth IoT; fog–cloud
[3]	NB-IoT Edge–Fog–Cloud (IoMT)	3-layer healthcare fog	Delay, Execution Time, Authentication	Delay ↓59.9%, Exec Time ↓38.5%, Auth Time ↓35.1%	CloudSim / iFogSim
[4]	LJAYA Service Placement	Lévy-flight JAYA optimisation	Energy, Optimisation Efficiency	Energy ↓31%, Efficiency ↑28.57%	Fog–cloud
[5]	TS-GWO	Grey-Wolf meta-heuristic scheduling	Makespan, Energy, Latency	Makespan ↓46.15%, Energy ↓28.57–80%, Latency ↓65%	Fog–cloud workloads
[8]	ML Authentication + ECC	Authentication + anomaly detection	Accuracy, Precision, Recall, F1	Acc 99.86%, Prec 99.89%, Recall 99.96%, F1 99.91%	Healthcare IoT
[10]	EEIoMT Scheduling	Priority weighted scheduling + encryption	Response Time, Network, Cost, Energy, Latency	RT ↓90%, Network ↓79%, Cost ↓80%, Latency ↓65%, Energy ↓81%	Healthcare simulation
[11]	DTA-FLE	Fuzzy-logic latency-aware scheduling	Delay, Energy	Delay ↓82% (132 s → 24 s), Energy Reduced	700 tasks
[12]	I-MODE ETC Scheduling	Multi-objective workflow optimisation	Energy, Execution Time, Cost	Energy ↓14–24%, Exec Time ↓14–25%, Cost ↓22–29%	Real + synthetic workflows
[13]	Telehealth Fog Integration	Hybrid fog–cloud healthcare	Energy	≈2% Energy Savings	Telehealth IoT
[14]	Hybrid Fog–Edge Healthcare	Rule-based + ML filtering at edge	Latency, Energy, Bandwidth	Latency ↓70%, Energy ↑30%, Bandwidth ↑60%	Real-time monitoring
[15]	Green Demand-Aware Fog	Predictive active/standby fog	Energy	Energy Savings up to 65%	Energy-constrained deployments
[16]	Power-Aware Fog Architecture	Swarm-intelligence optimisation	Power Consumption	Power ↓33%	Healthcare IoT
[16]	Zero-Trust Blockchain–SDN	Blockchain + SDN zero-trust	Intrusion Detection, Integrity, Response, Completion	ID ↑40%, Integrity ↑30%, Completion ↑15.29%, Response ↓39.66%	50 IoT devices; 10 fog nodes

To illustrate the layered distribution of processing responsibilities in fog computing, Figure 1 presents a conceptual three-layer architecture. This diagram highlights how tasks are delegated between the device layer, the fog layer, and the cloud layer, emphasising latency reduction and bandwidth optimisation through selective offloading.

5 DISCUSSION

The comparative evaluation demonstrates that integrating fog computing into real-time IoT systems consistently improves performance relative to traditional cloud-only architectures. In particular, fog-based designs significantly reduce latency, optimise bandwidth utilisation, enhance energy efficiency, and, in many cases, strengthen system security. However, the magnitude of improvement varies across architectures and depends strongly on workload characteristics, network conditions, fog resource capability, and the optimisation strategies employed.

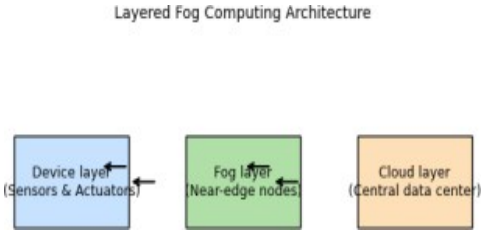

Figure 1: Conceptual three-layer fog architecture comprising the device layer (sensors and actuators), the fog layer (gateways, access points and micro-servers) and the cloud layer.

Fog-layer execution plays a central role in reducing latency by enabling localised processing and forwarding only essential information to the cloud. As illustrated in Figure 2, dynamic offloading approaches – such as the Dynamic Offloading Threshold Scheme (DTS + DEC) – achieve the most substantial latency reduction (up to 95%) because they adaptively allocate tasks based on real-time congestion, resource availability, and energy state. While these solutions also contribute to significant energy savings by avoiding unnecessary long-distance transmissions, they require accurate system monitoring and sophisticated prediction models, which introduce scheduling complexity and computational overhead.

Hierarchical fog architectures provide a balanced compromise between performance enhancement and scalability. Solutions such as NB-IoT Edge–Fog–Cloud frameworks and hybrid fog–edge designs partition workloads intelligently, assigning time-critical tasks to edge or fog nodes while offloading less urgent computation to the cloud. These systems typically achieve 60–70% latency reduction and approximately 30% energy savings. Nevertheless, their effectiveness may be sensitive to changing network topology, device mobility, and heterogeneous resource distributions.

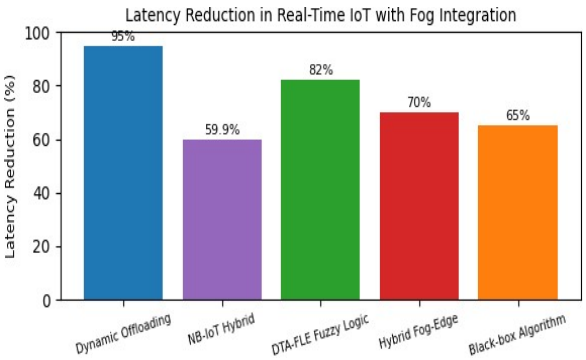

Figure 2: Latency reduction achieved by different fog integration approaches.

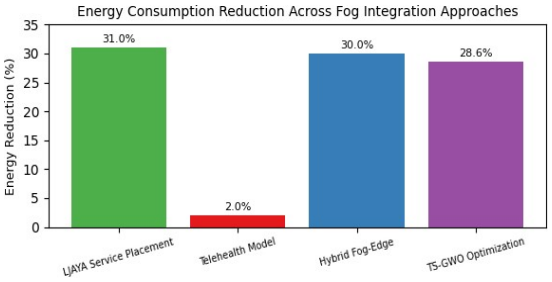

Figure 3: Energy consumption reduction across fog integration approaches. The LJAYA service placement and modified Grey-Wolf optimisation provide large energy savings; telehealth integration delivers modest improvements.

Intelligent scheduling and optimisation algorithms further strengthen fog computing performance. Approaches such as fuzzy logic-based scheduling (DTA-FLE) and meta-heuristic methods (TS-GWO) improve task allocation under uncertainty and support multi-objective optimisation. For example, fuzzy-logic-based schemes have demonstrated dramatic reductions in execution delay (e.g., from 132 s to 24 s), while Grey-Wolf-driven strategies provide favourable trade-offs between makespan and energy consumption. However, these techniques often require parameter tuning and scenario-specific calibration, which may limit their generalisability across diverse deployments.

Energy-aware frameworks represent another important design trend. Green demand-aware models and LJAYA-based service placement policies demonstrate notable efficiency gains, achieving energy reductions of 31%–65% by dynamically managing node operating states and optimising workload placement. These approaches are particularly valuable in battery-powered and remote sensing applications. However, because they primarily prioritise energy conservation, they may not deliver latency reductions comparable to aggressively adaptive scheduling techniques. Conversely, certain telehealth-oriented fog integrations yield only modest energy gains (≈2%) due to communication overhead dominating consumption.

Security-focused fog architectures further reveal that strong protection mechanisms can be integrated without incurring prohibitive performance penalties. Machine-learning-based authentication and intrusion detection frameworks achieve near-perfect accuracy, while zero-trust blockchain–SDN designs improve both data integrity and operational resilience, reducing response time by approximately 39.66%. Although these solutions may introduce additional computational and storage demand at the fog layer,

they are particularly suitable for privacy-sensitive domains such as healthcare and mission-critical industrial applications.

6 OPEN CHALLENGES AND FUTURE RESEARCH

Despite impressive progress, several challenges remain. Fog nodes are resource-constrained and often heterogeneous, making standardisation and interoperability difficult. Achieving optimal trade-offs between latency, energy consumption and cost requires accurate modelling and prediction of network conditions and workloads. Future research should explore adaptive weight selection for the unified cost function (2) based on real-time feedback, and incorporate security metrics into the optimisation. Mobility and reliability also pose challenges; fog nodes may join or leave the network frequently, and applications must handle dynamic topologies. Another important direction is sustainability: while fog computing reduces energy in communication, large-scale deployment of fog nodes consumes electricity; eco-friendly hardware and renewable energy integration are promising avenues [7]. Additionally, privacy preservation techniques such as federated learning could allow local model training without exposing raw data.

7 CONCLUSIONS

Fog computing offers a practical paradigm for real-time IoT data processing by relocating computation, storage, and analytics closer to data sources. This review systematically synthesizes quantitative evidence from at least eighteen peer-reviewed studies and confirms that fog-enabled designs can substantially outperform cloud-centric deployments in latency-sensitive settings. Reported results show improvements reaching up to 95% latency reduction, energy savings up to 65%, and measurable security enhancements when modern protection mechanisms are integrated at the fog layer.

A key contribution of this paper is the unified multi-objective offloading cost model that jointly captures latency, energy consumption, and operational cost, enabling more transparent trade-off analysis across heterogeneous IoT environments. The comparative analysis further indicates that no single solution is universally optimal: adaptive task offloading and scheduling deliver the strongest latency gains under dynamic workloads; hierarchical edge–fog–cloud architectures provide scalable workload partitioning; and energy-aware service placement and demand-aware management are most effective when power constraints dominate. In parallel, the surveyed security-aware schemes suggest that robust security and privacy controls can be incorporated without necessarily sacrificing QoS, provided that computation and protection are carefully placed within the fog layer.

Future work should prioritize intelligent orchestration that adapts offloading decisions online using prediction and learning, extends optimization objectives to explicitly include security and privacy, and strengthens mobility support and interoperability across heterogeneous nodes. Finally, sustainability remains essential; green resource management and renewable-powered fog infrastructure are promising directions for scalable and environmentally responsible IoT ecosystems.

Keywords: Integral Equation, Volterra-Fredholm, Existence and Uniqueness of Solution, Properties of Solutions, Banach Fixed-Point.

Abstract: The aim of this paper is to prove the existence and uniqueness of a solution for a Volterra-Fredholm nonlinear integral equation in two variables under certain conditions. For instance, by using the Lipschitz condition with Banach's contraction principle under assumptions (1)-(4), a unique solution exists in Banach space Z. Moreover, we examine some fundamental characteristics of the solutions for a Volterra-Fredholm nonlinear integral equation in two variables which occur in applications, using the inequality established in [6, Theorem 1]. It has also been demonstrated that the functions and parameters included in the equation under investigation continuously influence the behavior of solutions under perturbations in parameters. This investigation may allow for the extension of findings, and the last section contains an illustrative example for the validity of the obtained results, making the method much more attractive for practical applications. The examples show the method is straightforward and effective, and the approach can also be extended to other nonlinear integral equation problems.

1 INTRODUCTION

The problem under consideration is the general nonlinear Volterra-Fredholm integral equation of the form:

$$\varphi(\ddot{\imath},\ddot{\eta}) = \mathcal{A}\left(\ddot{\imath},\ddot{\eta},\varphi(\ddot{\imath},\ddot{\eta})\right) + \\ + \int_0^{\ddot{\eta}} \int_{\mathrm{e}} \mathcal{B}\left(\ddot{\imath},\ddot{\eta},\ddot{\iota},\beta,\varphi(\ddot{\iota},\beta),(\Gamma\varphi)(\ddot{\iota},\beta)\right) d\beta d\ddot{\iota}, \quad (1)$$

Where:

$$(\Gamma\varphi)(\ddot{\imath},\ddot{\eta}) = \int_0^{\ddot{\eta}} \int_{\mathrm{e}} \mathcal{H}\left(\ddot{\imath},\ddot{\eta},\ddot{z},\ddot{\zeta},\varphi(\ddot{z},\ddot{\zeta})\right) d\ddot{\zeta} d\ddot{z} \quad (2)$$

Where $\mathcal{A},\mathcal{B}$ and $\mathcal{H}$ they are provided, and the unknown function is φ .

The name integral equation for any equation involving the unknown function $\varphi(\chi)$ under the integral sign was introduced by du Bois- Reymond in 1888 [1].

In [2] A. M. Wazwaz also presented a reliable strategy for solving a Volterra-Friedholm mixed linear integral equation in the following form:

$$u(x,t) = f(x,t) + \int_0^t \int_\Omega F(x,t,r,s)u(r,s)drds$$

$(x,t) \in \Omega \times [0,T]$,

where f , F are known functions and u is an unknown function and Ω a closed partial set of R^n , $n = 1,2,3$

The integrodifferential equations that arise in reactor dynamics and mathematical epidemiology are examined while looking at certain initial boundary value problems for parabolic partial differential equations.

In [3] H. R. Thieme considered a model for the spatial spread of an epidemic consisting of a nonlinear integral equation of Volterra-Fredholm type which has an unique solution. The author showed that this solution has a temporally asymptotic limit which describes the final state of the epidemic and is the minimal solution of another nonlinear integral equation.

In [4] O. Diekmann described, derived and analysed a model of spatio-temporal development of an epidemic. The model considered leads to the following nonlinear integral equation of Volterra-Fredholm type:

$$u(t,x) = g(t,x) + \int_0^t \int_\Omega g\big(u(t-\tau,\xi)\big)S_0(\xi)A(\tau,x,\xi)d\xi d\tau,$$

for all $(t,x) \in [0,\infty) \times \Omega$ where Ω is a bounded domain in R^n. See [5] the form (1) of the equations naturally emerges.

Equation (1) is treated as a mixed Volterra–Fredholm integral equation, as it is of Fredholm type with respect to one variable and of Volterra type with respect to the other. By modifying the method introduced in [6] (see also [7]), an existence result for equation (1) can be formulated.

The primary aim of this paper is to establish the existence and uniqueness of solutions to a nonlinear Volterra–Fredholm integral equation in two variables under suitable assumptions [8].

In [9] B. G. Pachpatte considered the integral equation:

$$u(t,x) = g(t,x) + \int_0^t \int_\Omega g\big(t,x,s,y,u(s,y)\big)dyds,$$

for all $(t,x) \in [0,T) \times \Omega = \mathrm{D}$ where Ω is a bounded domain in R^n.

2 PRELIMINARIES

Definition 2.1, [10]. Let T a mapping from a set X into itself. The mapping T has a fixed point if there exists $x_0 \in X$ such that $Tx_0 = x_0$. The most known fixed-point theorem is the Contraction Mapping Principle, due to S.

Definition 2.2, [10]. Let (X,d) be a metric space. A mapping $T: X \to X$ is Lipschitz continuous if there exists a constant $\alpha > 0$ such that $d(Tx,Ty) \leq \alpha d(x,y)$ for all $x,y \in X$.

If $0 \leq \alpha < 1$, then T is called a contraction mapping. α is called the contractively factor of T.

A (not necessarily Lipschitz) mapping $T: X \to X$ is said to have a fixed point if there exists $x \in X$ such that Tx = x.

It is not hard to see that a (nonzero) Lipschitz continuous mapping $T: X \to X$ with Lipschitz constant q is continuous. Indeed, for $\varepsilon > 0$, if we choose $0 < \delta < \frac{\varepsilon}{q}$, then

$$x,y \in X, d(x,y) < \delta \Rightarrow d(Tx,Ty) \leq qd(x,y) < q.\frac{\varepsilon}{q} = \varepsilon.$$

Definition 2.3, [11]. Let $f(n), g(n)$ be known functions, we say that $f(n) = O(g(n))$ when $n \to 0$, if there is a positive constant A then

$$|f(n)| \leq A|\mathrm{g}(n)|, \forall\ |n| > n_0.$$

3 MAIN RESULTS

Let $\mathcal{R}$ represent the set of real numbers, $\mathcal{R}_+ = [0,\infty)$, and let $\mathfrak{e} = \Pi_{i=1}^n [a_i,b_i]$ and $(a_i < b_i)$ be the specified subsets of $\mathcal{R}$. Define $C(X_1,X_2)$ as the category of continuous functions spanning the sets X_1, X_2 and $\omega = \mathfrak{e} \times \mathcal{R}_+$.

Examine the following two-variable nonlinear integral problem of the Volterra-Fredholm type.

$$\begin{aligned} &\varphi(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}}) \\ &= \mathcal{A}\left(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}},\varphi(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}})\right) \\ &+ \int_0^{\ddot{\mathfrak{y}}} \int_{\mathfrak{e}} \mathcal{B}\left(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}},\ddot{\imath},\mathfrak{b},\varphi(\ddot{\imath},\mathfrak{b}),(\Gamma\varphi)(\ddot{\imath},\mathfrak{b})\right) d\mathfrak{b}d\ddot{\imath}, \end{aligned} \tag{3}$$

for all $(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}}) \in \omega$ where

$$\begin{aligned} &(\Gamma\varphi)(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}}) \\ &= \int_0^{\ddot{\mathfrak{y}}} \int_{\mathfrak{e}} \mathcal{H}\left(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}},\ddot{z},\ddot{\zeta},\varphi(\ddot{z},\ddot{\zeta})\right) d\ddot{\zeta}d\ddot{z}, \end{aligned} \tag{4}$$

and $\mathcal{A} \in C(\omega \times \mathcal{R},\mathcal{R})$, $\mathcal{B} \in C(\omega^2 \times \mathcal{R}^2,\mathcal{R})$, $\mathcal{H} \in C(\omega^2 \times \mathcal{R},\mathcal{R})$.

In this paper, we will demonstrate the presence and uniqueness of the Volterra-Fredholm integral equation solution in two variables. Using Banach's contraction principle, we investigate the existence and uniqueness of a solution to the Volterra-Fredholm integral problem. Additionally, a number of the solution's characteristics are identified.

Let $\mathcal{Z}$ denote the space of functions that satisfy the constraint $\ddot{\Phi} \in C(\omega,\mathcal{R})$.

$$\left|\ddot{\Phi}(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}})\right| = \mathrm{O}\left(exp\left(\mathfrak{z}(\ddot{\mathfrak{t}} + |\ddot{\mathfrak{y}}|)\right)\right) \tag{5}$$

where a constant is $\mathfrak{z} > 0$. We define the norm "The norms ||v|| of a vector v and ||A|| of a matrix A are nonnegative real numbers that measure the size of v and A. In the case of a vector, norms are generalizations of the Euclidean lengths of vectors" in space $\mathcal{Z}$.

$$\left|\ddot{\Phi}\right|_z = \sup_{(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}})\in\omega} \left[\left|\ddot{\Phi}\left(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}}\right)\right| exp\left(-\mathfrak{z}(\ddot{\mathfrak{t}} + |\ddot{\mathfrak{y}}|)\right)\right]. \tag{6}$$

It is easy to see that $\mathcal{Z}$ is a Banach space when the norm specified in (2.4 is used. And

$$|\ddot{\Phi}|_z \leq \mathcal{M} \tag{7}$$

where a constant is $\mathcal{M} \geq 0$. Presenting some qualitative elements of (3) solutions discovered in [12], [13] ,is the primary goal of this part.

The existence and uniqueness of the solution to problem (3) are established using the Banach fixed-point theorem.

Theorem 1. Assume that

1) (3) are functions $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{H}$ meet the requirements.

$$\left|\mathcal{A}(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}},\varphi) - \mathcal{A}(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}},\ddot{v})\right| \leq \mathcal{g}(\ddot{\mathfrak{t}},\ddot{\mathfrak{y}})|\varphi - \ddot{v}|, \tag{8}$$

$$\begin{aligned}&\left|\mathcal{B}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},\varphi,\bar{\varphi})-\mathcal{B}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},\ddot{v},\bar{\ddot{v}})\right|\\&\qquad\le r(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b})[|\varphi-\ddot{v}|\\&\qquad+|\bar{\varphi}-\bar{\ddot{v}}|]\end{aligned}\tag{9}$$

And

$$\begin{aligned}&\left|\mathcal{H}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\varphi)-\mathcal{H}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\ddot{v})\right|\\&\qquad\le m(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta})|\varphi-\ddot{v}|\end{aligned}\tag{10}$$

where $g\in C(\omega,\mathcal{R}_+)$ and $r,m\in C(\omega^2,\mathcal{R}_+)$

2) for λ as in (5);
3) there exists a nonnegative constant $\alpha<1$ such that:

$$\begin{aligned}&g(\ddot{\dagger},\ddot{\mathrm{q}})e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} r(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b})\left[e^{\lambda(\ddot{\imath}+|\mathfrak{b}|)}\right.\\&\left.+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} m(\ddot{\imath},\mathfrak{b},\ddot{z},\ddot{\zeta})e^{\lambda(\ddot{z}+|\ddot{\zeta}|)}\,d\ddot{\zeta}d\ddot{z}\right]d\mathfrak{b}d\ddot{\imath}\\&\le\alpha e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\end{aligned}\tag{11}$$

4) A nonnegative constant β exists such that

$$\begin{aligned}&|\mathcal{A}(\ddot{\dagger},\ddot{\mathrm{q}},0)|\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},0,(\Gamma 0)(\ddot{\imath},\mathfrak{b})\right)\right|d\mathfrak{b}d\ddot{\imath}\\&\le\beta e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\end{aligned}\tag{12}$$

where $\mathcal{A},\mathcal{B}$ are as defined in (3). Then, $\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\ in\ \omega\ on\ \mathcal{Z}$ is the only solution to (3).

$proof.$ Define the operator Ψ by letting $\varphi\in\mathcal{Z}$.

$$\begin{aligned}&(\Psi\varphi)(\ddot{\dagger},\ddot{\mathrm{q}})\\&=\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\right)\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},\varphi(\ddot{\imath},\mathfrak{b}),(\Gamma\varphi)(\ddot{\imath},\mathfrak{b})\right)d\mathfrak{b}d\ddot{\imath}\end{aligned}\tag{13}$$

for all $(\ddot{\dagger},\ddot{\mathrm{q}})\in\omega$

To prove the theorem, from (13) and applying the theories, we have

$$\begin{aligned}&\left|(\Psi\varphi)(\ddot{\dagger},\ddot{\mathrm{q}})\right|\\&\le\left|\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\right)\right|\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},\varphi(\ddot{\imath},\mathfrak{b}),(\Gamma\varphi)(\ddot{\imath},\mathfrak{b})\right)\right|d\mathfrak{b}d\ddot{\imath}\end{aligned}\tag{14}$$

$$\begin{aligned}&\le\left|\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\right)-\mathcal{A}(\ddot{\dagger},\ddot{\mathrm{q}},0)+\mathcal{A}(\ddot{\dagger},\ddot{\mathrm{q}},0)\right|\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left\{\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},\varphi(\ddot{\imath},\mathfrak{b}),\right.\right.\right.\\&\left[\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left|\mathcal{H}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\varphi(\ddot{z},\ddot{\zeta})\right)-\mathcal{H}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},0)\right.\right.\\&\left.\left.+\mathcal{H}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},0)\right|d\ddot{\zeta}d\ddot{z}]\Big)\\&-\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},0,(\Gamma 0)(\ddot{\imath},\mathfrak{b})\right)\\&\left.\left.+\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},0,(\Gamma 0)(\ddot{\imath},\mathfrak{b})\right)\right|\right\}d\mathfrak{b}d\ddot{\imath}\\&\le|\mathcal{A}(\ddot{\dagger},\ddot{\mathrm{q}},0)|\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},0,(\Gamma 0)(\ddot{\imath},\mathfrak{b})\right)\right|d\mathfrak{b}d\ddot{\imath}\\&+g(\ddot{\dagger},\ddot{\mathrm{q}})|\varphi|\\&\quad+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left\{r(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b})[|\varphi|+|\bar{\varphi}|]\right.\\&\quad\left.+\left[\int_0^{\mathfrak{b}}\int_{\mathrm{e}} m(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta})|\varphi|d\ddot{\zeta}d\ddot{z}\right]\right\}d\mathfrak{b}d\ddot{\imath}\\&\le\beta e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\\&+|\varphi|_z\left[g(\ddot{\dagger},\ddot{\mathrm{q}})e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\right.\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} r(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b})\left(e^{\lambda(\ddot{\imath}+|\mathfrak{b}|)}\right.\\&\left.\left.+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} m(\ddot{\imath},\mathfrak{b},\ddot{z},\ddot{\zeta})e^{\lambda(\ddot{z}+|\ddot{\zeta}|)}\,d\ddot{\zeta}d\ddot{z}\right)d\mathfrak{b}d\ddot{\imath}\right]\\&\le\beta e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}+|\varphi|_z\alpha e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\\&\le\beta e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}+\mathcal{M}\alpha e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\\&|(\Psi\varphi)(\ddot{\dagger},\ddot{\mathrm{q}})|\le[\beta+\mathcal{M}\alpha]e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}\end{aligned}$$

$$\left|(\Psi\varphi)(\ddot{\dagger},\ddot{\mathrm{q}})\right|_z\le[\beta+\mathcal{M}\alpha]\tag{16}$$

From (16), Consequently $\Psi\varphi\in\mathcal{Z}$. Let $\varphi,\ \ddot{v}\in\mathcal{Z}$. From (13) and applying the theories, we have

$$\begin{aligned}&\left|(\Psi\varphi)(\ddot{\dagger},\ddot{\mathrm{q}})-(\Psi\ddot{v})(\ddot{\dagger},\ddot{\mathrm{q}})\right|\\&\le\left|\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\right)-\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right)\right|\\&+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\{|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},\varphi(\ddot{\imath},\mathfrak{b}),\right.\\&\left[\int_0^{\mathfrak{b}}\int_{\mathrm{e}}\left|\mathcal{H}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\varphi(\ddot{z},\ddot{\zeta})\right)\right|d\ddot{\zeta}d\ddot{z}\right]\Big)\\&-\mathcal{B}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},\ddot{v}(\ddot{\imath},\mathfrak{b}),\\&\left.\left.\left[\int_0^{\mathfrak{b}}\int_{\mathrm{e}}\left|\mathcal{H}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\ddot{v}(\ddot{z},\ddot{\zeta})\right)\right|d\ddot{\zeta}d\ddot{z}\right]\right)\right|\right\}d\mathfrak{b}d\ddot{\imath}\\&\le g(\ddot{\dagger},\ddot{\mathrm{q}})|\varphi-\ddot{v}|\end{aligned}$$

$$+\int_0^{\ddot{\imath}}\int_{\mathrm{e}}\left\{r(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B})[|\,\varphi-\ddot{v}|+|\overline{\varphi}-\bar{\bar{v}}|]\right.$$
$$\left.+\left[\int_0^{\mathcal{B}}\int_{\mathrm{e}} m(\ddot{\imath},\mathcal{B},\ddot{z},\ddot{\zeta})|\,\varphi-\ddot{v}|d\ddot{\zeta}d\ddot{z}\right]\right\}d\mathcal{B}d\ddot{\imath}$$
$$\leq|\,\varphi-\ddot{v}|_z\left[g(\ddot{\dagger},\ddot{\imath})e^{\lambda(\ddot{\dagger}+|\ddot{\imath}|)}\right.$$
$$+\int_0^{\ddot{\imath}}\int_{\mathrm{e}} r(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B})\left(e^{\lambda(\ddot{\imath}+|\mathcal{B}|)}\right.$$
$$\left.\left.+\int_0^{\mathcal{B}}\int_{\mathrm{e}} m(\ddot{\imath},\mathcal{B},\ddot{z},\ddot{\zeta})e^{\lambda(\ddot{z}+|\ddot{\zeta}|)}\,d\ddot{\zeta}d\ddot{z}\right)d\mathcal{B}d\ddot{\imath}\right]$$

$$|\Psi\,\varphi)(\ddot{\dagger},\ddot{\imath})-(\Psi\ddot{v})(\ddot{\dagger},\ddot{\imath})|\leq|\,\varphi-\ddot{v}|_z\alpha e^{\lambda(\ddot{\dagger}+|\ddot{\imath}|)}$$
$$|\Psi\,\varphi-\Psi\ddot{v}|_z\leq|\,\varphi-\ddot{v}|_z\alpha$$

According to the Banach fixed point theorem see [14], [15], Ψ has a unique fixed point in Z. Since α < 1. (13) has a solution at the fixed point of Ψ. This evidence is comprehensive.

4 CHARACTERISTICS OF SOLUTIONS

In this section, we examine some fundamental characteristics of the solutions to (3) using the inequality established in [12] and Theorem 1.

First, we will provide the subsequent theorem regarding the estimate of the solution to (3).

Theorem 2. Assume that the functions $\mathcal{A}$, $\mathcal{B}$ and $\mathcal{H}$ in (3) and (4)" satisfy the requirements.

$$|\mathcal{A}(\ddot{\dagger},\ddot{\imath},\varphi)-\mathcal{A}(\ddot{\dagger},\ddot{\imath},\ddot{v})|\leq g(\ddot{\dagger},\ddot{\imath})|\varphi-\ddot{v}| \tag{17}$$

$$|\mathcal{B}(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},\varphi,\overline{\varphi})-\mathcal{B}(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},\ddot{v},\bar{\bar{v}})|$$
$$\leq q(\ddot{\dagger},\ddot{\imath})p(\ddot{\imath},\mathcal{B})[|\varphi-\ddot{v}|+|\overline{\varphi}-\bar{\bar{v}}|] \tag{18}$$

$$|\mathcal{H}(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},\varphi)-\mathcal{H}(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},\ddot{v})|$$
$$\leq q(\ddot{\dagger},\ddot{\imath})n(\ddot{z},\ddot{\zeta})|\varphi-\ddot{v}| \tag{19}$$

where $g,q,p,n\in C(\omega,\mathcal{R}_+)$, Let

$$c=\sup_{(\ddot{\dagger},\ddot{\imath})\in\omega}\left|\mathcal{A}(\ddot{\dagger},\ddot{\imath},0)\right.$$
$$\left.+\int_0^{\ddot{\imath}}\int_{\mathrm{e}}\mathcal{B}\left(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},0,(\Gamma 0)(\ddot{\imath},\mathcal{B})\right)d\mathcal{B}d\ddot{\imath}\right| \tag{20}$$

If φ $(\ddot{\dagger}$ $\ddot{\imath})$ is any solution of (3) on ω, then

$$|\varphi(\ddot{\dagger},\ddot{\imath})|\leq c[g(\ddot{\dagger},\ddot{\imath})+q(\ddot{\dagger},\ddot{\imath})\int_0^{\ddot{\imath}}\int_{\mathrm{e}}[p(\ddot{\imath},\mathcal{B})$$
$$+n(\ddot{\imath},\mathcal{B})]\times exp\left(\int_0^{\ddot{\imath}}\int_{\mathrm{e}} q(\ddot{z},\ddot{\zeta})[f(\ddot{z},\ddot{\zeta})\right.$$
$$\left.+n(\ddot{z},\ddot{\zeta})]d\ddot{\zeta}d\ddot{z}\right)d\mathcal{B}d\ddot{\imath}\Big] \tag{21}$$

for all $(\ddot{\dagger},\ddot{\imath})\in\omega$

Proof. Using the hypotheses and given that (3) can be solved by $\varphi(\ddot{\dagger},\ddot{\imath})$, we have

$$|\varphi(\ddot{\dagger},\ddot{\imath})|$$
$$\leq\left|\mathcal{A}\left(\ddot{\dagger},\ddot{\imath},\varphi(\ddot{\dagger},\ddot{\imath})\right)-\mathcal{A}(\ddot{\dagger},\ddot{\imath},0)+\mathcal{A}(\ddot{\dagger},\ddot{\imath},0)\right|$$
$$+\int_0^{\ddot{\imath}}\int_{\mathrm{e}}\left\{\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},\varphi(\ddot{\dagger},\ddot{\imath}),\right.\right.\right.$$
$$\left[\int_0^{\mathcal{B}}\int_{\mathrm{e}}\left|\mathcal{H}\left(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},\varphi(\ddot{z},\ddot{\zeta})\right)-\mathcal{H}(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},0)\right.\right.$$
$$\left.\left.+\mathcal{H}(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},0)\right|d\ddot{\zeta}d\ddot{z}\right]\Big)$$
$$-\mathcal{B}\left(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},0,(\Gamma 0)(\ddot{\imath},\mathcal{B})\right)$$
$$\left.\left.+\mathcal{B}\left(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},0,(\Gamma 0)(\ddot{\imath},\mathcal{B})\right)\right|\right\}d\mathcal{B}d\ddot{\imath}$$
$$\leq\Big|\mathcal{A}(\ddot{\dagger},\ddot{\imath},0)$$
$$+\int_0^{\ddot{\imath}}\int_{\mathrm{e}}+\mathcal{B}\left(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},0,(\Gamma 0)(\ddot{\imath},\mathcal{B})\right)d\mathcal{B}d\ddot{\imath}\Big|$$
$$+\left|\mathcal{A}\left(\ddot{\dagger},\ddot{\imath},\varphi(\ddot{\dagger},\ddot{\imath})\right)-\mathcal{A}(\ddot{\dagger},\ddot{\imath},0)\right|+$$

$$\int_0^{\ddot{\imath}}\int_{\mathrm{e}}\left\{\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},\varphi(\ddot{\dagger},\ddot{\imath}),\right.\right.\right.$$
$$\left[\int_0^{\mathcal{B}}\int_{\mathrm{e}}\left|\mathcal{H}\left(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},\varphi(\ddot{z},\ddot{\zeta})\right)-\mathcal{H}(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},0)\right.\right.$$
$$\left.\left.+\mathcal{H}(\ddot{\dagger},\ddot{\imath},\ddot{z},\ddot{\zeta},0)\right|d\ddot{\zeta}d\ddot{z}\right]\Big)$$
$$\left.\left.-\mathcal{B}\left(\ddot{\dagger},\ddot{\imath},\ddot{\imath},\mathcal{B},0,(\Gamma 0)(\ddot{\imath},\mathcal{B})\right)\right|\right\}d\mathcal{B}d\ddot{\imath}$$
$$\leq c+g(\ddot{\dagger},\ddot{\imath})|\varphi(\ddot{\dagger},\ddot{\imath})|$$
$$+q(\ddot{\dagger},\ddot{\imath})\int_0^{\ddot{\imath}}\int_{\mathrm{e}}p(\ddot{\imath},\mathcal{B})\Big[|\varphi(\ddot{\imath},\mathcal{B})| \tag{22}$$
$$\left.+q(\ddot{\imath},\mathcal{B})\int_0^{\mathcal{B}}\int_{\mathrm{e}}n(\ddot{z},\ddot{\zeta})|\varphi(\ddot{z},\ddot{\zeta})|d\ddot{\zeta}d\ddot{z}\right]d\mathcal{B}d\ddot{\imath}.$$

We can observe from (22) and Theorem 1 in [12] that

$$|\varphi(\ddot{\dagger},\ddot{\imath})|\leq c[g(\ddot{\dagger},\ddot{\imath})$$
$$+q(\ddot{\dagger},\ddot{\imath})\int_0^{\ddot{\imath}}\int_{\mathrm{e}}[p(\ddot{\imath},\mathcal{B})+n(\ddot{\imath},\mathcal{B})]$$
$$\times exp\left(\int_0^{\ddot{\imath}}\int_{\mathrm{e}} q(\ddot{z},\ddot{\zeta})[f(\ddot{z},\ddot{\zeta})\right.$$
$$\left.+n(\ddot{z},\ddot{\zeta})]d\ddot{\zeta}d\ddot{z}\right)d\mathcal{B}d\ddot{\imath}\Big] \tag{23}$$

This proof is complete.

Lastly, we provide a result regarding the (3) solution's continuous dependency on the functions involved. Analyse (3) and its equivalent equation.

$$\begin{aligned}\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}}) &= \bar{\mathcal{A}}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right)\\ &+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} \bar{\mathcal{B}}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\ddot{v}(\ddot{\imath},\mathcal{B}),(\bar{\Gamma}\ddot{v})(\ddot{\imath},\mathcal{B})\right)d\mathcal{B}d\ddot{\imath},\end{aligned} \tag{24}$$

for all $(\ddot{\dagger},\ddot{\mathrm{q}}) \in \omega$ where:

$$(\bar{\Gamma}\ddot{v})(\ddot{\dagger},\ddot{\mathrm{q}}) = \int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} \bar{\mathcal{H}}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\ddot{v}(\ddot{z},\ddot{\zeta})\right)d\ddot{\zeta}d\ddot{z},$$

and $\bar{\mathcal{A}} \in C(\omega\times\mathcal{R},\mathcal{R})$, $\bar{\mathcal{B}} \in C(\omega^2\times\mathcal{R}^2,\mathcal{R})$, $\bar{\mathcal{H}} \in C(\omega^2\times\mathcal{R},\mathcal{R})$.

Theorem 3. Assume that, respectively, the functions $\mathcal{A}, \mathcal{B}$ *and* $\mathcal{H}$ in (3) fulfil the requirements (17), (18) and (19). Additionally, assume that the supplied solution to (23) on ω is $\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})$.

$$\begin{aligned}&\left|\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right)-\bar{\mathcal{A}}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right)\right|\\ &+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\ddot{v}(\ddot{\imath},\mathcal{B}),(\Gamma\ddot{v})(\ddot{\imath},\mathcal{B})\right)\right.\\ &\left.-\bar{\mathcal{B}}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\ddot{v}(\ddot{\imath},\mathcal{B}),(\bar{\Gamma}\ddot{v})(\ddot{\imath},\mathcal{B})\right)\right|d\mathcal{B}d\ddot{\imath}\le\varepsilon,\end{aligned}$$

where $\mathrm{A},\mathrm{B},\Gamma\varphi$ and $\bar{\mathrm{A}},\bar{\mathrm{B}},\bar{\Gamma}\ddot{v}$ are as in (3) and (23) and ε > 0 is a small, arbitrary constant, respectively. Then, the functions involved in (3) determine the solution $\varphi(\ddot{\dagger},\ddot{\mathrm{q}})$ of (3) on ω continuously.

Proof. Let $\mathcal{D}(\ddot{\dagger},\ddot{\mathrm{q}}) = \left|\varphi(\ddot{\dagger},\ddot{\mathrm{q}})-\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right|$, for $(\ddot{\dagger},\ddot{\mathrm{q}}) \in \omega$. Using the hypotheses, we have:

$$\begin{aligned}\mathcal{D}(\ddot{\dagger},\ddot{\mathrm{q}}) &\le \left|\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\right)\right.\\ &\qquad\left.-\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right)\right|\\ &+\left|\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right)-\bar{\mathcal{A}}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right)\right|\\ &+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\varphi(\ddot{\imath},\mathcal{B}),(\Gamma\varphi)(\ddot{\imath},\mathcal{B})\right)\right.\\ &\left.-\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\ddot{v}(\ddot{\imath},\mathcal{B}),(\Gamma\ddot{v})(\ddot{\imath},\mathcal{B})\right)\right|d\mathcal{B}d\ddot{\imath}\\ &+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\ddot{v}(\ddot{\imath},\mathcal{B}),(\Gamma\ddot{v})(\ddot{\imath},\mathcal{B})\right)\right.\\ &\left.-\bar{\mathcal{B}}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\ddot{v}(\ddot{\imath},\mathcal{B}),(\bar{\Gamma}\ddot{v})(\ddot{\imath},\mathcal{B})\right)\right|d\mathcal{B}d\ddot{\imath}\\ &\le\varepsilon+\mathcal{g}(\ddot{\dagger},\ddot{\mathrm{q}})\mathcal{D}(\ddot{\dagger},\ddot{\mathrm{q}})\\ &+\mathcal{q}(\ddot{\dagger},\ddot{\mathrm{q}})\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\mathcal{p}(\ddot{\imath},\mathcal{B})\left[\mathcal{D}(\ddot{\imath},\mathcal{B})\right.\\ &\left.+\mathcal{q}(\ddot{\imath},\mathcal{B})\int_0^{\mathcal{B}}\int_{\mathrm{e}}\mathcal{n}(\ddot{z},\ddot{\zeta})\mathcal{D}(\ddot{z},\ddot{\zeta})d\ddot{\zeta}d\ddot{z}\right]d\mathcal{B}d\ddot{\imath}\end{aligned} \tag{26}$$

Now, applying [6] Theorem 1, the relation (26) produces:

$$\begin{aligned}&\left|\varphi(\ddot{\dagger},\ddot{\mathrm{q}})-\ddot{v}(\ddot{\dagger},\ddot{\mathrm{q}})\right| \le \varepsilon\left[\mathcal{g}(\ddot{\dagger},\ddot{\mathrm{q}})\right.\\ &\left.+\mathcal{q}(\ddot{\dagger},\ddot{\mathrm{q}})\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left[\mathcal{p}(\ddot{\imath},\mathcal{B})+\mathcal{n}(\ddot{\imath},\mathcal{B})\right]\right.\\ &\left.\times exp\left(\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\mathcal{q}(\ddot{z},\ddot{\zeta})\left[\mathcal{p}(\ddot{z},\ddot{\zeta})+\mathcal{n}(\ddot{z},\ddot{\zeta})\right]d\ddot{\zeta}d\ddot{z}\right)d\mathcal{B}d\ddot{\imath}\right]\end{aligned} \tag{27}$$

For $(\ddot{\dagger},\ddot{\mathrm{q}}) \in \omega$. From (27) Consequently, the functions involved in (3) determine the answer in a continuous manner.

This proof is complete.

5 AN EXAMPLE

The problem under consideration is described by the following nonlinear Volterra–Fredholm integral equation:

$$\begin{aligned}\varphi(\ddot{\dagger},\ddot{\mathrm{q}}) &= w(\ddot{\dagger},\ddot{\mathrm{q}})\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\\ &+\int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}}\left(d(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B})\varphi(\ddot{\imath},\mathcal{B})\right.\\ &\left.+\int_0^{\ddot{z}}\int_{\mathrm{e}} f(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta})\varphi(\ddot{z},\ddot{\zeta})d\ddot{\zeta}d\ddot{z}\right)d\mathcal{B}d\ddot{\imath}\end{aligned} \tag{28}$$

where $w(\ddot{\dagger},\ddot{\mathrm{q}}) = \frac{\lambda}{13}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}$

$$d(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B}) = \frac{\lambda^2}{e^{\lambda}-1}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}$$

$$f(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta}) = \frac{\lambda^2}{t(e^{\lambda}-1)}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}$$

$\mathrm{e} = [0,1]$, $\lambda > 0$ Here,

$$\mathcal{A}\left(\ddot{\dagger},\ddot{\mathrm{q}},\varphi(\ddot{\dagger},\ddot{\mathrm{q}})\right) = w(\ddot{\dagger},\ddot{\mathrm{q}})\varphi(\ddot{\dagger},\ddot{\mathrm{q}})$$

$$\mathcal{H}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\varphi(\ddot{z},\ddot{\zeta})\right) = \int_0^{\ddot{z}}\int_0^{1} f(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta})\varphi(\ddot{z},\ddot{\zeta})d\ddot{\zeta}d\ddot{z}$$

$$\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\varphi(\ddot{\imath},\mathcal{B}),(\Gamma\varphi)(\ddot{\imath},\mathcal{B})\right) = \int_0^{\ddot{\mathrm{q}}}\int_0^{1}\left(d(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B})\varphi(\ddot{\imath},\mathcal{B})+(\Gamma\varphi)(\ddot{\imath},\mathcal{B})\right)d\mathcal{B}d\ddot{\imath}$$

We can see that

$$\left|\mathcal{A}(\ddot{\dagger},\ddot{\mathrm{q}},\varphi)-\mathcal{A}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{v})\right| \le \frac{\lambda}{13}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}|\varphi-\ddot{v}|$$

$$\left|\mathcal{H}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\varphi)-\mathcal{H}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta},\ddot{v})\right| \le \frac{\lambda^2}{e^{\lambda}-1}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}|\varphi-\ddot{v}|$$

$$\left|\mathcal{B}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\varphi,\bar{\varphi})-\mathcal{B}(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B},\ddot{v},\bar{\ddot{v}})\right| \le \frac{2\lambda^2}{e^{\lambda}-1}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}|\varphi-\ddot{v}|.$$

By choosing $r(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B}) = \frac{2\lambda^2}{e^{\lambda}-1}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}$ and $m(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta}) = \frac{\lambda^2}{e^{\lambda}-1}e^{\lambda(\ddot{\dagger}+|\ddot{\mathrm{q}}|)}$

It is easy to see that the functions $r(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathcal{B})$ and $m(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{z},\ddot{\zeta})$ are continuous, and so the conditions (1)-(2) are satisfied on the order hand, we get that:

$$|\mathcal{A}(\ddot{\dagger},\ddot{\mathrm{q}},0)| + \int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} \left|\mathcal{B}\left(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b},0,(\Gamma 0)(\ddot{\imath},\mathfrak{b})\right)\right| d\mathfrak{b}d\ddot{\imath} \leq \beta e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)}$$

$$\frac{\lambda}{13} e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)} \leq \beta e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)}$$

Which satisfied the condition (4) of Theorem 1 with $\beta = \frac{\lambda}{13}$ and $\lambda > 0$. Moreover:

$$g(\ddot{\dagger},\ddot{\mathrm{q}})e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)} + \int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} r(\ddot{\dagger},\ddot{\mathrm{q}},\ddot{\imath},\mathfrak{b}) \left[e^{\lambda(|\ddot{\imath}|+|\mathfrak{b}|)} + \int_0^{\ddot{\mathrm{q}}}\int_{\mathrm{e}} m(\ddot{\imath},\mathfrak{b},\ddot{z},\ddot{\zeta})e^{\lambda(|\ddot{z}|+|\ddot{\zeta}|)}\, d\ddot{\zeta}d\ddot{z}\right] d\mathfrak{b}d\ddot{\imath} \leq \alpha e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)}$$

$$\Rightarrow \frac{\lambda}{13} e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)} + \frac{2\lambda^2}{e^{\lambda}-1} e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)} \int_0^{\ddot{\mathrm{q}}}\int_0^1 \left[e^{\lambda(|\ddot{\imath}|+|\mathfrak{b}|)} + \frac{\lambda^2}{e^{\lambda}-1} e^{\lambda(|\ddot{\imath}|+|\mathfrak{b}|)} \int_0^{\ddot{z}}\int_0^1 e^{\lambda(|\ddot{z}|+|\ddot{\zeta}|)}\, d\ddot{\zeta}d\ddot{z}\right] d\mathfrak{b}d\ddot{\imath} \leq \alpha e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)}$$

$$\Rightarrow \frac{\lambda}{13} e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)} + (e^{\lambda}+1)(e^{\lambda\ddot{\mathrm{q}}}-1)e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)} \leq \alpha e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)}$$

$$\left[\frac{\lambda}{13} + (e^{\lambda}+1)(e^{\lambda\ddot{\mathrm{q}}}-1)\right] e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)} \leq \alpha e^{\lambda(|\ddot{\dagger}|+|\ddot{\mathrm{q}}|)}$$

If we chose $\ddot{\mathrm{q}} = ln\left(\frac{e^{\lambda}+2}{e^{\lambda}+1}\right)^{\frac{1}{\lambda}}, \lambda > 0$

$$\alpha = \frac{\lambda}{13} + (e^{\lambda}+1)(e^{\lambda\ddot{\mathrm{q}}}-1) < 1$$

It follows that the condition (3) of Theorem 1 is satisfied for $\alpha < 1$.

From the results above, we infer that the problem (28) satisfied the all conditions of Theorem 1, which guarantees the problem (28) has a unique solution.

6 CONCLUSIONS

The existence and uniqueness of solutions for the nonlinear Volterra-Fredholm integral equation in two variables have been rigorously established through the application of the Banach contraction principle and the imposition of Lipschitz conditions within a Banach space. The qualitative properties of these solutions have been thoroughly analyzed using specific integral inequalities, providing a comprehensive understanding of their fundamental behavior and structural characteristics. Furthermore, the solutions exhibit continuous dependence on the governing functions and parameters, demonstrating the stability of the model under small perturbations and ensuring its robustness for practical applications. Illustrative examples confirm the mathematical consistency and effectiveness of the proposed framework, highlighting its potential for extension to a broader class of multidimensional nonlinear integral equations and its applicability in complex mathematical modeling scenarios.

Keywords: Image Inpainting, Cahn-Hilliard Model, Color Spaces, Image Quality Assessment, Finite Difference Method.

Abstract: One of the most important applications in image processing is digital image restoration, which attempts to restore sections of an image that have been lost or damaged. In this paper, we analyze and implement the Cahn-Hilliard model, a fourth-order nonlinear partial differential equation renowned for its efficiency and speed in preserving structural continuity and smoothness in the image. The model is designed to restore regions affected by intentional damage, scratches, or distortions. The model was numerically solved using the implicit finite difference method, which produced a stable and precise reconstruction using the convex partitioning technique. We applied the model to images with deliberate defects within eight different color spaces, including YUV, YCbCr, RGB, NTSC, XYZ, HSV, and others, and evaluated its performance in terms of restoration accuracy and the absence of visual distortions. The effectiveness of the Cahn-Hilliard model outperforms traditional restoration methods in reconstructing missing areas while preserving the original edges and fine details.

1 INTRODUCTION

A fundamental problem in digital image processing is the reconstruction of absent or impaired areas within an image by utilizing information derived from adjacent pixels. This technique, known as inpainting, serves as a specific type of interpolation. Furthermore, it facilitates the restoration of compromised photographs impacted by elements like aging, scratches, deterioration, or deliberate harm. Furthermore, inpainting can facilitate the recoloring of occluded objects by recreating the concealed information utilizing contextual clues [1]. Bretozzi was the pioneer in presenting a two-scale analytical model derived from the Cahn-Hilliard equation, which has demonstrated efficacy in the processing of binary images, especially those consisting solely of two hues (black and white). The Cahn-Hilliard framework, initially developed as a physical and mathematical model, has been effectively modified for image processing applications, particularly image inpainting, owing to its superior efficiency and rapidity in managing high-contrast images [2] - [4]. Bertozzi further advanced an extended model, known as the Bertozzi-Esedoglu-Gillette Cahn-Hilliard model, to accommodate images with n channels. Bertozzi and her partners specifically created a fidelity term to guarantee that the inpainted image closely resembles the original before purposeful damage or noise. The extended model exhibits robust mathematical and numerical performance; yet, it encounters a critical issue: the compromise of mass conservation, which pertains to maintaining the spatial average of the phase field [5]. Researchers continue to strive to address this constraint, particularly in ensuring mass conservation when incorporating the fidelity term. A recent study by Nils Boulerion proposed optimal control strategies for the fidelity parameter that balance inpainting accuracy and mass preservation [6], [7]. The study conducted by Bretozzi, Cecilia, Matteo, and M. Grasselli focuses on an image inpainting model that was initially presented by A. Bretozzi and associates, which is based on a Cahn-Hilliard-type partial differential equation. This model regulates the progression of an order parameter $u \in [0,1]$, which approximates the original image specified over a confined, two-dimensional domain Ω [8]. Carrillo, Kalliadasis, Liang, and Perez assessed the usefulness of utilizing a modified Cahn-Hilliard inpainting filter for inputting damaged images into a classification neural network. Utilizing the Modified National Institute of Standards Technology (MNIST) dataset, their findings indicate

that this methodology markedly enhances prediction accuracy by as much as 50% in certain instances, particularly for low to moderate damage levels [9]. Dandan Jiang, Mejdi Azaiez, Alain Miranville, and Chuahju Xu suggested an upgraded Cahn-Hilliard-type inpainting model using a nonlocal diffusion operator. This model exhibits exceptional efficacy in rebuilding absent areas in photographs [10]. Anis Mohamed, Hamdi Houichet, and Anis Theljani used the Cahn-Hilliard equation to devise an efficient method for inpainting binary images, concentrating on the restoration of low-order structures, including edges and corners, and the augmentation of image borders. The numerical results demonstrate the model's accuracy in attaining objectives [11]. Martin, Lin, and Carola introduced a novel paradigm in image processing, namely binary image refinement utilizing the Cahn-Hilliard equation. They examined the equilibrium state of the model and introduced a generalization for grayscale images with constrained contrast. They achieved a structural refinement of images distinguished by a smooth curving of the gradient levels [12]. Qiumei, Jiaxuan, and Zhen introduced a mass-preserving adaptive time-scaling model for Physics-Informed Neural Network (PINN) that dynamically segments the time domain based on the energy decay rate. This model addressed the Cahn-Hilliard equations with an autonomous neural network, and the outcomes illustrated the efficacy of this technique [13].

Jessica and Martin devised a model employing the vector-valued Cahn-Hilliard equation. Numerical examples illustrate that the sanctioned fractional Cahn-Hilliard method of interior mapping surpasses its non-fractional counterpart, enhancing the signal-to-noise ratio and structure similarity index. Experiments validate that the suggested model is comparable to prior interior mapping techniques, including total variance and fourth-order variable interior mapping methods [14]. Antun, Darko, and Anderj proposed a novel nonlocal partial differential equation derived from the Cahn-Hilliard model for the purpose of image restoration. The suggested linear model exhibits lower computational costs compared to the Cahn-Hilliard equation while still delivering high-quality interior painting outcomes. An example of internal coloring was presented to demonstrate the method's possibilities [15]. Qing Zou introduced a fourth-order partial differential equation model for picture coloration, integrating the Perona-Malik and Cahn-Hilliard equations through the principle of energy partitioning.

The numerical results indicate that the suggested model demonstrates superior colorization performance with reduced calculation time relative to traditional PDE models [16]. Despite the extensive application of the Cahn-Hilliard equation in binary image inpainting, comprehensive research examining its performance over many color spaces and comparing its efficacy among various color models remains insufficient. The classical Cahn-Hilliard model is adopted due to its well-established physical and mathematical foundation, which enables rigorous analytical treatment and clear energy estimates. This choice allows us to isolate the effect of the color space representation without introducing additional nonlocal complexities. Although nonlocal Cahn-Hilliard extensions exist and are physically relevant, they are beyond the scope of the present work.This paper examines the application of the Cahn-Hilliard model across multiple color spaces (CMY, YCbCr, RGB, YUV, XYZ, NTSC, HSL, and HSV) as seen in [17], evaluates the visual analysis of the resultant images, and assesses their quality through statistical metrics including mean square error (MSE), peak signal-to-noise ratio (PSNR), structural similarity (SSIM) and entropy [18]. The rest of the paper is organized as follows: Section 2 elucidates the digital images. Section 3 introduces the concept of picture inpainting. Section 4 reviews color spaces and their suitability for Cahn-Hilliard image modeling. Section 5 presents the Cahn-Hilliard model. Section 6 presents and discusses several numerical results of the proposed model. Section 7 will present the conclusion.

2 DIGITAL IMAGE

A two-dimensional digital image is made up of a certain set of digital values, which are pixels. In an image, each pixel has a unique location x_{ij} and is linked to an intensity number d(x_{ij}) which tells you about the color, and as a number, each value in the image ranges from 0 to 255, with 0 being the least intense and 255 being the most intense. Each pixel in a greyscale image has a single intensity number that ranges from 0 (black) to 255 (white). When talking about color images, the RGB (red, green, and blue) color range is usually used. According to the specified model, each pixel in a color image has three numerical values, one from 0 to 255, which represent the strengths of the red, green, and blue parts [19].

3 IMAGE INPAINTING

Image inpainting is the process of using information from the surrounding field to recreate missing or damaged areas of an image so that the viewer is unaware of the changes [20]. The size and nature of the missing areas have a significant impact on this method's effectiveness. The visual result is better when the inpainting zone is smaller and the surrounding texture is simpler. The inpainting technique relies heavily on texture, which represents the regularity, smoothness, and coarseness of image parts. When damage arises from intentional scratching, ageing, or weathering, images can be effectively restored [21]. However, reconstruction becomes more difficult when a significant portion of the image is missing because the remaining portions do not provide essential contextual information.

4 COLOR SPACES

Color spaces are mathematical constructs that represent colors as numerical values, each tailored for certain uses such as image reduction, broadcasting, and picture restoration. They are typically classified into two categories: those that utilize primary channels directly, such as RGB and CMY, and those that differentiate luminance and chrominance, including YCbCr, YUV, HSV, HIS, and XYZ. In RGB, each channel has completed structural and chromatic information, potentially leading to discrepancies when channels are handled separately. In contrast, YCbCr and YUV separate luminance (Y) from chrominance (Cb, Cr), hence augmenting compression efficiency and strengthening edge preservation [22]. HSV and HSL offer a perceptually intuitive depiction of hue, saturation, and value, closely correlating with human color perception; nonetheless, they exhibit instabilities in the hue axis when saturation is absent [23]. The XYZ model provides a linear depiction of the spectrum and underpins perceptual models such as (CIE-Commission International de I'E`clairage) CIELAB, although it lacks perceptual uniformity. CIELAB is not perceptually uniform [24].

The suitability of the Cahn-Hillird model depends on how different color space representations capture image structures and perceptual consistency. In the Y channel of YCbCr, the model enhances edge integrity and diminishes noise; however, in RGB, it may result in inconsistencies among R, G, and B due to the independent processing of channels. The efficacy of inpainting is significantly influenced by the selection of color space: RGB is optimal for display, YCbCr/YUV for compression and restoration, HSV/HSL for perceptual design, and XYZ for scientific applications necessitating spectral accuracy [9].

5 MODIFIED CAHN-HILLIARD MODEL

One semi-linear fourth-order partial differential equation (PDE) developed for binary image inpainting is the modified Cahn-Hilliard (mCH) equation [3]. The field of material sciences uses this equation [24]. with $\vec{x} = (x, y)$ and let D⊂Ω represent the inpainting domain; let f($\vec{x}$) be a specified image defined throughout the domain Ω. The resolution of (1) under Neumann boundary conditions is employed to restore the compromised images. The implicit finite difference method is utilized to solve (1), while the convex partition of (6) and (7) is employed to provide numerical stability. The equation is given by:

$$\partial_t u = \Delta\left(-\epsilon\,\Delta u - \frac{1}{\epsilon}F(u)\right) + \lambda(\vec{x})(f(\vec{x}) - u), \quad \text{in } \Omega \quad (1)$$

$$\text{Where } (\vec{x}) = \begin{cases} 0 & if\ \vec{x} \in D \\ \lambda_0 & if\ \vec{x} \in \Omega \backslash D \end{cases}$$

Equation (1) is known as the mCH equation, and it includes an additional fidelity term $\lambda(\vec{x})\,(f(\vec{x}) - u)$. The function $F(u)$ is referred to as a double-well potential, given by $F(u) = 1/u(1-u)^2$, and ϵ is a tiny positive parameter that approaches zero. To solve (1), it is sufficient to minimize the following energy functions:

$$\int_\Omega \left(\frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{\epsilon}f(u)\right) d\vec{x} + \lambda_0 \int_{\Omega\backslash D}(f-u)^2 d\vec{x}. \quad (2)$$

The initial component denotes the energy of a gradient flow based on the H^{-1}-norm, resulting in the mCH equation, whereas the subsequent component is a fidelity term derived from a gradient flow utilizing the L^2-norm. This process is similar to the convexity splitting used in an isotropic framework. Diffusion inpainting functions under a fourth-order total variation framework. The fitting term represents a gradient flow in $H^{-1}(\Omega)$. The fitting term represents a gradient flow in $H^{-1}(\Omega)$. The fidelity term is considered on $L^2(\Omega)$. In this context, $H^{-1}(\Omega)$ is the dual Sobolev space of $H_0^1(\Omega)$, with the associated norm defined as:

$$\|f\|_{-1}^2 = \|\nabla\Delta^{-1}f\|_{-1}^2 = \int_\Omega (\nabla\Delta^{-1})^2 d\vec{x} \quad (3)$$

Where Δ^{-1}refers to the inverse of the Laplace operator, such that $u = \Delta^{-1}f$ is $-\Delta u = f$ in Ω, with $u = 0$ on $\partial\Omega$. Let:

$$R_1 = \int_\Omega \left(\frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{\epsilon}F(u)\right) d\vec{x}, \quad (4)$$

$$R_2 = \lambda_0 \int_{\Omega\setminus D} (f-u)^2 d\vec{x} \quad (5)$$

Convexity splitting is applied separately to R_1 and R_2 decomposed as:

Where $R_1 = R_{11} - R_{12}$, then

$$R_{11} = \int_\Omega \left(\frac{\epsilon}{2}|\nabla u|^2 + \frac{C_1}{2}|u|^2\right) d\vec{x}, \quad (6)$$

$$R_{12} = \int_\Omega \left(-\frac{1}{\epsilon} + F(u) + \frac{C_1}{2}|u|^2\right) d\vec{x} \quad (7)$$

Likewise $R_2 = R_{21} - R_{22}$, where:

$$R_{21} = \int_{\Omega\setminus D} \frac{C_2}{2}|u|^2 d\vec{x}, \quad (8)$$

$$R_{22} = \int_{\Omega\setminus D} (-\lambda_0(f-u)^2) + \frac{C_2}{2}|u|^2 d\vec{x} \quad (9)$$

Based on the above, the resulting time-stepping scheme is given by:

$$\frac{u^{n+1}-u^n}{k} + \epsilon\nabla^4 u^{n+1} - C_1\nabla^2 u^{n+1} + C_2 u^{n+1} = \nabla^2\left(\frac{1}{\epsilon}f'(u^n) + \lambda(\vec{x})(f(\vec{x}) - u^n)\right) - C_1\nabla^2 u^n + C_2 u^n \quad (10)$$

We enforce Neumann boundary conditions on $\partial\Omega$. $\nabla U_{k+1}.\vec{n} = \nabla\Delta U_{k+1}.\vec{n} = 0$, $\left(\frac{\partial u}{\partial n} = 0,\ \frac{\partial(\Delta u)}{\partial u} = 0\right)$, on $\partial\Omega$.

The significance of this model lies in its ability to restore large missing regions without introducing artefacts [3]. The overall workflow of the proposed Cahn-Hilliard inpainting process is summarized in Figure 1, which illustrates the sequential steps from initialization, application of the modified PDE, convexity splitting, to the final image reconstruction.

6 NUMERICAL EXPERIMENTS AND RESULTS

The proposed Cahn-Hilliard model was implemented on 80 color images from the Berkeley Color Database [25], which includes high-texture color images. As shown in Figure 2, two experiments were conducted using the model and color spaces described earlier.

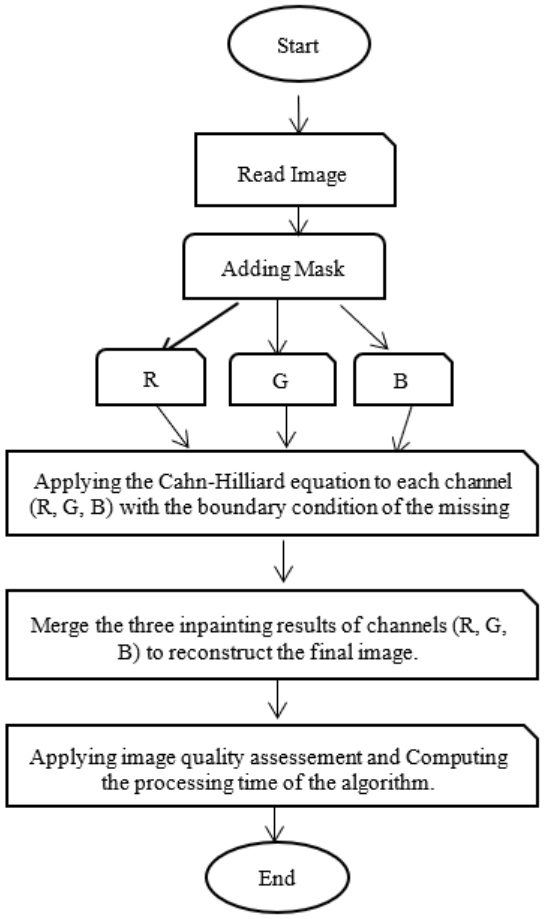

Figure 1: Flowchart of inpainting process using Cahn-Hilliard.

Figure 2: Example of four out of 300 trained natural images.

The process of image inpainting may be explained in the following way: $D \subset \Omega$ stands for the inpainting domain, $f: \Omega \longrightarrow R^{+1}$ for the specified image, and Ω for the image domain. Binary masks were used to create four instances of intrinsic

inpainting domains, which are damaged regions, in the image. Here is an equation that shows scratches and text may be added to the original image: f is the original image, M is the mask image, and M^{-1} is the logical inverse of the mask image.

$$f_{Damaged} = M^{-1}(x,y) \times f(x,y) + M\,(x,y). \quad (11)$$

As illustrated in Figure 3, the masks were selected based on the breadth of M, the scratches; specifically, the first two masks illustrate scratches of varying widths, which indicate minor damaged areas. The third mask depicts a big scratch, indicating vast damaged areas. Lastly, the fourth mask includes two missing blocks. The four masks will be applied to a series of high-texture, natural-colored photographs, as previously stated. To replace each image's missing parts, we will put the Cahn-Hilliard model into practice. After that, we use Structural quality measures (SQMs), including structural similarity indices (SSIM) [26], peak signal-to-noise ratio (PSNR) [27], mean square error (MSE) [28], and the information entropy of both the input image (E_0) and the output image E_1. To visually and statistically compare the experiment outcomes.

These SQMs are used to evaluate the model's efficiency in terms of its ability to retrieve missing regions from the image. The time taken to obtain results was also studied, and the image recovery was implemented in MATLAB code (elapsed for MATLAB R2020a, running on a laptop with an Intel (R) Core (TM) i7-9850H CPU at 2.60 GHz and 32 GB of RAM). Two experiments were conducted in this section. Section 6.1 presents an experiment analyzing the model's behavior on missing regions of different sizes; Section 6.2 presents an experiment analyzing the model's behavior on different numbers of iterations.

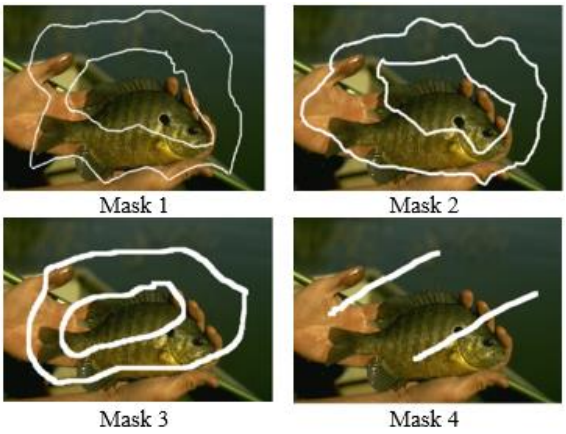

Figure 3: Illustrates the types of image masks, each with different missing areas.

6.1 Different Types of Missing Areas

In this section, four experiments were conducted, and their results were presented in four tables. Four different masks were adopted, representing different levels of damage in the images, with each mask varying in the area of the deleted region. To achieve the accuracy and stability of the results, processing was performed using a different iteration for each mask. These experiments were applied to images after converting them to eight different color spaces. The goal was to evaluate the model's performance across multiple color contexts and determine the color space that offers the best performance. The color space performance was correlated with the damage level (mask) to determine whether the mask type directly affects the effectiveness of the color space. And as shown in the Tables 1 - 4.

Table 1: The average values of MSE, PSNR, SSIM, and entropy for image inpainting using the Cahn-Hilliard equation in MASK 1 at iteration 50.

The first experiment involved 50 iterations of the numerical operation on a small erased region (Table 1). The color spaces are arranged from best to worst according to the MSE values. YCbCr achieved the best reconstruction accuracy, exhibiting the lowest MSE. In terms of other image quality metrics (PSNR and SSIM), NTSC, YCbCr, and YUV outperformed HSV, HSL, and XYZ. However, the maximum entropy (7.145394) was observed in XYZ, indicating higher information diversity or noise. Regarding computational time, RGB and YUV were the slowest, whereas CMY and YCbCr were the fastest.

The results after 100 iterations are summarized in Table 2. Again, the color spaces are ranked according to MSE. The best MSE, PSNR, and SSIM were obtained in RGB, while HSV was the fastest despite having the worst MSE and PSNR. XYZ exhibited the highest entropy (7.145744).

In Table 3, 250 iterations were performed on a large missing region (mask 3). CMY achieved the best MSE and PSNR, whereas RGB had the highest SSIM. The weakest performance was observed for XYZ. NTSC was the fastest, and HSL the slowest. Among all spaces, XYZ showed the smallest difference between Entr1 and Entr0.

Table 4 presents results for 300 iterations. CMY again had the best MSE and PSNR, while HSV performed the worst. RGB achieved the highest SSIM, and XYZ had the lowest entropy.

Based on these experiments, RGB demonstrated the best overall performance in terms of numerical accuracy (MSE), perceptual quality (PSNR, SSIM), and structural similarity. Figure 4 illustrates examples of restored images for four masks in the RGB space.

6.2 Different Iterations of Numerical Solutions

In this section, we conducted eight experiments across a variety of color spaces. We studied the behavior of the model for four different mask sizes, each with its unique size. For each mask, we performed four different iterations, each varying from one mask to another. The experimental results were evaluated using a set of statistical metrics. The goal of the experiment was to determine the relationship between the number of iterations, the mask type and the performance of color spaces to achieve the best restoration quality while, calculating execution time to ensure acceptable time efficiency. The adopted iterations for the masks were in the first mask (1, 10, 20, 50); in the second mask (1, 25, 50, 100); in the third mask (50, 100, 150, 250); and finally in the fourth mask (100, 150, 200, 300). Tables 5-8 show the experimental results for eight spaces. Figure 5 below illustrates the visual study of the outcomes in the RGB space for the restoration of ideal mask 1 across four iterations.

Table 5: The mean values of MSE, PSNR, SSIM, and entropy for image inpainting performed with the Cahn-Hilliard equation in eight spaces in MASK 1 at different iterations.

The above tables showed the final results as follows:

1) The first and second masks (Tables 1, 2) achieved the best performance when using the YCbCr space at 50 iterations and the RGB space at 100 iterations, where image reconstruction was high-resolution and relatively short [10]. This is due to the structural properties of the YCbCr and RGB spaces. The YCbCr space separates the image components into the luminance (Y) component and the color (Cb, Cr) components [29]. This separation is very useful for recovering small missing regions because it allows for more accurate and efficient processing [10]. The proposed Cahn-Hilliard model enables focusing on the important visual details in the Y channel while allowing some tolerance in the Cb and Cr color channels without affecting the quality of the recovered image. Therefore, this space is used in techniques (compression, restoration, etc.) [9]. Therefore, the RGB space requires a larger number of iterations (100) to improve accuracy [10].
2) In the third and fourth masks (Tables 3, 4), the CMY and RGB spaces achieved the best values in terms of MSE, PSNR, and SSIM. This is because the RGB and CMY color spaces represent colors directly, which allows for accurate reconstruction of large deleted areas. But they recorded the highest difference in entropy, indicating a significant amount of information change between the original and processed images, since the two spaces do not separate the lighting and color components. And because processing images in RGB and CMY spaces requires more calculations, it leads to increased execution time [30], [31].

3) The HSV space was approximately the fastest to execute, but it recorded poor results on the (MSE, PSNR, and SSIM) metrics. This is because the HSV space is primarily designed for color correction applications and not for pixel retrieval. Although it separates hue from value, this separation is not suitable for retrieving the original image structure. This renders it unfit for retrieving and enhancing high-resolution images, where image quality takes precedence over time [32]. The XYZ space had the lowest entropy difference of all the spaces, indicating that the image retained its information values after processing. The result may indicate that the changes did not significantly affect the image, and therefore, the XYZ space did not significantly improve it. This is because XYZ space is a theoretical color space designed to accurately represent colors according to the human visual model, without taking into account process ability or visual
enhancement [33].
4) We obtained lower MSE values and higher SSIM and PSNR; the execution time was faster in the first and second masks (Tables 5, 6). The Cahn-Hilliard equation can accurately retrieve the image because the surrounding pixels provide sufficient spatial and color information [9]. In contrast, the third and fourth masks had a large missing region (Tables 7, 8), so we required more time. We observed a significant increase in MSE values and a significant decrease in PSNR and SSIM values. The result indicates that the processed image differs significantly from the original image in terms of pixel values, structure, and visual content. This variation is because the retrieval algorithm lacks sufficient indifrom the original image, making it difficult to reconstruct structures and details, even with an increasing number of iterations (250, 300) [8].

7 CONCLUSIONS

The Cahn-Hilliard phase diffusion model was employed to reconstruct absent areas in images and was utilized across diverse images and configurations of missing regions. The proposed approach was executed in tests that encompassed many iterations and eight distinct color spaces. The findings indicated a strong correlation between the magnitude of the absent region and the number of iterations employed, since both influence the quality of retrieval. It was noted that small masks necessitated fewer iterations to attain satisfactory results, but masks with extensive missing areas demanded more iterations to acquire acceptable outcomes. The findings underscore the necessity of balancing the extent of the missing area, the iteration count, and the choice of a suitable color space to optimize future image retrieval. Based on the overall analysis of the results, it can be concluded that the model demonstrated stable preformance and several positive characteristics that confirm its effectiveness in image processing across different color spaces. The findings revealed that the selection of the color space has a direct impact on enhancing the quality of the reconstructed image and reducing numerical error, as the variation among spaces clarified the model's behavior toward spatial structure and color information. The experiments also showed that th interaction between the model and the missing regions depends on balancing visual properties and numerical accuracy.

Abstract: Developers offer various options for virtual simulators that allow training in diagnosing Internet of Things (IoT) systems. To select devices with the best characteristics, as well as to identify shortcomings and improve virtual simulators, tools for assessing their characteristics are in demand. An adequate selection of virtual simulators with the best characteristics, as well as the identification of their shortcomings for subsequent improvement, are urgent research problems. The presented research is aimed at solving these problems. A system has been developed for assessing the characteristics of virtual simulators intended for IoT systems training in diagnosis. It is based on the use of fuzzy logical inference. As indicators for assessing the characteristics of virtual simulators used for training IoT systems in diagnosis, it is proposed to use indicators of image realism, sound realism and diversity of training scenarios sets, as well as a general indicator of virtual simulator functioning. The parameters of the membership functions of fuzzy sets and individual outputs of fuzzy rules were automatically selected using a neural network setup. In order to study the proposed fuzzy logical inference system, a model of the process of assessing the virtual simulators characteristics intended for IoT systems training in diagnosis has been developed in the MATLAB software environment using the libraries of the Simulink package. Numerous computational experiments have been carried out using this software model. A comparison of their results with the results of real IoT systems diagnosing showed that the higher the values of the generalized indicator of the virtual simulator functioning, the greater the probability of correct diagnosis of IoT systems by the specialists who trained on it. Thus, the proposed fuzzy inference system can be recommended for evaluating the characteristics of virtual simulators designed to teach diagnostics of Internet of Things systems.

1 INTRODUCTION

A promising scientific and technological direction is the creation of virtual simulators that help to learn the skills of diagnosing and monitoring the correct operation of various technical systems. The object of our research was virtual simulators used to acquire skills in diagnosing the operation of Internet of Things (IoT) systems. The scope of Internet of Things systems application includes applications for smart home [1], industry [2], healthcare [3], [4], ecology [5], energy [6], construction [7] and others [8].Currently, manufacturers offer various options for virtual simulators, specializing in smart city systems [9], smart agriculture [10], smart manufacturing [11] and other IoT applications [12]. Such software facilitates the process of Mastering the specifics of IoT devices setting up and operating, building wireless Internet of Things networks and detecting their incorrect operation. An urgent task is to develop tools for evaluating such virtual simulators. Such evaluation tools are necessary to select devices with the best.

Mastering the specifics of IoT devices setting up and operating, building wireless Internet of Things networks and detecting their incorrect operation. An urgent task is to develop tools for evaluating such virtual simulators. Such evaluation tools are necessary to select devices with the best characteristics, as well as to identify shortcomings to improve.

The relevant research problems are the adequate selection of virtual simulators with the best characteristics, as well as the identification of their shortcomings for subsequent improvement. Adequate

assessment tools for such virtual simulators are needed to solve these problems.

Many studies have been devoted to evaluating the effectiveness of virtual simulators. In particular, an assessment of the effects resulting from the use of VR games for teaching engineering sciences is presented [13]. Work [14] It is devoted to evaluating the usefulness of a hysteroscopic surgery simulator. The study of students' perception of a virtual simulator designed to acquire fire extinguishing skills is presented [15]. The assessment of the success of mastering the necessary skills using a dental simulator was performed [16]. A method for evaluating the performance of helicopter rescue crews trained using virtual reality scenarios is proposed [17]. The advantages of the above studies are that they provide an opportunity to show that the use of virtual simulators can improve the effectiveness of training. The disadvantages of the available means of evaluating the effectiveness of the use of virtual simulators in various fields include the fact that they are based mainly on the use of subjectively compiled questionnaires and do not have the necessary theoretical justification. In addition, an analysis of publications has shown that insufficient attention is paid to evaluating the characteristics of virtual simulators used for training in the diagnosis of Internet of Things networks.

The significance of this study is to improve the process of evaluating the characteristics of virtual simulators used for training in the diagnosis of Internet of Things networks. This improvement is proposed based on the development of a new evaluation system for virtual simulators, which is based on the use of mathematical fuzzy inference.

2 CREATION AND CONFIGURATION OF A FUZZY LOGICAL INFERENCE SYSTEM

In order to evaluate the characteristics of virtual simulators, it is proposed to create a system based on fuzzy logical inference. The scientific reasoning behind this proposal is that the mathematical apparatus of fuzzy logical inference is successfully used to solve many applied problems [18] - [22], including tasks related to estimating various quantities [23] - [26]. A neural network was used to adjust the parameters of the fuzzy inference system. For this purpose, neural network tools were used, which are created in the MATLAB-Simulink software environment and are used to solve many problems [27] - [30].

In the process of forming a training sample for neural network setup, it is necessary to make some surveys. Each test person should learn how to diagnose IoT systems using one virtual simulator. The person then has the opportunity to evaluate the performance of the virtual simulator according to three criteria: image realism (IR), sound realism (SR), and variety of training scenario sets (VAR). Scores for these criteria are given on a scale from 1 (lowest score) to 10 (highest score).

After training, the person tests the functioning of real IoT systems and diagnoses their malfunctions. The diagnosis accuracy is assessed by the value DR=0 if the person incorrectly diagnoses the technical condition of the IoT system, and by the value DR=1 in the case of an error-free diagnosis. The assessments of the virtual simulator characteristics and the values of the correct diagnosis of the technical condition of the IoT system received from the test person are entered into a special relational database, a fragment of which is presented in Table 1.

Table 1: Fragment of the training sample.

Training sample line number	IR	SR	VAR	DR
1	9	9	8	1
2	8	7	6	1
3	4	5	3	0
…	…	…	…	…
800	5	7	9	1

The training sample presented in Table 1 contains 800 rows. To form it, it is necessary to involve 200 persons, each of whom evaluates the virtual simulator characteristics, and then diagnoses the operation of 4 real IoT systems. The training data obtained in this way is used to configure the neural network for the fuzzy inference system.

The created fuzzy inference system uses three input variables that characterize the image realism, the sound realism and the variety of training scenarios provided by the virtual simulator. At the output, the system produces the VSI value of a generalized indicator of the virtual simulator functioning.

The creation and configuration of the fuzzy logical inference system was carried out in the MATLAB software environment using the anfisedit command. Two triangular membership functions were used to fuzzily each input variable. The zero-order Sugeno algorithm was chosen as a fuzzy inference algorithm, which has been successfully

used to create various fuzzy control systems [31] - [33].

The system was configured over 200 training cycles. For training, a hybrid algorithm was used that implements a combination of the least squares method and the inverse gradient descending method [34] - [36]. In Figure 1, you can observe how the training error gradually decreases and reaches values close to zero after the 110th cycle of the system configuration.

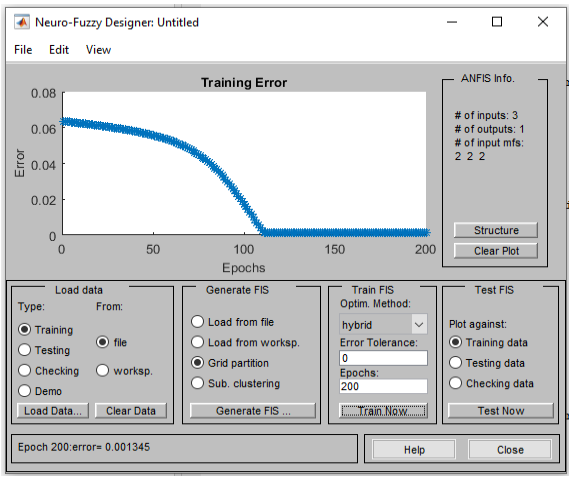

Figure 1: Setting up a fuzzy logical inference system.

The setup of the created fuzzy logical inference system is carried out using the generated neural network structure presented in Figure 2. This structure is a multilayer fuzzy neural network (Adaptive Neuro-Fuzzy Inference System, ANFIS), each layer of which serves to perform one or another fuzzy logical inference procedure in accordance with the zero-order Sugeno algorithm.

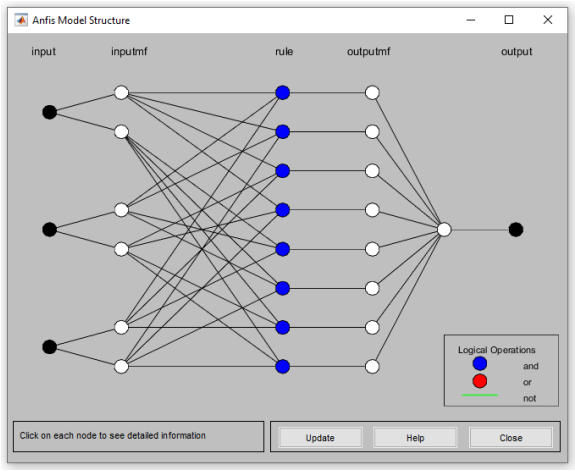

Figure 2: Structure of the ANFIS system.

Values of the membership functions parameters of input variables and individual outputs of fuzzy rules are automatically selected as a result of the execution of ANFIS training cycles. These values make the training errors minimal.

The fuzzy inference system configured in this way can be used to evaluate the characteristics of virtual simulators intended for t training in diagnostics of Internet of Things devices. As a result of system creating and configuration, 8 fuzzy rules were formed, the appearance of which is presented in Figure 3.

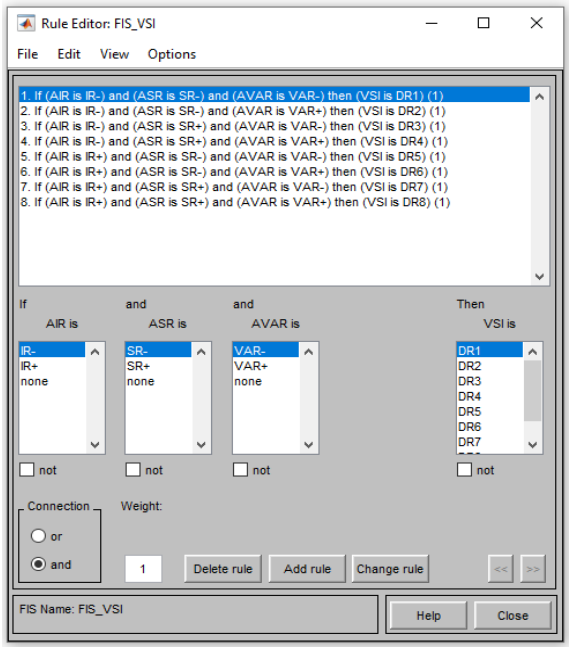

Figure 3: Basis of fuzzy rules.

The fuzzy rules include the following values: AIR is the average value for assessing the image realism; IR^+ is the fuzzy set “high value assessment of image realism”; IR^- is the fuzzy set “small value assessment of image realism”; ASR is the average value of sound realism assessment; SR^+ is the fuzzy set “high value of sound realism assessment”; SR^- is the fuzzy set “small value of sound realism assessment”; $AVAR$ is the average value of training scenarios diversity assessment. VAR^+ is the fuzzy set “high value of training scenarios diversity assessment”; VAR^- is the fuzzy set “small value of training scenarios diversity assessment”; DR_1, DR_2, …, DR_8 is the values of individual outputs of fuzzy rules.

In accordance with zero-order Sugeno algorithm, the following procedures are performed in the fuzzy inference process:

- Fuzzification;
- Aggregation;
- Activation;
- Defuzzification.

When performing the fuzzification procedure, the following values of the membership functions of the input variables to the fuzzy sets $IR^+(AIR)$, $IR^-(AIR)$, $SR^+(ASR)$, $SR^-(ASR)$, $VAR^+(AVAR)$ and $VAR^-(AVAR)$ are calculated in accordance with the expressions:

$$IR^-(AIR)=\begin{cases}1, & AIR \le IR_1^-;\\ \dfrac{IR_0^- - AIR}{IR_0^- - IR_1^-}, & IR_1^- < AIR < IR_0^-;\\ 0, & AIR \ge IR_0^-;\end{cases} \quad (1)$$

$$IR^+(AIR)=\begin{cases}0, & AIR \le IR_0^+;\\ \dfrac{AIR - IR_0^+}{IR_1^+ - IR_0^+}, & IR_0^+ < AIR < IR_1^+;\\ 1, & AIR \ge IR_1^+;\end{cases} \quad (2)$$

$$SR^-(ASR)=\begin{cases}1, & ASR \le SR_1^-;\\ \dfrac{SR_0^- - ASR}{SR_0^- - SR_1^-}, & SR_1^- < ASR < SR_0^-;\\ 0, & ASR \ge SR_0^-;\end{cases} \quad (3)$$

$$SR^+(ASR)=\begin{cases}0, & ASR \le SR_0^+;\\ \dfrac{ASR - SR_0^+}{SR_1^+ - SR_0^+}, & SR_0^+ < ASR < SR_1^+;\\ 1, & ASR \ge SR_1^+;\end{cases} \quad (4)$$

$$VAR^-(AVAR)=\begin{cases}1, & AVAR \le VAR_1^-;\\ \dfrac{VAR_0^- - AVAR}{VAR_0^- - VAR_1^-}, & VAR_1^- < AVAR < VAR_0^-;\\ 0, & AVAR \ge VAR_0^-;\end{cases} \quad (5)$$

$$VAR^+(AVAR)=\begin{cases}0, & AVAR \le VAR_0^+;\\ \dfrac{AVAR - VAR_0^+}{VAR_1^+ - VAR_0^+}, & VAR_0^+ < AVAR < VAR_1^+;\\ 1, & AVAR \ge VAR_1^+;\end{cases} \quad (6)$$

where IR_0^- and IR_1^- is the fuzzy set IR^- membership function parameters; IR_0^+ and IR_1^+ is the fuzzy set IR^+ membership function parameters; SR_0^- and SR_1^- is the fuzzy set SR^- membership function parameters; SR_0^+ and SR_1^+ – fuzzy set SR^+ membership function parameters; VAR_0^- and VAR_1^- is the fuzzy set VAR^- membership function parameters; VAR_0^+ and VAR_1^+ is the fuzzy set VAR^+ membership function parameters.

The aggregation procedure consists of estimating the degree of truth values G_1, G_2 … G_8 of fuzzy rules:

$$G_1 = IR^+(AIR) \wedge SR^+(ASR) \wedge VAR^+(AVAR), \quad (7)$$

$$G_2 = IR^+(AIR) \wedge SR^+(ASR) \wedge VAR^-(AVAR), \quad (8)$$

$$G_3 = IR^+(AIR) \wedge SR^-(ASR) \wedge VAR^+(AVAR), \quad (9)$$

$$G_4 = IR^+(AIR) \wedge SR^-(ASR) \wedge VAR^-(AVAR), \quad (10)$$

$$G_5 = IR^-(AIR) \wedge SR^+(ASR) \wedge VAR^+(AVAR), \quad (11)$$

$$G_6 = IR^-(AIR) \wedge SR^+(ASR) \wedge VAR^-(AVAR), \quad (12)$$

$$G_7 = IR^-(AIR) \wedge SR^-(ASR) \wedge VAR^+(AVAR), \quad (13)$$

$$G_8 = IR^-(AIR) \wedge SR^-(ASR) \wedge VAR^-(AVAR). \quad (14)$$

The activation procedure consists of calculating the numerator and denominator of the following expression:

$$VSI = \frac{\sum_{k=1}^{8} G_k DR_k}{\sum_{k=1}^{8} G_k}. \quad (10)$$

The defuzzification result is calculated by dividing the numerator by the denominator in expression (15).

As a result, the output of the created system receives the calculated value of the generalized indicator of the virtual simulator functioning.

So, in order to evaluate the performance of virtual simulators used for training in the diagnosis of Internet of Things networks, the following procedures are proposed:

1) The virtual simulator being evaluated is being studied by experts;
2) Each expert evaluates the image realism, sound realism, and variety of scenarios provided by the virtual simulator;
3) the grading results are fed to the input of the fuzzy inference system;
4) Fuzzification, aggregation, activation and defuzzification are performed during fuzzy inference, as a result of which the value of the generalized indicator of the functioning of the virtual simulator is evaluated.

The higher the value of the generalized indicator, the higher the resulting score of the virtual simulator.

3 EXPERIMENTAL STUDIES

Let's consider how a fuzzy inference system can be used to evaluate virtual simulators designed for diagnosis training of Internet of Things devices. The evaluated virtual simulator is studied by experts. Each expert then rates the visual realism, sound realism, and variety of scenarios provided by the virtual simulator. Scores for each parameter are averaged:

$$AIR = \frac{\sum_{j=1}^{J} IR_j}{J}, \quad (16)$$

$$ASR = \frac{\sum_{j=1}^{J} SR_j}{J}, \quad (17)$$

$$AVAR = \frac{\sum_{j=1}^{J} VAR_j}{J}, \quad (18)$$

where:

- J is the number of experts involved;
- IR_j is the assessment of the image realism given by an expert j;
- SR_j is the sound realism assessment given by an expert j;
- VAR_j is the scenarios diversity assessment given by expert j.

To conduct computational experiments to evaluate the characteristics of virtual simulators used in the field of IoT, a process model of estimating the characteristics of virtual simulators has been developed in the MATLAB software environment using the libraries of the Simulink package. The functional diagram of the model is presented in Figure 4.

The values AIR, ASR and $AVAR$ are calculated using the AIR_subsystem, ASR_subsystem and AVAR_subsystem, respectively, and are displayed by the virtual recorder Display_AIR_ASR_AVAR. Then the obtained values become the input of the Fuzzy Logic System.

The evaluation result is the value of the output VSI is a general indicator of the virtual simulator functioning. The value of the resulting indicator is displayed by the virtual recorder Display VSI.

Numerous computational experiments and real tests have shown that the estimated value of the virtual simulator VSI indicator correlates well with the PCD value is the probability of correctly diagnosing real IoT systems by those specialists who were trained on this virtual simulator.

Table 2 presents data that show how characteristics of 4 virtual simulators were assessed by 10 experts.

Using these data, the values AIR, ASR and $AVAR$ were calculated using formulas (16) – (18) applying AIR_ subsystem, ASR_ subsystem and AVAR_ subsystem. These values were entered to fuzzy inference system as input variables. Then, at the output of this system, the values of the generalized indicator of each virtual simulator functioning were obtained.

Then the probability of correct diagnosis of real IoT systems was assessed by experts who were trained on the studied virtual simulators. Data for probability estimation are presented in Table 3.

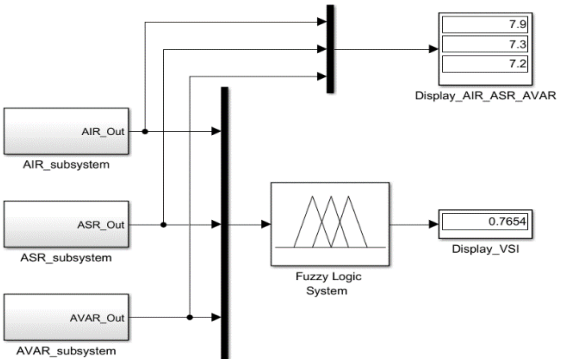

Figure 4: Functional diagram of the process software model of assessing the characteristics of virtual simulators used in the field of IoT.

The Table 3 contains values DR_{ix} that are the diagnosis results of IoT-system x by expert i, trained on a specific virtual simulator was calculated using the (19):

$$PCD = \frac{\sum_{i=1}^{I}\sum_{x=1}^{X} DR_{ix}}{I \cdot X}. \quad (19)$$

Diagrams were constructed based on the results of experiments and calculations. Figure 5 shows the VSI and PCD values obtained from a study of four different virtual simulators used for training in Internet of Things systems diagnosis.

10	1	1	0	1	0	1	1	1	1	1	1	1

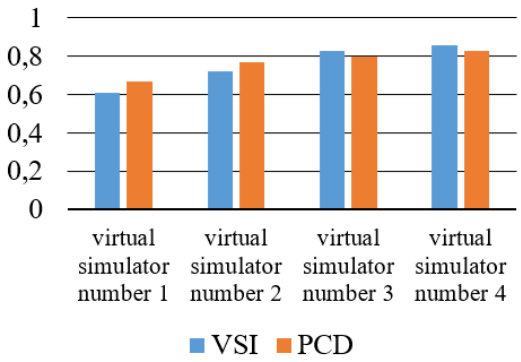

Figure 5: Diagrams of VSI and PCD values obtained from the study of four different virtual simulators.

Figure 5 shows that the higher the generalized indicator values of the virtual simulator, the greater the probability of correct IoT systems diagnosis by those experts who trained on it. Thus, the proposed fuzzy inference system can be recommended for on one of the simulators. The probability of correct diagnosis of real IoT systems by experts who were assessing the virtual simulators characteristics that are intended for training in Internet of Things systems diagnosis.

The value of the results obtained in comparison with the results of other modern studies lies in the fact that the proposed system makes it possible to evaluate the value of a generalized indicator that takes into account the most important criteria for the functioning of virtual simulators. It should also be noted that the quality of the fuzzy inference system settings depends on the number of experts involved. This can be attributed to the limitations of the proposed development.

3 CONCLUSIONS

The goal of the study was achieved, namely, a fuzzy logical inference system was developed that allows for improving the process of assessing the virtual simulators characteristics used for training in Internet of Things systems diagnosis.

The following results were obtained in the work:

1) An analysis of capabilities and specifics of the virtual simulators functioning used for training in Internet of Things systems diagnosis was carried out. The analysis showed that developers offer various options for virtual simulators that allow to train the diagnosing of IoT systems. To select devices with the best characteristics, as well as to identify shortcomings and improve virtual simulators, tools for assessing characteristics are used.
2) As indicators for assessing the characteristics of virtual simulators used for training in IoT systems diagnosis, it is proposed to use indicators of image realism, sound realism and training scenarios sets diversity, as well as a general indicator of the virtual simulator functioning. Scores for the first three indicators are given by experts in points from 1 (lowest score) to 10 (highest score). The values of the general indicator of the virtual simulator functioning should adequately take into account the values of the particular indicators of image realism, sound realism and the training scenarios sets diversity provided by the virtual simulator.
3) An assessment system has been developed for the characteristics of virtual simulators intended for training in IoT systems diagnosis. It is based on the use of fuzzy logical inference. The parameters of the membership functions of fuzzy sets and individual outputs of fuzzy rules were automatically selected using a neural network setup. The average values of assessments of image realism, sound realism, and the variety of training scenarios are fed to the input of the fuzzy logical inference system. Fuzzy inference procedures (fuzzification, aggregation, activation, and defuzzification) are then performed using these values. As a result, the desired value of the generalized indicator of the virtual simulator functioning is recorded at the output of the fuzzy logical inference system.
4) In order to study the proposed fuzzy logical inference system in the MATLAB software environment using the libraries of the Simulink package, a model of the process of assessing the characteristics of virtual simulators intended for training in diagnosing IoT systems has been developed. Numerous computational experiments have been carried out using this software model. A comparison of their results with the results of real IoT systems diagnosing showed that the higher the values of the generalized indicator of the virtual simulator functioning, the greater the probability of correct IoT systems diagnosis by the experts who trained on it. This confirms the feasibility of using the developed fuzzy logical inference system to evaluate the characteristics of virtual simulators used to IoT systems diagnosis.

The results obtained can be recommended for use in companies that develop and improve virtual simulators designed for educational purposes. The proposed development can be used as the basis for creating software for evaluating the usefulness of virtual simulators created for training in the correct diagnosis of the technical condition of Internet of Things systems.

Future work will focus on developing tools for evaluating the performance of virtual simulators used to teach IoT network management.

The reported study was funded by Russian Science Foundation, project number 25-21-00431, https://rscf.ru/project/25-21-00431/.

Keywords: Chitosan, Polyethylene Oxide, Silver Nanoparticles, Nanocomposites, Antibacterial Activity.

Abstract: The current study investigates the enhancement of the structural, morphological, and antibacterial properties of a nanocomposite material composed of chitosan (CS) and polyethylene oxide (PEO). The improvement is achieved through the incorporation of silver nanoparticles (AgNPs) at varying concentrations of 1%, 3%, and 5%. A variety of analytical techniques were applied. The XRD, FE-SEM, and FTIR investigations revealed that the introduction of AgNPs induced substantial alterations in the crystallinity of the material, the characteristics of its surface, and the behavior of functional groups within the polymer matrix. The changes observed in these parameters underscore the influence of AgNPs on the fundamental properties of the CS/PEO blend. To further characterize the nanocomposites, Zeta Potential analysis was performed. This technique provides important information about the stability and surface charge characteristics of the nanocomposites, which in turn allows for a better understanding of the dispersion and distribution of nanoparticles within the polymer matrix. Antibacterial tests demonstrated enhanced inhibition against Staphylococcus aureus and Escherichia coli, particularly in AgNP-containing films. The combined effects of chitosan and AgNPs contributed to strong antibacterial performance, especially against Gram-positive bacteria.

1 INTRODUCTION

Material science benefits greatly from nanotechnology since it allows scientists to alter polymer characteristics for creating new materials. The ratio between surface area and volume makes nanotechnology-based composites both thermally and electrically stable which makes them more efficient at reduced cost [1], [2]. Multiple studies explore nanocomposites that use synthetic polymers combined with metal oxide and carbon filler nanomaterials for enhancing multiple functional properties [3], [4].

Chitosan obtains its nature as a biodegradable biocompatible polymer from chitin through deacetylation. The many functional groups in chitosan strengthen structure while enhancing biological functions which results in its efficient antimicrobial properties. The medical sector frequently employs chitosan as an effective material because this compound achieves low toxicity alongside its capability to develop films and hydrogels and nanoparticles [5]-[10].

The properties of chitosan nanoparticles (CNPs) become more useful for biomedical and environmental applications because they show improved biocompatibility together with antimicrobial activity and membrane penetration capabilities [11]-[13]. PEO features versatility as a stretchable non-toxic substance because it dissolves well in water through hydrogen bond interactions that unite with chitosan into a single homogeneous material that demonstrates better physicochemical behavior. PEO demonstrates ideal properties for medical uses because it matches human tissue composition so it finds applications in wound dressing and drug delivery systems [5], [14]. The casting method functions as a common approach to develop nanocomposite systems which exhibit improved structural and optical properties [15]. Nanotechnology integration into polymers resulted in the development of nanocomposites that boost biomedical materials' properties and support complex medical applications [16]. The materials achieve outstanding properties regarding mechanical performance combined with strength and durability alongside wear resistance characteristics thus providing high effectiveness for medical implementations and engineering applications [2], [17] and [18]. Additionally, several polymer blends have shown antibacterial potential when reinforced with metal oxide or silver nanoparticles [19]. Among

nanomaterials, metallic nanoparticles (1-100 nm) possess unique physical and chemical properties, such as high catalytic activity, making them valuable in research on microbial resistance to antibiotics [20], [21]. Silver, copper, and zinc are commonly used as antimicrobial agents, with studies showing that silver nanoparticles (AgNPs) demonstrate the highest effectiveness against Streptococcus mutans [22]. Additionally, AgNPs exhibit strong antimicrobial activity against bacteria, fungi, and viruses, renewing interest in their medical applications, particularly against resistant strains [23].

This study investigates the structural and antibacterial properties of chitosan/PEO nanocomposite films reinforced with silver nanoparticles. XRD, FE-SEM, AFM, FTIR, EDX, zeta potential analysis, and antibacterial testing were employed to assess the impact of AgNP concentration to emphasize their potential for biomedical applications.

2 EXPERIMENTAL WORK

2.1 Materials

Chitosan (≥90% purity, 30–50 nm) was obtained from Nanochemazone, Polyethylene oxide (PEO) (Mw = 3,000,000 g/mol, ≥98% purity) was purchased from Cheng Du Micxy Chemical Co., Ltd., and silver nanoparticles (AgNPs) (10–20 nm, ≥99.9% purity) were supplied by Sky Spring Nanomaterials. Acetic acid (≥99.7% purity) was used as a solvent and deionized distilled water to ensure the purity of the sample.

AFM test was conducted to analyze the initial surface morphology and roughness of the raw materials, which include chitosan, polyethylene oxide (PEO), and silver nanoparticles (AgNPs). Measurements were performed at a scan size of 2.0 × 0.2 µm. Table 1 indicates that the PEO powder demonstrated the greatest surface roughness (Rq = 25.72 nm), signifying a markedly uneven structure. Conversely, chitosan powder exhibited a more uniform shape (Rq = 19.91 nm). AgNPs demonstrated the lowest Rq value (12.78 nm), indicating their nanometric scale and reasonably uniform distribution, as illustrated in Figure 1. The average particle sizes determined via AFM line analysis were 48.18 nm for chitosan, 78.88 nm for PEO and 38.87 nm for AgNPs, thereby affirming the nanoscale characteristics of the materials.

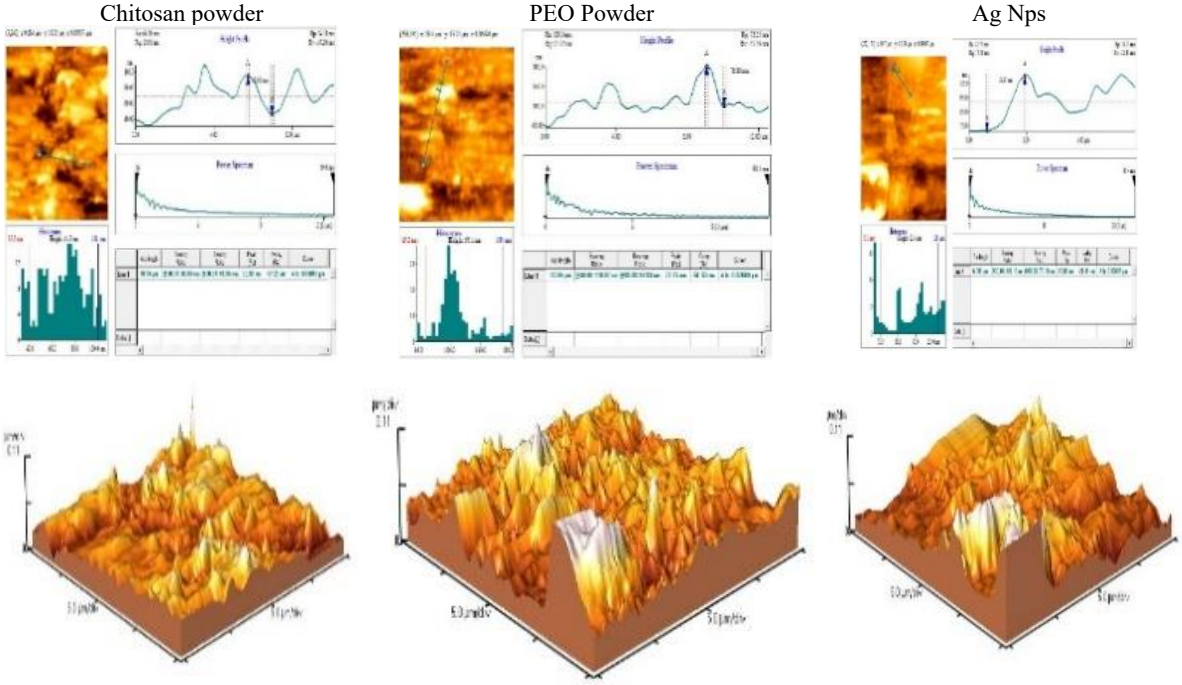

Figure 1: AFM images of chitosan, PEO, and AgNPs powders at 2.0 µm/div magnification.

Table 1. AFM roughness parameters and average particle sizes of raw materials:

Sample	Rq (nm)	Rp (nm)	Rv (nm)	Max Height (nm)	Average Particle Size (nm)
Chitosan	19.91	39.38	-37.20	61.3	48.18
PEO	25.72	72.25	-51.59	99.1	78.88
AgNPs	12.78	19.03	-21.41	32.4	38.87

2.2 Methods of Preparation

The chitosan/polyethylene oxide (Cs/PEO) composite augmented with silver nanoparticles (AgNPs) was synthesized via the solution casting technique. One gram of chitosan was dissolved in 100 milliliters of 1% acetic acid and agitated at 300 revolutions per minute for six hours at ambient temperature. PEO (1 g) was independently dissolved in 100 mL of distilled water at 50°C. The PEO solution was incrementally incorporated into the chitosan solution while maintaining continuous agitation until a uniform mixture was achieved. Silver nanoparticles (AgNPs) were integrated at concentrations of 1%, 3%, and 5%, thereafter subjected to ultrasonic treatment (120 W, 1 hour) to guarantee uniform dispersion. The finished solution was deposited into 14 cm Petri plates and desiccated at ambient temperature for 5 days; the preparation methods are illustrated in Figure 2.

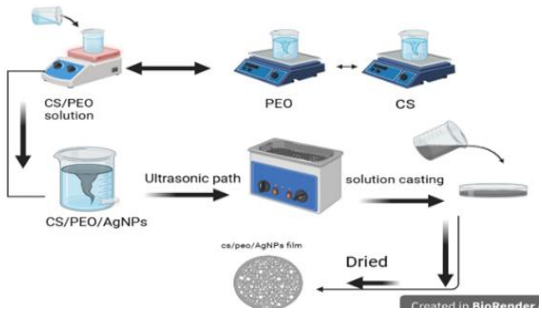

Figure 2: Schematic representation of the preparation process of chitosan/PEO/AgNPs nanocomposite films.

2.2.1 Characterization Techniques

Structural, and morphological, properties were analyzed using multiple techniques such as XRD (Philips XPERT-PRO) to determine crystallinity and phase composition (Cu-Kα, 10°–80°), EDX confirmed elemental composition, and the presence of AgNPs, FTIR (Shimadzu IR Affinity) was used to identify functional groups in the range of 4000–400 cm^{-1}, Zeta Potential measurements (Horiba SZ-100) were conducted to evaluate the surface charge and colloidal stability at 25°C, The agar disk diffusion was used to identify the antibacterial activity against S. aureus and E. coli. The tested sample was loaded on the well, and bacterial cultures were placed on Mueller-Hinton agar plate. Measurement of inhibition zones was done after a 24 hours incubation at 37 o C. Distilled as the negative control water was used.

3 RESULTS AND DISCUSSION

3.1 XRD Analysis

Figure 3 displays the XRD patterns of chitosan (Cs) (S1), polyethylene oxide (PEO) (S2), Cs/PEO mix (S3), and Cs/PEO combined with varying concentrations (1, 3, 5) % of silver nanoparticles (AgNPs) (S4, S5, S6) accordingly. The diffraction peaks at 2θ = 10.5° and 20.1° signify an orthorhombic structure, with supplementary peaks corroborating the semi crystalline characteristics of chitosan [24]-[26]. In contrast, PEO had specific peaks at 2θ = 19.2°, 21.0°, 23.3°, and 26.3°, signifying its monoclinic crystalline structure, accompanied by smaller peaks at 27.1° [27]. The XRD pattern of the Cs/PEO blend exhibited peaks from both constituents, hence affirming effective synthesis. The peak at 2θ = 23.1°, linked to PEO, diminished in intensity and widened, signifying hydrogen bonding interactions between Cs and PEO [28]. The crystallite size (D) for the (111) peak was determined using the Debye-Scherrer equation [29] ($D=K\lambda/\beta \cos\theta$), where K is a constant (0.91), λ represents the X-ray wavelength (0.154 nm), β denotes the full width at half maximum (FWHM), and θ signifies the diffraction angle. The mean crystallite size of AgNPs rose from 15.8 nm (S4) to 21.6 nm (S5) and 25.7 nm (S6), signifying improved crystallization with increased AgNP concentrations, and a decrease in FWHM from 0.52° to 0.32°. The peak at 2θ = 32.004° indicates potential surface crystallization on AgNPs resulting from polymer-nanoparticle interactions, a process documented in prior nanocomposite research [30].

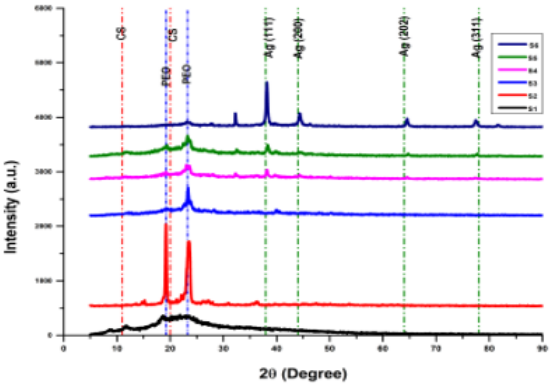

Figure 3: XRD patterns of all samples, including pure chitosan, pure PEO, chitosan/PEO blend, and chitosan/PEO blend with 1%, 3%, and 5% AgNPS.

3.2 FTIR Analysis

Figure 4 presents the FTIR spectra of chitosan (Cs), PEO, their blend (Cs/PEO), and Cs/PEO reinforced with different AgNP concentrations.

In the chitosan spectrum, a broad peak at 3360–3285 cm^{-1} corresponds to –OH and –NH stretching vibrations, indicating strong hydrogen bonding. Peaks at 1645 cm^{-1} (C=O) and 1534 cm^{-1} (N–H) confirm the presence of amide structures [25], [31].

The PEO spectrum exhibits a strong absorption peak at 1094 cm^{-1}, attributed to C–O–C ether stretching, along with weak absorptions around 2872 cm^{-1}, corresponding to C–H stretching vibrations, characteristic of PEO [26]. In the Cs/PEO blend, a slight shift and intensity reduction of the 3360–3285 cm^{-1} band indicates hydrogen bond formation between chitosan and PEO. Additionally, peaks at 1645.95 cm^{-1} (NH) and 1119.48 cm^{-1} (C–O–C) confirm structural interactions within the blend [1].

Upon silver incorporation (S3–S6), spectral changes were observed, particularly in the 4000–1000 cm^{-1} range. While the 4000–3000 cm^{-1} region remained stable, the 3000–1500 cm^{-1} range showed variations in C–H (2900 cm^{-1}) and C=O (1650 cm^{-1}) peaks, indicating silver interactions. The most significant changes occurred in the fingerprint region (1500–1000 cm^{-1}), where increased silver content enhanced C–O (1000–1200 cm^{-1}) intensity, suggesting direct interactions with oxygen-containing groups. The results suggest that silver modifies the molecular structure by interacting with oxygen-containing groups while maintaining the composite's fundamental structure, consistent with previous studies like Mahmoud et al. (2019) [19], [32].

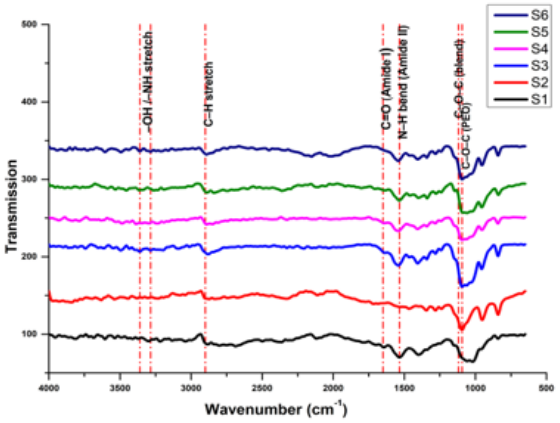

Figure 4: FTIR spectra of all samples, including pure chitosan, pure PEO, chitosan/PEO blend, and chitosan/PEO blend with 1%, 3%, and 5% AgNPS, showing the characteristic functional groups and interactions.

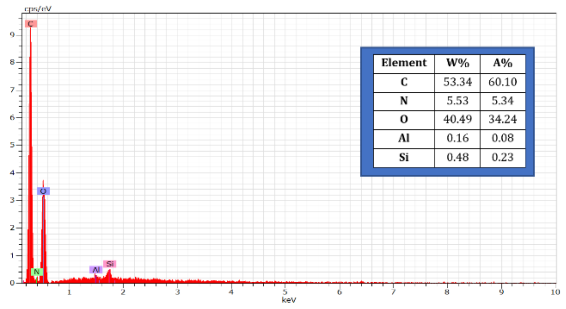
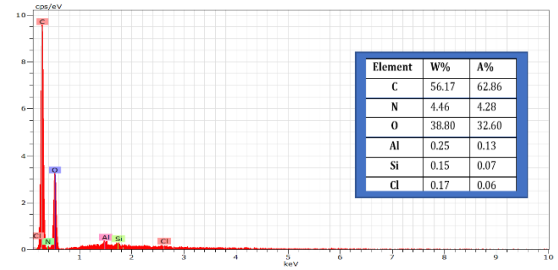


3.3 Energy Dispersive X-Ray Spectroscopy (EDX) Results

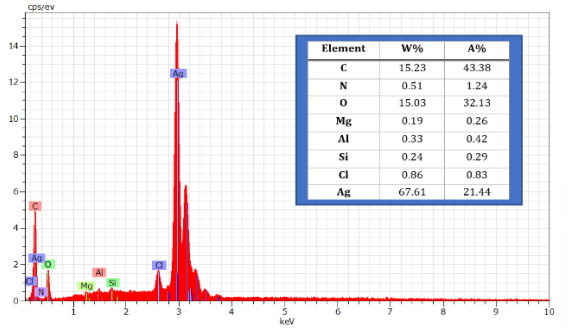
The elemental composition of the polymeric samples was analyzed using energy-dispersive X-ray Spectroscopy (EDX) to identify the presence of key elements and confirm the structural integrity of the prepared composites.

The EDX spectrum of S1 (Fig. 5), representing pure chitosan, confirmed its organic nature as it primarily consists of carbon (C) and oxygen (O). This composition aligns with the well-documented molecular structure of chitosan, which mainly consists of polysaccharide chains containing carbon, oxygen, and nitrogen [33].



In addition, trace amounts of aluminum (Al) and silicon (Si) were detected, likely originating from the natural mineral content in crustacean shells used as raw material. Previous studies have reported the persistence of these elements despite the demineralization steps during preparation [34].

In sample S3 Figure 6, characterized by an equal mixture of chitosan and PEO, EDX analysis indicated elevated concentrations of carbon (56.17%) and oxygen (38.80%), underscoring the organic composition of the polymeric structure. Nitrogen is derived from chitosan, whereas the oxygen concentration is indicative of both components' contributions. A minimal quantity of chlorine was also identified, presumably due to the processing procedure. The results demonstrate the effective amalgamation of both polymers and the establishment of a stable composite structure.



Element	W%	A%
C	53.34	60.10
N	5.53	5.34
O	40.49	34.24
Al	0.16	0.08
Si	0.48	0.23

Figure 5: EDX spectrum and elemental composition of S1 (Cs).

Element	W%	A%
C	56.17	62.86
N	4.46	4.28
O	38.80	32.60
Al	0.25	0.13
Si	0.15	0.07
Cl	0.17	0.06

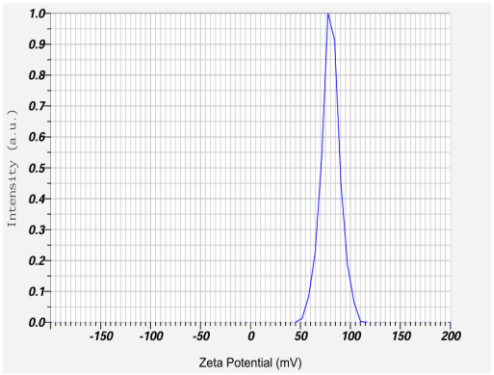


Figure 6: EDX spectrum and elemental composition of S3 (chitosan/PEO blend).

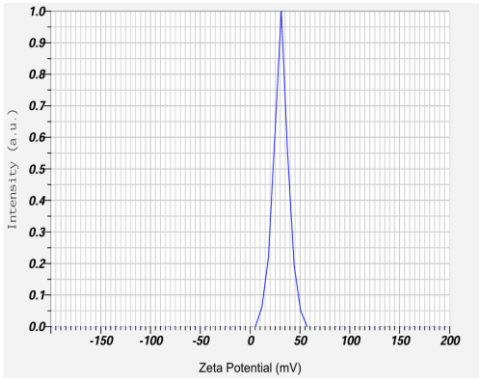
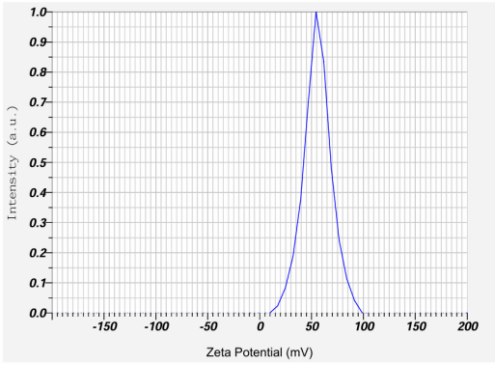
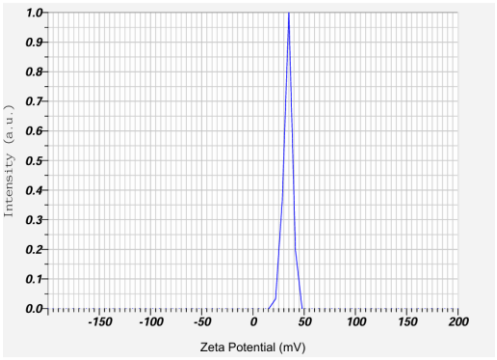


Element	W%	A%
C	15.23	43.38
N	0.51	1.24
O	15.03	32.13
Mg	0.19	0.26
Al	0.33	0.42
Si	0.24	0.29
Cl	0.86	0.83
Ag	67.61	21.44

Figure 7: EDX spectrum and elemental composition of S6 (chitosan/PEO blend with 5% AgNP.



EDX analysis of sample S6 Figure 7 confirmed the presence of silver at 7.52 wt%, indicating the successful incorporation of silver nanoparticles into the polymer matrix. The carbon and oxygen contents remained stable, suggesting that the polymer structure was not significantly affected. The nitrogen content (3.96%) was within the expected range.



S1

S2

S3

S6

Figure 8: Zeta potential curves of the selected samples (S1, S2, S3, and S6).

3.4 Zeta Potential Analysis

The surface charge of the prepared films was evaluated using Zeta Potential measurements at 25 °C using a Horiba SZ-100 as in Table 2 and Figure 8.

The chitosan membrane (S1) exhibited a high positive Zeta Potential of 80.2 mV, attributed to the protonation of amino groups, indicating excellent stability in acidic environments [35]. In contrast, the PEO film (S2) showed a significantly lower value (30.8 mV), consistent with its neutral chemical nature and known tendency to screen surface charges, thereby reducing electrostatic interactions [36].

Table 2: Zeta Potential values of the selected membrane samples.

Samples	Zeta Potential (Mv)
S1	80.2
S2	30.8
S3	55.7
S6	34.0

The CS/PEO blend (S3) showed an intermediate value (55.7 mV), suggesting enhanced intermolecular interaction and partial retention of chitosan's surface charge. This can be attributed to hydrogen bonding between –NH and –OH groups of chitosan and the ether oxygen in PEO [28].The nanocomposite film containing 5% AgNPs (S6) exhibited a reduced Zeta Potential (34.0 mV), which may be attributed to nanoparticle agglomeration or surface charge masking by the polymer matrix. This observation agrees with previous reports suggesting that at higher AgNP concentrations, particles tend to aggregate, reducing the active surface area and weakening electrostatic interactions [37], [38].

Despite the lower surface charge, it is reported that chitosan-AgNPs systems can retain some positive charge due to protonated amino groups, which contributes to their antibacterial potential [39].

3.5 Antibacterial Activity Analysis

The antibacterial properties of the chitosan/PEO-AgNPs solution were evaluated using the agar well diffusion method, showing a concentration-dependent effect. According to Table 3, inhibition zones ranged from 6.5 mm (lowest concentration) to 26 mm (highest concentration), confirming their effectiveness.

When tested against Staphylococcus aureus, S6 exhibited the highest antibacterial activity, with an inhibition zone of 26 mm at 100% concentration, consistent with previous findings reporting that Cs/Ag NPs maintain strong antibacterial effects even at low concentrations [40]. S3, S4, and S5 also showed inhibition zones exceeding 23 mm, reinforcing the bactericidal effect of silver incorporation Figure 9.

Table 3: Antibacterial activity of chitosan/PEO nanocomposite solution against Staphylococcus aureus (Gram-positive) and Escherichia coli (Gram-negative) bacteria, represented by the inhibition zone (mm) at different concentrations.

Samples		A control	B 12.5%	C 25%	D 50%	E 100%
S.aures	S 1	6	6.5	11	14.5	19
	S 2	6	8.6	12.7	14	17
	S 3	6	8	9	20.9	23.7
	S 4	6	7	12	19.5	24
	S 5	6	11	16	21	23
	S 6	6	8.5	10	20	26
E. coli	S 1	6	9	12	14	18
	S 2	6	11	12	13	17
	S 3	6	10.5	14	15	18
	S 4	6	8	13	17	20
	S 5	6	9	9.5	16	22
	S 6	6	8	11	17	21

Against Escherichia coli, antibacterial efficacy was lower, with S5 showing the highest inhibition zone (22 mm at 100%), likely due to the outer membrane barrier of Gram-negative bacteria, which limits nanoparticle penetration, as previously reported Figure 10 [41], [42].

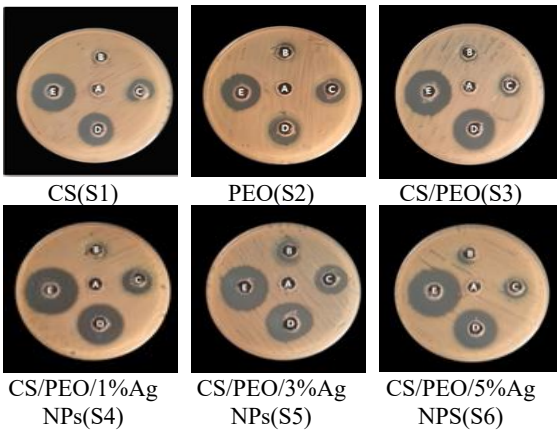


Figure 9: Antibacterial activity of chitosan, PEO, and chitosan/PEO nanocomposite films with different silver nanoparticle concentrations against Gram-positive Staphylococcus aureus bacteria, showing the inhibition zones for each sample.

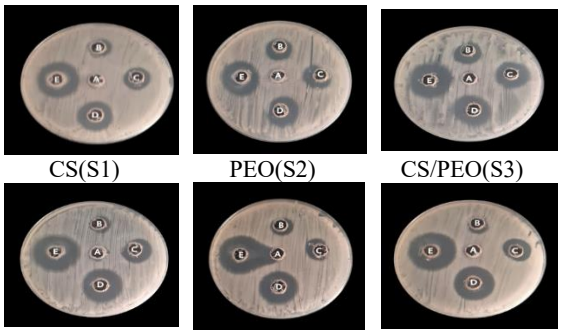

Figure 10: Antibacterial activity of chitosan, PEO, and chitosan/PEO nanocomposite films with different silver nanoparticle concentrations against Gram-negative Escherichia coli bacteria, showing the inhibition zones for each sample.

The observed antibacterial properties a direct correlation was observed between silver concentration and inhibition zone size, with increased silver content enhancing bacterial inhibition, as confirmed by previous studies reporting that higher silver content promotes antimicrobial ion release [40], [41].

The potential of silver-based nanocomposites has been confirmed, particularly against Gram-positive bacteria, while further modifications are still required to improve their efficacy against E. coli. The importance of continued research on long-term stability and interactions in medical applications has also been highlighted in previous studies [40], [43].

4 CONCLUSIONS

Incorporating silver nanoparticles (AgNPs) into the chitosan/PEO composite improved their structural integrity and antibacterial efficacy. XRD analysis confirmed the semi-crystalline nature of the blend and verified AgNPs incorporation through distinct diffraction peaks, including those corresponding to silver, while EDX verified silver presence and increasing Ag content with concentration. FTIR revealed strong chitosan-PEO hydrogen bonding, with spectral shifts indicating AgNP-polymer interactions. With spectral shifts indicating chemical interactions between AgNPs and polymer. Zeta potential analysis demonstrated significant variations in surface charge, reflecting changes in colloidal stability and electrostatic interactions due to AgNPs addition, where Antibacterial activity shows improved inhibition zones against Staphylococcus aureus and E. coli, with stronger effects on Gram-positive bacteria, confirming the synergistic antimicrobial effect of chitosan and AgNPs. The antibacterial response depended on both concentration and strain. S6 (5% AgNPs) demonstrated the most potent suppression of Staphylococcus aureus, while S5 (3% AgNPs) exhibited the greatest antibacterial efficacy against Escherichia coli. The results indicate that AgNP-reinforced CS/PEO composites are viable options for biomedical applications, including antimicrobial wound dressings. Future investigations must prioritize the assessment of long-term stability, cytotoxicity, and in vivo biocompatibility for clinical application.

Keywords: Electrospinning, Nanofibers, PVA, GA, GO.

Abstract: In recent years, electrospinning has gained significant attention for the production of innovative nanofibrous materials with diverse applications in science and engineering. The use of graphene oxide and natural products derived from plants and/or trees has gained remarkable popularity in many scientific disciplines due to their availability, eco-friendliness, and unique properties. In this study, an approach is presented for producing nanofibers using a carefully prepared mixture of 2 wt% Gum Arabic (GA), a natural tree gum extract, 8 wt% Polyvinyl alcohol (PVA), an environmentally friendly stabilizer, and 0.5 wt% Graphene Oxide (GO), which was incorporated to enhance the durability and performance of the fabricated nanofibers. The electrospinning process was carried out using a laboratory-made electrospinning system under controlled conditions. X-ray diffraction (XRD) and field emission scanning electron microscope (FESEM) analysis were employed to characterize the GO. Furthermore, FESEM was also utilized to investigate the morphology, distribution, and diameters of the nanocomposite fibers.

1 INTRODUCTION

In recent years, electrospinning has become a widely recognized method for fabricating polymer nanofibers with adjustable diameters and morphologies through the regulation of processing and solution variables. Consequently, electrospinning has been extensively employed as an effective technique for fabricating composite nanofibers [1]. Moreover, the design versatility and component controllability of electrospun nanofibers are considerable advantages. Due to the superior characteristics derived from these structural benefits, electrospun nanofibers possess significant potential for extensive application in protective textiles, filtration, composite reinforcement, and biomedical fields, including tissue engineering scaffolds, wound dressings, and drug delivery systems [2].

Nanomaterials have demonstrated excellent properties that surpass those of bulk materials in various fields [3] - [6]. One of the most interesting materials is graphene oxide (GO). It has recently been regarded as an essential material in the domain of carbon nanostructures. GO resembles graphene, with the hexagonal planes of graphene adorned by oxygen atoms. The presence of oxygen-containing functional groups (hydroxyl, epoxy, and carboxyl) on the GO surface makes it more hydrophilic and easier to spread in water and other polar solvents. The remarkable chemical and physical features of GO render it highly effective in catalysis [7], [8], energy [9], and drug delivery [10], as well as numerous further applications [11] - [15].

The polydispersity of the graphene/polymer solution before the electrospinning process is a critical component in the manufacturing of graphene-based nanofibers. Numerous materials have been evaluated as co-blending solutions for nanofiber manufacturing [16]; Nonetheless, there exists a significant deficiency in the utilization of "green" polymers (for instance, tree-derived gums [17], [18]) for this purpose. This can render the entire process more sustainable and cost-effective. Consequently, we have endeavored to close this gap by utilizing GA as a renewable, eco-friendly, biodegradable agent for the synthesis of graphene-based nanofibers. GA or Acacia gum is the exudate from the Acacia Senegal and Acacia seyal trees, which are part of the Leguminosae family. It is a complex, branching heteropolysaccharide, either neutral or somewhat acidic, and composed of 1, 3-linked β-D-galactopyranosyl units. L-arabinose, L-rhamnose, and D-glucuronic Acids have also been identified as

components of this polymer [19]. The side chains consist of two to five 1, 3-linked β-D-galactopyranosyl units that connect to the primary chain through 1, 6-linkages [20]. Historically, PVA has proven to be a superior co-solvent in gum solutions for the electrospinning process, markedly outperforming PEO (polyethylene oxide) [21]. Despite substantial research on electrospun polymer and polymer/graphene-based nanofibers, controlling fiber continuity and morphology while preserving environmental sustainability is still a challenge. Many biopolymers show poor mechanical stability or restricted spinning ability, which limits their practical application.

In the present study, a ternary PVA/GA/GO composite system is constructed in which each component serves a specific function. The PVA is selected as the main matrix due to its superior electrospinning ability, mechanical stability, and water solubility [22]. The GA, a naturally occurring and biodegradable polysaccharide, is used as a green modifier to improve intermolecular interactions and solution viscosity; nevertheless, when used alone, its high molecular complexity may have a negative impact on jet stability. It must add to synathic polymer to produce fibers [23]. Incorporating the GO as an electrically conductive and nanoscale reinforcing filler enhances the mechanical properties of fibers and modifies optical properties [24]. The purpose of this work is to understand how fiber production and optical behavior in electrospun nanofibers are influenced by the synergistic combination of PVA, GA, and GO.

2 EXPERIMENTAL PART

2.1 Materials

All chemicals used in this study were of analytical grade. Polyvinyl alcohol molecular formula (C4H6O2C2H4O)X, 67000 g/mol molecular weight, 1400 degree of polymerization, 88% degree of hydrolysis, viscosity of 8 mPa.s (in 4% aqueous solution), and physical form pure, solid, white, odorless, granular. It was purchased from ME Scientific Engineering Ltd. GA was purchased from THOMAS BAKER, India, with maximum impurity limits: acid-insoluble ash of 1.0%, water-insoluble matter of 1.0%, loss of 15.0% on drying at 105 °C, and 5.0% sulfated ash. GO was purchased from Platonic Nano Private Limited, India, with a purity of 98%, APS (Average Particle Size) of 20 nm, and a thickness of less than 5 nm.

2.2. Preparation of PVA/GA/GO Solutions

In the first step, a PVA solution was prepared by adding 1 gram of PVA polymer to 10 ml of deionized water and homogenizing the solution at 80 °C with continuous stirring for 60 minutes.

In the second stage, a PVA-GA solution was prepared by adding 0.8 grams of the synthetic polymer PVA in 10 ml of deionized water and mixing them as in the first step under continuous stirring at a temperature of 80 °C for 60 minutes. Then, 0.2 grams of GA was added to the solution and left to homogenize overnight under continuous stirring.

In the final stage of preparation, a GO solution was prepared by dissolving 0.05 grams of graphene oxide in 10 ml of deionized water. This mixture was ultrasonicated for 70 minutes to achieve a fine and even consistency. After the dispersion process was completed, the solution was transferred to a magnetic mixing device, where 0.8 grams of PVA were added to the mixture. The mixing process continued for 90 minutes at 80 °C to ensure complete dissolution and homogeneity of the polymer. Then, 0.2 grams of GA were added to the mixture, with continuous magnetic stirring overnight to ensure optimal homogeneity and achieve the desired physical and chemical properties of the resulting solution.

2.3 Electrospinning Process

A laboratory-scale electrospinning system was used to produce nanofibers. This system includes a high-voltage power supply (HVPS) capable of delivering up to 30,000 V with integrated voltage measurement, an acrylic injection pump with Bluetooth connectivity for wireless control and Arduino-based modification, and an aluminum sheet accumulator to ensure electrical conductivity. Two electronic circuits manage the HVPS and injection pump, providing operational precision and adaptability.

Prepared solutions were loaded into a 5 ml syringe within our lab-built electrospinning system. This system comprises a smart syringe pump, a high-voltage power supply, and a collector. Electrospinning was performed with a 16 cm needle-collector distance, a 30 kV voltage, and a 0.02 ml/min flow rate.

2.4 Characterization

XRD (Shimadzu-6000, Japan; 1.2 kW; Cu) with a wavelength of 1.5406 Å was used for the characterization of GO.

The morphology of the prepared nanofibers was observed using a FESEM (Nova NanoSEM 450, FEI, USA, and Axia ChemiSEM, Thermo Fisher Scientific, USA, and TESCAN Vega2, Czech Republic). Before analysis, the samples were sputter-coated with gold to improve conductivity during imaging. To determine the average diameters and diameter distribution of the prepared nanofibers, 40 different fibers were randomly selected, and their diameters were measured using ImageJ software.

A UV-visible spectrometer (DU-8800, DRAWELL, China) was used to study the optical properties of the prepared samples.

3 RESULTS AND DISCUSSION

3.1 XRD and FESEM Analysis of GO

GO was analyzed via XRD and FESEM, as depicted in Figure 1. The XRD pattern reveals significant peaks, notably at 10°, associated with the (001) plane, reflecting interlayer spacing attributed to oxygen functionalities [25]. Conversely, the weak peak at 42° pertains to a short-range order inside the layers of stacked graphene, which are characteristic of the semicrystalline profile of the turbostratic graphite structure [26] - [29]. The FESEM image of GO reveals a broad surface and an intricate sheet with a smooth morphology. The GO appears to be thin, transparent, crumpled layers with notable overlapping regions and folded edges. The visible wrinkles and ripples could indicate that the sheets of graphene oxide have a few layers. The edges of the GO sheets are clear and display the thin nature of the material.

3.2 UV-Visible Spectrum

The optical properties of the prepared solutions of PVA, PVA/GA, and PVA/GA/GO were studied using a UV-visible spectrometer. The spectrum exhibits a distinct absorption within the 200-300 nm band, as shown in Figure 2a. No significant absorption occurs above 300 nm, signifying an absence of robust optical response in the visible band. This verifies that PVA alone does not substantially enhance absorption at elevated wavelengths; this demonstrates that PVA alone has limited optical absorption in the visible region. It was seen that pronounced absorption peaks in the range of 200-300 nm, akin to the PVA spectra, albeit with alterations attributable to the influence of GA, see Figure 2b. Nevertheless, there is no notable alteration beyond 300 nm, suggesting that the incorporation of GA did not substantially enhance the optical responsiveness of the solution.

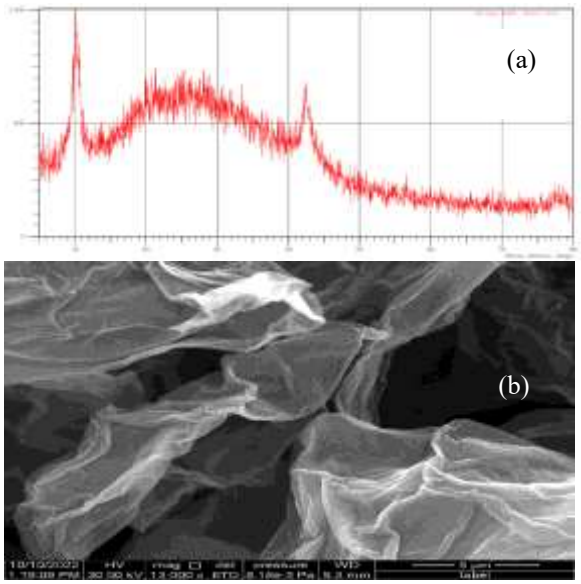

Figure 1: GO characterization: a) XRD analysis of GO and b) FESEM.

Although GA does not considerably widen the absorption range, it may alter other material properties that were not examined in this study. The incorporation of GO results in a notable alteration in the spectrum, as shown in Figure 2c. A notable rise in absorption is observed beyond 250 nm, succeeded by the appearance of a wide absorption band that extends to 400 nm and beyond. This illustrates the characteristics of optical transitions in GO, noted for its significant absorption in ultraviolet and visible light. In contrast to the two preceding solutions, it is evident that GO is the principal element influencing this novel optical response; thus, GO plays a dominating role in changing the optical absorption behavior of the composite.

The energy gaps of the three produced solutions, yielding a value of 5.22 eV for the PVA solution, Figure 3a, which is consistent with [30], 4.95 eV for the PVA-GA solution, Figure 3b, and 4.41 eV for the PVA/GA/GO solution, as shown in Figure 3c. It is clear that the bandgap decreases with the addition of GA and GO in the PVA. The GO is a non-stoichiometric, filled with defects carbon material whose electrical configuration is determined by the arrangement of sp^2 and sp^3 domains rather than a distinct crystalline band structure. The observed reduction in optical band gap following GO integration does not signify typical semiconductor behavior; instead, it demonstrates improved

electronic coupling, defect-state absorption, and π–π* interactions between GO sheets and the polymer matrix. Comparable decreases in the apparent optical band gap following the insertion of graphene oxide into polymer matrices have been reported, attributable to defect-induced localized states and enhanced charge delocalization [31], [32].

An optical absorption study alone is inadequate to confirm direct applicability in optoelectronic devices; additional electrical and device-level research is necessary.

3.3 Measurements of Nanofiber Diameters

Although solution viscosity, surface tension, and electrical conductivity were not directly measured in this study, these parameters are well known to have a significant impact on electrospinning behavior. Previous studies have shown that increasing the solution viscosity of the polymer leads to larger fiber diameters [33], [34]. Also, GO is known to reduce fiber diameter by increasing charge density in the jet [35]. Based on recognized electrospinning principles and previously documented patterns in

polymer–polysaccharide and polymer–graphene oxide systems, the observed differences in fiber diameter are therefore qualitatively addressed.

The effect of adding both GA and GO on the formation of PVA nanofibers was studied using a FESEM at 50kx magnification for PVA and PVA/GA and 20kx for PVA/GA/GO. Images were analyzed using ImageJ software to calculate the average diameter of the formed nanofibers, where 50 fibers were measured to determine the diameters. The results showed that the fibers formed from pure PVA were homogeneous and stable, extending to an unlimited length proportional to the amount of solution used, as clearly shown in Figure 4. This result indicates that the base solution is capable of producing continuous, homogeneous fibers under the selected electrospinning conditions.

When 2 wt% GA was added to the solution, 8 wt% of PVA, a significant change in the structure of the resulting fibers was observed, with the fibers appearing discontinuous and irregular, as shown in Figure 5. This change indicates the difficulty of forming cohesive fibers in the presence of GA, which may be due to its effect on the viscosity of the solution or the intermolecular forces during the forming process. GA may have disrupted the flow of the solution during the spinning process, resulting in discontinuous fibers with irregular shape and length.

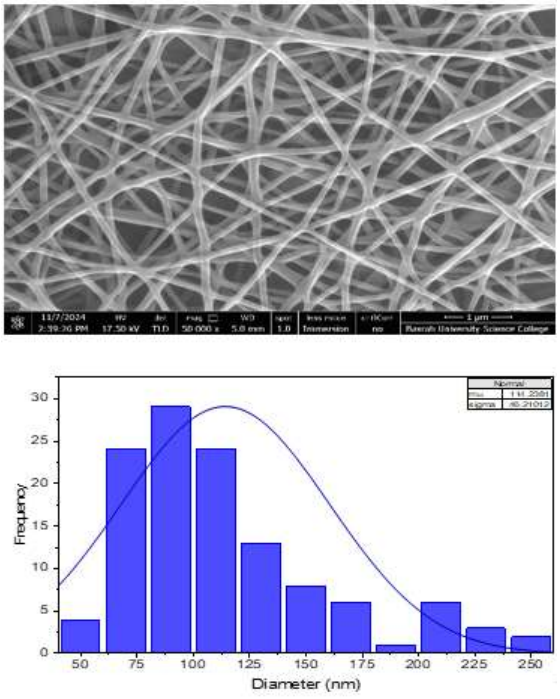

Figure 4: FESEM image of PVA nanofibers and fiber diameter distribution graph using 10 wt% concentration.

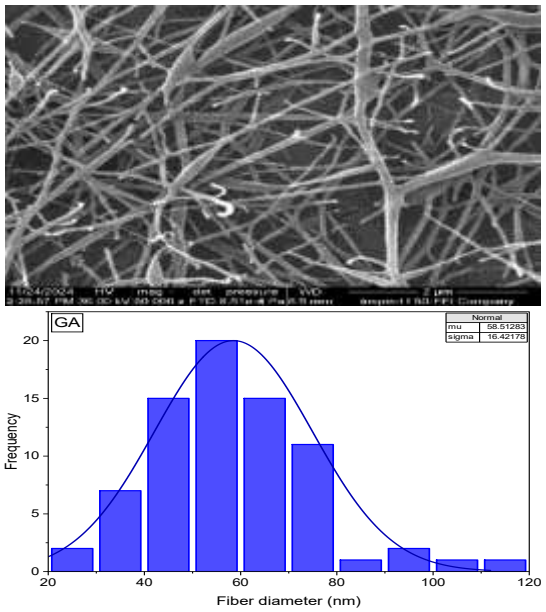

Figure 5: FESEM image of PVA/GA nanofibers and fiber diameter distribution diagram using 2 wt% GA and 8 wt% PVA concentrations.

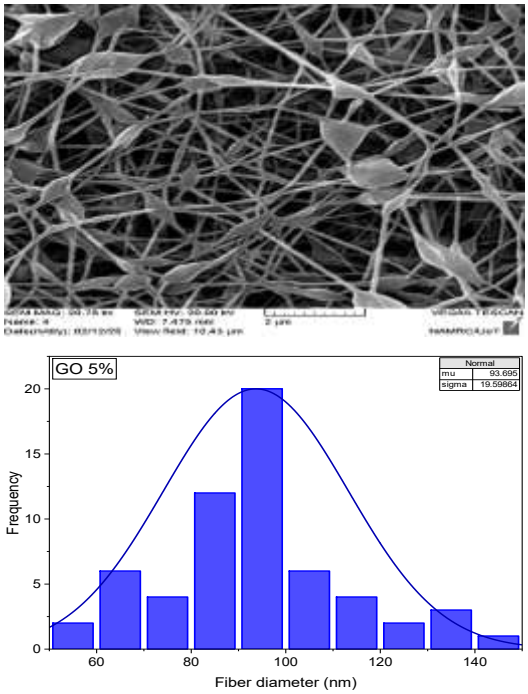

Figure 6: FESEM image of PVA/GA/GO nanofibers and fiber diameter distribution diagram using 2 wt% GA, 8 wt% PVA, and 0.5 wt% GO concentrations.

In an attempt to improve the fiber structure and restore its cohesion, 0.5 wt% GO was mixed with a

solution containing PVA 8 wt% and GA 2 wt%. The results showed that the resulting fibers became more interconnected and continuous, indicating that GO contributed to improving fiber continuity and structural integrity, as shown in Figure 6. This positive effect is attributed to the unique physical and chemical properties of graphene oxide, which likely enhanced the interaction between the various components of the solution, resulting in a more stable and interconnected fiber network.

The creation of continuous electrospun fibers is determined by the balance of solution rheological characteristics and electrical forces acting on the charged jet. The addition of GA, a highly branched polysaccharide, can disrupt polymer chain entanglement and modify solution viscoelasticity, resulting in jet instability and fiber discontinuity. In contrast, adding GO creates conductive channels and raises charge density within the electrospinning jet [35]. This improved electrical conductivity enhances the stretching forces beneath the applied electric field, stabilizing the jet. In addition, GO nanosheets may operate as physical bridges between polymer chains, partially compensating for GA's destabilizing effect and restoring fiber continuity. The seen morphological change can thus be attributed to a combination of GA-induced rheological modification and GO-induced electrical and reinforcing effects.

The mean fiber diameter achieved using pure PVA was found to be 114.23 nm. The incorporation of GA into PVA resulted in a reduction of the average diameters to 58.51 nm. The incorporation of GO into the GA and PVA combination resulted in an increase in average diameters to 93.69 nm.

4 CONCLUSIONS

PVA alone demonstrates minimal absorption in the visible spectrum, with its absorption confined to the ultraviolet range. The incorporation of GA into PVA resulted in a minor alteration of the absorption spectrum, as indicated by the decrease in the energy gap. Adding GO to the mixture significantly improved the absorbance in the visible spectrum, making it the material responsible for the optical modification. The change in optical absorption induced by GO incorporation indicates that the presence of GO would affect the electronic structure of the polymer, which may be of interest for optically sensitive polymer composites.

FESEM results reveal that the incorporation of GA influences fiber continuity and diminishes their diameter, whereas GO enhances the fiber structure's cohesiveness and integrity, increasing the diameter in comparison to GA. This illustrates the possibility of regulating fiber structure and altering its characteristics to suit the needs of specific applications, particularly in applications where controlled fiber morphology is required. Viscosity, surface tension, and electrical conductivity were not measured in this study but will be examined in future studies. Moreover, chemical structure, thermal stability, and mechanical properties need to be considered in future work.

Remote Sensing-Based Numerical Methods for Water Surface Area Estimation

Mutasim Ibrahim Malik
Physics Department, College of Sciences, Wasit University, 52001 Al-Kut, Wasit, Iraq
mutasim@uowasit.edu.iq

Keywords: Remote Sensing, Numerical Analysis, Iraqi Lakes, Lake Hamrin, Copernicus.

Abstract Monitoring water bodies in Iraq is vital in light of increasing climatic and human pressures, especially for Lake Hamrin, a major source of drinking and irrigation water in Diyala Governorate. This research relied on Sentinel-2 L2A images from the Copernicus program for the period 2019–2025 to determine changes in the lake's surface area. The Normalized Water Index (NDWI) was used to extract the water boundaries, then convert the geographic coordinates to metric (UTM) coordinates to accurately draw the shoreline. Two numerical methods were applied to calculate the water surface area of Lake Hamrin the Shoelace and Simpson's methods. Comparing the results with reference values extracted from the Copernicus platform, it was found that the shoelace method yielded a lower error (0.7–3.1%) than the Simpson method (1.3–5.1%). This is attributed to the complexity of the coastal shape of Lake Hamrin. Shoelaces provide a more accurate representation of coastal details, while Simpson's method tends to simplify the boundaries. However, the differences between the two methods diminish when the water level is low, as in 2021–2023, as the shape of the lake becomes more regular.

1 INTRODUCTION

Iraq's natural and artificial lakes such as Tharthar, Habbaniyah, Razzaza, Hamrin, Dukan, Darbandikhan, and the Mosul Dam reservoir are vital pillars of water security, the environment, and the economy (flow storage and regulation, irrigation, hydropower, fishing, and biodiversity) [1]. Over the past two decades, strong observational evidence has accumulated that these bodies of water are subject to increasing pressures due to climate change (increasing temperatures, increased evaporation, and more frequent droughts) and human factors (upstream regulations and transboundary hydropower projects) [2]. This pressure has resulted in shrinking surface area, fluctuating water levels, and deteriorating water quality characteristics. Analyses of water budgets and climate in the Tigris and Euphrates basins show that droughts and extreme heat waves have become a central player in resource scarcity and fluctuating surface storage, with wide-ranging social and environmental impacts [3]. One of the most important of these lakes is Lake Hamrin. It is water basin that was completely submerged in 1981 with the construction of the Hamrin Dam as part of preventative measures against the flooding that plagued Iraqi cities. The lake supplies Diyala Governorate with approximately 70-80 percent of its drinking and agricultural water needs, according to the governorate's Water Resources Directorate, with a capacity of more than 2.4 billion cubic meters of water. Therefore, due to the importance of this lake and other lakes in Iraq, we need to monitor this lake with modern technologies that save time and effort and provide sufficient information upon which to base decisions, especially since the world is experiencing dangerous climate changes. One of the most important of these modern technological methods is remote sensing and the technologies associated with it [4]. At the spatial level, remote sensing imagery has provided a highly reliable time series for tracking water surface fluctuations across Iraq's large water bodies. Recent studies have observed clear seasonal and interannual shrinkage in major lakes such as Tharthar, Habbaniyah, and Hamrin, linking this to increasing climate stress and declining water releases, highlighting the sensitivity of these reservoirs to air temperature and increased evaporation. Other studies have documented the shrinkage of water surface boundaries [4], [5].

In dry and semi-dry environments such as Iraq, peer-reviewed studies have demonstrated significant

shrinkages in major reservoirs and lakes (such as Razzaza and Hamrin) based on Sentinel-2, classification algorithms, and hydrological indices, supporting water management decisions under drought and heat stress. Jumaah et al. (2023) studied the decline of Lake Hamrin using Sentinel-2 satellite imagery and GIS analysis. Using the Normalized Water Index (NDWI), the researchers documented a sharp decline in the lake's surface area between 2017 and 2022, with the water cover decreasing from approximately 144 km² to less than 40 km² [6]. Ameen et al. (2025) extended this research by analyzing the hydrological dynamics of Lake Hamrin over two decades (2004–2024). Using a multi-temporal approach using GIS, they were able to measure spatial and temporal changes in both coastal morphology and water area [7]. Mousa (2022) focused on Lake Sawa in southern Iraq, presenting a comparative case study of the long-term degradation of closed lakes. Using Landsat imagery from 1985 to 2020, the study revealed a continuous decrease in surface area, attributing this to declining groundwater recharge, over-abstraction, and prolonged droughts [8].

Remote sensing is a quantitative framework for non-contact Earth surface observation. Change detection methods were established early on through systematic reviews that formed multi-temporal comparison and their spectral/statistical processing. Capacities have evolved from comparing two or more snapshots to continuous time series observations using all Landsat views. Within aquatic systems, the NDWI and MNDWI spectral indices have become the standard for extracting water bodies and tracking their expansion and contraction in different environments [9].

Sentinel-2 is a wide-band multispectral imaging mission for land and vegetation monitoring, built on a constellation of identical satellites to achieve high pass frequency. Each platform carries a 13-band MSI with 10/20/60 m spatial resolution, a 290 km path width, and a 5-day revisit time at the equator (with two satellites in operation). The S2A (2015) and S2B (2017) satellites were launched, followed by S2C (5 September 2024) to enhance operational continuity. Sentinel-2 is a part of the Copernicus program. Copernicus is the Earth observation component of the European Union Space Program, managed by the European Commission in partnership with the European Space Agency (ESA) and other European stakeholders. It provides data and operational services to support environmental management, climate change adaptation, and civil security, under a policy of free and open access to users. The program includes the Sentinel families (radar, optical, oceanographic, etc.), as well as thematic services (land, air, oceans, climate, emergencies, and security) [10].

2 MATERIAL AND METHOD

The Hamrin Dam Lake (Lake Hamrin) was designated as the research area on the Diyala River, about 120 km northeast of Baghdad, Iraq, 340-square-kilometer. It is an artificial reservoir located between 34° 00′ 30″ to 34° 21′ 30″ N and 44° 52′ 00″ to 45° 12′ 00″ E, created after the establishment of Hamrin Dam in June 1981 Figure 1. The principal objective of Hamrin Dam's construction was to regulate the yearly flooding of the Diyala River; it furthermore functions as a vital irrigation supply and generates electrical power for Diyala Governorate.

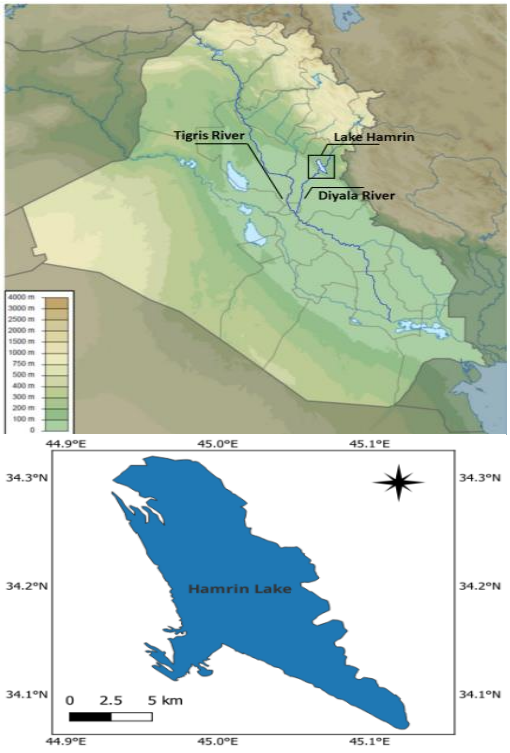

Figure 1: Geographical location of Lake Hamrin within the map of Iraq [6].

Most methods for calculating lake area from satellite images rely on spectral separation of image classes. Then the surface area of water in that lake is calculated using several different mathematical methods. This study introduced numerical method to

estimate the water surface area of the lake Hamrin by Shoelace method and Simpson's. The results of these methods were compared with the calculation of the surface area of the lake water calculated by the Copernicus website [7], [9]. The main steps of this work are explained as Figure 2.

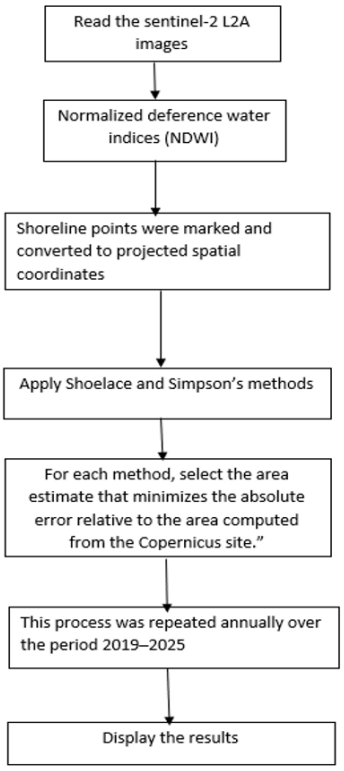

Figure 2: Block diagram for methodology of the work.

The Shoelace algorithm is the standard method for calculating the area of any polygon whose vertices are known in order (the boundary of the lake after being converted to a polygon). It works directly on plane coordinates. We arrange the boundary points x_i, y_i around the circumference (clockwise/ counterclockwise), then add the two "directions" and take half the absolute difference between them [11]. This gives a signed area: positive when arranged counterclockwise and negative when arranged clockwise. For a simple polygon has n vertices the formula of shoelace is given as follow (1):

$$A = 1/2 \sum_{i=1}^{n} |x_i * y_{i+1} + x_{i+1} * y_i|. \quad (1)$$

A is area of polygon.

Simpson's Rule is used to approximate definite integrals and relies on approximating the function using a parabola (a second-degree polynomial) between the division points. The interval is divided into an even number of subintervals [12]. Simpson's Rule is yet another method of numerical integration, given by the (2):

$$\mathrm{J} = \int_a^b f(x) = \frac{\mathrm{h}}{3} [\mathrm{fo} + \mathrm{fn} + 4 \sum_{i=odd}^{n-1} f(i) + 2 \sum_{i=even}^{n-2} f(i)]. \quad (2)$$

Where: $h = \frac{b-a}{n}$.

Sentinel-2 is a European mission that utilizes wide-swath, high-resolution, multi-spectral imaging. Dedicated to Europe's Copernicus program, the mission supports operational applications primarily for land services, including the monitoring of vegetation, soil and water cover, as well as the observation of inland waterways and coastal areas. The twin satellites S-2B and S-2C fly in the same orbit but are phased at 180°, and the full mission specification is designed to provide a high revisit frequency of 5 days at the Equator. In addition, satellite S-2A is temporarily operating at position 36° away from S-2B. Sentinel-2 L2A refers to the Level-2A data processing for the Sentinel-2 satellite, which is part of the Copernicus program by the European Space Agency (ESA).

Sentinel-2 L2A images from the European Copernicus site were used to study the deterioration occurring in Lake Hamrin for a period from 2019 to 2025, where seven images were obtained to cover this period over five years [10], [13]. Locations on the Earth's surface are typically recorded using geographic coordinates, represented by longitude and latitude in degrees. However, this system is impractical when it comes to linear measurements or calculating distances and areas, as it relies on an irregular elliptical surface. To overcome this, geographic coordinates are converted to a projected coordinate system, such as UTM (Universal Transverse Mercator) or Gaussian–Krüger. These coordinates are then converted to metric values (Easing, Northing) on a flat surface. The conversion process is performed using mathematical projection equations that take into account the Earth's elliptical shape. Points are then projected onto a two-dimensional plane using parameters such as the polar radius, central longitude, and scale factor. For example, in the UTM system, the globe is divided into longitudinal zones of 6 degrees width, and the Transverse Mercator projection is applied to each zone to minimize distortions. The result is a metric coordinate system that allows for the calculation of distances and angles with high accuracy, making it essential for applications in geographic information systems (GIS), remote sensing, and surveying. For this purpose, often use GIS tools such as ArcGIS or QGIS [14], [7].

The Normalized Difference Water Index (NDWI) is one of the most important spectral indices derived from satellite imagery. It is widely used to detect surface water bodies (such as rivers, lakes, and reservoirs) and monitor changes in their spatial and temporal distribution. NDWI relies on the spectral contrast between the high reflectivity of water in the green band and its low reflectivity in the near-infrared band (NIR) [15]. The mathematical equation for calculating NDWI is:

$$NDWI = (Green - NIR) / (Green + NIR). \quad (3)$$

Green: Green band reflectivity (usually Landsat band 2 or 3, depending on the sensor).

NIR. Near-infrared band reflectivity (usually Landsat band 4 or 5).

The Sentinel-2 L2A (Level-2A) data from the Copernicus program provide surface reflectance after atmospheric correction, making it suitable for accurate spectral analyses such as extracting water cover indices. The Normalized Difference Water Index (NDWI) from Sentinel-2 L2A is calculated using two channels [16]:

$$NDVI = (B3 - B8)/(B3 + B8). \quad (4)$$

- B3 (Green, 560 nm, 10 m spatial resolution);
- B8 (NIR, 842 nm, 10 m spatial resolution).

We will choose large number of points around the lake shore so that they cover all the details of the shore of lake, including dents, cracks, and bends, so that we get as close as possible from the actual area of the lake's water surface also for more accurate.

A sufficient number of points was selected to cover all details of the lake shoreline, including indentations, curvatures, and irregularities, in order to apply both Simpson's Rule and the Shoelace Formula. This approach ensures achieving high accuracy in calculating the lake's surface area using these methods. Figure 2 illustrates steps the methodology of the work.

3 RESULTS AND DISCUTIONS

The Hamrin Lake is an artificial reservoir created in 1981 after the construction of the Hamrin Dam on the Diyala River in Diyala Governorate, northeastern Iraq. Its variable surface area is approximately 300–400 km², depending on the water storage level. Figure 3 shows two sets of images taken from the Copernicus site during the period from 2019-2025 in the month of July, which represents the drought month in Iraq. A sufficient number of points were marked around the coast of Lake Hamrin, shown in white. After that, the coordinates of these points were recorded and converted from the Geographic Coordinates to the metric coordinates (UTM). The shoelace method and the Simpson method were applied, and the results were included in Table 1.

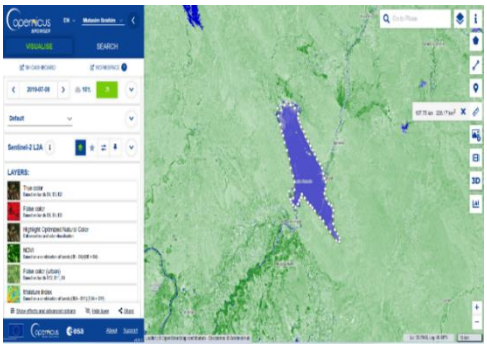

Table 1: The calculated area of water surface of Lake Hamrin in Km^2 using three methods for the period from 2019 – 2025.

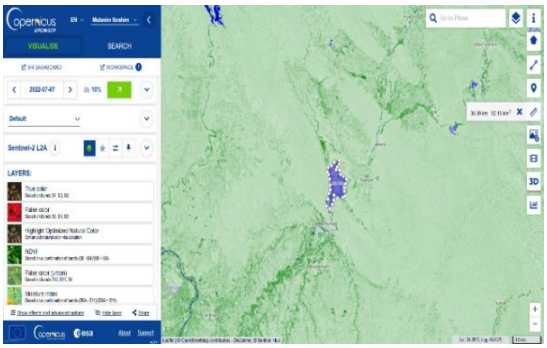
Year	Copernicus	Shoelace Method	Simpson's method
2019	107.75	105.2	102.3
2020	77.17	76.11	75.21
2021	38.81	37.61	37.32
2022	36.39	36.13	35.84
2023	49.58	49.12	48.93
2024	81.71	80.51	79.73
2025	101.38	99.34	98.71



In Table 1, the relative error is defined as the ratio of the absolute error to the reference (true) value. The Percentage Relative Error (PRE) is expressed as follows:

$$PRE = (|Numerical\ Value - Copernicus\ Value|)/(Copernicus\ Value) * 100\% \quad (5)$$

Here, the numerical value denotes the surface area calculated by each method. By applying (5) [17], [18], the percentage relative error (PRE) was obtained for both methods over the study period 2019–2025, thereby providing a quantitative assessment of their accuracy relative to the Copernicus-derived values. The comparison between Copernicus-derived water surface areas and the results of the Shoelace and Simpson's methods demonstrates consistent accuracy across the study period (Fig. 3). The Shoelace method produced values with lower absolute and relative errors (0.7–3.1%) compared to Simpson's method (1.3–5.1%) (Fig. 4). This outcome is logically consistent with the complex geometry of Lake Hamrin's shoreline, which is characterized by numerous indentations and irregularities. Since the Shoelace formula directly utilizes the spatial coordinates of all vertices along the lake boundary, it is able to capture fine shoreline details more accurately than Simpson's numerical approximation. Therefore, the Shoelace method is considered more reliable for estimating the water surface area of Lake Hamrin.

Lake Hamrin 2020

Lake Hamrin 2023

Lake Hamrin 2021

Lake Hamrin 2024

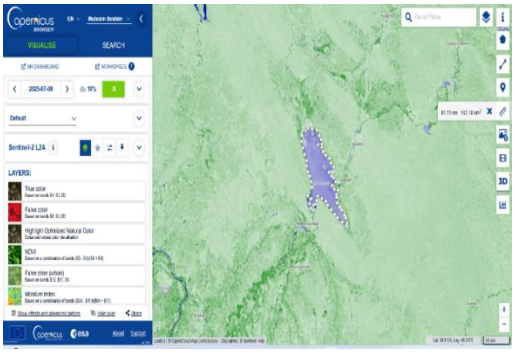

Figure 3: Shoreline of Lake Hamrin marked with white points during 2019–2025.

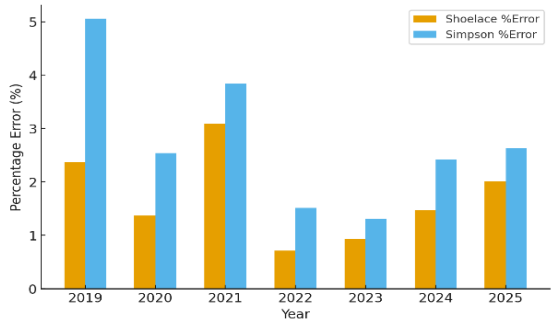

Figure 4: Percentage relative error of shoelace verses simpson's methods (2019–2025).

It can be observed from the Table 1 that during the years 2021, 2022, and 2023 the difference between Simpson's and the Shoelace methods is relatively small. This reduction in discrepancy is primarily attributed to the significant decline in the water surface area of the lake during these years. When the water extent decreases, the shoreline becomes less complex with fewer indentations and irregularities, which reduces the geometric sensitivity of the applied methods. Consequently, both Simpson's numerical integration and the Shoelace polygon-based calculation produce closely aligned results under such conditions. Simpson's method relies on the numerical integration method by dividing the shape into parabolic segments. It is suitable for relatively regular shapes or when the region's boundaries are close to smooth curves. The Shoelace method is a straightforward algebraic formula for calculating the area of a polygon from its vertices' coordinates (x, y). It gives more accurate results for complex and irregular shapes. It relies solely on point coordinates and can accurately represent coastal details if the number of points is large. It does not require integration or approximation assumptions.

4 CONCLUTIONS

The shoreline of Lake Hamrin is characterized by numerous curvatures, indentations, and irregularities, as clearly observed in the delineated boundary derived from Sentinel-2 L2A imagery. Under such complex geometrical conditions, the Shoelace Formula provides a more accurate estimation of the water surface area compared to Simpson's Rule. This is because the Shoelace method directly utilizes the Cartesian coordinates of all marked vertices along the shoreline, thereby capturing even small-scale variations and irregular shapes. In contrast, Simpson's Rule is based on numerical integration and tends to approximate the boundary as smooth segments, which may underestimate or overestimate the area when applied to irregular coastlines. Consequently, given the dense set of points digitized along the shoreline, the Shoelace method yields higher accuracy and reliability for Lake Hamrin's water surface area estimation. The shoelace method is more reliable when dealing with lakes with complex and winding shorelines. The Simpson method may be sufficient when the water surface is low or in regular shapes. Finally, Lake Hamrin has been affected, like the rest of the lakes in Iraq, by a decrease in its water level as a result of climate change and the lack of water releases into Iraq's rivers by neighboring countries.

5 RECOMMENDATIONS

Cooperation with neighboring countries to increase Iraq's water share. Relying on satellite imagery (Sentinel, Landsat) to regularly monitor changes in the lake's area. Preventing agricultural and urban encroachments on the lake basin.

Keywords: NZEB, Degree Days, Optimization, Energy Demand.

Abstract: The growth in energy demand from the residential sector in Uzbekistan points to the urgency to adopt nearly zero-energy building (nZEB) strategies that can be tailored to domestic climate and economic conditions. The present building stock, represented by weak thermal performance, results in excessive energy consumption for heating and cooling and excessive CO_2 emissions. To address this, the study examines multi-objective optimization methods for residential building retrofitting via integration of advanced insulation systems and renewable energy technology. The calculation uses heating and cooling degree days (HDD/CDD), which is in compliance with national standards ShNK 2.08.01-24 (Thermal Protection of Buildings) and KMK 2.01.04-18 (Building Climatology), to determine energy loads, taking techno-economic factors into consideration in terms of cost-effectiveness. Simulations were conducted for a typical three-room house, varying insulation thickness (0–50 mm), solar collectors, and photovoltaic panels. Results show that particular annual energy requirements decreased from 53.9 to 34.6 kWh/(m²·yr), and CO_2 emission decreased from 45.44 to 18.84 kg/(m²·yr) with improved insulation. Additionally, payback periods decreased from 8.94 to 8.45 years, confirming economic feasibility. The findings suggest that enhanced retrofitting coupled with solar technologies can greatly reduce operational energy usage and environmental impact, offering a sustainable solution for residential development in Uzbekistan.

1 INTRODUCTION

The demand for energy-efficient buildings in Uzbekistan is both environmentally and sustainably required by the climatic variation requirements of a country. An energy understanding of heating and cooling requirements is paramount to building design to the near-optimal energy use levels in Uzbekistan. Heating and cooling degree days throughout the present study are a tool to be analyzed for climatic conditions throughout the region, building insulation, and density to focus on energy efficiency in dwelling buildings. National and international standards, ShNK 2.08.01-24 and KMK 2.01.04-18, are calibrated within the study to offer accurate estimates of energy needs and information regarding energy efficiency and thermal performance that dwelling buildings in Uzbekistan can be designed to offer.

2 MATERIALS AND METHODS

2.1 Data Description

To compare how external temperature variability influences the cooling and heating energy requirements of buildings, this study employed the tried method of heating and cooling degree days (HDD and CDD) [1], [2].

To compare how external temperature variability influences the cooling and heating energy requirements of buildings, this study employed the tried method of heating and cooling degree days (HDD and CDD) [1], [2].

A degree day is the temperature difference (in °C) between the indoor comfort level and the mean daily outdoor air temperature whenever such a difference is larger than some specified base value. The latter depends on the quality of building insulation and on its thermal properties. As specified in the national standard ShNK 2.08.01-24 for Uzbekistan, the reference temperature of the indoor comfort is 20 °C [3].

Different base thresholds were used for buildings with different standards of insulation. Since this variable is quite different by building type, two heating thresholds—10 °C and 12 °C—were selected following the approach of Christenson et al. (2006) [4]. These thresholds were fixed based on each building's volume-weighted heat loss, as computed in accordance with ShNK 2.08.01-24 [3]. In older, non-retrofitted homes, thresholds of 10–12 °C were appropriate, while in newer buildings, there are lower thresholds. In buildings built after 1995, when national thermal protection standards were adopted, the usual heating base temperature of 10 °C was applied to HDD calculation.

The case study is based on a typical three-room residential building, as shown in Figure 1. The geometric characteristics of the building, including room dimensions and calculated areas and volumes, are presented in Table 1.

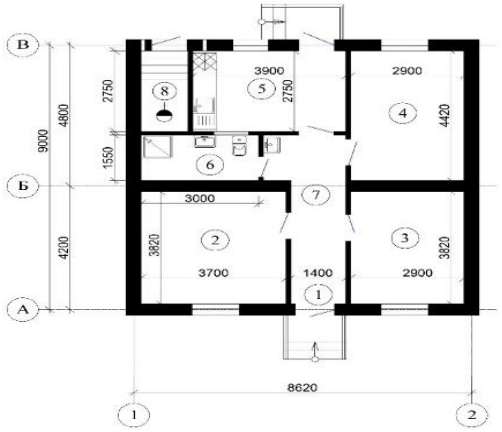

Figure 1: Three-room residential building used as the case study object.

As there is no unified European definition of cooling degree days, most research applies the American standard assuming comfort temperature to be 18.3 °C (65 °F) [5]; [4]. Since this value doesn't include in consideration indoor comfort conditions in Uzbekistan, where by default 20 °C was used, the present research utilized 22 °C as an upper limit of comfort for cooling based on previous works [6]. Accordingly, the indicators of degree-days were calculated as follows:

$HDD = \sum_{i=1}^{n}(20℃ - \theta)$ for n=days per year and $\theta \leq 10℃$, or 12℃,

and cooling degree days (CDD) by

$CDD = \sum_{i=1}^{n}(\theta - 20℃)$ for n=days per year and $\theta \geq 22℃$.

Because residential development across Uzbekistan is spatially heterogeneous, the HDD and CDD values were weighted according to regional population distribution derived from CORINE Land Cover (CLC) data [7]. Thereby, population weighting was applied using Thiessen polygons (for STAR II data) and grid-cell population density (for the CCLM model) to ensure representative climate coverage.

Heating energy demand represents the total heat required to maintain indoor comfort and is affected by transmission and ventilation losses, both of which are temperature and degree-day-dependent. Simultaneously, it is reduced by solar and internal gains, such as heat emitted from electrical appliances and occupants [8]. When outdoor temperatures exceed indoor levels, these heat flows reverse direction, thereby defining the building's cooling energy demand [3].

The annual heating energy demand (Q_h) for each residential building was determined according to the national regulation KMK 2.01.04-18 [9] [10], using:

$$Q_h = 24 \times 10^{-3} \cdot ƒ \cdot HDD \cdot (H_T + H_V) - \eta \cdot (Q_S + Q_I)(kWh/a), \quad (1)$$

where ƒ is the factor for inclusion of a night setback of the heating system temperature=0.95 (kh/d), H_T is the transmission heat losses, H_V is the heat ventilation losses, η is the factor for inclusion of the utilisation factor of internal and solar heat gains, Q_S is the usable solar heat gains (constant value), Q_I is the usable internal heat gains (constant value).

The wall surface specifications and their orientations used in the calculations are summarized in Table 2.

Transmission losses (H_T) quantify conductive and convective heat flow through building elements and depend on the thermal quality (U-values) of envelope components. Lower U-values indicate improved insulation performance [11]. These losses are computed as:

$$H_T = \sum_{i=1}^{4}(F_{xi} \cdot U_i \cdot A_i) + A \cdot \Delta U_{TB}\ (W/K), \quad (2)$$

where F_{xi} is the temperature correction factor (depending on the kind of building component), F_{xi} [wall, window, roof]=1, F_{xi} [basement]=0.6, U_i is the mean U-value of a building component (W/(m^2 K)), A_i is the surface area of each building component (m^2), A is the heat transmitting surrounding area (m^2), ΔU_{TB} is the thermal bridge correction factor=0.05 (W/(m^2 K)).

Ventilation heat losses (H_V) result from air exchange between the interior and exterior. Assuming uniform air tightness for all building types:

$$H_V = 0.19\left(\frac{W}{Km^3}\right) \cdot V(m^3), \quad (3)$$

where V is the heated building volume (constant per building type).

The properties of windows and doors used for solar gain calculations are presented in Table 3.

Solar heat gains (Q_S) arise primarily through glazing and depend on the total solar transmittance (g), window area, and orientation-specific solar radiation intensity (I_i). Assuming full solar exposure:

$$Q_S = \sum_{i=1}^{4} 0.567 \cdot I_i \cdot g_i \cdot A_i \ (kWh/a), \quad (4)$$

where I_i = 155 (East), 270 (South), 55 (West), 100 (North) (kWh/(m^2 a)), g_i is the total energy transmittance of glazing type in case of vertical insolation [–], A_i is the area of windows (m^2).

Internal gains (Q_I) result from occupants and electrical equipment. Due to their variability, KMK 2.01.04-18 [9] recommends the following simplified expression:

$$Q_I = 22 \cdot \left(\frac{kWh}{m^3}\right) \cdot 0.32 \cdot V \ (m^3), \quad (5)$$

For comparability across building types, the simplified KMK approach was also used to estimate annual cooling energy demand (Q_c) [kWh/a]:

$$Q_c = (1 - \eta_{HP}) \cdot (0.024 \cdot CDD \cdot (\sum_{i=1}^{4} F_{xi} \cdot U_i \cdot A_i + 0.05 \cdot A + 0.19 \cdot V) + (\sum_{i=1}^{4} 0.567 \cdot I_i \cdot g_i \cdot A_i + 22 \cdot 0.32 \cdot V)). \quad (6)$$

2.2 Solar collectors

As it intends to cover the energy demand for water heating as much as possible using solar collectors, we introduce two types of solar collectors: glazed flat-plate and evacuated tubular solar collectors. Both types of solar collectors were analyzed for their potential integration into domestic hot water (DHW) installations and combined space heating and DHW configurations (commonly referred to as *combi-systems*). Therefore, we use the annual solar collectors' energy outputs (kWh/year) using the method proposed by the IEA-SHC[1]:

$$Q_{gc_{DHW}} = 0.44 H_0 A_{sc}^{DHW}, \quad (7)$$

$$Q_{gc_{combi}} = 0.33 H_0 A_{sc}^{combi}, \quad (8)$$

where, H_0 is the annual global horizontal solar irradiation (kWh/m^2), A_{sc}^{DHW} and A_{sc}^{combi} are solar collector aperture area (m^2) for DHW system and combi-system, respectively.

Table 1: Room dimensions and calculated areas and volumes.

Name	Width	Length	Height
Hall	1,4	3,82	3
Living room	3,7	3,82	3
Bedroom	2,9	3,82	3
Bedroom	2,9	4,42	3
Kitchen	3,9	2,75	3
W/c	1,55	3	3
Corridor	1,4	5,15	3
Furnace	1,2	2,75	3

Table 2: Wall surface specifications and orientation.

Name	W.r	L(m)	h(m)	Aw (m2)	Ad (m2)	As (m2)
Wall1	West	9,4	3	0	0	28,2
Wall2	South	9	3	3,6	2,5	20,9
Wall3	East	9,4	3	0	0	28,2
Wall4	North	9	3	3,15	4,5	19,35

Table 3: Window and door properties for Solar gain.

Name	W.r	L (m)	Width (m)	Area (Ai)	gi	Ii
Window1	South	1,5	1,2	1,8	0,75	700
Window2	South	1,5	1,2	1,8	0,75	700
Window3	North	1,5	1,2	1,8	0,75	250
Window4	North	1,5	0,9	1,35	0,75	250
Door1	South	2,5	1	2,5		
Door2	North	2,5	0,9	2,25		
Door3	North	2,5	0,9	2,25		

Since the share of air-conditioned dwellings is significantly lower than that of heated ones, the computed cooling demand was multiplied by the proportion of households equipped with cooling units to obtain the actual cooling energy requirement. Equal distribution of air-conditioning systems across building types was assumed.

2.3 Comprehensive Energy Balance Analysis of a Retrofitted Single-Family House

As discussed earlier, the retrofitting measures encompass the addition of thermal insulation to the external walls, ceiling, floor, and roof, along with the installation of a rooftop solar photovoltaic (PV) system and solar thermal collectors to enhance the building's overall energy performance. Therefore, the total annual energy consumption (Q_t^*, kWh/year) in the building after retrofitting can be defined as follows:

$$Q_t^* = \frac{1}{\eta_{wh}}\left[\frac{Q_{heat}^* - Q_{gc_{combi}}}{\eta_{hs}} + Q_{water} - Q_{gc_{DHW}}\right] + E_{el} - E_{PV}, \quad (9)$$

where Q_{heat}^* is the space heating demand (kWh/year) in the building after respective retrofitting envelopes of the building.

2.2.1 Reduction of CO_2-Emission Through the Refurbishment Measures

The emission of carbon dioxide (CO_2) to the environment caused by utilizing energy from the primary energy sources that are obtained by combustion of fossil fuels. The annual CO_2 emission (M_{CO_2}, kg/year) can be defined by the following formula:

$$M_{CO_2} = \mu_f(Q_t - E_{el}) + \mu_{el}\, E_{el}, \quad (10)$$

where μ_f and μ_{el} are the specific CO_2 emission (kg/kWh) due to utilization of fuel (in our case natural gas) and electricity from the local network (obtained by utilizing fossil fuel). Accordingly, after retrofitting, CO_2-emission can be written as follows:

$$M_{CO_2}^* = \mu_f(Q_t^* - E_{el} + E_{PV}) + \mu_{el}\,(E_{el} - E_{PV})\begin{cases} E_{el} - E_{PV} \geq 0 \\ Q_t^* - E_{el} + E_{PV} \geq 0 \end{cases}. \quad (11)$$

2.2.2 The Retrofit Measure

During the simultaneous optimization, retrofitting windows, external wall insulation materials, ceiling, floor, and roof insulation materials and installation of PV panels and solar water heating systems were considered. As items for retrofitting external walls insulation materials, windows, ceiling, floor, and roof insulation materials, the following variables are introduced:

$$U_{win}^* = \frac{U_{win}}{1 + U_{win} x_{ins}^{win}}, \quad (12)$$

$$U_r^* = \frac{U_r k_r}{k_r + U_r x_{ins}^r}, \quad (13)$$

$$U_{ew}^* = \frac{U_{ew} k_w}{k_w + U_{ew} x_{ins}^w}, \quad (14)$$

$$U_f^* = \frac{U_f k_f}{k_f + U_f x_{ins}^f}. \quad (15)$$

which will be used instead of U-values mentioned in (2) for envelopes of the building: x_{ins}^{win} is the R-value of windows; k_r, k_w and k_f are the thermal conductivities (W/m·°C) of insulation materials embedded in the roof-floor external walls, and the floor of the buildings, respectively; x_{ins}^r, x_{ins}^w, and x_{ins}^f are the thicknesses (m) of the same accorded insulation materials.

In the same way, x_{sc}^{DHW}, x_{sc}^{combi}, and x_s^{PV} are variables (m^2) introduced instead of surfaces areas of solar collectors for DHW system and "combi-system", and solar PV panels, which will be designed for the building. Solar collectors and PV panels are installed on the south-oriented roof area. Therefore, it is necessary to optimize solar collectors and PV panels with constrains:

$$x_{sc}^{DHW} + x_{sc}^{combi} + x_s^{PV} \leq \frac{A_r}{2}. \quad (16)$$

2.2.3 Economic Analysis for the Optimal Design

It is obvious that when retrofitting envelopes of buildings and installing solar collectors and PV panels, the initial investment cost of materials increases while reduction of the heating and cooling loads, the electricity consumption from the local network and consequently the energy cost is expected [10]. The optimal design of retrofitting and installation of solar collectors and PV panels is that design, at which the total cost reaches the minima. The total cost is the sum of the cost of all used material and the present value factor (PVF) of the cost of energy consumption over the lifetime of materials that is given by:

$$C_t = (C_{ther} + C_{ae})PVF + C_m, \quad (17)$$

where C_{ther} is the annual energy cost (US $) for supplying the thermal energy is calculated as follows:

$$C_{ther} = \frac{C_{fuel}}{\eta_{hs}}\left[\frac{Q^*_{heat} - Q_{gc_{combi}}}{\eta_{hs}} + Q_{water} - Q_{gc_{DHW}}\right], \quad (18)$$

where C_{fuel} is the specific fuel cost (US \$/kWh). The cost of annual electricity consumption (C_{ae}, US \$) with the specific cost of electricity (C_{el}, US \$/kWh) is:

$$C_{ae} = (E_{el} - E_{PV})C_{el}. \quad (19)$$

The material cost (C_m) is considered as the initial investment cost that consists of:

$$C_m = C_{wall}x_{ins}^{w} + C_{win}x_{ins}^{win} + C_r x_{ins}^{r} + C_f x_{ins}^{f} + C_{DHW}x_{sc}^{DHW} + C_{combi}x_{sc}^{combi} + C_{PV}x_{s}^{PV}, \quad (20)$$

where C_{wall}, C_f, and C_r are the specific costs (US \$/m) of insulation materials for the external walls, floor, and roof, respectively; C_{win} is the specific cost ($\frac{US\,\$}{\frac{W}{m^2 ℃}}$) for windows refurbishment; C_{DHW}, C_{combi}, and C_{PV} are the specific costs (US \$/m^2) of solar collectors for DHW and combi-system, and PV panels.

The PVF depends on the inflation rate g, and the rate of interest i. The PVF can be defined as follows:

$$PVF = \frac{(1+r)^N - 1}{r(1+r^N)}, \begin{cases} r = \frac{i-g}{1+g} & i > g \\ r = \frac{g-i}{1+i} & g > i \end{cases}, \quad (21)$$

$$PVF = \frac{N}{1+i}, i = g, \quad (22)$$

Taking into account time value of investment, the discounted payback periods (in year) of retrofit measure can be defined by:

$$\tau_D = \frac{\ln\left|1 - \frac{rC_m}{C_t - C_{t0}}\right|}{\ln|1+r|}, \quad (23)$$

where C_{t0} is the annual cost of total energy before retrofitting (US \$).

2.3 Optimization Problem and Solution Technique

For simultaneous optimizing envelopes of buildings and integration of various energy generators powered by the renewable energy sources, the optimal designs were considered for three scenarios. As optimization parameters of envelopes, the insulation level of windows, roof, floor, and external walls was considered while as optimization parameters, integrating the solar collectors for the DHW and combined space and water heating, and PV panels on rooftop of buildings were considered. In the first scenario, the life-cycle cost (LCC) is minimized so that the optimal values of parameters are obtained for buildings designed with various levels of thermal insulation. In the second scenario, it is aimed at maximizing the primary energy consumption saving for space heating while minimizing the investment costs. In the final scenario, to create nearly zero carbon communities, the total primary energy consumption is minimized for buildings whereas the investment cost is minimized. The formulated optimization problem was implemented in Python and solved using the package of GEKKO.

Thermal properties and economic parameters of retrofit measure are given in Table 4.

Table 4: Techno-economic parameters of retrofit measure.

Parameter	Unit	Value
Fuel cost	US \$/kWh	0.004
Electricity cost	US \$/kWh	0.029
Insulation cost for roof	US \$/m^3	26.0
Insulation cost for walls		26.0
Insulation cost for floor		26.0
Cost of solar collector (DHW)	USD \$/m^2	300
Cost of solar collector (combi)		200
Cost of solar PV		340
Thermal conductivity of roof insulation	W/mK	0.035
Thermal conductivity of walls insulation		0.04
Thermal conductivity of floor insulation		0.04
Inflation rate	%	17
Interest rate	%	16
Exploitation (lifetime) year	Year	30
DHW demands	kWh/year	3000
Electricity consumption	kWh/year	6000

3 RESULTS AND DISCUSSIONS

The research revealed considerable differences in the Specific Annual Energy Demand as a function of varying levels of insulation. Results (Table 5) show a constant reduction in energy demand from 53.9 kWh/(m²×yr) at baseline to 34.6 kWh/(m²×yr) with an insulation thickness of 50 mm. Initial investment is negatively correlated with the payback period, with a corresponding decrease in payback period from 8.94 to 8.45 years with increased investment. Carbon dioxide emission also decreased significantly with increment in proportionate insulation levels, from 45.44 kg/(yr×m²) at baseline to 18.84 kg/(yr×m²) with 50 mm thickness. The above results emphasize the sustainability of increased building insulation and integration with renewable energy technologies, with PV panels and solar collectors to maximize energy efficiency in residential buildings.

Table 5: Results.

Specific annual energy demand. kWh/(m²×yr.)	Initial investment, mln UZS	Payback periods, yr.	Saved CO2 emission. kg/(yr.×m²)
0	53.9	8.94	45.44
10	50.0	8.87	40.12
20	46.2	8.79	34.80
30	42.3	8.70	29.48
40	38.4	8.59	24.16
50	34.6	8.45	18.84

4 CONCLUSIONS

This study demonstrated that multi-objective optimization integrating building envelope retrofitting with renewable energy systems offers a highly effective pathway toward achieving nearly zero-energy residential buildings in Uzbekistan. Through simulation of a representative three-room house, it was found that increasing insulation thickness from 0 to 50 mm led to a consistent reduction in annual specific energy demand from 53.9 to 34.6 kWh/(m²·yr) and a notable decline in CO_2 emissions from 45.44 to 18.84 kg/(m²·yr). These improvements were accompanied by a modest decrease in the payback period from 8.94 to 8.45 years, indicating that enhanced energy efficiency can be achieved without compromising economic feasibility. The results clearly highlight that insulation improvements, when combined with solar photovoltaic panels and solar thermal collectors, can simultaneously reduce operational costs, energy dependency, and environmental impacts. The integrated optimization approach based on HDD/CDD analysis proved particularly suitable for Uzbekistan's diverse climatic zones, enabling tailored solutions for both cold northern and hot southern regions. Such strategies can serve as a foundation for region-specific nZEB design standards, promoting a balance between cost, comfort, and sustainability. Moreover, the findings underline the importance of adopting national policies and incentive mechanisms that encourage the use of local insulation materials and solar technologies. Scaling up these retrofit and renewable integration measures across Uzbekistan's residential building stock could lead to substantial reductions in national natural gas consumption and greenhouse gas emissions, supporting the country's low-carbon development goals.

Future work should focus on extending this optimization framework to different building typologies (e.g., multi-story or rural dwellings), including dynamic simulations that consider occupant behavior, real-time energy pricing, and lifecycle carbon assessment. Ultimately, the study provides an evidence-based framework for guiding policymakers, engineers, and designers toward a more resilient, energy-efficient, and sustainable housing sector in Uzbekistan.

Keywords: Vinylidene Fluoride, Radiation Grafting, Monomer, Heat Capacity, Hydrophobicity, Whiteness, Thermal Stability, Hydrocellulose Structure and Fluorinated Cellulose.

Abstract: Modifying cellulose hydrate using chemical and physicochemical techniques is one option to get rid of its drawbacks. Radiation-chemical grafting of different monomers is one of the most promising modification techniques [1] for improving the characteristics of hydrated cellulose and its derivatives. Radiation grafting of various monomers to hydrated cellulose (H/c) and its derivatives has been the subject of numerous studies [2], and some of these are now starting to find widespread application in the economy. Given the aforementioned, grafting fluorine-containing monomers onto hydrated cellulose and its derivatives – whose polymers and copolymers have highly valuable and specific properties like chemical resistance, high thermal stability, decay resistance, and hydrophobicity – represents a significant scientific and practical interest [3]. This work aims to synthesise grafted copolymers of hydrated cellulose with vinylidene fluoride from the vapour phase using a radiation-chemical method. The effects of radiation dose intensity, exposure duration, and solvent type on the process and grafted copolymer yield are investigated. Important physicochemical and functional characteristics of the original, irradiated and grafted copolymers are also examined in this study. These characteristics include sorption capacity, density, hydrophobicity, degree of whiteness, mechanical properties, thermal stability, and the type of supramolecular structure alterations brought about by grafting fluorine-containing polymers.

1 INTRODUCTION

Graft copolymerisation with vinylidene fluoride is one efficient method of changing the characteristics of hydrated cellulose fibre textiles. Important physicochemical and functional characteristics of hydrated cellulose, such as sorption capacity, whiteness degree, resistance to microbes, chemical and thermal capacity, and others, are significantly improved as a result. Numerous investigations into the graft copolymerisation process of various vinyl monomers to cellulose have revealed that the yield of the graft copolymer rises when water, alcohols, amines, and dimethyl formamide are present [4]. However, the graft copolymerisation reaction continues with relatively poor efficiency when nonpolar liquids like benzene, toluene, and others are present. Japanese researchers have demonstrated [5] that cellulose swelled in water is adequate for the manufacture of high-yield graft copolymers when cellulose is irradiated with methyl methacrylate, styrene, or another vinyl monomer using γ-rays from Co^{60}.

The objective of this work was to create new copolymers with grafts that combined cotton and hydrated cellulose with a fluorine-based monomer in a lab setting, choose synthesis techniques, and thoroughly examine some physicochemical and operational characteristics of the synthesised samples to identify potential applications.

2 EXPERIMENTAL PART

Cotton cellulose and moistened cellulose fibres served as our first samples. It is noteworthy that the density, molecular packing, and other crucial physicochemical characteristics of these samples vary greatly from one another. The reactivity of cotton and hydrated cellulose fibres is greatly

impacted by a variety of contaminants, including hemicellulose, lipids, wax, lignin, and others. As a result, the samples were completely lubricant-free before being used. We created the monomer vinylidene fluoride (VF_2) by pyrolysing monochlorovanilidene at temperatures between 680 and 700^{0}C; $-CH_2Cl - CHF_2$;

$$CH_2CI\text{-}CHF_2 \quad -HCI \rightarrow \quad CH_2{=}CF_2.$$

Gas chromatography was used to assess the resulting monomer [6] after it had been chemically purified to an exceptionally high level of purity. The presence of two fluorine atoms in the molecule (VF_2) results in the polymer of this monomer exhibiting more pronounced specific properties compared to polyvinyl fluoride. For example, it is more resistant to the action of microorganisms, thermo-oxidative effects, possesses high strength, atmospheric stability, and low water absorption [7]. Therefore, grafting this monomer onto natural fibers represents both theoretical and practical interest. In addition, it should be noted that there is no literature available on the grafting of VF_2 to C/F [8]. Our studies on the radiation polymerization of VF_2 and its grafting onto cellulose fibers showed that it has greater polymerization activity than grafting, compared to vinyl fluoride. Based on this, radiation graft copolymerisation was performed in the presence of vapours of different solvents with an integrated irradiation dosage of 2.5 M rad and a dose rate of 70 rad/sec in order to speed up the grafting rate of C/F and boost the yield of the grafted copolymer.

The obtained results are presented in Table 1.

Table 1: Effect of vapors of various solvents on the grafting degree of vinylidene fluoride onto cotton cellulose.

Solvent	Weight Added %	Content Of PVF_2, %	Solvent	Weight Added %	Content Of PVF_2,, %

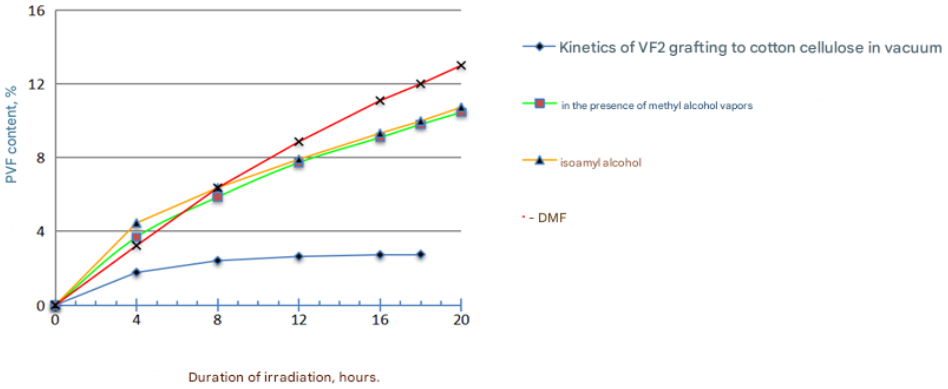

Figure 1: Grafting to cotton fiber.

As seen from Table 1, under the same conditions, the vapors of various solvents have a different effect on the formation of the grafted copolymer. A high graft yield is observed in the presence of a solution of DMF, methyl, isoamyl and ethyl alcohols. Therefore, in studying the kinetic patterns of the graft copolymerization of VF_2 onto C/F in the presence of alcohols, we chose these liquids as solvents. The results of the study on the grafting kinetics are shown in Figure 1, where the graphical dependence of the content of PVDF (poly vinylidene fluoride) in percentage on the irradiation duration is presented. As seen from the data obtained, when grafting was carried out in the presence of solvent vapors, both the grafting yield and the content of poly vinylidene fluoride significantly increased with the irradiation duration.

Under the same conditions, the highest yield of the grafted copolymer is observed in the presence of DMFA vapors. The maximum content of PVDF in the copolymer is 12.8%. In order to study the effect of dose rate on the grafting efficiency, the grafting of VF_2 onto C/F was carried out at dose rates of 11, 60, and 90 rad/sec, within an irradiation time range of 2 to 15 hours, with an initial polymer-to-monomer ratio of 1:2. Table 2.

As seen from the presented Table, at all dose rates, the content of PVDF in the grafted copolymer increases with the irradiation duration. The experiment showed that in the absence of a solvent, VF2 is also difficult to graft onto cotton cellulose; in this case, the grafted copolymer after 19 hours of irradiation at a dose rate of 80 rad/s in the absence of solvent vapors, the yield is 2.2%, and in the presence of methyl alcohol vapors under the same conditions, the yield is 8.1%.

Table 4: Data on the grafting of vinylidene fluoride to cellulose hydrate fiber in the absence and presence of vapors of various solvents (dose rate 70 rad/sec).

Solvent	Weight gain, %	Content of PVF_2 in the copolymer
-	1,0	2,2
Water	3,0	3,5
Methanol	4,1	6,2
Ethanol	2,9	3,2
Propanol	1,8	2,5
Isopropanol	1,9	2,5
Amyl Alcohol	2,8	3,2
Isoamyl Alcohol	2,4	5,3
Diethylamine	3,1	3,4
Dimethylformamide	6,2	7,0

The grafting of vinylidene fluoride to G/c was carried out in the presence of solvents at an integral irradiation dose of 2.5 Mrad and a dose rate of 70 rad/s. The obtained data are presented in Table 3.

As seen from the Table 3, under the same conditions, the vapors of the solvents used have a different effect on the formation of the grafted copolymer. The most favorable effect on the grafting process is exerted by dimethylformamide, isoamyl alcohol, and methyl alcohol vapors. In this case, the yield of the grafted copolymer is significantly higher than in the presence of vapors of other solvents. Next, we studied the kinetics of VF_2 grafting onto H/C in the absence and presence of the vapors of the aforementioned solvents at a dose rate of 70 rad/sec over a wide irradiation time range. The obtained results are presented in Table 4. As seen from the data, grafting of VF2 in the absence of solvent vapors occurs very insignificantly. For example, the maximum content of PVDF after 17 hours of irradiation reached only 2.5%, whereas under the same conditions, in the presence of water vapor, it reached 6.1%, in the presence of methyl alcohol vapors – 9.1%, and in the presence of dimethyl formamide vapors – 11.5%. As a rule, the behavior of the grafting process in the presence of vapors of solvents that cause polymer substrate swelling always leads to an increase in the grafting rate. This pattern was also observed in our case of grafting VF_2 onto hydrated cellulose fabric.

Table 5: Results of grafting vinylidene fluoride onto cellulose hydrate fibers at different dose rates

Irradiation duration, hours	Integral radiation doses, Mr	Content of PVF_2 in the copolymer, %	Inoculation rate, %/hour	Radiochemical yield 10^3 mol/100 eq.
Dose rate 11 r/s				
3	0,12	1,4	0,47	3,42
5	0,20	1,9	0,39	2,81

Table 7: Results of the change in water vapor sorption of grafted copolymers of C/F and H/C with different PVDF content.

Obtained in vacuum			Obtained in the vapour of methanol		
Grafted copolymers of hc fibers					
Starting Materials	0	6,3	0	0,0	6,3
2	0,7	6,0	2	2,6	5,2
4	1,9	5,4	4	4,7	4,4
6	2,1	5,2	9	6,8	4,1
12	2,8	5,0	12	8,0	4,0
15	2,9	4,9	15	9,2	4,3
Grafted Copolymers of G/C Fibers					
Starting Materials	0	11,4	0	0	11,4
3	0,4	10,8	3	3,2	10,0
5	2,0	11,2	5	5,0	10,5
10	2,1	10,8	11	7,0	10,2
13	2,2	10,5	13	8,8	10,0
17	2,3	10,4	17	9,1	9,2

In order to study the effect of different dose rates on the formation of the grafted copolymer, the grafting was carried out in the presence of methyl alcohol vapors at dose rates of 11, 68, and 100 rad/sec, with irradiation doses ranging from 0.12 to 7.20 M/rad (Table 5). From the obtained data, it follows that with an increase in the irradiation duration, at all dose rates, both the grafting yield and the content of PVD_2 in the grafted copolymer increase. The increase in irradiation duration is due not only to the continuous progression of grafting over time but also to the radiation stability of the grafted PVD_2.

As seen from Table 6, as a result of irradiation, with an increase in the integral dose, the H/C fabric significantly loses its whiteness, and the higher the absorbed irradiation dose, the greater the decrease in whiteness degree. When irradiating cotton/linen fabric in a methyl alcohol vapor environment, this effect is only slightly reduced. For example, for the initial H/C fabric, this value is 79%, while for the irradiated fabric at 69.5% Mr, this value increases to 88.9% for the grafted copolymers. For the irradiated fabric in the presence of methyl alcohol vapors under the same conditions, the whiteness degree is 86.2%.

The results of the change in water vapor sorption at 50% relative humidity of grafted copolymers of C/F and H/C with VF_2 are presented in Table 7. From the data provided, it is evident that as the content of PVD_2 increases, the sorption values gradually decrease.

Table 7 presents the results of the study on the mechanical properties of viscose fabrics irradiated in vacuum and in the presence of methyl alcohol vapor, as well as their grafted copolymers obtained under identical conditions. As seen, the properties of the irradiated fabrics, both in the vacuum and in the methyl alcohol vapor environment, are relatively similar. At an integral irradiation dose of 1.62 Mrad, these values remain almost unchanged. As the irradiation dose increases, the tensile strength and elongation decrease slightly. The loss of fabric strength under radiation is also due to the loosening of the cellulose structure [9] and the partial destruction of intermolecular hydrogen bonds [10]. For the grafted copolymer of H/C fabric with PVDF

obtained under the same conditions, the decrease in strength is observed to a lesser extent compared to the fabric modified by the grafting of PVDF. This result is related to the nature of the grafted polymer. It is possible to assume that during the grafting of VF under the continuous action of gamma rays, a large amount of hydrogen fluoride is formed. In this case, an acceleration of the cellulose loosening process is observed, and on the other hand, the higher the content of the grafted polymer, the greater the possibility of the disorienting arrangement of chains in ordered regions, which leads to further weakening of intermolecular bonds.

To study the effect of the dose rate on the changes in the physical-mechanical properties of the fibers, we investigated the changes in the strength and elongation of H/C fibers irradiated in a vacuum and in the presence of methyl alcohol vapor at a dose rate of 90 rad/sec over a wide irradiation time range, as well as their grafted copolymers with PVDF obtained under identical conditions. As seen from the data in Table 8, the strength of the irradiated fibers significantly worsens with an increase in irradiation duration, while the reduction in breaking elongation is less pronounced than the reduction in strength. However, this effect is more noticeable in fibers irradiated in a vacuum. The grafted copolymer obtained under the same conditions loses even more strength.

Table 8: Weight loss of the original, irradiated and modified G/C with PVDF within 12 hours at 230°C, %.

Irradiation duration, hours	Irradiated Samples	Grafted Copolymers	
	Weight Loss	Content of PVF_2, %	Weight loss, %
In the vacuum			
Initial	10,1		10,1
5	10,5	3,3	9,0
10	10,9	4,4	8,2
15	11,2	4,7	8,0
18	11,9	7,2	6,8
		9,0	4,3
In the air			
Initial	27,6	7,2	20,8
18	31,9	9,019,7	
In the vacuum			
Initial	25,1		
22	29,3	7,2	21,7

The obtained results are presented in Table 8. When irradiating H/C in both a vacuum and in the presence of methyl alcohol vapors, its weight loss slightly increases. This effect is explained by destructive processes that lead to the formation of labile points in relation to the effect of elevated temperatures.

3 CONCLUSIONS

Radiation grafting of vinylidene fluoride was performed under various conditions on cotton cellulose, hydrated cellulose, and fabrics based on them in order to improve the most significant physical and chemical qualities and impart new ones. The effects of solvent type and radiation dose rate on the grafting procedure were investigated. The findings demonstrated that the grafting rate and yield increased while decreasing as the dose rate increased. The dosage rate and the grafting rate are proportionate. Due to the hydrophobicity of the modifying polymers, it was found that the sorption and swelling capacities of samples in water increase as the concentration of grafted fluorine-containing polymers increases. Graft copolymers of cellulose and fluorinated polymers have been demonstrated to have improved thermal stability. Additionally, the quantity of weight loss reduces and the decomposition temperature rises with increasing grafted polymer concentration.

Abstract: The evaluation of teaching effectiveness through Student Evaluation of Teaching (SET) remains a critical measure in enhancing instructional quality and guiding faculty development. Despite widespread implementation, most studies focus on isolated term analyses, neglecting longitudinal patterns and contextual insights. This study addressed this gap by investigating faculty performance trends from Academic Years 2021–2022 to 2023–2024 using student evaluations stored in the Main Management Information System (MMIS). Specifically, it aimed to determine the level of faculty performance, identify trends and patterns in student evaluations, explore strengths and areas for improvement, and recommend actionable strategies for faculty development. Employing an explanatory sequential design, the study analyzed quantitative data from over 49,000 student evaluations across six domains: learning process, instructional delivery, assessment, learning environment, classroom management, and teacher qualities. This was complemented by thematic analysis of qualitative feedback through text mining. Descriptive and trend analyses revealed an overall "Excellent" faculty performance across all years, with a slight decline in 2022–2023, followed by improvement in 2023–2024. Notably, the learning process and instructional delivery indicators showed fluctuations that mirrored post-pandemic instructional adjustments. Qualitative feedback highlighted strengths such as compassion, clarity, and responsiveness, as well as areas needing improvement, including technological proficiency and emotional sensitivity. These findings suggest that while instructional quality remained high, evolving student needs and rapid shifts in teaching modalities affected performance consistency. The study underscores the value of integrating digital analytics with student narratives to inform evidence-based interventions. It recommends targeted faculty development programs focusing on digital pedagogy, student engagement, and assessment literacy. Ultimately, this study contributes to strengthening institutional capacity for reflective teaching, data-informed decision-making, and sustainable educational excellence in dynamic learning environments.

1 INTRODUCTION

The evaluation of teaching effectiveness remains a cornerstone of quality assurance and faculty development in higher education. Student Evaluation of Teaching (SET) is widely used as both a performance measure and a tool for instructional improvement [1]. Over time, SET has evolved from a summative appraisal to a formative mechanism that promotes reflective teaching. In the post-pandemic academic landscape, where instructional modalities rapidly shifted from remote to hybrid and in-person formats [2], examining the validity and developmental implications of SET data over time has become crucial. However, most institutional analyses remain limited to single-term evaluations, which overlook evolving instructional dynamics and student expectations. Without temporal analysis, SET scores risk being misinterpreted or disconnected from actual teaching transformations [3]. In developing contexts, underutilized digital systems such as the MMIS further limit the potential to harness analytics for faculty development [4].

Globally, institutions are integrating learning analytics to enhance evidence-based teaching evaluations [5], yet the human interpretive element students lived experiences and feedback remains underexplored [6]. This study employed an

explanatory sequential design to analyze MMIS-stored evaluations from 2021 to 2024, identifying statistical trends and exploring their underlying causes. Specifically, it examines faculty performance levels, trends and patterns in evaluations, key strengths and gaps, and strategies to enhance faculty development programs using MMIS data across six instructional domains.

2 METHODS AND METHODOLOGY

This study employed an explanatory sequential and retrospective design to investigate faculty performance based on student evaluations retrieved from the Main Management Information System (MMIS) from Academic Years 2021–2022 to 2023–2024. The quantitative phase involved analyzing student evaluation scores across six key domains: learning process, instructional delivery, assessment, learning environment, classroom management, and teacher qualities as reflected in the instrument. Data were derived from the MMIS answered by the enrolled students from academic years 2021-2024 which varies by number who completed the Student Evaluation for Teachers (SET) instrument in all courses they took handled by the professors during the three academic years, which included three semesters each which include data from different programs such as information technology, computer science, architecture, civil engineering, computer engineering, accountancy, management accounting, business administration, tourism management, hospitality management, physical education, communication, psychology, general education, and senior high school. The instrument utilized was the standardized SET evaluation tool of the university being used both for onsite and online classes. a 7-point scale ranging from "Very Unsatisfactory" to "Truly Exceptional," and ratings were analyzed using descriptive statistics and trend analysis to identify patterns in faculty performance over time.

In the qualitative phase, student narrative feedback from the MMIS was thematically analyzed to identify strengths and areas for improvement in faculty performance. This phase provided contextual insights to supplement the quantitative results and inform relevant faculty development recommendations. Ethical approval was obtained from the university's ethics review board and management. All data were anonymized and aggregated, ensuring compliance with institutional and national data privacy regulations. The limitation of this study was the data which focused only in the SET which excluded the faculty evaluation to students and the data was limited up AY 2024-2025 as SET is administered per Terms, meaning the data from AY 2025-2026 was not yet available.

3 LEVEL OF FACULTY PERFORMANCE BASED ON STUDENT EVALUATION

The evaluation data from A.Y. 2021 to 2024 consistently shows high ratings in the Learning Process component, with overall means ranging from 6.02 to 6.30 (Excellent). Deep and critical thinking scored highest, notably 6.35 in A.Y. 2021–2022 and remained above $\bar{x}$ =6.10 thereafter. A decline in A.Y. 2022–2023, especially in reflection ($\bar{x}$ =6.00), suggests post-pandemic instructional adjustments. Comments such as *"She was able to fully adjust in the finals..."* and *"explains the lessons in a way we're able to understand"* affirm the value of clarity, patience, and scaffolding as summarized in Table 1.

Meanwhile, negative remarks like *"no learning process, no instructional deliveries"* align with lower scores, highlighting inconsistencies. These trends support findings by [7] and [8] that structured communication, collaboration, and reflection shape student perceptions. This underscores the need for continuous faculty training in reflective, student-centered, and flexible pedagogy [9], [10].

Student evaluation data on instructional delivery from A.Y. 2021–2024 showed consistently "Excellent" performance across all indicators, as summarized in Table 2. However, the overall mean slightly declined from 6.28 in 2021–2022 to $\bar{x}$ = 6.00 in 2022–2023, then recovered to $\bar{x}$ = 6.11 in 2023–2024. The dip corresponds with pandemic-related instructional shifts.

Notably, Alignment ($\bar{x}$ = 6.34 → 6.06 → 6.11) and Technology Integration ($\bar{x}$ = 6.33 → 6.01 → 6.11) saw marked decreases in the second year, signaling challenges in maintaining engagement during extended flexible learning. Students remarked, *"Please avoid just reading what was in the presentation,"* and *"All lessons are recorded and students can't even ask questions,"* highlighting reduced interaction and professor presence.

Overall, while instructional standards remained high, real-time engagement and clarity suffered when teaching relied heavily on asynchronous and recorded formats. This aligns with [11], which emphasizes students' need for authentic interaction and timely

feedback in online learning environments. The slight rebound in 2023–2024 suggests adaptation, supported by comments like *"The professor did an excellent job of sparking my interest,"* and *"The professor makes this stressful subject seem like a great intro to programming."*

Table 3 indicates consistently excellent performance across all indicators, with minor fluctuations pointing to areas for improvement. The overall mean declined from 6.26 in A.Y. 2021–2022 to 5.97 in 2022–2023, then rose to 6.10 in 2023–2024, reflecting transitional challenges during the shift to post-pandemic hybrid learning.

Performance-based Assessment remained highest, supported by feedback such as, *"The professors always give us activities to practice communication and teamwork."* In contrast, Feedback showed lower means ($\bar{x}$ = 6.22 → 5.93 → 6.09), with students noting, *"No feedback for students to learn because our papers and quizzes can't get returned in time,"* underscoring the need for more timely and transparent grading.

Qualitative data also pointed to a demand for clearer instructions and assessment transparency. Diagnostic Assessment maintained strong ratings ($\bar{x}$ = 6.28 → 6.01 → 6.10), with students highlighting, "May pre-test and post-test to evaluate learnings." These findings align with [12], [13], emphasizing the value of authentic and diversified assessments.

Meanwhile, declines in enrichment scores and concerns over workload suggest pacing and fairness issues. As [14] notes, effective feedback and fair assessments enhance learner agency, highlighting the need to recalibrate assessment strategies to remain rigorous, transparent, and student-centered, as summarized in Table 4.

Table 1: Distribution of Mean along with Learning Process from 2021-2024.

Table 4: Distribution of Mean along with Learning Environment from 2021-2024.

Indicator	A.Y. 21-22	A.Y. 22-23	A.Y. 23-24	M	Description
	$\bar{x}$	$\bar{x}$	$\bar{x}$		
Cooperative and Supportive Environment	6.31	6.00	6.12	6.14	Excellent
Open Communication	6.30	6.01	6.10	6.14	Excellent
Technology Availability	6.24	6.00	6.11	6.12	Excellent
Interest and Enthusiasm in Learning	6.28	5.96	6.09	6.11	Excellent
Relaxed and Comfortable Environment	6.20	5.92	6.09	6.07	Excellent
Minimized Distractions	6.40	5.92	6.08	6.13	Excellent
Overall Mean	6.29	5.97	6.10	6.12	Excellent

n A.Y 2021-2022 = 3010
n A.Y. 2022-2023 = 5201
n A.Y. 2023-2024 = 6926

The learning environment from A.Y. 2021–2022 to 2023–2024 maintained excellent ratings overall, with a dip in 2022–2023 followed by recovery in 2023–2024. Minimized Distractions scored highest in 2021–2022 ($\bar{x}$ = 6.40) but fell to 5.92 in 2022–2023, indicating difficulties in sustaining focused learning, likely due to digital fatigue and online interaction issues.

Cooperative and Supportive Environment and Open Communication also declined during 2022–2023, reflecting weaker student–teacher dynamics. Students shared, *"Medyo terror po kayo and intimidating"* and *"Always galit tuwing synchronous class,"* contrasting with remarks like *"safe place for us to learn"* and *"interactive approach."* This mix of experiences points to variability in faculty engagement, which affects academic and emotional well-being [15].

Scores improved in 2023–2024, notably in Relaxed and Comfortable Environment and "Interest and Enthusiasm in Learning" ($\bar{x}$ = 6.09), suggesting faculty adaptation and growing use of student-centered pedagogies, aligning with [16], [17], as summarized in Table 5. However, ongoing concerns about unreturned assessments, unclear communication, and classroom atmosphere highlight the need for targeted training in inclusive and empathetic teaching strategies to sustain equitable learning environments.

The results from 2021 to 2024 show a consistent "Excellent" rating in classroom management across all indicators, with a slight dip in the overall mean from 6.23 in A.Y. 2021–2022 to 5.99 in 2022–2023, followed by a modest rise to 6.13 in 2023–2024. Indicators like Class Routines and Session Conduct dropped in the second year, reflecting post-pandemic

adjustments and issues in maintaining regular class schedules, as echoed in student feedback citing irregular meetings and scheduling conflicts. A rebound in 2023–2024 suggests improved structure and delivery, supported by positive student comments. However, lower means in Attention and Engagement and Smooth Activities indicate ongoing challenges with time management and classroom continuity. These findings align with [18], emphasizing the importance of consistency and engagement in classroom management, as summarized in Table 6. Overall, while ratings remain strong, sustained improvement in communication, scheduling, and student interaction remains crucial to maintaining excellence.

A retrospective analysis of faculty evaluations from A.Y. 2021–2022 to 2023–2024 shows consistently excellent ratings across all Teacher Qualities: Subject Knowledge ($\bar{x}$ = 6.22), Communication Skills ($\bar{x}$ = 6.14), Professional Appearance ($\bar{x}$ = 6.23), Positive Attitude ($\bar{x}$ = 6.15), and Technical Skills ($\bar{x}$ = 6.19). A slight improvement in 2023–2024, especially in Subject Knowledge (6.18 → 6.25) and Communication Skills (6.09 → 6.19), suggests gains in teaching competence and relational capacity.

Student feedback supports this trend: *"You always had the patience for my questions and knew just how to explain the answers"* and *"Very nurturing and considerate. She knows what she is doing."* These highlight faculty expertise and student-centered approaches, consistent with literature on engagement and academic success [19], [20].

However, some remarks reveal gaps *"He's a good prof but doesn't communicate well"* and *"She is not techy"* indicating areas for targeted development in communication and digital skills. As [21] notes, professional learning communities and regular feedback loops are essential to address such disparities and sustain pedagogical excellence.

Table 7 shows consistently excellent ratings across six instructional indicators Learning Process, Instructional Deliveries, Assessment, Learning Environment, Classroom Management, and Teacher Qualities with a grand mean of 6.13. The highest scores were in A.Y. 2021–2022, led by Learning Process ($\bar{x}$ = 6.30), Instructional Deliveries ($\bar{x}$ = 6.28), and Learning Environment ($\bar{x}$ = 6.29). A notable dip appeared in 2022–2023, especially in Assessment ($\bar{x}$ = 5.97), likely due to post-pandemic instructional transitions and rising student expectations in hybrid learning.

A modest rebound followed in 2023–2024, particularly in Classroom Management ($\bar{x}$ = 5.99 → 6.13), reflecting improved faculty engagement. Student feedback supports this mix of strengths "He always made sure that everyone of us would learn," "very nurturing and considerate" and areas for growth "Insensitive… nanghihingi pa ng picture ng baha na kasama kami," "She is not techy." These point to the importance of both compassion and technological adaptability.

The fluctuations mirror shifting pedagogical demands and varying faculty readiness, aligning with literature emphasizing ongoing faculty development in digital pedagogy, student well-being, and assessment literacy [22] - [24]. These findings underscore the need for institutional support through targeted training, feedback-driven evaluations, and responsive leadership to sustain instructional quality in evolving learning environments.

Table 5: Distribution of Mean with Classroom Management from 2021-2024.

Indicator	A.Y. 21-22	A.Y. 22-23	A.Y. 23-24	M	Description
	$\bar{x}$	$\bar{x}$	$\bar{x}$		
Class Routines	6.35	6.06	6.16	6.19	Excellent
Session Conduct	6.39	5.98	6.14	6.17	Excellent
Proper Behavior in the Classroom	6.35	6.03	6.15	6.18	Excellent
Learner recognition	6.37	5.98	6.12	6.16	Excellent
Attention and Engagement	6.04	5.97	6.11	6.04	Excellent
Clear Instruction	6.05	5.98	6.11	6.05	Excellent
Smooth Activities	6.03	5.96	6.1	6.03	Excellent
Overall Mean	6.23	5.99	6.13	6.12	Excellent

n A.Y 2021-2022 = 3010
n A.Y. 2022-2023 = 5201
n A.Y. 2023-2024 = 6926

n A.Y. 2023-2024 = 6926

4 TRENDS AND PATTERNS IN STUDENT EVALUATION USING THE MAIN MANAGEMENT INFORMATION SYSTEM

4.1 Learning Process

The learning process evolved from Application-Oriented Deep Learning in 2021–2022 to Fragmented Learning in 2022–2023, and eventually to Instructional Coherence and Learning Continuity in 2023–2024. The initial emphasis on hands-on learning was disrupted by unstructured content delivery, leading to demotivation and shallow engagement, which was later restored by streamlined instruction. This pattern indicates that continuity and coherence are essential to sustain deep learning. Recent studies affirm that a coherent curriculum and active engagement strategies significantly influence student motivation and higher-order thinking [25], [26]. Thus, maintaining structured, application-driven learning is crucial for fostering cognitive development and motivation.

4.2 Instructional Deliveries

Instructional delivery was initially marked by Interactive and Strategic Facilitation in 2021–2022, regressed to Lack of Interactive Pedagogy in 2022–2023, and then improved to Interactive Delivery and Content Accessibility by 2023–2024. The dip in interaction and content variation negatively impacted conceptual understanding, which was later mitigated by reintroducing dynamic tools and teaching methods. This progression indicates that active learning strategies are central to maintaining student attention and comprehension. Research by [16][9] demonstrates that interactivity in both face-to-face and digital settings enhances learner satisfaction and knowledge retention. Consequently, educators must prioritize diverse, student-centered delivery formats to promote engagement.

4.3 Assessment

Assessment practices transitioned from Aligned and Developmental in 2021–2022 to Rigid and Unconstructive in 2022–2023, before improving to Transparent and Formative Evaluation in 2023–2024. The absence of timely feedback and flexibility hindered students' ability to improve during the rigid phase. Recovery was marked by the reintroduction of formative and transparent practices that supported learning autonomy. This reflects the importance of feedback-rich and learner-aligned assessment systems. According to [27], [28], transparent and formative assessment practices promote reflective learning and drive academic success. Institutions should thus embed clear evaluation mechanisms to empower student growth and performance, as summarized in Table 8 and 9.

4.4 Learning Environment

The learning environment shifted from an Inclusive and Psychologically Safe Space (2021–2022), to Disjointed Instructional Design (2022–2023), and rebounded to an Inclusive Supportive Ecosystem (2023–2024). Psychological safety gave way to detachment and low participation when the learning design lacked alignment and support structures. The restoration of inclusive strategies in the final year, such as clearer communication and access to resources, re-established student engagement. This evolution underscores the importance of emotionally and academically supportive environments. Scholars like [29], [30] stress that inclusive learning climates promote belongingness and resilience, especially in times of uncertainty. Hence, inclusive designs should be an ongoing priority in learning environments.

4.5 Classroom Management

Classroom management reflected a progression from Empathetic and Structured (2021–2022), to Ineffective and Insensitive (2022–2023), and back to Structured and Responsive Facilitation (2023–2024). Students initially felt secure with consistent routines, but the loss of structure and emotional awareness disrupted their well-being and focus. By reinstating consistency and empathy in the final year, instructors rebuilt trust and learning efficiency. This variation reveals how crucial adaptive and student-aware

Table 8: Trends and Patterns of Student Evaluations.

Component	A.Y. 21-22	A.Y. 22-23	A.Y. 2023-2024
1. Learning Process	Application-Oriented Deep Learning	Fragmented Learning Undermines Motivation and Cognitive Engagement	Instructional Coherence and Learning Continuity
2. Instructional Deliveries	Interactive and Strategic Facilitation	Lack of Interactive Pedagogy Hinders Clarity and Conceptual Understanding	Interactive Delivery and Content Accessibility
3. Assessment	Aligned and Developmental Evaluation	Rigid and Unconstructive Assessment Limits Student Growth	Transparent and Formative Evaluation
4. Learning Environment	Inclusive and Psychologically Safe Space	Disjointed Instructional Design Reduces Engagement and Inclusivity	Inclusive Supportive Learning Ecosystem
5. Classroom Management	Empathetic and Structured Management	Ineffective Time Management and Insensitivity Affect Student Wellbeing	Structured and Responsive Facilitation
6. Teacher Qualities	Compassionate Professionalism	Teacher Approachability and Competence Drive Student Trust and Learning	Professional Presence and Student-Centered Ethos

Table 9: Strengths and Areas for Improvement in Student Evaluations.

Component	Strengths	Areas for Improvement
Learning Process	Contextualized and Student-Centered Concept Delivery	Inconsistent Instructional Continuity and Cognitive Scaffolding
Instructional Delivery	Engaging, Structured, and Multi-Modal Pedagogy	Disjointed Delivery and Lack of Instructional Depth
Assessment	Fair, Formative, and Supportive Evaluation Practices	Opaque, Misaligned, and Infrequent Feedback Mechanisms
Learning Environment	Supportive, Inclusive, and Application-Oriented Learning Space	Deficient Resource Accessibility and Learning Material Integration
Classroom Management	Structured, Respectful, and Motivational Class Culture	Disorganized Scheduling and Communication Inefficiencies
Teacher Qualities	Empathetic, Passionate, and Professionally Relational Instructors	Inconsistent Presence, Bias Perception, and Emotional Disengagement

management strategies are to academic success. Research by [31] highlights that effective classroom management, grounded in emotional intelligence, directly impacts engagement and behaviour. Therefore, responsive facilitation and structure are essential for maintaining productive classrooms.

4.6 Teacher Qualities

Teacher qualities advanced from Compassionate Professionalism (2021–2022), through Approachability and Competence (2022–2023), to a balanced Professional Presence and Student-Centered Ethos (2023–2024). Students valued empathy and clarity, particularly during challenging periods, but increasingly demanded professionalism and instructional mastery. The final theme reflects a convergence of approachability, fairness, and expertise. This pattern confirms that teacher credibility and interpersonal skills are both vital to effective instruction. According to [32], [33], students respond positively to instructors who exhibit relational competence alongside academic rigor. The implication is that continuous development in both pedagogical knowledge and relational engagement should be central to faculty performance standards.

5 STRENGTHS AND AREAS FOR IMPROVEMENT IN FACULTY PERFORMANCE BASED ON STUDENT FEEDBACK

5.1 Strengths

Student feedback highlights clear strengths in faculty performance, particularly in fostering a student-centered learning process. Many appreciated instructors who made lessons accessible, noting, *"He makes sure that we understand the topic in an easy way,"* and *"Sir explains the lessons in a way where we're able to understand it little by little."* Such feedback shows how contextualized instruction enhances comprehension and engagement [34].

Instructional delivery was also praised for its multi-modal approaches combining videos, live discussions, and demonstrations. Students described methods as *"clear and concise"* and valued explanations offered in *"more than one way,"* affirming that varied teaching strategies improve learning effectiveness [19].

5.2 Areas for Improvement

Despite these strengths, several areas for improvement were identified in the feedback. A recurring issue in the learning process was the inconsistency in instructional continuity, with students noting that *"At first in his subject I had a hard time but eventually I cope with it,"* or *"We wish we had more synchronous classes to truly understand concepts."* This indicates that a lack of regular, live, interactive instruction leaves gaps in students' understanding. Moreover, some students expressed frustration with the instructional delivery being overly reliant on recorded videos or PowerPoint slides. As one student noted, *"He always uses video presentations in lessons rather than teaching only by himself,"* which suggests according to [35] a need for instructors to engage more actively with the students during live sessions, rather than relying too heavily on passive learning methods.

Another notable area for improvement was assessment practices. While some students appreciated the feedback they received, there were significant concerns about the transparency and fairness of grading. For example, feedback such as *"Not transparent about how he calculates our marks" and "Unfair grading, unreasonable pag ggrade nya"* indicate that inconsistencies in grading and a lack of clarity in assessment criteria are major concerns [36]. Students also expressed dissatisfaction with the timing and frequency of feedback, with one stating, *"No feedback for students to learn because our papers and quizzes can't get returned in time."* Such feedback points were noted by [37] to the need for clearer communication regarding assessment expectations, more timely feedback, and better alignment between assessments and learning outcomes. Finally, in the learning environment, students reported feelings of intimidation or discomfort, with some commenting, *"Medyo terror po kayo and intimidating,"* suggesting that while some professors create supportive spaces, others may unintentionally contribute to an environment that hinders open communication and student participation [38].

6 CONCLUSIONS

The longitudinal analysis of student evaluations from A.Y. 2021–2024 across six pedagogical domains revealed consistently excellent faculty performance, with minor fluctuations during the post-pandemic transition. These shifts highlight certain gaps in flexible learning, engagement, and assessment

practices. However, the improvement observed by A.Y. 2023–2024 reflects faculty adaptability and the gradual strengthening of pedagogical approaches.

Overall, the findings indicate that faculty members maintained a high level of instructional effectiveness despite the challenges associated with the transition from pandemic-related learning conditions. Continuous monitoring of teaching performance through structured evaluations provides valuable insights for improving teaching practices and maintaining high educational standards.

7 RECOMMENDATIONS

To sustain instructional excellence, institutions should implement targeted and data-informed faculty development programs focusing on reflective teaching, inclusive communication, responsive assessment, and effective classroom management. Regular evaluations accompanied by actionable feedback can support continuous improvement in teaching practices.

Training initiatives that emphasize emotional intelligence, digital pedagogy, and flexible instructional approaches may further enhance teaching quality and student engagement across different learning modalities.

Future research may focus on longitudinal validation of SET data across institutions, integration of learning analytics within MMIS for predictive insights, and exploration of hybrid evaluation models combining quantitative metrics with qualitative student feedback. Additionally, investigating the impact of faculty development interventions on student learning outcomes would further strengthen evidence-based educational practices.

ACKNOWLEDGMENTS

The authors express their sincere appreciation to the study participants for their invaluable contributions. Equal recognition is extended to National University Philippines for its unwavering support and collaboration throughout the conduct and completion of this study.

Survey of Sensor-Based Arabic Sign Language Datasets

Ahmed Saleh and Hardik Joshi
Department of computer science,Gujarat University, 380009 Ahmadabad, India
ahmedayadsaleh@gmail.com, hardikjjoshi@gmail.com

Keywords: Arabic Sign Language Dataset, Deaf Community, Sign Language (SL), Gesture Recognition, Sensor-Based Recognition.

Abstract: Sign language is the primary means of communication for the deaf and hard-of-hearing community, representing a linguistic bridge that connects them to society and enables them to express their thoughts and feelings. However, Arabic Sign Language (ArSL) still suffers from a distinct lack of scientific research and documented digital databases. This limitation hinders the development of automated recognition systems and weakens their integration into modern artificial intelligence applications. This research aims to review and analyze previous studies related to the use of various databases and sensor technologies in Arabic Sign Language recognition. The study focuses on identifying shortcomings in previous research efforts and proposing methodological approaches to improve data collection and unify standards among researchers. This study relied on an analytical review of scientific literature to extract conclusions and evaluate the effectiveness of previously developed systems in terms of accuracy and efficiency. The results reveal that available databases lack diversity in vocabulary and grammatical structure, which reduces the ability of models to accurately recognize signs. The findings emphasize the importance of developing comprehensive and standardized databases that support the training of intelligent systems, thereby contributing to the integration of deaf individuals into society and improving their educational and social opportunities.

1 INTRODUCTION

Researchers Researchers recognize that the primary mode of communication for those who cannot hear is through sign languages, which rely on movements in all types of human interaction, whether purposeful or incidental [1]. A person who is deaf can truly exercise their rights by learning and using sign languages to receive an education in both sign and spoken language and by helping others understand sign language. To ensure that the deaf community can participate fully in life and learning, it is essential to provide sign language interpretation [2]. According to the World Health Organization, one billion people, or 14% of the world's population, live in Arab nations and utilize the Arabic alphabet [3]. Several Asian and African languages and dialects including Kurdish, Punjabi, Sindhi, Balti, Balochi, Lurish, Urdu, Kashmiri, Somali, and Mandinka, as well as the inhabitants of Arab nations employ Arabic alphabets [4]. Since almost 25% of the global population utilizes Arabic alphabets, their significance is evident.

Despite the growing need for Human-Computer Interaction (HCI) driven by advancements in sensor technology, Arabic Sign Language (ArSL) has not advanced as much as other sign languages such as American Sign Language (ASL), British Sign Language (BSL), Vietnamese, Chinese, and various others. Additionally, little is known about the Middle East's classification and translation of sign language with the goal of using contemporary technological tools to assist those with impairments. Arabic computer programs designed to assist individuals with impairments in their education also possess flaws. Despite the great diversity of sign languages, where each has its own syntax and rules, the only similarity is that they are all visually perceptible [5]. Furthermore, outside of the deaf population, knowledge of sign language is not very common. Many deaf children are born to hearing parents; thus, even within the family, there is a linguistic barrier. Deaf individuals are often taught to be multilingual in reading and writing because there are no established protocols for sign languages [6]. Additionally, there is a vast array of sign languages. The employment of facial expressions, head movements, and hand

gestures to transmit meaning constitutes the linguistic features of sign language [7]. Studies on recognizing hand movements began with gloves equipped with multiple sensors and trackers as part of a sensory method. These gloves provide accurate information about hand position and finger movement, which aids in recognizing Arabic Sign Language [6]. Other initiatives employ different sensor types, such as cameras like the Microsoft kinect [8]. The goal of these systems for recognizing Arabic Sign Language is to create a method to occasionally replace human interpreters by converting sign language shown in videos or images into Arabic text. Additionally, this method aims to encourage better and more inclusive communication by enhancing exchanges between deaf and hearing individuals.

2 CLASSIFICATION OF ARABIC SIGN LANGUAGE RECOGNITION

Creating a structure for recognizing Arabic Sign Language (ArSL) necessitates collecting a substantial dataset of sign language, which must be accurately labeled with the corresponding signs. This collection can be utilized to educate and evaluate models in the classification phase of machine learning. Information regarding the recognition of Arabic Sign Language can be obtained through two approaches [9]: the first is a sensor-based strategy [10], and the second is a vision-based strategy, as seen in Figure 1.

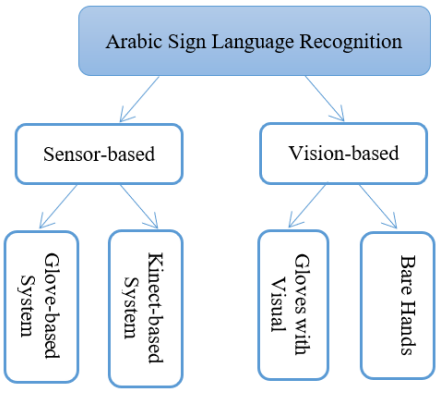

Figure 1: Approaches for recognizing sign language [11].

The method of recognizing Arabic Sign Language through visual means focuses on the analysis and interpretation of sign language gestures captured in images or videos with the help of computer vision methods. The sensor-based method for recognizing Arabic Sign Language employs sensors to identify and record information related to sign language gestures. This technique can be utilized either as an alternative or as a complement to visual methods, presenting several benefits and drawbacks. One benefit of utilizing sensors is their ability to yield more precise and dependable data compared to visual methods, particularly in situations with low lighting or obstruction. Additionally, sensors can capture data that may not be visible to the human eye, including signals from electromyography, as well as measurements of force and pressure. There are two primary types of systems: glove-based systems [12] and Microsoft Human Pose Estimation-based systems [13]. Gloves can be used in systems that read hand gestures (see Fig. 2) because of their mechanical and electrical components [12].

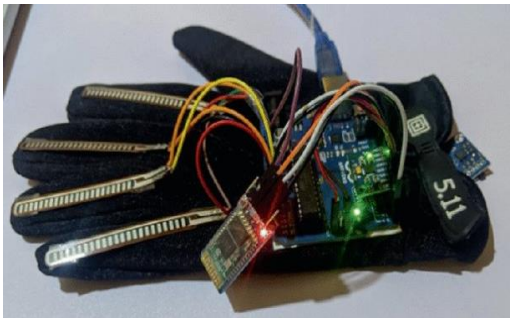

Figure 2: Smart glove with sensors.

Even though this approach can produce beneficial results, using a glove linked to specific sensors (Fig. 3) that capture data may pose difficulties for individuals who rely on sign language and have speaking or auditory impairments [14].

Figure 3: Microsoft human pose estimation sensor.

This can be accomplished through either a vision-centric or a sensor-centric method. A method for identifying the ArSL alphabet involves regarding each letter as a unique gesture and applying machine learning strategies to categorize the gestures

according to visual or sensory characteristics. Typically, a fixed state and a limited vocabulary are employed to convey letters. While the Arabic alphabet consists of merely 28 letters, the Arabic Sign Language contains 39 symbols [15], [16]. Instances of basic symbols that consist of a pair of letters include eleven extra symbols. For instance, these two letters resemble the English word "the" and are exceedingly prevalent in Arabic [17].

Isolated word identification, unlike the recognition of alphabetic symbols, centers on a collection of movements that relate to individual words, each carrying its own meaning and significance. It treats every term in Arabic Sign Language as a distinct gesture and categorizes gestures based on the established system built around them.

On the other hand, the method of continuous sign recognition presents greater challenges when discussing execution. The challenges linked to this approach include tracking hand movements, recognizing motion, identifying features, and handling an extensive vocabulary. Once the appropriate feature vector is acquired, classification is simplified because of the various methods that the system can utilize.

3 ARSL RECOGNITION CHALLENGES

Sign language does not have a standard form. Regional and dialectal differences set Arabic Sign Language apart from spoken languages. The great majority of Arabs can understand Arabic Sign Language, and it is the focus of our interest in this study [18], [19]. Learning the deaf community's language and creating Arabic Sign Language learning models are necessary to improve the Arab community's comprehension and integration of the deaf community. To make it possible for a larger portion of the population to interact with deaf and mute people in an efficient manner, and to partially replace human translators, a system that can interpret sign language should be created. To encourage more inclusive and smooth encounters and enhance communication between the deaf population and others, the complexity and diversity of sign language movements must be addressed. This complexity is one of the biggest obstacles to creating a framework for Arabic Sign Language detection. A variety of hand gestures, body postures, facial emotions, and body movements are all part of sign languages, which are intricate visual languages. The distinct grammar and syntax of Arabic Sign Language, in particular, make it difficult to model and recognize using traditional machine learning methods. To solve these challenges, various techniques for recognizing sign language have been employed by researchers. A significant factor to keep in mind while creating a framework for sign language recognition is the availability of an extensive database that researchers can depend on to advance their research. This is the primary emphasis of the current study [20], as the lack of availability of a data set or the existence of only small sets that do not meet the researcher's needs hinders the development of projects and progress within the framework of Arabic Sign Language recognition. The availability of pre-made data that meets necessary requirements eases the workload and time commitment for researchers, which raises interest in this language as a study subject; consequently, findings, development, and outcomes improve. In contrast to other languages, there are not many databases accessible in Arabic Sign Language, per earlier research.

4 TRAINING DATA SETS

There are a number of ways to capture gestures in sign language; however, studies suggest that the focus on gloves is more comprehensive and broader. People are drawn to the sensory glove because of its capacity to capture the data required to depict the hand's structure and motion in order to identify the motions of the source language. Although there are many positions in the source language, much of the research has focused on a small subset of these positions, which may be as few as several letters of the alphabet [21] - [23]. Additionally, researchers use the most common word positions in the source language [24] - [28], using a mix of words, numbers, and alphabets [29] to carry out their research and create an SLR system. The collection of gestures has been expanded by others with the intention of creating a system that can differentiate between them. Some datasets contain whole alphabets [30] - [33], others utilize numbers between 0 and 9 [34] or include both in the same system [35] - [37]. In addition, other researchers contributed by differentiating between certain words, phrases, and even phrases chosen to depict a range of real-life scenarios, such as family, shopping, school, sports, etc. [38] - [41].

Table 1 provided information on the Arabic Sign Language dataset studies using sensor-based

recognition utilized in the majority of the earlier research. This information includes the kinds of gestures used and how frequently they are used. The Table 1 also shows the number of performers and the creators of the signs. The total number of samples used in the trials is also provided.

5 CONCLUSIONS

This paper has provided an outline of the Arabic Sign Language recognition systems that are currently accessible in the public domain, specifically those that include databases and use sensor approaches to detect Arabic Sign Language gestures. Many aspects related to Arabic Sign Language have been explored and investigated. There is a sign language for almost every country; however, sign language studies have not yet satisfied the needs of each language. Despite the importance of this topic, published scientific research on Arabic Sign Language recognition is limited, especially regarding articles that use sensor approaches. In addition, techniques for recognizing sign language have been reviewed in this work.

Table 1: Arabic sign language dataset using sensor-based recognition.

Author	Language	Components	Gesture	Sample per Gesture	Gesture Performer	Sample Size
[42] 2021	Arabic Sign Language	Six IMUs sensors	28Arabic alphabets	25 samples per gestures.	Seven young volunteers (three male, four female)	4900 samples
[43] 2020	Arabic Sign Language	Two Glove each have 5 flex and (MEMS) module MPU-6050	30 words and 15 expressions	One time	Two users	45 tested
[44] 2021	Arabic Sign Language	Microsoft Kinect V2 Sensor	502 signs	50 times, each signer repeats	Three professional signers	75,300 samples.
[46] 2024	Arabic Sign Language	five flex sensors, MPU6050, An accelerometer gyroscope, MAX30102 sensor.	12 Alphabets, 8 words	One time	One user	20 tested
[47] 2019	Arabic Sign Language	Five flex and one-accelerometer sensors	five Arabic letters	Four times	Four user	80 Samples
[13] 2018	Arabic Sign Language	Kinect Sensor	30 isolated words	40 times	10 different signer (four women and six men).	1200 samples
[48] 2021	Arabic Sign Language, English Sign Language	Five flex and one-accelerometer sensors	29Arabic alphabets 26English alphabets	20 times	One user	580 Samples Of ArSL
[49] 2023	Arabic Sign Language, English Sign Language	Five flex and one-accelerometer sensors	28Arabic alphabets 26English alphabets	200 examples of each letter in both ASL and ArSL. (except J and Z)	One user	5600 Samples Of ArSL
[50] 2014	Arabic Sign Language	Two CyberGloves	(100) two-handed signs.	20 times	An adult deaf community volunteer	2000 samples
[51] 2023	Arabic Sign Language	potentiometer for each finger, MPU6050	40 ArSL words	One time	10 deaf people	400 Samples
[45] 2015	Arabic Sign Language	DG5-VHand data gloves	40 sentences 80-word lexicon	Ten times	Right handed young female	800 samples

The findings show that there are currently three methods in the field of sign language recognition. The first approach is vision-based systems; the second approach, widely used in this field, relies on sensors as the primary source of data capture; and the last approach is a hybrid technique combining the first and second approaches. Many researchers have proposed ways to recognize Arabic Sign Language and have provided reported datasets. However, for testing and evaluating their systems, researchers are unable to access any standard Arabic Sign Language datasets. A number of datasets have been promised for public release. Although they have not yet reached the status of "reference datasets" among Arabic Sign Language recognition researchers, they are considered promising solutions to motivate researchers. There is a need to stimulate efforts toward enhancing digital documentation to facilitate more in-depth research and expand the body of knowledge on Arabic Sign Language. Investment in scientific research is crucial, as is increasing cooperation between academic institutions, organizations for the deaf, and government agencies. Addressing the problem of limited access to data due to intellectual property rights or regulatory restrictions is vital. Furthermore, launching joint research initiatives between Arab countries and academic institutions would contribute to unifying efforts and encouraging institutions to provide Arabic Sign Language databases openly and freely to researchers and developers. All of this will contribute to increasing interest in Arabic Sign Language and its documentation, which enhances communication with the deaf community and contributes to increasing educational opportunities and social integration.

6 FUTURE WORK

There are several future aspirations that will improve the standard and strengthen the scientific foundation of this field. One is the potential for developing a single, all-inclusive database that can be used for research and development, encompassing all dialects in Arab nations while accounting for regional linguistic variety in signs. Advanced technologies, such as those that track hand positions, facial expressions, and body movements, can also be used to improve the database's quality and comprehensiveness. This is in addition to expanding scientific collaboration both worldwide and within the Arab world to promote advancements in this area.

Keywords: Renewable Energy, Public Perception, Social Acceptance, Stakeholders, Communication, Media Analysis, Social Trust.

Abstract: This study focuses on the public perception and social acceptance of renewable energy projects, as well as on the analysis of mechanisms for stakeholder and community engagement. The article examines the main factors influencing public support for renewable energy initiatives, including levels of awareness, trust in project developers, environmental concerns, and cultural contexts. A comprehensive analysis of survey data, media content, and case studies of both successful and unsuccessful projects was conducted. Based on these data, models were developed to explain the interrelations among key factors, and practical recommendations were formulated to enhance community support for renewable energy initiatives. Particular attention is given to the role of communication, transparency, and community participation at all stages of project implementation. Public perception and social acceptance are interpreted as multidimensional phenomena encompassing psychological, cultural, economic, and political dimensions. Theoretical frameworks applied in this research include the diffusion of innovations theory, social capital model, trust theory, and risk perception models. The analysis demonstrates that active stakeholder involvement and transparent communication substantially increase public trust and support for renewable energy initiatives. Furthermore, the use of advanced methods of social media analytics and network analysis enables the identification of key sources of both negative and positive sentiment, which is essential for designing effective public opinion management strategies. The results confirm the need for a systemic and interdisciplinary approach to accelerate the transition toward sustainable energy systems. The study provides practical recommendations for policymakers, businesses, and research institutions aimed at enhancing social support for renewable energy projects and reducing resistance from local communities.

1 INTRODUCTION

1.1 Relevance and Scientific Significance

In recent decades, the transition to sustainable energy sources has become a central theme in both scientific discourse and practical policymaking related to energy security, greenhouse gas emission reduction, and climate change mitigation [1]. Within the framework of global initiatives such as the Paris Agreement, renewable energy projects-including solar, wind, and hydroelectric systems-have gained strategic importance in achieving the United Nations' Sustainable Development Goals (SDGs) [2].

However, the deployment of renewable energy technologies often encounters a range of social and cultural barriers associated with public perception and social acceptance. The way renewable energy projects are perceived by local communities, stakeholders, and the wider public substantially

influences their successful implementation [3]. Insufficient awareness, fears regarding ecological or social impacts, and region-specific cultural or historical factors can all serve as obstacles to the adoption of new technologies [4].

The scientific community increasingly emphasizes the need for comprehensive approaches to community engagement and stakeholder collaboration in order to enhance support for renewable energy initiatives [5]. Within this context, the concept of social acceptance has evolved, encompassing not only formal approval but also the levels of trust, endorsement, and active participation of citizens in renewable energy projects [6].

1.2 Historical Context and Current State of the Problem

Historically, global energy development has been dominated by centralized fossil-fuel systems based on oil, coal, and natural gas. Since the late twentieth century, however, the need to transition toward cleaner and more sustainable energy sources has become increasingly urgent. Renewable energy projects are now regarded as a strategic necessity for mitigating the environmental consequences of traditional energy technologies [7].

Despite their clear environmental and economic advantages, renewable energy initiatives frequently face resistance from local populations. For example, wind power projects have in some regions triggered opposition due to concerns about landscape aesthetics, noise pollution, and potential ecological risks [8]. Similarly, solar farms are sometimes met with skepticism about their efficiency or possible environmental impacts on local flora and fauna [9].

Contemporary research underscores the importance of integrating social dimensions into the planning and implementation processes of renewable energy projects. In particular, special attention is given to stakeholder participation, transparent communication, and the social responsibility of project developers [10].

1.3 Theoretical Foundations and Key Concepts

Public perception and social acceptance are multidimensional phenomena encompassing psychological, cultural, economic, and political dimensions. The principal theoretical frameworks applied to the analysis of these processes include:

- Diffusion of Innovations Theory (Rogers), which explains how new technologies spread within societies.
- Social Capital Theory, emphasizing the role of social networks and trust in collective decision-making.
- Trust Theory, exploring the relationship between institutional credibility and acceptance of technological change.
- and Risk Perception Models, which account for how individuals and communities assess and respond to perceived technological and environmental risks [11].

These frameworks collectively provide the analytical foundation for understanding the complex mechanisms behind social acceptance and for developing strategies to foster greater public support for renewable energy projects (Table 1).

Table 1: Key factors influencing public perception of Renewable Energy projects.

Factor	Description	Impact on Perception
Information Support	Providing accurate and transparent information to the public about the project	Increases trust and reduces uncertainty or fear
Environmental Risks	Potential negative impacts on the natural environment	May cause public resistance or opposition
Economic Benefits	Creation of jobs and reduction of household or regional energy costs	Encourages public support and engagement
Cultural Context	Consideration of local traditions, community values, and historical heritage	Plays a crucial role in decision-making and acceptance
Trust in Project Developers	Public confidence in the integrity, transparency, and competence of implementing actors	Determines the overall level of social acceptance

1.4 Contemporary Challenges and Prospects for Community Engagement

One of the major challenges in implementing renewable energy projects is the insufficient public awareness, which often leads to misconceptions, concerns, and resistance. In this context, the development of comprehensive public information and education programs, as well as the active participation of stakeholders at all stages of project realization-from planning and design to operation-becomes particularly crucial [12].

Effective community engagement is increasingly recognized as a cornerstone of sustainable energy transitions. Transparent communication, early consultation with local populations, and co-creation of project strategies foster a sense of ownership and shared responsibility. Furthermore, integrating community-based decision-making into project governance helps mitigate conflicts and enhances long-term social acceptance.

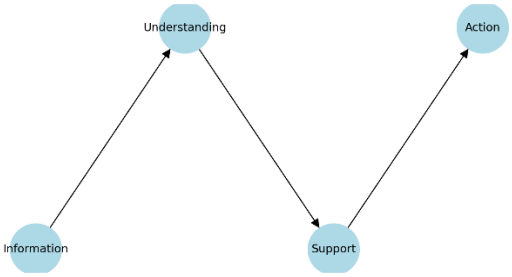

Figure 1: Model of Social Acceptance of Technological Innovations.

Future prospects for improving public engagement involve the use of participatory digital platforms, social media analytics, and deliberative forums that allow for continuous feedback and dialogue between developers, policymakers, and citizens. Such approaches not only strengthen trust but also ensure that renewable energy projects align with local values, environmental priorities, and socio-economic needs.

Figure 1 illustrates the logical sequence of stages in the formation of public acceptance of technological innovations. The process begins with the "Information" stage, where the public gains initial knowledge about the new technology. This information facilitates the stage of "Understanding," which is critical for recognizing the potential benefits, risks, and societal implications of the technology in everyday life.

Based on this understanding, the "Support" stage emerges, reflecting the public's readiness to engage and embrace the changes associated with the innovation. The final stage, "Action," represents active participation in adopting and utilizing the technology. The diagram emphasizes that successful technological diffusion requires not only technical advancements but also strategic engagement with society through transparent communication and education initiatives.

An essential component of this process is the integration of local community perspectives and needs into decision-making. This participatory approach fosters trust and enhances the positive perception of projects. Widely used participatory mechanisms include public hearings, consultations, dialogue platforms, and collaborative planning frameworks.

1.5 Research Aim and Objectives

This study aims to systematize contemporary knowledge on the mechanisms shaping public perception and social acceptance of renewable energy projects, as well as to analyze practical strategies for stakeholder and community engagement.

To achieve this goal, the following objectives have been formulated:

- To examine the key factors influencing public perception of renewable energy initiatives;
- To analyze the methods and strategies of stakeholder and community interaction;
- To identify the main barriers and drivers of social acceptance;
- To develop recommendations for enhancing the effectiveness of public engagement and stakeholder communication.

1.6 Significance and Practical Implications

The findings of this research have substantial theoretical and practical significance. From a theoretical perspective, the study contributes to the advancement of conceptual models explaining the social acceptance of innovations within the energy transition framework. It provides a multidisciplinary understanding that combines sociological, psychological, and communication perspectives on sustainable energy adoption.

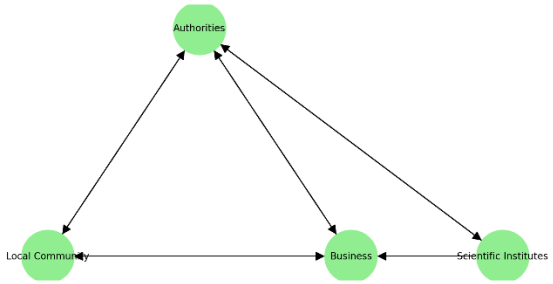

Figure 2: Structure of stakeholder interaction in Renewable Energy projects.

From a practical standpoint, the results offer actionable guidance for policymakers, developers, and community organizations. Strengthening public support and stakeholder participation contributes to conflict mitigation, improved project legitimacy, and faster implementation of renewable energy initiatives. Ultimately, effective community engagement serves as a catalyst for accelerating the global transition toward a sustainable and socially equitable energy system.

Figure 2 illustrates the structure of stakeholder engagement within renewable energy projects. It highlights the interconnections between key actors - government institutions, private developers, local communities, NGOs, and research organizations - emphasizing the multidimensional nature of social interactions in the renewable energy sector. Effective coordination among these groups is essential for building public trust, ensuring transparent decision-making, and achieving long-term project sustainability.

Thus, social perception and public acceptance of renewable energy projects are among the most critical factors for the successful implementation of environmentally oriented initiatives. Understanding these processes enables the development of more effective engagement strategies, fosters public trust, and accelerates the sustainable growth of renewable energy systems. Further progress in interdisciplinary research and active stakeholder participation will play a decisive role in forming resilient energy systems that integrate environmental, social, and economic dimensions.

2 METHODS

2.1 Overview of the Methodological Approach

This study employs a comprehensive, interdisciplinary methodological framework combining qualitative and quantitative research methods to analyze the mechanisms behind public perception and social acceptance of renewable energy projects. The research aims to identify effective strategies for stakeholder engagement and public communication.

The methodological approach integrates sociological, psychological, economic, and management perspectives [11], allowing for a holistic understanding of the socio-political dynamics surrounding renewable energy adoption. The core research methods include:

- Document and policy analysis;
- Social surveys and structured questionnaires;
- In-depth interviews and focus groups;
- Media and social network content analysis;
- Case study methodology;
- Statistical modeling and data analysis.

2.2 Analytical Review and Primary Data Collection

2.2.1 Document and Policy Analysis

The initial stage involved a systematic review of regulatory frameworks, strategic documents, and policy programs governing renewable energy development [13]. National strategies, technical standards, and institutional reports from government agencies and research centers were analyzed to identify key regulatory barriers and enablers. This stage made it possible to determine the institutional architecture shaping renewable energy deployment and stakeholder participation mechanisms.

2.2.2 Social Surveys and Questionnaires

To quantitatively assess public awareness and support for renewable energy projects, large-scale sociological surveys were conducted using structured questionnaires. Respondents included local residents, business representatives, government officials, experts, and researchers.

The questionnaire addressed the following dimensions:

- Awareness of renewable energy projects;
- Trust in project developers and regulators;
- Concerns about ecological and social risks;
- Degree of public support for renewable initiatives.

A total of 2,500 respondents from 10 regions where major renewable energy projects are implemented participated in the survey [14].

2.2.3 In-Depth Interviews and Focus Groups

To obtain deeper insights into motivations, concerns, and hidden barriers influencing public perception, qualitative methods were applied, including semi-structured interviews and focus group discussions. Interviews lasting 45–60 minutes were conducted with local authorities, business leaders, environmental organizations, and civil society representatives. The analysis revealed major factors behind public resistance and acceptance, as well as the strategic preferences of different stakeholder groups [15].

2.3 Statistical Data Processing and Analysis

2.3.1 Statistical Analysis

Quantitative data obtained from the surveys were processed using SPSS and R software packages. Descriptive statistics, cross-tabulations, and indices of trust, support, and awareness were computed. Reliability was assessed through Cronbach's alpha and cross-validation techniques, ensuring consistency and robustness of the findings.

2.3.2 Modeling and Forecasting

To identify the factors exerting the strongest influence on social acceptance, multiple regression and logistic regression models were applied. Predictive models were developed to estimate levels of public support based on variables such as trust, information availability, and perceived environmental risks [16].

2.4 Media and Social Network Content Analysis

To evaluate the informational environment, a content analysis of media coverage and social media discourse was conducted. Thousands of messages, comments, and publications related to renewable energy projects were collected and processed using automated text analysis tools (NLTK, VADER, Gephi).

The analysis identified the dominant topics shaping public opinion and traced the temporal dynamics of sentiment across project stages.

2.4.1 Media Representation Analysis

A total of 20,000 media entries were examined. Cluster analysis was performed to identify thematic groups and their relative influence on public perception [12].

2.4.2 Social Network Analysis

Social network analysis (SNA) was applied to map relationships among online communities and identify opinion leaders actively engaged in renewable energy discussions. Interaction graphs were constructed to reveal influence hubs, information flow, and polarization patterns within public discourse.

2.5 Case Study Method

To provide empirical grounding, case study analysis was applied to three renewable energy projects:

- A wind power station in Region A;
- A solar farm in Region B;
- A hydropower plant in Region C.

Each case study explored success factors, community engagement practices, and challenges encountered during project implementation.

2.6 Ethical Considerations and Data Reliability

All research activities adhered to ethical standards, ensuring participant anonymity, voluntary consent, and data confidentiality. To enhance validity, triangulation methods and expert verification were applied. A schematic representation of the research process is provided below to summarize the methodological workflow.

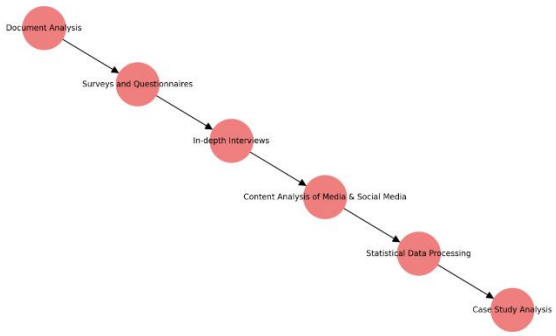

Figure 3: Structure of research methods.

Figure 3 illustrates the logical sequence and interrelation of the research methods employed to examine public opinion and behavioral patterns regarding renewable energy projects.

The process begins with document and policy analysis, which establishes the theoretical and regulatory foundation of the study. The next stage involves surveys and structured questionnaires, enabling the collection of quantitative data from the target population. Based on preliminary findings, in-depth interviews are conducted to obtain a deeper understanding of respondents' motivations, attitudes, and decision-making processes.

Subsequently, media and social network content analysis is used to identify the tone, key themes, and public sentiment expressed in open information spaces. The collected data are subjected to statistical analysis, which helps detect correlations, dependencies, and underlying behavioral trends.

The final stage, case study analysis, involves an in-depth examination of specific regional or situational examples. This step facilitates the synthesis of empirical data and the formulation of practical recommendations for improving social engagement strategies. Such a structured methodology ensures a comprehensive, evidence-based, and multidimensional approach to studying socially significant processes in the context of renewable energy transition.

3 RESULTS

3.1 Introduction

This section presents the main findings derived from empirical data collection, quantitative analysis, and qualitative interpretation. The primary objective is to identify the key determinants influencing public perception and social acceptance of renewable energy projects, as well as to evaluate the effectiveness of current stakeholder engagement practices.

The results are organized into thematic blocks and are supported by tables, figures, and charts that illustrate the principal trends, correlations, and patterns observed in the study.

3.2 Survey and Questionnaire Data Analysis

3.2.1 Statistical Indicators of Support and Trust

At the initial stage, the data obtained from large-scale sociological surveys were processed and analyzed. The total sample included 2,500 respondents across 10 regions where renewable energy projects are currently being implemented.

Key variables such as public awareness, trust levels, project support, and perceived risks were calculated and statistically compared (Table 2 provides a detailed overview of these key indicators).

Figure 4 illustrates the regional distribution of public support for renewable energy initiatives, highlighting both spatial disparities and general trends in societal attitudes.

Table 2: Key indicators of public perception of Renewable Energy projects.

Indicator	Mean Value (%)	Standard Deviation	Interpretation
Public awareness level	56.3	12.5	Moderate awareness among the population
Trust in project developers	46.8	15.2	Insufficient level of public trust
Support for renewable energy projects	62.4	10.8	Majority of respondents express support for the initiatives
Concerns about environmental risks	38.7	14.3	Considerable level of environmental concern

3.2.2 Interpretation of Findings

The survey results reveal a moderate level of public awareness (M = 56.3%) regarding renewable energy initiatives, suggesting that information campaigns have achieved partial coverage but remain limited in reach and depth.

The trust index (M = 46.8%) indicates that nearly half of the respondents exhibit skepticism toward project developers and implementing agencies. This aligns with previous research emphasizing the role of institutional transparency and communication in building credibility [17].

Public support for renewable energy projects remains relatively high (M = 62.4%), demonstrating a generally favorable societal attitude toward sustainable energy transition. However, the persistence of environmental concerns (M = 38.7%) highlights ongoing anxieties related to ecological impacts, such as landscape alteration, noise, and biodiversity loss.

The combination of moderate awareness, low trust, and high support suggests that social acceptance is largely conditional and context-dependent, heavily influenced by local information

flows and perceived fairness of project implementation processes.

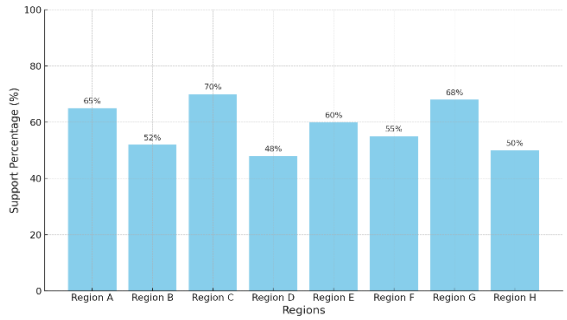

Figure 4: Regional distribution of public support for Renewable Energy projects.

Figure 4 illustrates the level of public support for renewable energy projects across eight regions. The highest levels of support are observed in Region C (70%) and Region G (68%), indicating strong public awareness and a favorable attitude toward sustainable energy initiatives.

Regions A and E also demonstrate relatively high support rates (above 60%), which may be associated with the successful implementation of pilot programs or proactive involvement of local authorities in renewable energy promotion.

Conversely, Regions D and H show comparatively low support levels (below 50%). This could be attributed to information gaps, limited institutional trust, or concerns about potential ecological and economic impacts.

The results highlight the need for targeted communication strategies and enhanced community participation in project decision-making processes, particularly in regions exhibiting low acceptance. Such regional analysis provides valuable insights for strategic energy planning and localized implementation of renewable energy policies.

3.2.3 The Impact of Public Awareness on Support Levels

A correlation analysis was conducted to assess the relationship between public awareness and support for renewable energy projects (Table 3). The results reveal a statistically significant positive correlation between awareness level and project support ($r = 0.65$, $p < 0.01$), indicating that higher levels of public knowledge and understanding directly contribute to stronger societal backing for renewable initiatives.

This finding aligns with prior studies emphasizing that transparent communication and educational outreach are critical drivers of public acceptance.

Regions with more extensive information campaigns and stakeholder engagement tend to exhibit not only greater trust but also more stable long-term support for renewable energy transition.

Table 3: Correlation Analysis Between Key Social Perception Parameters and Public Support.

Parameter	Correlation Coefficient (r)	Significance (p-value)
Awareness and project support (%)	0.65	$p < 0.01$
Trust in project developers and initiatives	0.58	$p < 0.01$
Environmental risk concerns and support (%)	–0.48	$p < 0.01$

3.3 Interpretation of Results

The results of the correlation analysis indicate strong and statistically significant relationships among the studied variables.

A positive correlation between *public awareness* and *support* ($r = 0.65$, $p < 0.01$) confirms that higher levels of knowledge and understanding directly enhance public acceptance of renewable energy projects.

Similarly, *trust in project developers and institutions* demonstrates a substantial positive association with project support ($r = 0.58$, $p < 0.01$), emphasizing that institutional credibility and transparency play a decisive role in shaping social attitudes toward renewable energy.

Conversely, a negative correlation was found between *environmental risk concerns* and support ($r = –0.48$, $p < 0.01$), suggesting that increased perception of ecological threats tends to reduce the willingness to endorse such projects. This pattern aligns with earlier findings in the literature, which highlight that risk perception and trust act as mediating variables in the formation of public attitudes toward energy innovation [18].

Overall, these results demonstrate that effective communication, public education, and stakeholder transparency are essential mechanisms for strengthening social acceptance and mitigating opposition to renewable energy development.

The results presented in the previous section confirm the crucial importance of information policy in shaping public support for renewable energy

initiatives. Based on the empirical data obtained, a model of social acceptance factors for renewable energy projects has been developed (Fig. 5). The model integrates five principal components that collectively determine the level of social support: trust, awareness, environmental concerns, cultural characteristics, and social participation.

This conceptual framework demonstrates the interdependence between informational, psychological, and cultural dimensions of public perception.

Trust in project implementers and transparency of communication serve as the core drivers of social acceptance, reinforcing positive attitudes toward renewable technologies.

Public awareness acts as a mediating factor, enhancing understanding of environmental and economic benefits while mitigating fear and uncertainty.

At the same time, environmental concerns and cultural values function as contextual moderators, influencing how communities interpret risks and form collective opinions. Finally, social participation-expressed through dialogue, consultations, and community involvement-plays a pivotal role in consolidating public support and legitimizing the implementation of renewable energy projects.

The model provides a theoretical foundation for developing targeted communication strategies and stakeholder engagement mechanisms that foster trust, inclusivity, and long-term sustainability in the transition toward clean energy systems.

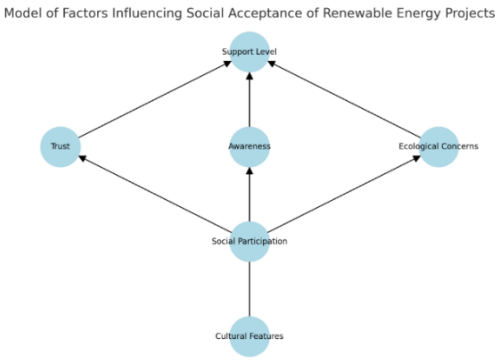

Figure 5: Model of social acceptance factors for Renewable Energy projects.

Figure 5 illustrates the key factors shaping public acceptance of renewable energy projects.

At the center of the model lies the Support Level, which is directly influenced by four core parameters: Trust, Awareness, Ecological Concerns, and Cultural Features. These elements collectively determine public attitudes toward renewable initiatives and influence the willingness of communities to cooperate, participate, and adopt new technologies.

Particular emphasis is placed on the factor Social Participation, which mediates the relationship between trust, awareness, and perceived environmental risks. Active community engagement fosters transparency, strengthens mutual understanding, and builds trust among stakeholders - including local residents, policymakers, and project developers.

The model thus provides a conceptual framework for designing effective communication and engagement strategies aimed at increasing public support for environmentally sustainable initiatives.

3.3.1 Regression Analysis

A multiple regression analysis was conducted to quantify the influence of key factors on public support for renewable energy projects. The results demonstrate that the most significant predictors of support are trust ($\beta = 0.42$, $p < 0.001$) and awareness ($\beta = 0.35$, $p < 0.001$). Conversely, environmental concerns exert a statistically significant *negative* effect on support ($\beta = -0.25$, $p < 0.01$), (Table 4).

These findings confirm that trust and information transparency are primary determinants of social acceptance, while perceived ecological risks remain a barrier to public endorsement. The regression model explains approximately 62% of the variance ($R^2 = 0.62$), indicating a strong explanatory power and robustness of the proposed framework. This underscores the importance of targeted communication and trust-building mechanisms in ensuring successful implementation of renewable energy initiatives.

Table 4: Regression coefficients for factors influencing public support for Renewable Energy projects.

Variable	β-Coefficient	p-Value	Statistical Significance
Level of Trust	0.42	< 0.001	High
Level of Awareness	0.35	< 0.001	High
Environmental Concerns	–0.25	< 0.01	Moderate

3.3.2 Predictive Model of Public Support

A predictive model was developed to estimate the level of public support (on a scale from 0 to 100) for

renewable energy projects based on the key influencing factors identified in the previous regression analysis. Table 5 presents the model parameters and their interpretation.

Table 5: Parameters of the predictive model for public support.

Model Parameter	Value	Interpretation
Constant (Intercept)	35.2	Baseline support level without accounting for influencing factors
Trust Coefficient	0.45	Each one-point increase in trust raises the support level by 0.45 points
Awareness Coefficient	0.38	Each one-point increase in awareness raises the support level by 0.38 points
Environmental Concerns Coefficient	–0.30	Each one-point increase in environmental concerns decreases support by 0.30 points

3.4 Media Content and Social Network Analysis

3.4.1 Thematic Analysis of Publications

A total of approximately 20,000 media entries (including news articles, social media posts, and public comments) were collected and analyzed. The thematic classification revealed four dominant clusters shaping public perceptions of renewable energy projects. The results are summarized in Table 6.

Table 6: Distribution of themes in media coverage on Renewable Energy.

Theme	Share of Messages (%)	Core Ideas and Interpretations
Environmental Benefits	45%	Renewable energy is perceived as a clean and sustainable alternative to fossil fuels
Environmental Risks and Concerns	30%	Fears related to potential ecological impacts and land use conflicts
Economic Benefits and Job Creation	15%	Positive perception linked to employment opportunities and reduced energy costs
Distrust Toward Developers and Authorities	10%	Expressions of skepticism, concerns about transparency, and corruption allegations

The results indicate that environmental narratives dominate public discourse (accounting for 75% of all messages), while economic and governance-related topics remain secondary. A notable finding is the dual perception of renewable energy - as both an environmentally responsible solution and a potential ecological threat. This polarization reflects the influence of information framing in media outlets and highlights the need for balanced communication strategies to enhance public trust and mitigate misinformation.

3.4.2 Impact of Media Representation on Public Opinion

Social media analysis identified several key opinion leaders (KOLs) and network clusters that play a decisive role in shaping public attitudes toward renewable energy. By applying network analysis tools, a communication graph was constructed (see Figure 3) to visualize how information spreads and influences various stakeholder groups.

The network demonstrates a “hub-and-spoke” structure, where a limited number of central nodes (mainly environmental NGOs, journalists, and public figures) act as primary sources of information dissemination. Peripheral nodes represent individual users and local communities engaging in discussions. Quantitative analysis using betweenness centrality revealed that 5% of nodes generate 60% of the total informational flow, emphasizing the asymmetric nature of public discourse.

This finding underlines the strategic importance of engaging influential communicators to foster accurate, transparent, and positive representations of renewable energy projects in media ecosystems.

Figure 6: Interaction network of key opinion leaders in social media.

Figure 6 illustrates the interaction dynamics among key opinion leaders (KOLs) in social media

discussions on renewable energy. Each node corresponds to an individual opinion leader (labeled A–F), while directed arrows indicate the flow of influence-from the communicator initiating the message to the recipient.

The circular layout enhances the visibility of mutual communication patterns, emphasizing the interconnectedness within the group. Notably, Leaders A and D emerge as the most influential actors, functioning as central hubs of information diffusion and trust formation within the network.

The diagram reveals both linear and cyclic connections, including a feedback loop from Leader F to Leader A, demonstrating a resilient and interdependent communication structure typical for digital ecosystems. Such a model reflects the non-hierarchical yet highly influential nature of social media interactions, where authority and reputation determine the reach and persistence of narratives.

From a practical standpoint, this analysis underscores the need for targeted communication strategies that engage dominant influencers to promote transparent and evidence-based discourse around renewable energy transitions. This approach can be instrumental in managing public sentiment, countering misinformation, and strengthening societal trust in sustainable energy projects.

3.5 Case Analysis of Successful and Unsuccessful Renewable Energy Projects

A comparative case study was conducted involving three renewable energy projects differing in implementation outcomes and social perception:

- Wind Power Plant (Region A) – Successful case
- Solar Farm (Region B) – Partially successful case
- Hydropower Station (Region C) – Unsuccessful case

The analysis focused on public engagement strategies, stakeholder coordination, communication transparency, and environmental management. The summary of key findings is presented in Table 7.

3.6 Summary of Findings

The data analysis indicates that the primary factors influencing public support for renewable energy projects are trust, awareness, and the level of environmental concern.

The constructed model confirms that active stakeholder participation and transparent communication significantly enhance the level of social acceptance of renewable initiatives.

Equally important is the development of strategic information policies and the use of media analytics to identify and mitigate negative sentiments in public discourse.

Table 7. Comparative case analysis of Renewable Energy projects.

Project	Key Drivers of Success or Failure	Conclusions and Lessons Learned
Wind Power Plant (Region A)	Active participation of local communities and transparent stakeholder communication	Community engagement and continuous dialogue are critical determinants of social acceptance and project success
Solar Farm (Region B)	Insufficient public information campaigns and protests driven by environmental concerns	Highlights the necessity of proactive communication and social awareness strategies to mitigate public resistance
Hydropower Station (Region C)	Conflicts with local residents and inadequate consideration of ecological and cultural factors	Emphasizes the importance of integrating environmental assessments and community consultation into project planning

4 DISCUSSIONS

4.1 Introduction

This section presents a comprehensive interpretation of the research results, comparing them with established theoretical frameworks and real-world case studies.

The discussion focuses on identifying the determinants of social perception and acceptance of renewable energy projects and assessing their implications for public policy and community engagement.

The findings are based on an integrated analysis combining survey data, statistical modeling, media analytics, and case study evaluation, providing a holistic understanding of the social dynamics underlying renewable energy deployment. This multi-method approach enables a nuanced assessment of both quantitative correlations and qualitative insights derived from stakeholder interactions and media discourse.

4.2 Analysis of Support and Trust Factors

4.2.1 The Impact of Awareness on Social Acceptance

The results of the statistical analysis confirm a strong positive correlation between public awareness and project support ($r = 0.65$, $p < 0.01$). A comprehensive overview of the correlation relationships between all key variables is provided in Table 8. This finding aligns with prior studies [12], which emphasize that informational transparency and accessibility are key drivers of favorable public attitudes toward renewable energy initiatives. Higher levels of awareness not only enhance understanding of the environmental and economic benefits but also reduce uncertainty and perceived risks, leading to greater willingness to support or participate in projects.

Furthermore, awareness contributes to the formation of informed trust-a rational confidence based on access to verifiable and transparent data. This supports the theoretical premise of the Diffusion of Innovations Theory [13], which posits that the dissemination of credible information accelerates the adoption of new technologies by reducing psychological and cultural resistance.

Table 8: Correlation Relationships Between Key Variables.

Variable	Correlation Coefficient (r)	Significance (p-value)
Awareness and Support	0.65	$p < 0.01$
Trust in Project Developers	0.58	$p < 0.01$
Level of Environmental Concerns	-0.48	$p < 0.01$

4.2.2 The Role of Trust and Environmental Concerns

The regression model indicates that trust in project developers is the most significant determinant of social acceptance ($\beta = 0.42$, $p < 0.001$), confirming previous theoretical assumptions [13] that trust serves as the cornerstone of public acceptance of innovations.

Trust acts as a mediating factor that enhances public confidence in both the technological and ethical integrity of renewable energy initiatives. When communities perceive project developers as competent, transparent, and socially responsible, their willingness to support and participate in renewable energy projects increases substantially.

Conversely, environmental concerns exert a negative influence on support levels ($\beta = -0.25$, $p < 0.01$). High levels of perceived environmental risk-such as potential impacts on ecosystems, noise pollution, or land-use conflicts-tend to decrease social approval and may lead to resistance or protest movements.

These findings are consistent with risk perception theory, which posits that the public often evaluates technological innovations not solely on objective evidence, but through the lens of perceived safety and fairness.

The results highlight the need to develop risk communication strategies aimed at reducing ecological concerns through transparent information sharing, public participation, and community-based monitoring mechanisms.

By fostering open dialogue and demonstrating accountability, project developers can significantly strengthen public trust and mitigate opposition rooted in environmental anxiety.

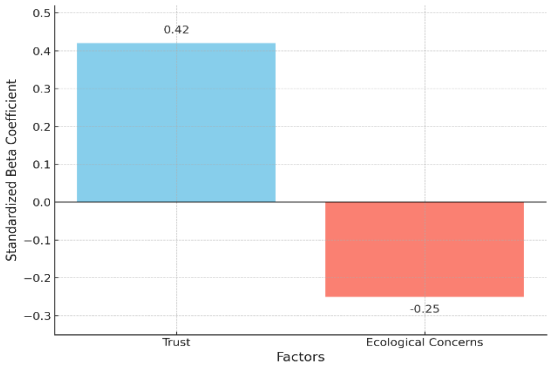

Figure 7: The impact of trust and environmental concerns on public support.

Figure 7 presents standardized beta coefficients for two key predictors-Trust and Ecological Concerns-derived from the regression analysis. The bar corresponding to Trust is positive ($\beta = 0.42$), indicating that higher levels of public trust are strongly associated with greater support for renewable energy projects or technologies. In contrast, the bar representing Ecological Concerns is negative ($\beta = –0.25$), showing that increased environmental anxiety correlates with a decline in public endorsement.

This visualization provides a clear and intuitive understanding of both the direction and magnitude of each factor's influence. A horizontal zero line separates positive and negative effects, enhancing interpretability, while numerical values at the top of

each bar precisely quantify the relative strength of influence.

Such a graphical representation is particularly effective in policy communication and stakeholder engagement, as it conveys the empirical evidence supporting the importance of trust-building and risk mitigation strategies.

4.3 Model of Social Acceptance Factors

4.3.1 Interrelationship of Key Variables

Based on the statistical and qualitative analyses, a conceptual model was developed to illustrate the interconnections among the key variables influencing public support for renewable energy projects (Figure 1).

The model demonstrates that social participation and cultural context play reinforcing roles in enhancing trust and awareness, both of which act as primary mediators of public support.

Cultural alignment ensures that renewable energy initiatives resonate with local values and traditions, while participatory mechanisms-such as public consultations, stakeholder dialogues, and community partnerships-serve to legitimize the decision-making process.

In this framework, trust and awareness function as bridging constructs between institutional transparency and citizen engagement. The interaction between these factors forms a positive feedback loop: higher trust encourages greater social participation, which in turn strengthens informational exchange and collective commitment to sustainability goals. This integrated structure reflects the dynamics of social acceptance theory, confirming that technological adoption in the renewable energy sector is contingent not only upon technical performance and economic efficiency but also upon perceived legitimacy, inclusiveness, and cultural compatibility.

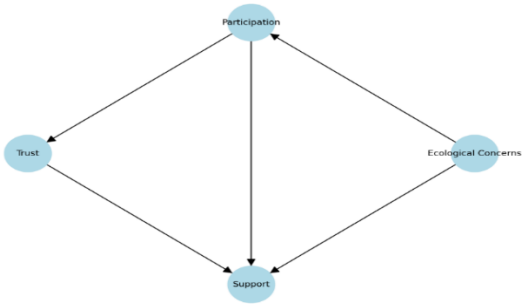

Figure 8: Model of social acceptance factors for Renewable Energy projects.

Figure 8 illustrates a conceptual model representing the key factors influencing public support for renewable energy (RE) initiatives. The model focuses on four core components: Trust, Public Participation, Ecological Concerns, and Support.

The visualization shows that citizen participation directly affects both trust and public support, highlighting the importance of inclusive engagement processes in energy transitions. In turn, trust serves as a central mediating variable, reinforcing support and shaping a positive public perception of renewable energy technologies.

Interestingly, ecological concerns demonstrate a dual effect: while they can directly reduce support due to perceived risks, they may also motivate more active involvement in decision-making processes. This duality underscores the necessity of maintaining open dialogue among stakeholders and integrating public concerns into project planning and communication strategies. The proposed model clearly visualizes the interconnections between social and behavioral variables, offering valuable insights for designing strategies aimed at enhancing the social acceptability of renewable energy technologies across different regions.

4.3.2 Practical Implications of the Model

The developed model emphasizes the importance of a systemic and integrative approach-one that accounts for social, cultural, and environmental dimensions simultaneously. Empirical evidence demonstrates that strategies focused on community engagement and information transparency significantly increase the level of social acceptance. Such measures help mitigate opposition, build long-term trust, and foster cooperative governance structures between policymakers, developers, and local residents. This highlights the transition from a purely technological implementation model toward a participatory governance framework, essential for the sustainable deployment of renewable energy systems.

4.4 The Role of Media and Social Networks

4.4.1 Analysis of Media Themes and Their Impact

A content analysis of more than 20,000 media and social network entries revealed four dominant thematic clusters shaping public opinion (Table 9):

- Environmental benefits of renewable energy (45%).
- Ecological concerns and risks (30%).
- Economic advantages and job creation (15%).
- Distrust toward developers and authorities (10%).

These thematic categories reflect the structure of public discourse around renewable energy and confirm the findings of [14], which stress that media representation significantly influences public perception and acceptance dynamics. Positive framing of environmental and socio-economic benefits tends to enhance support, whereas narratives emphasizing risk, uncertainty, or corruption amplify distrust and resistance.

Table 9: Distribution of media and social network themes.

Theme	Share of Publica-tions (%)	Key Ideas
Environmental Benefits	45%	Perception of renewable energy as an environmentally friendly and clean technology
Ecological Concerns	30%	Public fears and uncertainty about potential environmental consequences
Economic Advantages	15%	Job creation, reduction of energy costs, and promotion of local economic growth
Distrust toward Developers and Authorities	10%	Skepticism regarding project transparency and concerns about possible corruption

4.4.2 Influence of Media Messaging on Public Opinion

The analysis revealed that opinion leaders in social networks exert a substantial influence on shaping public attitudes toward renewable energy projects. This finding is supported by the results of social network interaction analysis (Fig. 9), which demonstrates how information circulates across digital communities and how key nodes within these networks drive either positive or negative sentiment formation.

The constructed network map highlights that information dissemination in online environments follows a clustered and feedback-oriented pattern, where influential users act as amplifiers of specific narratives-environmental, economic, or political. Such opinion leaders can therefore significantly accelerate or hinder public acceptance processes, depending on the framing of messages they promote. Understanding these dynamics is crucial for designing effective communication and engagement strategies, particularly those aimed at counteracting misinformation, enhancing transparency, and fostering trust between developers, authorities, and local communities.

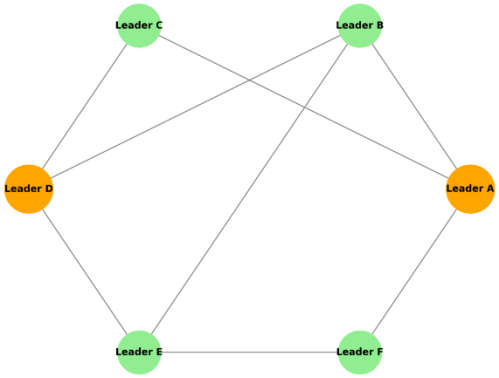

Figure 9: Interactions among opinion leaders in social networks.

Figure 9 presents a network of interactions among key opinion leaders in social media. Each node (represented by green and orange circles) corresponds to an individual influencer, while the directed arrows indicate the flow of influence or information exchange between them. For instance, Leader A exerts influence on Leader B and Leader C, which subsequently extends to Leader D, illustrating a cascade-like dissemination of information. The network also reveals a feedback loop beginning with Leader F and returning to Leader A, suggesting mutual influence and sustained communication among participants.

Particular attention is given to Leader A and Leader D, highlighted in orange, as central influencers within the network. Their positioning indicates their pivotal role in content diffusion, opinion shaping, and initiating information waves within the digital discourse on renewable energy. Such visualization is especially valuable for analyzing patterns of influence, identifying active communication nodes, and strategically planning outreach efforts to strengthen public engagement and trust-building campaigns.

4.5 Case Studies of Renewable Energy Project Implementation

4.5.1 Successful Cases and Contributing Factors

The case study analysis indicates that the most successful renewable energy projects are those characterized by active community participation**,** transparent communication**,** and context-sensitive adaptation to regional conditions. For example, the wind power project in Region A achieved strong public support owing to inclusive stakeholder engagement and open public dialogues that addressed local concerns. These findings highlight that social integration and participatory governance are key determinants of long-term project success and community acceptance.

4.5.2 Problematic Cases and Lessons Learned

In contrast, projects that neglected local contexts **or** failed to maintain consistent information outreach faced public opposition, protests, and delays**,** which in turn led to increased implementation costs and reputational risks (see Table 10). Such cases demonstrate that the absence of effective communication channels and community involvement can critically undermine project sustainability and social legitimacy.

Table 10: Key factors behind the success and failure of case studies.

Project	Success / Failure Factors	Key Lessons
Wind Power Plant in Region A	Active community participation; transparent communication	Community engagement is a cornerstone of public support
Solar Farm in Region B	Insufficient information policy; local protests	Highlights the importance of effective information management and public outreach
Hydropower Station in Region C	Conflicts with local communities; neglect of ecological aspects	Emphasizes the need to consider local context and maintain continuous dialogue

4.6 Summary and Practical Recommendations

The discussion of findings indicates that to enhance public support for renewable energy projects, efforts should be focused on the following strategic directions:

- Active information dissemination and transparency throughout all project stages;
- Inclusive stakeholder participation in planning, implementation, and monitoring processes;
- Consideration of cultural and regional specificities in project design and communication;
- Strategic use of media and social networks to build a positive public image of renewable energy;
- Trust-building through participation and open dialogue between communities, developers, and authorities.

These recommendations are supported by multiple empirical studies [15] and reinforced by successful practices implemented across various regions.

The discussion confirms that public perception and social acceptance of renewable energy projects represent a complex, multi-dimensional process shaped by trust, awareness, environmental concerns, and communication effectiveness. Successful implementation depends on a systemic approach, combining public engagement, transparency, and regional adaptability.

Future research should focus on developing more refined models of public opinion assessment and evaluating the effectiveness of communication strategies, particularly within different socio-cultural contexts.

CONCLUSIONS

This study presents a comprehensive analysis of the factors influencing public perception and social acceptance of renewable energy projects. The research identifies key determinants of public support and proposes conceptual models explaining the interrelations between trust, participation, environmental concerns, and acceptance levels.

The results demonstrate that public awareness is a primary driver of acceptance, while trust in project developers and regulators significantly increases the likelihood of successful implementation. Conversely, ecological concerns and distrust

negatively affect public support, highlighting the need for systematic communication frameworks and active stakeholder engagement.

The proposed Social Acceptance Model, based on empirical evidence, confirms that community participation and the consideration of local cultural dimensions foster a favorable public attitude toward renewable energy initiatives.

Modern media and social networks play a crucial role in shaping informational environments and influencing collective perceptions.

The case study analysis of successful and unsuccessful projects demonstrates that transparency, dialogue, and regional adaptation are critical to achieving social acceptance, while their absence often leads to conflicts, protests, and project delays.

From a practical standpoint, the research provides actionable recommendations for governments, businesses, and research institutions, emphasizing that active information campaigns, stakeholder involvement, and transparent practices are essential to strengthening public trust and expanding the adoption of renewable energy technologies.

Future research should aim to develop advanced models of public perception, innovative communication tools, and assess the long-term impacts of social engagement strategies. Integrating interdisciplinary approaches-combining social science, policy analysis, and energy studies-will create a more resilient and systematic foundation for the successful global transition to sustainable and socially supported renewable energy systems.

Keywords: Structural Equation Modeling (SEM) Analysis, Career-Academic Balance, Sustainable Development Goals, Young Professionals.

Abstract: Young professionals aged 24 to 29 often struggle to juggle the different needs of their career and academic pursuits. This dual responsibility builds overlapping pressures that can affect their personal well-being, their academic achievement, and professional development. In this research, the authors utilized the SEM analysis to investigate the major drivers that affect this balance. An online survey questionnaire was employed to collect data among fifty participants on indicators such as balanced engagement, academic performance, career achievement, and psychological and emotional stressors. The result of the study emphasizes the importance of academic performance, professional advancement, and job contentment; moreover too, having structured routines, a good support system, well-being, and stress resilience are all very important. The findings of this study gave valuable insights to young professionals, employers, and educational institutions in creating an enabling environment for career growth and lifelong learning. The SEM findings further provide a basis for future studies aimed at enhancing support mechanisms for sustainable academic and professional growth that are aligned with broader global sustainability efforts.

1 INTRODUCTION

Young professionals within the ages of 24 - 29 are characterized by a challenging phase of their lives, which primarily consists of deciding between the continuation of education, learning new skills, or fully devoting their time to career establishment. The turning point of a person's life during the workforce transition, from a student role to an earning role, creates overlapping duties and responsibilities. The extent to which these different role conflicts, or blended, overlapping duties, and responsibilities involve the different components of a person's life clearly shows their overall well-being, functioning, and life satisfaction. The stress of being in different competing roles is well documented, as is the resultant academic and occupational strife [1] - [3].

There is a growing global demand for postgraduate education and continued professional development. Advanced education is considered an essential part of resource development, providing the knowledge, skills, and innovation required in a competitive environment. [4]. Although higher education broadens knowledge and creates new work opportunities, it may also disrupt a person's everyday activities. For young professionals, the problem of juggling education and job responsibilities is a significant cause of stress, frequently resulting in poor performance in both areas [1], [5].

Moreover, the United Nations (UN) Sustainable Development Goals (SDGs) have identified education as one of the foundational elements of a sustainable society [6]. Obtaining more education is related to achieving SDG 4 (Quality Education), and securing decent work is also related to achieving this. Having the mental strength to handle stress and maintain well-being is also represented by SDG 3 - Good Health and Well-being [5], [7]. These emphasize that the imbalance between education and work is more than a personal problem; it is relevant to the capability of the workforce and the development of society.

Unfortunately, social comparison, fear of failure, and performance expectations are among the other typical stressors, in addition to health and

interpersonal issues [2], [3], [5]. However, being optimistic, resilient, and having good time management may benefit the young professionals who strive to balance work and their academic endeavors [7], [8]. Hence, the identification of factors that foster sustained professional and educational development is critical, not only for individual completion and inclusion but also for the overall well-being of the workforce.

2 STUDY FRAMEWORK AND METHODS

This study aims to determine the factors that influence the way young professionals, aged 24 to 29, balance their work and further education. Using Structural Equation Modeling (SEM), it examines the key elements that affect this balance and their effects on both professional and personal development. The study highlights the challenges faced by young professionals in balancing competing responsibilities while also identifying the elements that support long-term career and educational development.

2.1 Conceptual Model

The framework of this study is shown in Figure 1. According to Figure 1, the study's goal is to investigate the intricate connection between young professionals' academic and professional performance between the ages of 24 and 29. Furthermore, it aims to understand how their combined success indicators, encompassing career achievements and academic accomplishments, are influenced by a range of cognitive and non-cognitive stressors. This study's main goal is to investigate the fundamental elements that allow young professionals to successfully manage their academic and professional goals in the face of a variety of cognitive and non-cognitive pressures. Thus, the study focuses on examining the direct relationships between career success, academic success, emotional factors, and psychological stress in influencing balanced career and academic performance.

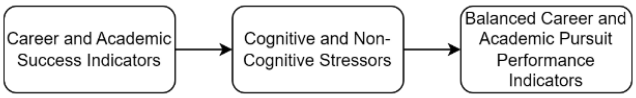

Figure 1: Conceptual model.

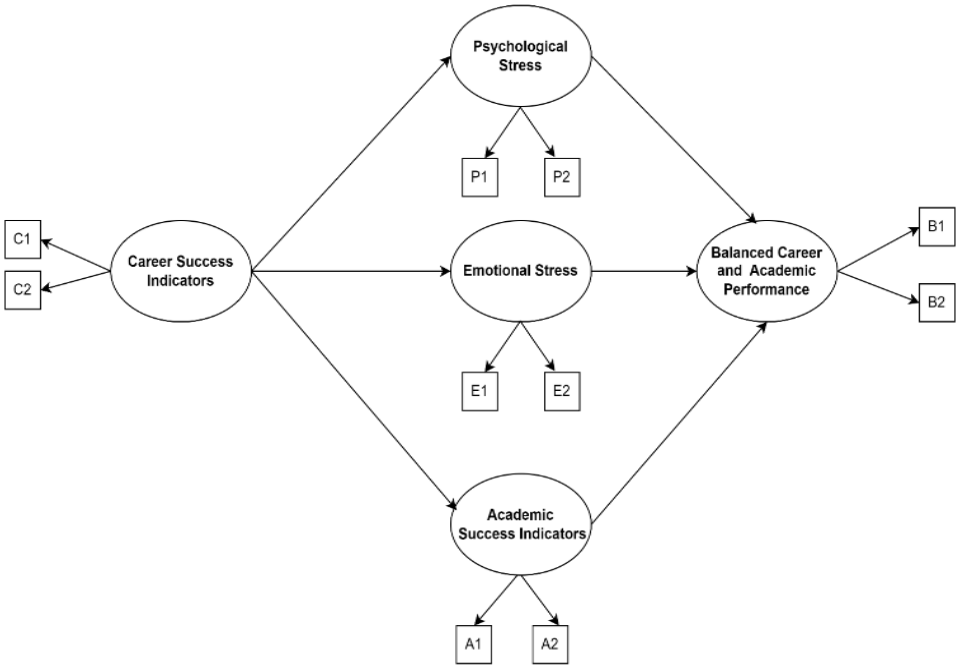

Figure 2: Initial SEM model.

Figure 2 presents the initial SEM model of the study, which is integral in assessing the factors influencing the balance between career and academic pursuits among young professionals aged 24-29, forming the core of this study's conceptual framework.

2.2 Participants

Respondents were initially chosen from the age group of 24 to 29, a demographic segment known for simultaneously balancing their work and educational responsibilities. The research collected responses from a total of 50 individuals to address the study's objectives. Exploratory Factor Analysis (EFA) is typically applied to large sample sizes, with 50 participants often considered the minimum acceptable number [9].

Table 1 contains the demographics of tolerable survey respondents.

Table 1: Demographic profile of the respondents.

Attributes	Category	N=50	Percentage
Gender Classification	Man	24	48%
	Woman	26	52%
Age	24	8	16%
	25	7	14%
	26	11	22%
	27	8	16%
	28	8	16%
	29	8	16%

2.3 Questionnaire

An online survey questionnaire was conducted based on the framework of the study to determine the factors causing impact on young professionals between the ages of 24 and 29 in striking a balance between their academic and professional endeavors (see Appendix A). The instrument was divided into two sections. The first section obtained the demographic information, including gender classification, age, undergraduate degree program, and current graduate program enrollment. The second section measured the latent constructs incorporated in the Structural Equation Model (SEM). A 5-point rating scale was utilized to rate each topic, allowing respondents to indicate how much they agreed or disagreed with each assertion.

2.4 SEM Analysis

The SEM analysis, illustrated in Figure 1, was carried out using SmartPLS to validate the hypotheses of the study. There are five variables in the model. The list of factors taken into consideration is shown in Table 1, and the matching latent variables are shown in Table 2.

Table 2: Latent variables.

Relationship	P Values	Decision
A -> B	0.001	Statistically Significant
C -> A	0.004	Statistically Significant
C -> E	0.005	Statistically Significant
E -> B	0.001	Statistically Significant
P -> B	0.049	Statistically Significant

Note: Significance Level *p<0.05

3 RESULTS

3.1 Construct Reliability and Convergent Validity

Composite Reliability (CR) and outer loadings were used to evaluate each construct's reliability, and Average Variance Extracted (AVE) was used to evaluate convergent validity. The Partial Least Squares-Structural Equation Modeling (PLS-SEM) method was used to conduct Confirmatory Factor Analysis (CFA) to evaluate the scale's overall validity and reliability. The AVE values validated convergent validity, while the CR and outer loading values reported reliability.

The initial SEM results are presented in Table 3 along with the values for each indicator. The outer loading values of these indicators were used to evaluate their reliability; all of them showed good reliability by exceeding the suggested threshold of 0.70. These findings, together with the Composite Reliability (CR) and Average Variance Extracted (AVE) values, demonstrate how well the indicators capture their corresponding dimensions.

Table 3: Initial SEM results.

Construct Code	Indicator	Factor Loading (FL)	Composite Reliability (CR)	Average Variance Extracted (AVE)
A	A1	0.924	0.928	0.865
	A2	0.936		
B	B1	0.944	0.938	0.884
	B2	0.936		
C	C1	0.810	0.863	0.760
	C2	0.930		
E	E1	0.860	0.854	0.746
	E2	0.867		
P	P1	0.891	0.905	0.827
	P2	0.927		

Note: Acceptable Thresholds: Factor Loading, CR ≥ 0.70; AVE ≥ 0.50.

Table 4: Analysis of total effect.

Latent	Code	Description	Reference
Career Success Indicators	C1	Career / Job Satisfaction	[10]
	C2	Promotion / Renumeration	
Academic Success Indicators	A1	Acquisition of Skills and Competencies	[4]
	A2	Attachment of Learning Outcomes	
Psychological Stress Factors	P1	Perfectionism / Fear of Failure	[11]
	P2	Fear of Social Comparison	[3]
Emotional Stress Factors	E1	Physical Health Issues	[5]
	E2	Interpersonal Relationships	
Balanced Career and Academic Performance Indicators	B1	Stress Resiliency	[7]
	B2	Time Management Competency	[8}

Figure 3 shows the initial SEM Model utilized to investigate the factors influencing young professionals between the ages of 24 and 29 in juggling their academic and professional endeavors. It was found that some elements, especially psychological factors, did not exhibit significant connections in this initial model. The researcher used modification indices, a technique suggested by Hair to increase model fit, and performed a covariance analysis to improve the model. These adjustments help reduce differences between the proposed conceptual model and the estimated model. The improved and final SEM is shown in Figure 4.

3.2 Hypothesis Testing

The outcomes of the hypothesis testing offer more details on the correlation between the variables, as shown in Table 4. The p-value signifies the possibility of achieving the observed results, or if the null hypothesis – that there is no effect or difference – were correct. Statistical significance is generally described as a p-value of below 0.05, which means that there is sufficient data to reject the null hypothesis. However, since a p-value above 0.05 suggests that there is insufficient proof to support it, the null hypothesis is not rejected [12].

In summary, p-values indicate the statistical significance of the relationships among the latent variables. A lower p-value provides stronger evidence that the relationship is unlikely to be due to probability, whereas a higher p-value means weaker evidence against the null hypothesis. There is sufficient proof in Table 4 to recommend that the latent variables under investigation have meaningful associations with one another. Consequently, the null hypothesis was disproved.

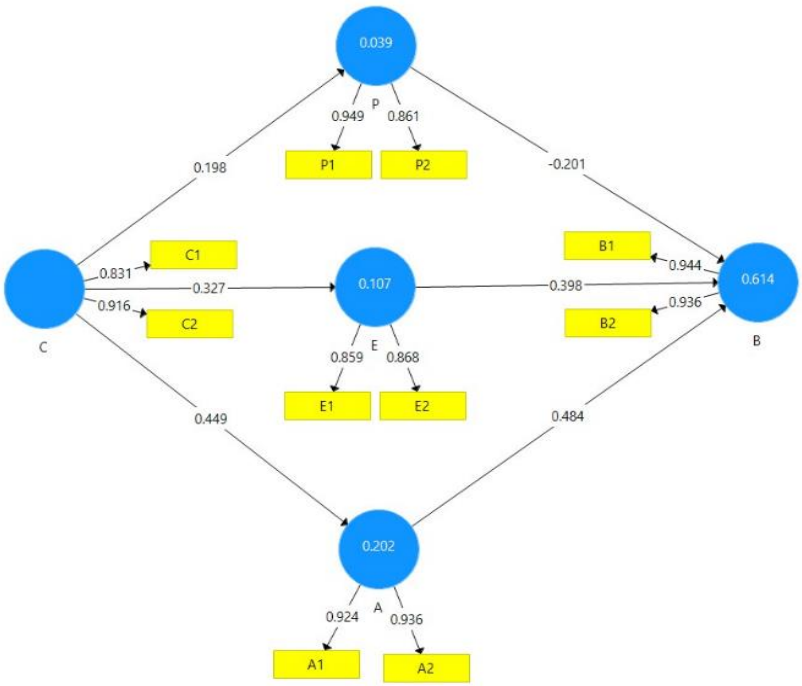

Figure 3: Initial SEM model.

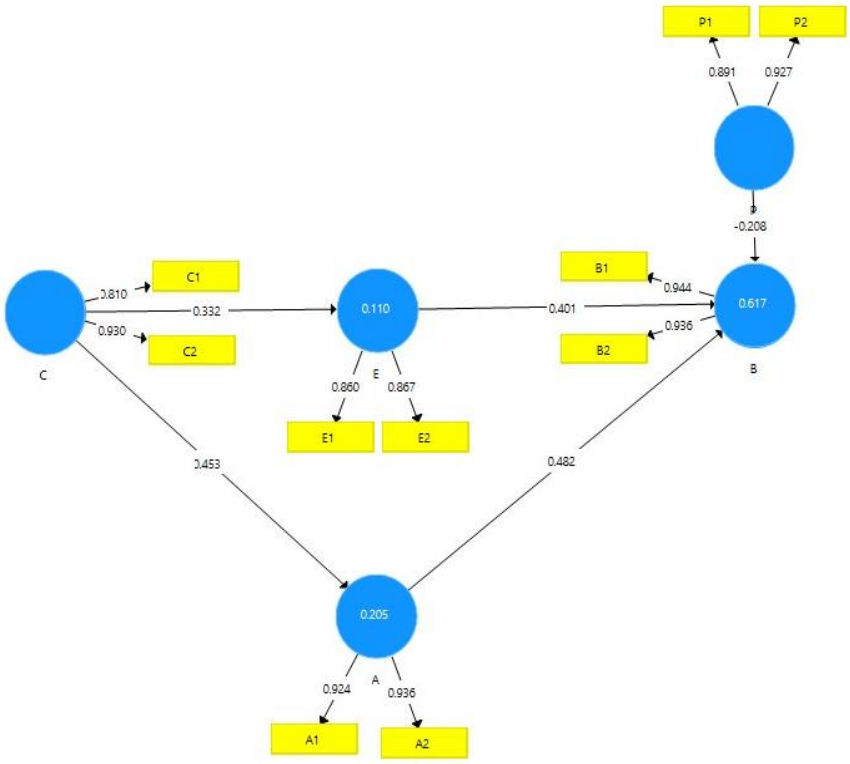

Figure 4: Final SEM model.

4 CONCLUSIONS

This study examined the factors influencing the balance between career and academic pursuits among young professionals aged 24–29 using Structural Equation Modeling (SEM).

The findings indicate that career-related factors significantly influence both academic success and emotional-related factors. Furthermore, academic success and emotional factors were found to have significant effects on balanced career and academic performance. Psychological stress factors also demonstrated a statistically significant, although weaker, relationship with balanced performance.

These results suggest that achieving balance between career and academic responsibilities is shaped by a combination of performance-related factors and stress-related conditions. In particular, the interplay between career development, academic outcomes, and emotional well-being plays a critical role in sustaining this balance.

From a practical perspective, the findings imply that young professionals may benefit from strengthening both their academic competencies and emotional coping mechanisms to effectively manage dual responsibilities. Institutions and employers may also consider providing structured support systems that address both performance demands and stress-related challenges.

However, given the limited sample size, the results should be interpreted with caution. Future research may expand the sample and incorporate additional variables to further validate and refine the proposed model.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to Mapúa University and their instructors for the invaluable guidance and encouragement that greatly contributed to the success of this study.

APPENDIX

Survey Questionnaire:

1) Career Success Indicators:
   - I find my current job or career to be fulfilling and meaningful.
   - I am satisfied with the opportunities for career advancement and promotions in my organization.

2) Academic Success Indicators:
   - I believe that the curriculum is designed to enhance both subject-specific knowledge and broader skills such as critical thinking and communication.
   - I am content that the assessments (exams, projects, etc.) used in my courses effectively measure the attainment of the learning outcomes.

3) Psychological Stress Factors:
   - I often set unrealistically high standards for myself, which can lead to stress and anxiety.
   - I frequently compare myself to others in terms of appearance, achievements, or success.

4) Emotional Stress Factors:
   - I make it a priority to take care of my physical health by staying active and maintaining a balanced diet.
   - I have a strong support network of friends and family members with whom I can openly communicate and seek guidance.

5) Balanced Career and Academic Performance Indicators:
   - I am generally resilient in the face of stress and can effectively cope with academic and career-related pressures.
   - I have a structured daily or weekly routine that helps me manage my academic and career responsibilities effectively.

AI in Education: Revolutionizing Learning and Personalized Instruction

Keywords: Automation in Education, Artificial Intelligence (AI), Educational Technology, Administrative Tasks, Personalized Learning, Teacher Support, Smart Classrooms, Data Privacy, Collaboration, Future of Education.

Abstract: Artificial Intelligence (AI) is quickly reshaping industries globally, and the field of education is particularly poised for transformative innovation. Conventional instructional approaches frequently find it difficult to meet the varied needs and speeds of students, often resulting in deficiencies in both understanding and involvement. In response to these shortcomings, technology leveraging AI has been deployed to enrich educational experiences and boost learning achievements. The purpose of this research is to investigate how AI is fundamentally changing education, specifically concentrating on customized learning, smart tutoring systems, and improved efficiency in administrative tasks. The study adopted a literature review approach, analyzing current academic studies, case analyses, and AI implementations across both compulsory (K-12) and post-secondary education sectors. The results show that AI substantially raises student performance by providing customized teaching, adaptive evaluations, and immediate feedback via Intelligent Tutoring Systems (ITS). Furthermore, predictive data analysis enables instructors to proactively identify vulnerable students, while automation solutions alleviate administrative pressures, including tracking attendance and grading. AI-driven accessibility and language translation tools also promote an inclusive environment by assisting students from varied linguistic and cultural origins. Ultimately, AI exhibits considerable promise for enhancing individualized teaching, boosting educational effectiveness, and broadening access to high-quality learning. Nevertheless, critical issues like ethical dilemmas, data security, and the potential for decreased human interaction in educational settings require careful consideration. In summary, AI is a powerful resource that can supplement existing teaching methods, guiding the development of an educational system that is more adaptive, accessible, and successful.

1 INTRODUCTION

1.1 Background and State of the Art

The swift progression of Artificial Intelligence (AI) has significantly impacted numerous sectors, with the field of education proving to be one of the most ripe for transformation [1], [2]. Incorporating AI technologies – such as machine learning, algorithms for adaptation, natural language processing, and predictive analytics – has fundamentally changed the methods by which knowledge is conveyed, absorbed, and evaluated [3], [4]. As educators globally aim to address the complex requirements of contemporary students, AI offers a solution to the limitations of standardized, universal instruction by facilitating dynamic, data-informed, and highly tailored learning environments [5], [6]. Within conventional classroom settings, instructors struggle to accommodate the varying aptitudes, interests, and learning preferences of all students simultaneously [7]. This difficulty often contributes to inconsistencies in student achievement, engagement, and understanding.

AI-powered tools – specifically automated assessment systems, adaptive learning platforms, and Intelligent Tutoring Systems (ITS) – are designed to overcome this issue by modifying both teaching methods and content in real-time to align with each student's specific requirements [8], [9], [10]. By analyzing data instantaneously, AI can detect trends in student behavior, forecast future performance, and deliver customized feedback that improves both retention and learning results [11], [12]. Furthermore, AI assists teachers by automating routine administrative responsibilities, such as managing attendance, grading assignments, and analyzing performance metrics [13], [14]. This benefit not only saves time but also frees up teachers to dedicate more attention to student mentoring, creativity, and direct interaction [15].

In university settings, AI applications are increasingly being embedded into Learning Management Systems (LMS) to provide customized course suggestions, detect plagiarism, and automatically generate feedback [16], [17]. The rapid shift to online and hybrid education following the COVID-19 pandemic [18], [3] has amplified the need for these capabilities, underscoring the necessity for scalable and responsive educational systems. AI is also vital for boosting educational access and inclusivity. Technologies like text-to-speech, speech recognition, and automated translation enable students with language barriers or disabilities to participate more effectively in learning activities [19], [20]. Early identification and proactive, tailored support for students at risk is made possible through predictive analytics [21]. These innovations are consistent with the worldwide push for equitable education, as set out in the United Nations Sustainable Development Goal 4 (SDG 4), which seeks to ensure universal access to quality and inclusive education [18].

Despite these hopeful advancements, introducing AI into education is not without its difficulties. Concerns remain regarding ethical usage, data privacy, algorithmic bias, accountability, and the preparedness of educators [4], [2], [12]. A potential hazard is that excessive reliance on automated systems could diminish crucial human interaction and empathy within the learning environment [15]. Moreover, existing differences in digital infrastructure between regions could exacerbate the educational disparity between well-resourced and technologically advanced institutions and those with limited resources [6], [17]. Consequently, a balanced strategy is essential – one that marries the computational capability of AI with expert human pedagogical judgment to deliver educational experiences that are meaningful, ethical, and learner-centric [1], [4]. This paper investigates the pivotal role of AI in education, highlighting its potential to transform both instruction and personalized learning. Specifically, the discussion covers the structure and operation of ITS, methods for representing knowledge and domain expertise, the advantages and drawbacks of AI-powered learning, and the automation of processes for administration. By conducting a critical review of recent theoretical and empirical studies, this work intends to clarify how AI can be utilized to improve both teacher effectiveness and student engagement while simultaneously tackling the practical and ethical hurdles of its integration into modern schooling [5], [13].

1.2 Research Gap and Questions

Despite the rapid increase in studies concerning AI's role in education, there is still a significant need for a comprehensive synthesis that clearly defines the precise teaching and learning mechanisms that yield better student results, alongside offering practical and ethical guidance for implementation. Current literature frequently focuses exclusively on the technological capacity of AI or engages in abstract discussions about ethics. This paper attempts to address this deficiency by systematically examining AI's application across three core areas – Intelligent Tutoring Systems (ITS), customized instruction, and administrative automation – and presenting tangible examples of existing systems along with their related ethical challenges.

Therefore, this article seeks to answer the following research questions:

1) What distinguishes AI-driven personalized learning methods from Intelligent Tutoring Systems (ITS), and what concrete evidence is available regarding their influence on student achievement and engagement levels?
2) Which administrative functions are principally being automated by AI in educational environments, and how does this automation impact the efficiency of institutions and the changing roles of educators?
3) What are the major ethical, pedagogical, and operational challenges linked to the widespread adoption of AI in education, and what mitigating strategies are proposed based on established international ethical guidelines?

2 THE ROLE OF AI IN EDUCATION

2.1 Overview of AI

AI is a branch of computer science dedicated to developing intelligent machines capable of performing tasks typically requiring human intellect. Key subsets of AI include machine learning (ML), natural language processing (NLP), expert systems, and computer vision. These technologies allow computers to simulate human intelligence through processes like pattern recognition, data analysis, human-like interaction, and decision-making. Formally, AI involves computational systems modeling human cognitive functions such as reasoning, learning, and problem-solving [22], [2]. Historically evolving from systems based on explicit rules, the concept, which originated in cognitive psychology and computer science, has advanced to modern deep neural networks and machine learning models that facilitate independent decision-making [13], [14].

Within the educational sphere, AI is broadly understood as using computational intelligence to bolster administrative functions, learning processes, and teaching [3], [4]. Current AI systems rely on several primary subfields: NLP, ML, robotics, computer vision, and expert systems [6], [8]. ML allows systems to analyze data patterns and continuously improve performance without being explicitly programmed [5]. Through text and speech comprehension, NLP enables smoother human-computer interaction, evident in educational virtual assistants and chatbots [19]. Computer vision enables features like automated remote proctoring, gesture recognition, and accessibility tools for disabled students [20]. Expert systems replicate the logic of human experts, while robotics provides opportunities for hands-on, practical experiences, especially in science, technology, engineering, and mathematics (STEM) fields [21].

The proliferation of Big Data, combined with enhanced computing power, has significantly sped up the adoption and development of AI in educational contexts [1], [11]. Intelligent Tutoring Systems (ITS), adaptive learning environments, and Learning Management Systems (LMS) now leverage real-time data analysis to optimize teaching strategies and customize content [12], [10]. For example, AI algorithms can track student interactions, predict their future learning path, and suggest specific resources to address knowledge gaps [4], [17]. These advancements are part of the larger movement toward data-driven education, where instructional decisions are constantly refined using evidence from digital feedback loops [16].

The influence of AI also increasingly covers institutional management and educational administration. Systems for automated resource allocation, enrollment prediction, and grading enhance operational effectiveness and decrease the workload on staff [15], [13]. Furthermore, AI-powered analytical tools assist educators and policymakers in evaluating institutional performance and curriculum effectiveness [2], [14]. By merging natural language comprehension and predictive analytics, institutions can implement early warning systems to identify and proactively support students facing academic difficulty [6], [12]. Despite these promising uses, AI remains a multifaceted, cross-disciplinary domain that integrates cognitive science, educational psychology, data analytics, and computer science [1]. Its effective deployment necessitates not only technological infrastructure but also a foundational understanding of pedagogy and ethical principles to ensure AI serves as a complement to, rather than a replacement for, human instruction [4], [8]. Consequently, educators and researchers must grasp the fundamental workings and mechanisms of AI to utilize its potential effectively and ethically in the pursuit of fair and personalized learning.

2.2 AI Applications in Education

AI has found diverse applications in education, altering traditional teaching models and opening up new possibilities for customized training and adaptive instruction. The following subsections outline key areas where AI is making a substantial impact on education.

2.2.1 Personalized Learning

The capacity of AI to deliver learning experiences tailored to the individual is one of its most compelling advantages in education. AI-driven systems are able to collect and process vast amounts of student data, including academic progress, performance metrics, preferred learning methods, and individual learning styles. Algorithms then leverage this information to customize educational materials, learning activities, and assessments to match the specific needs of each learner. By focusing on areas needing more attention and presenting suitable challenges to encourage continuous progress and engagement, personalized learning ensures that students advance through their education at a suitable pace.

2.2.2 Adaptive Learning Technologies

AI-enabled adaptive learning platforms have fundamentally revolutionized the classroom experience. These platforms continuously analyze and assess student responses, behavioral data, and performance results using machine learning algorithms. To optimize the learning process, adaptive platforms dynamically adjust the lesson content, difficulty level, and instructional speed, providing focused feedback, advanced challenges, and remedial resources. This adaptive methodology guarantees that every student receives individualized instruction by addressing their unique learning strengths and deficiencies.

2.2.3 Intelligent Tutoring Systems (ITS)

ITS are advanced AI platforms designed to replicate the individualized attention a human tutor provides. They use AI to interact with students, evaluate their comprehension, offer instructional guidance, and deliver corrective feedback to foster deep subject mastery and active participation. In contrast to more general adaptive systems, ITS typically incorporate a detailed domain model (representing expert knowledge) and a student model (reflecting the learner's current knowledge state) to inform pedagogical decisions, making them highly effective for mastering complex topics [8], [21].

2.2.4 Automated Administrative Tasks

AI technologies are also critical in automating a variety of administrative functions in educational settings. Grading stands out as a key area where AI has brought major advancements. Automated systems utilize machine learning to grade examinations, assignments, and quizzes, which drastically cuts down on the manual time required from educators. Furthermore, AI-powered analytical tools examine student data to pinpoint patterns, trends, and areas needing improvement, thereby empowering educators to make evidence-based decisions. By streamlining these administrative duties, AI provides teachers with more time to concentrate on instructional activities, personalized mentorship, and direct student engagement.

2.3 Benefits of AI in Education

The integration of AI into education has yielded substantial and transformative benefits across administration, learning, and teaching. Utilizing adaptive algorithms, data analytics, and computational intelligence, AI improves instructional personalization, efficiency, inclusivity, and decision-making capabilities [1], [4]. Beyond enhancing student outcomes, these advantages contribute to a more responsive and fair learning environment.

Equity and Individualized Instruction: AI enables individualized instruction, allowing teachers to effectively accommodate the varied learning styles and unique requirements of their students. By adjusting the pace and content, AI ensures optimal learning for every student.

Increased Engagement: AI fosters student motivation and participation through engaging and immersive educational experiences. Components like ITS and gamification keep students actively invested in the learning journey.

Improved Efficiency: AI boosts the efficiency of administrative operations, lessening the burden on educators and allowing them to focus more on student support and instruction.

Evidence-Based Decision-Making: AI supports decision-making informed by data, offering valuable insights into student performance, learning trends, and specific areas for development.

3 PERSONALIZED INSTRUCTION AND ADAPTIVE LEARNING

3.1 Differentiating Personalized Instruction, Individualized Learning, and Adaptive Learning

Personalized instruction is an educational philosophy that customizes the learning experience to align with a student's unique talents, interests, and requirements. It is founded on the recognition that students possess distinct learning preferences, styles, and existing knowledge bases, and therefore aims to match instructional methods and content to what is most appropriate for each learner. This approach moves beyond generic education models by striving to establish bespoke learning paths that maximize student achievement, motivation, and engagement. Although often used interchangeably, it is important to clarify the distinctions among three key terms:

- Individualized Learning. The main focus here is on the rate of progress. Students cover the identical curriculum but at a pace that suits them.
- Personalized Instruction. This goes beyond merely regulating the pace to actively

differentiate how and what students learn, modifying learning goals, content, and pedagogy based on demonstrated competence, individual needs, and interests. It centers on progression based on mastery.

- Adaptive Learning. This represents a mechanism driven by technology that instantaneously modifies instruction in response to a student's actions and performance. It employs AI algorithms (such as Bayesian knowledge tracing) to dynamically adjust the nature and complexity of the material or questions to immediately target specific learning deficiencies [2], [10]. Essentially, adaptive learning functions as a tool that facilitates personalized instruction.

3.2 AI-Powered Techniques for Personalization

AI technologies are fundamental to implementing personalized instruction. By utilizing machine learning algorithms, AI systems can gather, analyze, and interpret large datasets concerning each student. This data encompasses information such as their progress tracking, learning preferences, performance evaluations, and other relevant metrics. AI algorithms then use this analyzed data to create tailored interventions, adaptive learning routes, and unique recommendations. The core of personalization lies in AI's capacity to model the learner's current knowledge state and make dynamic, real-time adjustments to the content flow, instructional support, and sequence of material.

Adaptive learning systems use AI to dynamically adjust content, pacing, and difficulty based on real-time student performance [2], [10]. These systems rely on machine learning models that continuously analyze learner interactions – such as quiz responses, time spent on tasks, and error patterns – to predict knowledge mastery and suggest appropriate next steps [6], [21].

Example: Bayesian Knowledge-Tracing (BKT). Platforms like ALEKS and Knewton employ BKT models to map individual learning trajectories, ensuring that each student receives instruction suited to their current skill level [11], [12]. BKT algorithms calculate the probability that a student knows a specific skill based on their history of correct/incorrect answers, and then presents problems that are optimally challenging (the "zone of proximal development").

3.3 Adaptive Learning Technologies in Practice

One of the most significant practical applications of AI in personalized instruction involves adaptive learning technologies. Adaptive learning systems use AI algorithms to continuously evaluate and track student progress, subsequently adjusting the instructional pace and content to match. These systems are capable of identifying subjects where students struggle or excel, and then providing dynamically appropriate challenges, materials, and activities. By adapting to the specific requirements of learners, adaptive technologies refine the learning experience, promoting greater mastery of the subject matter, engagement, and understanding.

3.3.1 Machine Learning Algorithms in Adaptive Learning

The foundation of adaptive learning technologies is built upon machine learning algorithms. These algorithms analyze data trends, recognize patterns, and forecast students' learning styles, strengths, and existing knowledge gaps. As students interact with the adaptive system, their performance data and responses are constantly being analyzed, enabling the system to provide real-time, personalized and adaptive instruction. Furthermore, ML algorithms can utilize aggregated data from numerous students to refine and enhance the underlying adaptive learning models.

3.3.2 Real-Time Feedback and Remedial Support

Adaptive learning systems offer instant feedback on student performance, allowing students to immediately grasp their weaknesses and strengths. This rapid feedback loop empowers students to self-assess their comprehension and modify their study approach as necessary. Additionally, adaptive learning platforms are able to deliver customized remedial support, offering targeted resources and instruction to overcome areas of particular difficulty.

3.3.3 Customized Learning Paths

Adaptive learning technologies create customized learning paths for each learner based on their individual needs and progress. Learners can navigate through the content at their own pace, receiving

additional support or advanced challenges as necessary. The learning paths can be adjusted dynamically, ensuring that learners are appropriately challenged and engaged throughout their educational journey. Customized learning paths allow learners to take ownership of their learning, fostering autonomy and self-directedness.

3.4 Influence on Learning Outcomes and Student Engagement

Adaptive learning and personalized instruction have a substantial influence on student achievement and engagement. When instruction is customized to individual preferences and needs, students are more likely to be motivated and take an active role in their learning. Adaptive learning platforms maintain consistent student engagement by delivering challenging and relevant materials. Moreover, personalized instruction fosters a deeper command of the subject matter by addressing specific knowledge gaps and building upon prior knowledge. Consequently, students see better academic performance, including greater retention, higher levels of mastery, and improved overall learning outcomes.

4 INTELLIGENT TUTORING SYSTEMS

4.1 Defining Intelligent Tutoring Systems (ITS)

ITS constitute a class of educational technology that utilizes AI to deliver personalized support, instruction, and guidance to students. Their core purpose is to simulate the high degree of effectiveness seen in one-on-one human tutoring, which is widely recognized as one of the most impactful teaching modalities. Unlike static instructional software, an ITS engages with students interactively, adapting the teaching sequence based on the learner's evolving knowledge state, correcting misconceptions, and offering immediate feedback [8], [21].

A typical ITS is composed of three interconnected modules:

- Domain Model. This module stores the foundational expert knowledge, key concepts, and problem-solving methods for the subject being taught.
- Student Model. This component monitors the student's current understanding, learning rate, progress, and areas of confusion.
- Pedagogical Model. This module determines the instructional strategy, specifically how and when to intervene, and what content to present next, by drawing insights from both the student and domain models.

4.2 Domain Expertise and Knowledge Representation in ITS

The specialized knowledge and expertise of a subject form the necessary underpinning of ITS. These systems operate using extensive knowledge bases and expert models relevant to the material being taught. These models enable the ITS to accurately assess student performance, deliver justifications, and provide relevant feedback and guidance. Foundational to any AI-driven educational platform is effective knowledge representation. This dictates how the relationships, skills, and subject matter knowledge are organized, stored, and accessed by the intelligent algorithms [22], [14]. In the realm of AI in education, domain expertise signifies the system's ability to imitate the instructional approaches and cognitive comprehension of human subject-matter experts [21], [9]. This is achieved using diverse formalisms for representation, such as Bayesian networks, semantic networks, and production rules, which allow the ITS to execute sophisticated reasoning tasks like diagnosing errors, solving problems, and generating customized learning content [10], [15].

4.2.1 Student Modeling and Assessment

Each learner's unique traits, knowledge, abilities, learning preferences, and progress are captured in a comprehensive model that ITS build. Learner interactions and performance data are used to continuously update these models. To evaluate the learner's comprehension, spot knowledge gaps, and decide on the right amount of instructional support, the system uses AI algorithms.

4.2.2 Instructional Strategies and Feedback

To enhance learning, ITS use a range of teaching techniques. They can present instructional content through multimedia resources, interactive activities, and virtual simulations. Learners receive real-time feedback from the system, which fixes mistakes, rewards accurate answers, and provides clarifications when necessary. A deeper comprehension of the material is encouraged by the feedback, which is customised and suited to each learner's unique needs.

4.2.3 Adaptive Instruction and Scaffolding

ITS capacity to modify instruction to meet each student's unique needs is one of their main advantages. The system offers advanced challenges for proficient learners, offers extra practice or remedial resources for difficult concepts, and dynamically modifies the tasks' level of difficulty. By ensuring that students are suitably challenged and assisted, this adaptive approach fosters ongoing development and mastery.

4.3 Limitations and Advantages of ITS

The adoption of ITS in education has shown significant promise for improving learning and teaching outcomes across numerous subjects. By integrating cognitive science, AI, and data analytics, ITS deliver personalized learning experiences that adapt to individual student requirements, promoting deep understanding and continuous engagement [21], [14], [15].

- Customized Support and Instruction. ITS, leveraging AI, provide individualized support and teaching based on the distinct requirements of each learner. The system modifies itself based on the student's unique learning preferences, progress, and knowledge gaps, ensuring that instruction is delivered at an appropriate pace. This bespoke strategy enhances motivation, engagement, and learning outcomes.
- Individualized Assessment and Feedback. ITS offer immediate, highly targeted feedback on performance, a crucial element often absent in conventional classrooms. This rapid, error-specific feedback facilitates instant correction and more effective learning for students. Furthermore, ITS enable ongoing, non-disruptive assessment, replacing traditional high-stakes testing with formative evaluation that continuously guides the learning process.

However, integrating ITS also faces several hurdles:

- High Development Costs and Required Expertise. Creating a comprehensive and effective ITS demands significant time, substantial development effort, and profound domain expertise. The considerable initial investment in funding, time, and specialized knowledge can hinder widespread implementation.
- Transferability and Scalability. An ITS designed for one domain may not be easily or successfully applied to another. ITS often have a high degree of domain specificity, which restricts their general applicability and transferability across different educational contexts and subjects.
- Emotional and Social Factors. ITS frequently prioritize cognitive aspects of learning, often neglecting the emotional and social dimensions. While they offer customized instruction, ITS cannot fully replicate the emotional support and social interactions provided by human educators.
- Ethical Concerns. The use of AI in education, including ITS, raises numerous ethical questions. Privacy and security for student data must be rigorously protected. To prevent unfair discrimination or bias, the underlying AI algorithms must be transparent and understandable.
- Risk of Over-Reliance. A notable pedagogical concern is the potential for excessive dependence on technology. Over-automation may reduce human connection and emotional involvement, both essential for cultivating critical thinking skills and motivation [17], [16].

5 AUTOMATION OF ADMINISTRATIVE TASKS IN EDUCATION

5.1 Overview of Administrative Automation

AI-powered automation is becoming increasingly central to optimizing the administrative and operational duties of educational organizations. Beyond direct classroom teaching, AI is now being integrated into the educational sphere to automate essential administrative functions that are critical for efficient institutional operation. By automating repetitive and time-intensive administrative tasks, institutions empower staff and teachers to dedicate more energy to strategic, student-focused, and pedagogical activities [14], [2]. Through the use of intelligent algorithms, natural language processing (NLP), and machine learning, institutions can manage routine operations with greater accuracy, efficiency, and financial prudence [21].

5.2 Key Areas of Administrative Automation

AI is currently being employed to automate a wide spectrum of administrative duties across higher education, secondary, and primary levels:

5.2.1 Registration and Student Enrollment

The processes of student registration and enrollment can be streamlined through automation, improving the management and collection of student data. Automated online registration forms, document uploads, and data entry systems substantially lessen the manual effort required by administrative personnel. Moreover, automation facilitates real-time data validation, which ensures that student records are accurate and current, thereby supporting improved resource allocation and planning.

5.2.2 Automated Feedback Generation and Grading

AI tools are increasingly used for the automated grading of various assessments, particularly essay questions, short answers, and multiple-choice tests [16], [17]. Systems use NLP and machine learning algorithms to accurately evaluate student responses against predefined assessment standards. AI is also capable of going beyond simple score assignment to generate tailored, constructive feedback on student submissions, which saves instructional time and accelerates the student learning cycle [23].

5.2.3 Monitoring and Attendance Tracking

AI is enabling a shift from traditional manual attendance procedures to automated monitoring systems. AI platforms can automatically log and track student presence by integrating with LMS log-in data, utilizing Wi-Fi tracking in classrooms, or employing facial recognition technology. This not only enhances the precision of attendance records but also provides instant data that can be used to promptly identify and address problems related to absenteeism.

5.2.4 Resource Management and Scheduling

Optimization algorithms rooted in AI can generate highly efficient academic schedules, considering factors like pedagogical needs, classroom availability, teacher workload, and student enrollment. Automated scheduling minimizes scheduling conflicts and optimizes the utilization of resources (e.g., equipment, lab facilities), thus reducing the time administrative staff spend on manual adjustments and rescheduling.

5.2.5 Data Analysis and Report Generation

The automation of generating various reports – including student progress summaries, attendance reports, and financial statements – is possible to save time and ensure data accuracy. AI-driven data analytics tools can analyze institutional data to predict future needs (e.g., budget, enrollment), identify emerging trends, and support strategic decision-making by institutional leaders [14], [2].

5.3 Advantages of Automating Administrative Tasks

The application of AI to automate administrative processes represents a major development in modern education management. By employing predictive analytics, NLP, and machine learning, educational institutions can streamline their operations, boost productivity, and improve service delivery [14], [2].. Automating these tasks also reduces human error and workload, freeing up time for both teachers and administrators to focus on high-quality instruction, strategic planning, and deeper student engagement [15], [21].

- Resource and Time Savings. Automation of administrative duties allows administrators and educators to conserve a significant amount of time. By spending less time on manual labor, they can concentrate on high-priority activities such as instructional planning, curriculum development, and student support.
- Consistency and Accuracy. Automated systems process data with high levels of precision, which drastically minimizes the human errors commonly linked with manual grading, data entry, and record-keeping. This ultimately enhances the consistency and trustworthiness of institutional data.
- Support for Strategic Decisions. AI-driven data analysis and reporting offer timely, reliable insights into resource utilization and institutional performance for school leaders. This facilitates evidence-based and more informed strategic planning.

5.4 Ethical Considerations and Challenges in Administrative Automation

While administrative task automation offers many advantages, it also presents complex practical and ethical concerns [25]:

- Security and Data Privacy. The process relies on gathering and processing sensitive information about staff and students, making strict compliance with data privacy regulations (e.g., FERPA, GDPR) and robust cybersecurity measures absolutely mandatory.
- Algorithmic Bias. When algorithms used for predictive modeling, admissions, or resource allocation are trained on historical data that exhibits bias, they risk reinforcing or even amplifying systemic prejudices against certain demographic groups.
- Accountability and Transparency. The lack of transparency, sometimes called the "black box" problem, associated with specific AI algorithms makes it challenging to explain the reasoning behind automated decisions, which is a major ethical issue when these decisions involve high-stakes outcomes like resource distribution or a student's academic status.
- Job Displacement and Change Management. Implementing automation necessitates substantial investment in staff training and infrastructure. A legitimate concern exists that automating administrative tasks could result in job losses for support staff, necessitating proactive strategies for staff retraining and role reassignment.

5.5 Mitigation Strategies

To ensure that administrative automation is deployed both effectively and ethically, institutions should follow these guidelines:

- Maintain Human Oversight. Decisions deemed critical, especially those with significant personal consequences, must always be subject to human review and supervision, with AI serving purely as a tool for recommendation.
- Conduct Bias Audits and Ensure Fairness. Automated systems must be regularly tested and audited for algorithmic bias across all demographic lines to guarantee equitable results.
- Enforce Strict Data Governance. Implement clear policies for data governance and robust measures for data security that comply with all pertinent privacy laws.
- Focus on Augmentation, Not Substitution. Automation of administration should be viewed as a tool to enhance staff capabilities and free up time for high-value human tasks, rather than a method for reducing staff numbers to cut costs.

6 CONCLUSIONS

The way educational institutions run could be completely changed by automating administrative duties, giving administrators and teachers more time and resources to devote to more worthwhile endeavours. Administrative procedures like scheduling, grading, student enrolment, attendance tracking, and report generation can be made more efficient, accurate, and data-managed by utilising technology and AI.

AI also offers powerful tools for revolutionizing the core of education: teaching and learning. Through ITS and adaptive learning technologies, AI enables true personalization by dynamically adjusting content and pacing to meet the unique needs and knowledge state of every student, leading to higher mastery and engagement [21].

The implementation of automation and AI in education presents certain challenges, including infrastructure constraints, equity concerns, data privacy issues, and resistance to change. However, these challenges can be addressed with careful planning, ethical considerations, and training. It is essential to make sure that automation is applied in a way that respects privacy, is inclusive, and does not reinforce prejudices or discriminate against particular people or groups.

Educational institutions can establish a more productive and efficient administrative environment by embracing automation in the classroom, which will ultimately benefit students, teachers, and the educational community as a whole. While administrators can strategically manage their time and resources, educators can concentrate on their primary duties of teaching, curriculum development, and student support thanks to automation. In order to establish a learner-centred educational ecosystem, it is critical to modify automation strategies and remain proactive in seizing new opportunities as technology develops.

Keywords: KPI, Automation, Defect Recognition, Machine Learning, Convolutional Neural Network, Packaging.

Abstract: The paper presents a comprehensive study aimed at improving the efficiency of the mayonnaise manufacturing and packaging process by analyzing the key performance indicators of the mayonnaise making machine, developing the structure of a packaging quality recognition system, and modeling a convolutional neural network to identify packaging defects. The article analyzes key performance indicators for productivity, energy efficiency, product quality and equipment downtime. A system has been developed for recognizing the quality of packaging, which is part of the indicator of the level of product defects, based on the use of modern machine vision algorithms. The final part of the study presents the results of modeling and training a convolutional neural network for automatic detection of packaging defects. Experimental results demonstrate a high level of accuracy and reliability of the proposed system, which makes it possible not only to timely identify defective products, but also problems in the operation of the machine in the early stages of its operation. This in turn helps reduce waste, improve production process efficiency and reduce maintenance costs.

1 INTRODUCTION

Improving the efficiency and quality of production processes is a key challenge for the modern food industry. The production of mayonnaise as one of the popular food products requires special attention to quality control at all stages of the production cycle. One of the most important components of this process is the analysis of key performance indicators (KPIs) [1], [2] of production equipment, which allows timely identification of problems and optimization of machine operation.

In addition to control over the production process, the quality of the final product, in particular its packaging, is also important. Packaging defects can lead to significant losses for both the manufacturer and the consumer. Incorrect or damaged packaging not only detracts from the appearance of the product, but can cause mayonnaise to spoil due to the penetration of air or bacteria. This leads to a reduction in expiration date, possible complaints from consumers and additional costs for processing or disposal of defective products [3]. Therefore, the development of an effective system for recognizing packaging defects is a necessary condition for ensuring high quality standards [4]-[6].

In this context, machine learning and modern image processing techniques play an important role in automating quality control processes. Convolutional neural networks (CNNs) have proven to be a powerful tool for pattern recognition and can be effectively used to identify defects in product packaging [7], [8]. However, confidence is required regarding the capture of individual defects characteristic of the process being studied. Such defects, in addition to the typical obvious tears, damage and missing parts of the packaging, also include the absence of a manufacturing date and a significant printing defect. Using CNN in combination with KPI analysis opens up new

opportunities for automating quality control and increasing production efficiency.

The goal of this research is to create an integrated system that combines analysis of mayonnaise machine KPIs, system structure for packaging quality recognition, and CNN modeling for defect detection. The combination of these aspects will not only improve the quality of the final product, but also ensure timely identification and elimination of problems in the operation of production equipment.

2 LITERATURE REVIEW

Performance measurement and management methodology (PMM) provides management with many critical, useful and necessary functions and consists of three stages: performance planning, performance improvement and performance analysis [9]. Equipment KPIs are typically used to identify problems related to equipment performance. These include: low productivity, frequent breakdowns, high maintenance costs. Careful analysis and monitoring of key performance characteristics allows tracking changes in equipment performance and reliability [10], [11]; make informed, timely decisions to relevant specialists regarding drawing up plans for various types of repair work, modernization or replacement of equipment; optimize costs for equipment maintenance and repair, improve product quality[12]. KPIs must be measurable, achievable, relevant and timely.

KPIs are also tools for management, decision support and forecasting [13]. Accurate performance forecasting allows you to refocus decisions to optimize performance while reducing cost and effort. For this purpose, various methods of artificial intelligence [14], machine learning [15]-[17], etc. have been actively used recently.

In the production of mayonnaise, packaging defects can affect the quality of the product, its shelf life and demand. The main types of packaging defects include deformation, problems with the lid, printing defects on the packaging, and mismatched labels.

The article uses two main methods to achieve the research goal: analysis of key performance indicators (KPIs) of production equipment, development of a system for recognizing packaging quality, and CNN modeling for identifying packaging defects.

3 METHODS

Considering [1], [2], it can be argued that KPIs of equipment for the production of mayonnaise are a set of indicators used to quantify the performance and reliability of the equipment. For sauce production equipment, the following KPIs can be distinguished (Fig. 1): productivity (the amount of sauce that can be produced by the equipment per hour, day or week), downtime (the time during which the equipment does not work due to breakdown or maintenance), maintenance costs (the total cost of all types of expenses associated with equipment maintenance), uptime (operation time (may be an average indicator) of equipment without breakdowns), product quality (sauce quality), energy efficiency (the amount of energy resources used by the equipment during mayonnaise production), resource efficiency (amount of resources (except energy) used by the equipment in the production of sauce), defect rate (proportion of products that do not meet standards from the total production volume), packaging deficiency (percentage of sauce packs that do not meet quality standards and must be removed from the line.

Cloud platforms provide centralized data storage, processing and visualization, which helps identify trends, predict failures and optimize production processes. Visualization of key performance indicators is carried out using dashboards that provide clear graphs, charts and other visual elements for monitoring that meet quality standards), uptime (measured as total uptime without failures), resource efficiency (use of ingredients and energy), failure and downtime rates, and identification of packaging shortages.

To effectively use KPIs, it is necessary to improve the data collection and analysis system, which is integrated into the production process and includes industrial Internet of Things (IoT) architecture. Integration of other KPIs into the cloud is carried out through field buses of the machine control system and IoT gateway (for example, Raspberry Pi). The IoT gateway acts as a central node that collects data from various sensors and devices (Fig. 2 also shows exchange protocols), including cameras that monitor the quality of packaging. The IoT gateway processes data on site and transfers it to the cloud for further analysis and storage of production processes in real time. As a dataflow development platform, Node-RED is the ideal tool for creating such dashboards.

Dashboards created in Node-RED can be accessed through web interfaces or specialized applications on phones and tablets, allowing you to quickly respond to changes and make informed decisions. This makes production management more flexible and efficient, helping to improve overall productivity, reduce costs and ensure high product quality.

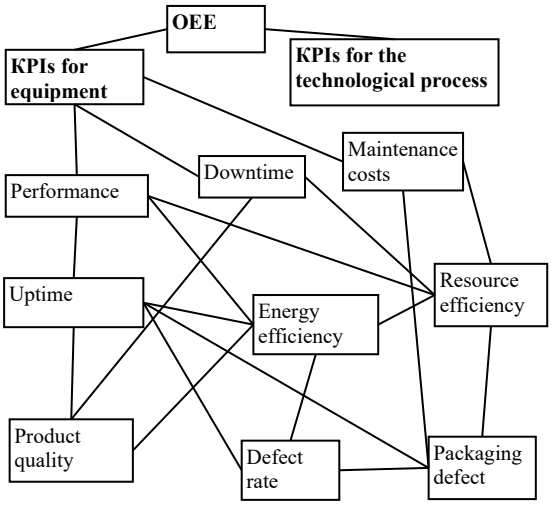

Figure 1: KPIs connection diagram for mayonnaise production.

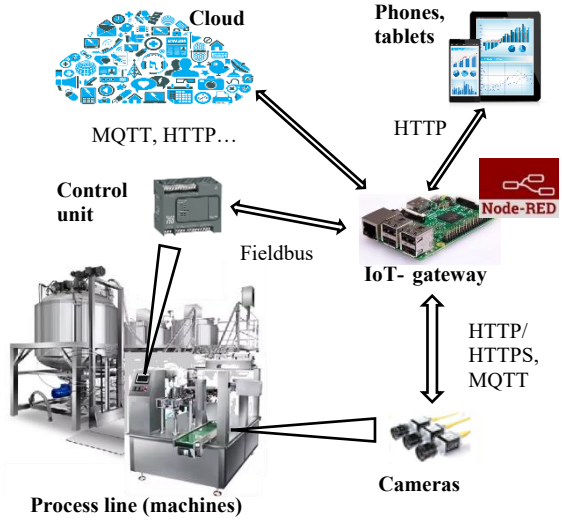

Figure 2: Automated control system with integration.

CNN modeling for mayonnaise packaging defect detection involves data collection and annotation, image pre-processing, model building and training, and model performance evaluation. The images are captured using high quality cameras installed on the production line. To ensure data diversity, images are collected from different angles, under different lighting conditions and with different types of defects implemented (simulated) by the developer. To quickly implement the system, several training samples were collected and a decision was made to use pre-trained models. The images are manually annotated to label defects (Fig. 3).

Transfer learning [18] is a popular deep learning method that uses already trained models for new tasks. This approach offers significant benefits, making training faster, more accurate and cost-effective. Pre-trained models have knowledge of basic features and patterns, saving time and resources that would otherwise be spent on training from scratch. This leads to better results, especially when the data set for a new problem is small or limited. Transfer learning helps avoid overfitting and saves computing resources. However, transfer learning also has disadvantages. Models may not be flexible for specific tasks, and retraining may require significant resources. There are also architectural limitations, risk of overfitting, licensing restrictions, influence of biases and knowledge limitations. Therefore, it is recommended to use transfer learning as a quick start, and then, after collecting a representative sample of typical defects, retrain the model from scratch for better adaptation to the task.

Figure 3: Examples of a dataset for recognizing packaging defects.

Before using the image to train the model, pre-processing is carried out, including: normalization, reducing pixel resolution to reduce computational complexity to 620x288, data augmentation (rotation, horizontal and vertical display, changing brightness and contrast) to increase data diversity.

The model architecture includes the following layers:

- base model without an upper classification layer, which allows you to save all pre-trained features.
- Global Average Pooling 2D to reduce spatial dimensions and obtain one value for each channel.
- Dense layer – a fully connected layer with 1024 or 512 neurons for additional training on a new data set.
- Dropout layer to reduce overtraining by randomly disconnecting neurons during training, values of 0.05 and 0.2 were used.
- the original layer with the softmax function for classifying the presence of defects.

To train the model, we used the binary cross-entropy loss function and the Adam optimizer. The batch size is the entire set, the number of epochs is 20. To evaluate the performance of the model – the proportion of correctly classified images, taking into account that the number of defective and normal samples is the same, the Accuracy metric was used.

4 SIMULATION RESULTS

Python and R programming languages were used to develop the CNN model for rapid implementation. Python was used to develop and train the CNN model using libraries such as TensorFlow or PyTorch. R, known for its statistical and visualization capabilities, is used for data preprocessing and analysis of results.

Table 1 shows the results of training the specified network with different hyperparameters. Apparently, the accuracy on the test set for the last two architectures is 1.00, that is, the model achieved an ideal result, classifying all images without errors. This indicates the model's strong ability to recognize packaging defects, although further testing on more diverse data sets may be required to confirm the generalization ability of the model.

Table 1: Training results.

Architecture for CNN	Loss		Accuracy	
	Training set	Test set	Training set	Test set
1. n_dense=1024, dropautrate=0.05	0.31	0.93	0.65	0.50
2. n_dense=1024, dropautrate=0.2	0.34	0.91	0.32	1.00
3. n_dense=512, dropautrate=0.2	0.37	0.89	0.34	1.00

For test samples p_i, (where i=1,2,3 is the network architecture), a detailed determination of the probability of the presence of non-defective packages is presented. Figure 4 shows four samples from the test set.

The probability for the first architecture on all samples is less than the threshold (threshold =0.5), that is, even good samples are classified as bad – here the model is clearly overtrained. The second and third architectures have different p_i values. Considering that when the model is functioning, it is unacceptable for defective products to reach the manufacturer, the second architecture was finally chosen. This choice was also confirmed by considering Learning curves (Fig. 5).

The implementation of the developed CNN model in Node-RED can be done through special nodes that allow to run Python code. In addition, there are nodes that allow to run R scripts, which integrates statistical analysis directly into the data stream. This combination of Python and R provides a flexible and powerful system for automatically detecting packaging defects, which improves the efficiency of the developed model.

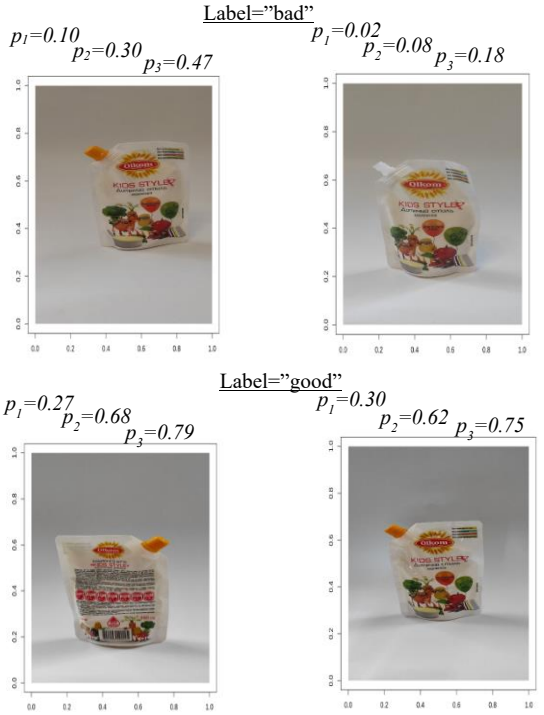

Figure 4: Test results.

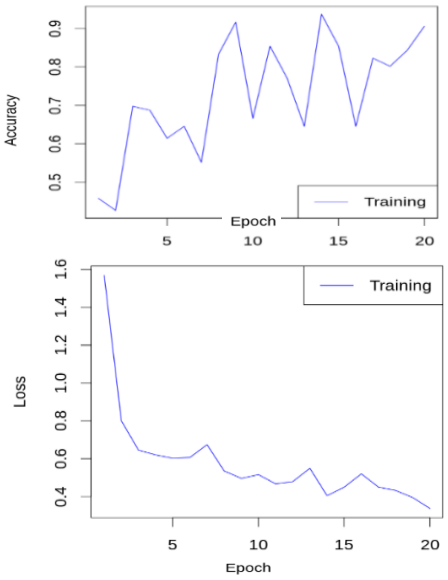

Figure 5: Learning curves on the training sample.

5 CONCLUSIONS

An integrated system for efficient mayonnaise production management, including a packaging quality control module, was successfully developed.

1) The IoT-based KPI monitoring system provides automated real-time data collection and visualization, enabling the timely tracking of productivity, downtime, and defect rates to optimize equipment operation.
2) The packaging defect recognition subsystem was implemented using a CNN model with the Transfer Learning approach.Experimental results demonstrate high accuracy: two CNN architectures achieved an accuracy of 1.00 on the test set. Based on learning curve analysis and reliability requirements, an architecture was selected to minimize the passing of defective products.
3) The proposed integrated system significantly reduces the number of defective products, improves the overall efficiency of the production process (OEE), and lowers the costs associated with error correction and maintenance.

Future work will focus on gathering a more representative defect sample to retrain the model from scratch, thereby improving its generalization ability.

Keywords: Visual SLAM, RTAB-Map, Indoor Mapping, Smart Walking Aid, Assistive Technology, Edge Computing.

Abstract: The underlying research project aims to enhance independent mobility for elderly users by enabling indoor navigation assistance in a smart walking aid. A robust mapping system is crucial for such a device to ensure safety, effectively avoid obstacles, and create an optimal navigation path for users. Current approaches often rely on expensive sensors (e.g. LIDAR) or suffer from drift in unstructured environments. This paper proposes an optimized Visual SLAM solution based on the RTAB-Map framework for indoor mapping with a walking aid-mounted RGB-D camera. The method leverages appearance-based loop closure detection and parameter optimization to reliably generate both 2D occupancy grids and 3D point clouds under challenging conditions, like rooms located on different levels and transitions between rooms that are difficult to detect due to their layout. Indoor experiments demonstrate that the optimized system successfully handles typical walking aid motions and indoor scene features, achieving accurate reconstruction of corridors and rooms. Mapping accuracy is validated against the floor plan, showing lower drift than the baseline Visual SLAM setup. The results indicate that RTAB-Map, with proper parameter tuning, provides a solid and cost-effective mapping solution for assistive walking aid platforms, facilitating safe navigation support for the elderly.

1 INTRODUCTION

By the middle of the 2030s, the number of people in Germany at retirement age is expected to increase by approximately 4 million to at least 20 million, as seen on Figure 1. The number of individuals aged 80 or over will remain stable initially, but is expected to rise significantly after the mid-2030s [1], likely leading to a higher demand for long-term care. These demographic changes pose challenges for society that are already visible in today's age structure.

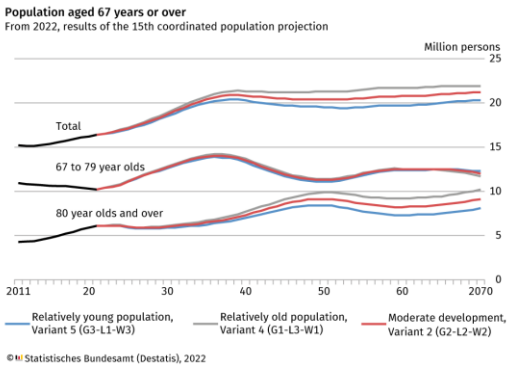

Figure 1: German population projection [1].

To address this trend, the AktiMuW[1] project [2] was initiated to provide an ageing population with a degree of autonomy by integrating technical solutions into a conventional walking aid. In addition to key functions such as sensor fusion-based analysis of body posture [3] and machine learning-based detection of potentially hazardous objects to respond to the high risk of injuries and mortality in road traffic accidents that pedestrians face with increasing age [4], another goal is to assist users in navigating indoor spaces (e.g., living environments, care facilities), which motivates integrating a Visual SLAM (Simultaneous Localization and Mapping using cameras) system on the walking aid. Visual SLAM [5] enables a device to map unknown environments and localize itself without GPS. RGB-D and stereo cameras provide both visual and depth, making them well-suited for robust indoor SLAM tasks. Combining with robotic interaction and reinforcement learning enables to handle objects [6].

This work investigates the use of RTAB-Map (Real-Time Appearance-Based Mapping) [7] on a walking aid-mounted stereo camera and an embedded GPU board. RTAB-Map is an open-source Visual SLAM framework that incrementally builds 3D maps

[1] https://www.hs-anhalt.de/aktimuw/uebersicht.html

with appearance-based loop closure. It is ROS2-compatible (Robot Operating System 2) [8] and can run on resource-limited hardware.

Few studies explicitly explore vision-based SLAM on walker-like aids. Notably, Panteleris and Argyros developed the c-Walker – a rollator platform equipped with an RGB-D (Kinect) camera – and implemented a Visual SLAM system that simultaneously tracks moving objects and builds a 3D map of the static environment. They report real-time mapping on the walker with low-end CPUs [9]. Feltner et al. also describe a Kinect-based rollator for the visually impaired, pointing out that a Kinect and Visual SLAM approach is promising for the c-Walker [10]. In summary, the only published SLAM work on rollator-style devices we found involves specialized walkers with RGB-D cameras (e.g. the c-Walker). To our knowledge, no prior work has run modern feature-based SLAM (RTAB-Map, ORB-SLAM3, etc.) on a standard push-style rollator. Thus, applying an up-to-date visual SLAM framework on a commodity walker as a modular system remains novel.The main contribution integrates a ZED Mini stereo camera and Jetson Orin Nano into a ROS2-based SLAM pipeline; correcting TF transforms for consistent spatial frames; optimizing SLAM parameters (e.g., switching from GTFF/ORB (Good Features To Track / Oriented FAST and Rotated BRIEF) [11] to KAZE (jap. wind) [12] feature descriptor); and demonstrating stable 2D/3D mapping results in real indoor environments.

2 COMPARISON OF SLAM FRAMEWORKS

Recent SLAM systems for indoor embedded use were compared to find the most suitable approach. ORB-SLAM3 (Oriented FAST and rotated BRIEF) is highly accurate (monocular/stereo/RGB-D, can fuse IMU) but requires a powerful CPU/GPU to run in real time; it “outperforms others in accuracy” on desktop hardware [13]. VINS-Mono and other VIO systems (Visual-Inertial Odometry) use inertial data to improve robustness, but still strain embedded CPUs [14]. DSO/SVO (Semi-/Direct Sparse Odometry) are direct methods (no feature extraction) that can run on grayscale cameras; they track well on textured scenes but easily drift or fail in low-texture or changing light [15]. In one study on an Nvidia Jetson TX1, DSO had much higher drift (Absolute Trajectory Error RMSE ≈0.46 m) than ORB-SLAM (≈0.17 m) or RTAB-Map [15]. RTAB-Map is a graph-based SLAM that supports RGB-D or stereo and loop closures in ROS2; it is widely used for robotics and can run on CPU-only boards. In the same Jetson test, RTAB-Map achieved one of the lowest errors (≈0.16 m) and compared favorably with ORB-SLAM [15]. RTAB-Map was chosen for our walker prototype because it supports RGB-D input, is ROS2-ready, and has proven performance on embedded platforms [16]

3 SYSTEM COMPONENTS

In this section, we outline the system architecture for our indoor mapping solution, featuring a robust integration of hardware and software components. The Nvidia Jetson Orin Nano and Stereolabs ZED Mini provide the necessary computational and sensory capabilities. The ROS 2-based software stack orchestrates data processing and communication, enabling real-time map generation via Visual SLAM.

3.1 Hardware

Nvidia Jetson Orin Nano: Selected for its balance of compute performance (up to 67 TOPS at 25 W) and compact form factor. The single-board computer’s (SBC) Ampere GPU generalizes to various parallel SLAM tasks, while its ARM CPU cores handle ROS2 middleware and peripheral integration.

Stereolabs ZED Mini: A stereo camera providing synchronized 1080p RGB streams at up to 30 fps and depth maps via hardware disparity calculation. It features a built-in IMU (6-axis gyroscope + accelerometer) at 800 Hz sampling, facilitating visual-inertial odometry.

Walking Aid Platform: A standard four-wheel walking aid instrumented with a rigid mount for the camera and an under-seat housing for the Jetson Orin Nano. Power is supplied via a portable battery capable of a stable 20 V/5 A output (per USB-PD profile).

Smartphone: A regular Android smartphone was selected for wireless and convenient visualization of the SBC’s desktop.

The fully assembled walking aid platform can be seen in Figure 2. The SBC is mounted in a specially designed device carrier under the seat. The stereo camera rests in a holder on the bend of the left handle from the user's perspective.

3.2 Software

The software architecture mainly focuses on ROS 2 (Humble Hawksbill). It provides Data Distribution

Service (DDS)-based publish–subscribe messaging, node lifecycle management, and real-time QoS configuration. For camera the ZED Wrapper is an official driver, packaging the ZED SDK into ROS2 nodes, exposing topics for left/right RGB images, depth images, point clouds, IMU data, and visual-inertial odometry. With RTAB-Map, a ROS2 node encapsulating the RTAB-Map core functions. It subscribes to camera and odometry topics, executes SLAM threads internally, and publishes 2D occupancy grids, 3D point clouds, and pose trajectories. Rviz2 is used for visualization and real-time monitoring of SLAM outputs, including map rendering and trajectory display.

Figure 2: AktiMuW walking aid platform with stereo camera and SBC mounted under the seat.

4 PRELIMINARY WORK

Initial map outputs exhibited warped and misaligned point clouds. Inspection of the ROS2 transformation tree revealed the absence of a transform edge between the base_link and zed_left_camera_optical_frame, preventing correct pose propagation. Additionally, the ZED optical frame conventions differed from ROS's REP-103 [17] conventions, causing rotated axes to be interpreted incorrectly.

4.1 Frame Correction

A zero-offset static transform was published to connect base_link to zed_left_camera_optical_frame:

```
ros2 run tf2_ros
static_transform_publisher 0 0 0 0 0 0
base_link zed_left_camera_optical_frame
```

This closed the TF gap, but the point cloud remained rotated as seen in Figure 3.

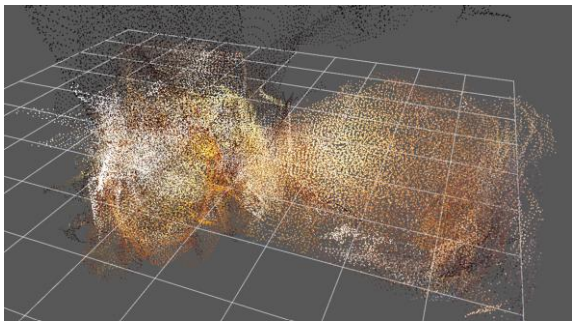

Figure 3: Distorted point cloud of a room after a 360° horizontal camera turn.

4.2 Axis Alignment

After examining the optical frame conventions of ROS2 and the camera, it became apparent that there is a discrepancy in the alignment of the optical axes (see Table 1).

Table 1: Comparison of ZED Wrapper and ROS2 Optical Frame Conventions and required Transformation.

Axis	ROS2 Optical Frame Convention	ZED Wrapper Optical Frame Convention	Required Transformation
X / Roll	Forward	Right	Right (ZED) → -90° → Forward (ROS2)
Y / Pitch	Left	Down	Not required due to other applied transformations
Z / Yaw	Up	Forward	Forward (ZED) → -90° → Up (ROS2)

The camera's optical axes require 90° (−π/2 radians) rotations about the roll and yaw axes to align with ROS2 conventions.

Additionally, the camera center sits approximately 90 centimetres above the walking aid's base. The final static transform command was:

```
ros2 run tf2_ros
static_transform_publisher 0 0 0.9 -
1.5708 0 -1.5708 base_link
zed_left_camera_optical_frame
```

After this update, the point cloud aligned correctly with the physical environment as seen in Figure 4:

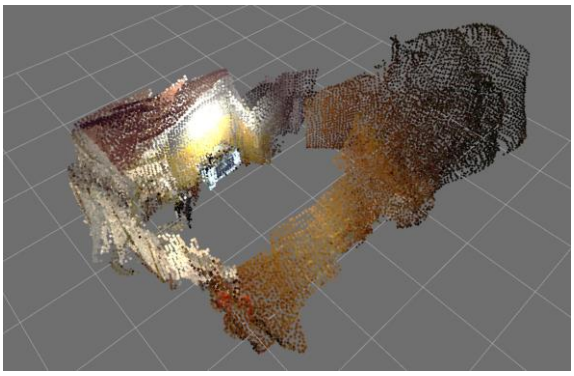

Figure 4: Corrected point cloud of a room after a 360° horizontal camera turn.

4.3 Selection of a Test Environment

The selected test environment is intended to resemble a living environment due to its varied structure and arrangement. A 47.52 m² office space, rich in differentiable characteristics (features), alternates with a 25.2 m² feature-poor entrance hall with complex geometry, which leads into further small bathrooms as seen in Figure 5.

Figure 5: Floor plan of the selected test environment.

Another distinctive characteristic is that the office space is situated 73 cm above the entrance hall, which means that the mapping algorithm is also required to overcome a certain height difference.

5 MAPPING RESULTS

As mentioned beforehand, the entrance hall and the two bathrooms have very few distinctive features, so this area of the test environment was primarily used for the baseline performance test and optimization process.

5.1 Baseline Performance

With the default settings (camera angle 0°, no depth limit, default settings for RTAB map functions), the initial mapping in the entrance hall exhibited several deficiencies as seen in Figure 6.

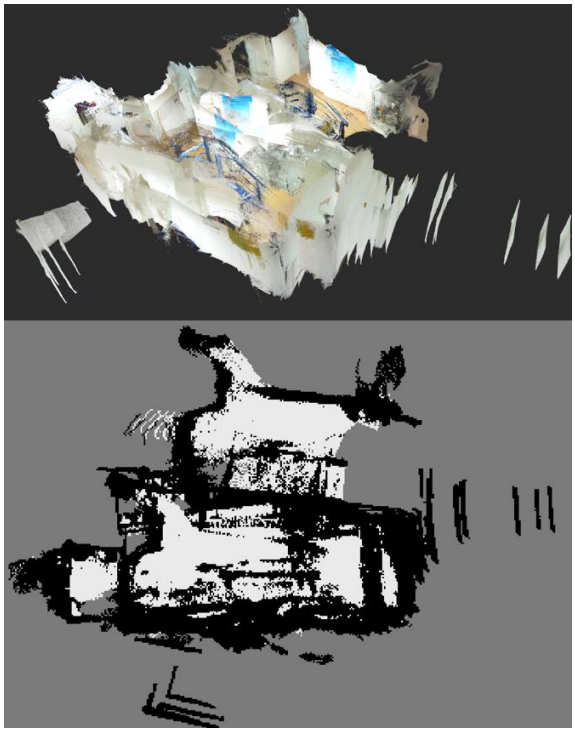

Figure 6: 3D point cloud and 2D occupancy grid with default settings.

Comparing reality vs. reconstructed map the main weakness is about:

1) Repeated Walls: Consecutive walls were often rendered multiple times in slightly shifted positions, creating "ghost" wall artifacts in the 3D point cloud and the 2D occupancy grid.
2) Poor Corridor Geometry: The long corridor segment was barely recognizable in outline, but

walls failed to align properly, leading to kinks and misalignments that did not match the actual room geometry.

3) Loss of Feature Tracking: In particularly difficult to differentiate areas, such as the bathrooms, feature tracking was often discontinued, which required the effort of identifying the last camera view detected.
4) Loop-Closure Gaps: Upon walking a closed loop, no automatic closure of the map occurred.

5.2 Experimental Challenges

During the baseline experiments, several challenges emerged that significantly affected SLAM performance on the walking aid platform:

- Reflective and low-texture surfaces: Glossy floor tiles and plain, bright bathroom walls provided very few reliable features, which led to tracking loss and occasional map discontinuities.
- Repetitive corridor geometry: Long corridors with visually similar wall and floor patterns caused perceptual aliasing, resulting in false loop-closure matches and duplicated wall segments.
- Dynamic disturbances: Moving people occasionally entered the scene, corrupting stereo matches and temporarily degrading odometry estimation.
- Illumination changes: Transitions between rooms with different lighting conditions introduced exposure artifacts, reducing feature matching robustness.

5.3 Optimized Result

After systematic parameter tuning, a set of parameters could be found that enabled a stable mapping result:

- Camera Angle: Tilted downward by 20° to the ground to minimize ceiling and window capture.
- Depth Range Limit: Reduced to a maximum of 5 m to exclude noisy distant measurements and reduce point-cloud clutter.
- Odometry: Switching from purely ZED Mini IMU-based odometry to visual-only odometry considerably improved path tracking performance.
- Feature Detector: Switched from GFTT/ORB to KAZE to enhance feature extraction in unvaried environments like brightly tiled bathrooms.
- Feature Tracking and Loop-Closure Optimization: Lowered the minimum number of inliers for feature matching (Vis/MinInliers) from 20 to 8 and raised the maximum number of features extracted per image (Vis/MaxFeatures) from 500 to 2000, enhancing image recognition and therefore loop-closure detection as seen in Figure 7.

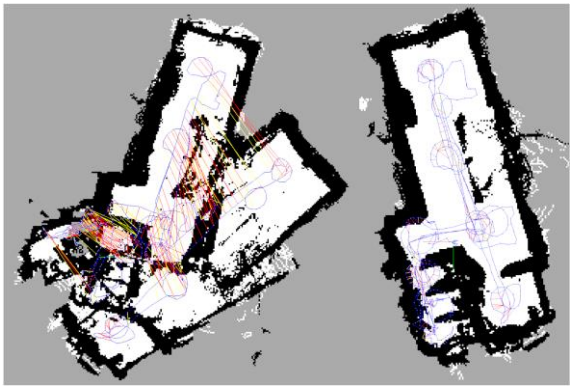

Figure 7: 2D occupancy grid before (left) and after loop closure (right).

5.4 Application to the Room Complex

The optimized mapping parameters were next applied to the full room complex, encompassing both the feature-rich office space and the adjacent entrance hall with the two bathrooms. A single uninterrupted path was executed, starting with the entrance hall and the bathrooms and proceeding to the office via stairway transition.

Despite the low-texture bright and in places tiled walls, the entrance hall and bathrooms were mapped without major gaps. The 20° camera tilt directed more features toward the floor-wall boundary, enabling the SLAM algorithm to maintain tracking in these challenging areas. The height difference between the entrance hall and office level was captured as a smooth vertical offset in the 3D map, with the staircase geometry correctly represented as seen in Figure 8.

As also seen in Figure 8, the office area was reconstructed with high fidelity. Desks, chairs, and shelving units appeared as distinct clusters in the 3D point cloud. The 2D occupancy grid accurately delineated walking aisles between desk clusters as seen in Figure 9.

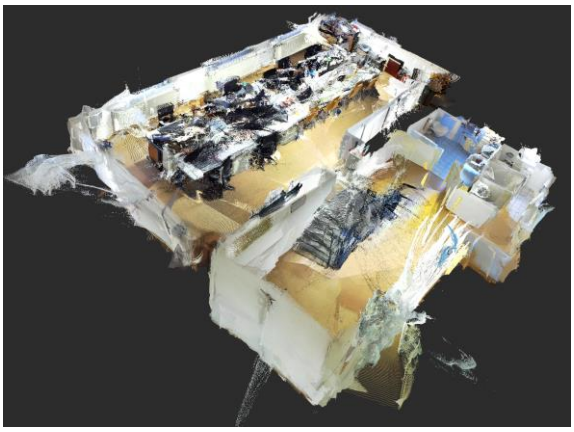

Figure 8: 3D point cloud of the complete test environment with visible offset between room levels.

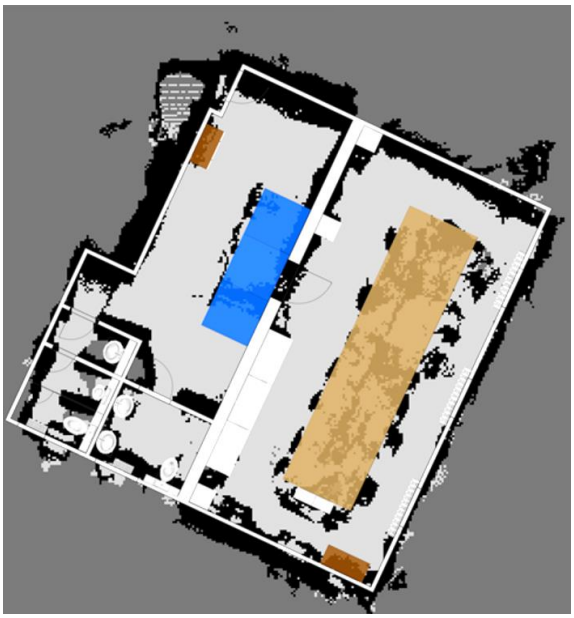

Figure 9: 2D occupancy grid of the complete test environment with validation against the floor plan.

Each rotation at the waypoint returned successfully closed prior loops, resulting in a fully connected 2D grid of the entire complex. No discontinuities were observed at room transitions or while overcoming the staircase.

6 CONCLUSIONS

Reliable indoor mapping is a critical enabler for navigation in smart assistive devices. This work shows that, even on a resource-constrained mobile platform like a smart walking aid, Visual SLAM can deliver accurate, consistent maps, provided that the system is carefully calibrated and adapted to real-world constraints.

By combining a stereo camera, an SBC and the open-source RTAB-Map framework, a full SLAM pipeline was deployed and optimized for real-time use. Key modifications, including depth limiting, camera tilt, axis-aligned TF corrections, and parameter tuning, proved essential for handling texture-poor environments, minimizing mapping artifacts, and preserving loop consistency.

The system did not just perform thoroughly in a controlled test zone; it successfully scaled to a full floor, including stairs, bathrooms, and low-feature areas. The resulting maps were geometrically accurate, loop-closed, and complete, forming a solid foundation for downstream tasks like path planning and user guidance.

These findings demonstrate that high-quality indoor SLAM is within reach even for compact, affordable assistive systems. With careful tuning, visual sensing alone can match the reliability once reserved for more expensive LIDAR-based setups. Future work on this topic will include the implementation of user-interface-guided real-time navigation.

6 FUTURE WORK

Future work will focus on transforming the presented SLAM-based mapping system into a fully integrated indoor navigation solution for assistive walking aids.

One important step will be the implementation of a user-friendly interface that allows elderly users to request navigation assistance and receive intuitive visual or haptic guidance. To further increase safety, the system will be extended with real-time obstacle detection and avoidance features, enabling reliable operation even in highly dynamic environments with moving people or pets.

Energy efficiency is another priority, as optimizing computation pipelines and sensor duty cycles will be essential to ensure extended operating times on battery-powered platforms. In addition to on-device improvements, the integration of Bluetooth Low Energy (BLE) beacons and other infrastructure-based localization technologies will be investigated to provide absolute positioning in large or feature-poor areas, such as open corridors or lobbies, where Visual SLAM performance can be limited. Furthermore, enriching geometric maps with semantic labels – for example, identifying doors, furniture, or hazard zones – offers the potential for context-aware navigation and improved caregiver support.

Finally, scalability will be addressed through the exploration of cloud-based map optimization and multi-floor map sharing, enabling operation in complex care facilities without overloading the embedded platform. These developments aim to evolve the current prototype into a robust, comprehensive navigation solution that seamlessly integrates on-board SLAM with infrastructure support, offering greater autonomy and safety to users.

Keywords: Goose Nest Design, Egg Collection, Animal Welfare, Mechanical Entry System, Modular Construction.

Abstract: This work presents the conception and prototyping of a modular goose nest system intended as a first step towards an intelligent, sensor-based nesting environment. Motivated by the lack of suitable laying sites in deep-litter and raised-floor systems, the study focuses on the mechanical design of nest frames, entrance mechanisms, floor geometries and passive egg-collection elements and evaluates their acceptance under farm conditions. Two wooden frame prototypes with different door and floor configurations were constructed and tested with a small group of geese. Nest use and laying behaviour were monitored continuously via video and analysed through manual event annotation (approach, entry, exit, egg laying, and interactions with structural elements). The experimental results show that, although the frame construction and basic floor concepts are mechanically robust and suitable for barn environments, the tested entrance mechanisms substantially reduced nest acceptance. Across all phases, only 1 of 40 eggs was laid in the nest, and none were successfully transported to the collection tray. Video analysis linked this low use primarily to aversive features of the side-hinged door with magnetic stop (noise, partial closing, transient trapping) as well as to strong group-nesting tendencies at floor-laid eggs outside the nest. Rather than demonstrating a ready-to-use solution, the present study identifies critical design constraints and behavioural failure modes that must be addressed in subsequent development stages. The findings highlight the need for quieter, low-resistance and low-risk entrance designs, mechanically robust yet chew-resistant materials, and management strategies that prevent the formation of external group nests. These lessons provide a concrete basis for the next generation of intelligent goose nests and for more targeted experimental evaluation of integrated sensor systems.

1 INTRODUCTION

Conventional goose husbandry presents numerous challenges, particularly in terms of monitoring egg-laying, ensuring hygienic conditions, and maintaining animal welfare [1]. Traditional goose husbandry systems, such as deep-litter systems, offer hygienic advantages as excrement and excess water fall directly into a pit or onto the floor beneath. However, such systems often lack suitable, species-appropriate nesting environments, leading to increased instances of floor eggs [2][3]. As [4] highlights, these systems struggle to provide optimal conditions for egg-laying. Social and reproductive behaviors, including group nesting tendencies, further complicate these issues and impact nest acceptance. These behaviors, along with the natural tendencies of geese to form external group nests, are crucial factors in the design and evaluation of artificial nesting systems [5]. One commonly applied method for identifying individual laying geese is trap nesting, which allows targeted selection and culling. Typically, this involves installing a mechanical door on a standard nest box that closes once the goose enters, preventing escape until manually released. While effective under controlled conditions, this method proves unreliable when geese lay eggs in alternative locations, especially in deep-litter systems, where multiple potential nesting sites complicate individual egg attribution [3].

An alternative approach involves manually inspecting geese in the evening to detect those ready to lay. Identified individuals are then placed in separate nesting compartments equipped with locking doors. This labor-intensive process is usually conducted four to seven days per week. Egg counts are then estimated proportionally. In more intensive systems, raised flooring is employed to optimize space and reduce bedding requirements. Commonly used materials include wooden slats or expanded metal/plastic grids. These setups offer hygienic advantages, as excrement and

excess water fall directly into a pit or onto the floor beneath. However, while efficient in terms of space and maintenance, such systems often lack suitable, species-appropriate nesting environments, as [6] describe, making them less ideal for natural egg-laying behavior.

To address these shortcomings, the present study focuses on the development of a structurally optimized, modular, and automatable goose nest that facilitates secure, species-appropriate egg-laying while enhancing monitoring and collection processes.

Figure 1 illustrates the overall operational workflow of the intelligent nest system; from the moment a goose enters the nest to the final storage of processed event data. The sequence begins with controlled nest access through the mechanical entry system, followed by detection of the animal's presence through load cell measurements. Once inside, the goose is identified via RFID, enabling individual attribution of subsequent events. A characteristic pattern in the weight signal indicates the laying of an egg, which triggers the recording of relevant sensor data. These data are then evaluated algorithmically to link the detected egg to the identified animal. After validation, the egg is marked with its corresponding identifier, and all information is transferred to the database for long term storage and later analysis. The diagram highlights the coordinated interaction between mechanical elements, sensor systems, microcontrollers, and backend infrastructure, illustrating how local detection and global data processing together form the foundation of the intelligent nest system.

This paper reports on the first project phase, which focuses on the conception, construction and behavioural evaluation of mechanical nest prototypes, including frame, entrance mechanisms, floor designs and egg collection elements. The electronic architecture shown in Figures 1 and 2 has been implemented at the prototype level but is not yet evaluated experimentally in this work. A subsequent project phase will systematically assess the performance of the load cell subsystem, the RFID based identification, the database backend and the connected output devices under farm conditions.

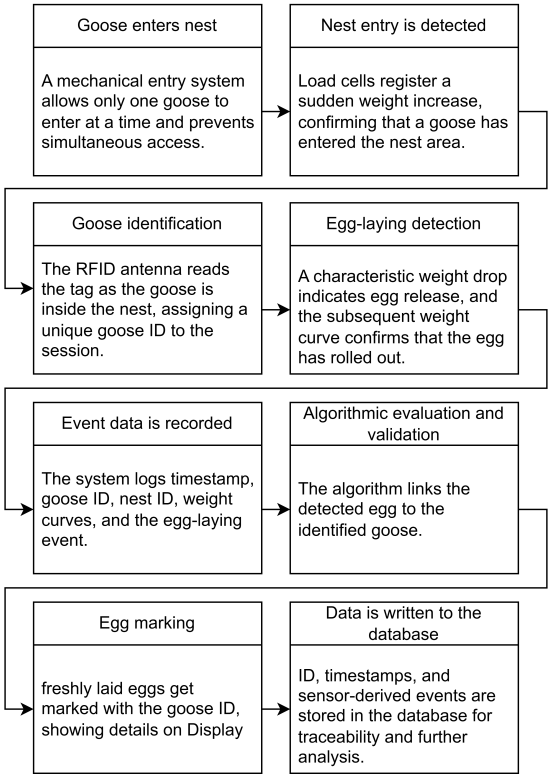

Figure 1: Overview of the functional workflow of the intelligent nest system, illustrating the sequence from controlled nest entry and sensor-based event detection to animal identification, egg attribution, marking, and database integration.

2 GOOSE ELECTRONIC AND MECHANIC SYSTEM DESIGN

2.1 Electronic System Design

Figure 2 illustrates the system architecture underlying the intelligent nest prototype, highlighting the interaction between local sensing components and the external processing infrastructure. Inside the nest, the RFID reader and the load cell module collect identification and weight data, which are transmitted to a central database computer for event reconstruction, validation, and storage. Based on the processed information, the system triggers two peripheral units located outside the nest: an automated marking device that applies a unique identifier to each egg, and a user display that presents real-time information such as the laying sequence or animal-specific events.

This architecture separates environmental sensing inside the nest from computational tasks and actuator control outside, allowing robust operation in barn conditions while ensuring reliable communication and data flow across all system components. In the present project phase, this electronic architecture is defined conceptually and serves as the target framework for later integration. The practical work reported in this paper therefore focuses on the design and behavioural evaluation of the key mechanical components that support the electronic system, namely the nest frame, entrance doors and ramp, floor geometries and passive

egg collection paths. The detailed implementation and experimental testing of the electronic subsystems (load cell and RFID units, microcontroller modules, communication links and backend processing) will follow in subsequent project phases, building on the mechanical baseline established in this study.

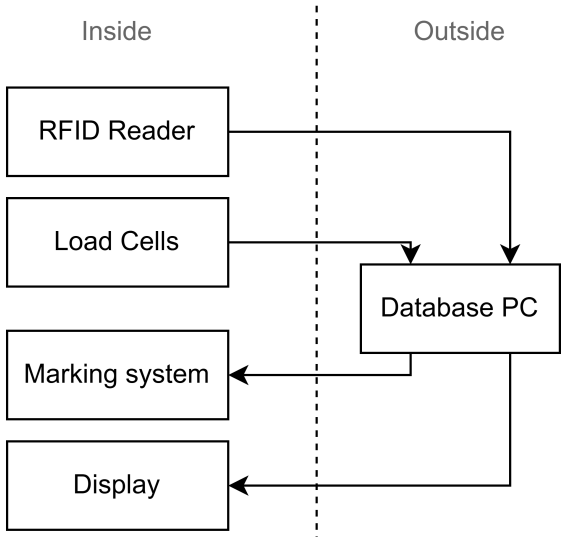

Figure 2: System architecture of the intelligent nest prototype, showing internal sensing components (RFID reader and load cells) and external processing units (database PC, marking system, and display) interconnected through bidirectional communication.

2.2 Frame Design

The primary objective of the frame design is to create a safe, comfortable, and functional environment for egg-laying. The nest must allow geese to enter and exit freely while preventing multiple geese from occupying the same nest simultaneously, thereby reducing stress and disturbances during egg-laying. Additionally, the frame should accommodate sensors, such as load cells, for monitoring purposes. As [7] points out, lightweight construction principles are key in ensuring both stability and ease of manufacturing. Therefore, both wooden and aluminum frame variants were designed with a two-level structure: the upper section serves as the nesting area, while the lower section houses technical components.

Where possible, the use of electrical components was avoided to minimize system complexity, eliminate the need for wiring, and facilitate thorough cleaning. The frame must also withstand high humidity, dust, and frequent exposure to water and detergents [6]. Structural integrity and long-term material durability were thus key design criteria.

2.2.1 Wooden Frame Design

The first frame design is constructed from wood and consists of two side walls, a rear wall, and two front walls, as illustrated in Figure 3.

Figure 3: Wooden frame design.

The walls are connected using wooden battens, with four along the bottom and two at the top, to ensure structural integrity. Since the material is wood, the walls are fastened using self-tapping screws to provide a stable and durable connection. Additionally, a handle and a window are integrated into one of the side walls. A horizontal batten at the top adds further structural stability.

2.2.2 Aluminum Profile Frame Design

The aluminum frame is constructed from aluminum profiles cut to various lengths and assembled into a stable structure. The individual profiles are joined using screws to ensure structural robustness (see Fig. 4).

The wooden frame is the preferred option due to its simplicity, ease of construction, and integration of practical features like a handle and window for accessibility. It provides sufficient structural integrity using battens and screws, aligns well to minimize system complexity, and allows easier customization or adjustments during use.

2.3 Entrance Mechanism Design

2.3.1 Gravity-Activated Mechanism (Option 1)

The developed entrance system features an automatic door mechanism based on a combination of gravitational force, leverage, and a two-part flap door. Before entry, the door remains open. When a goose steps onto the inclined, pivot-mounted floor, the resulting downward motion activates a mechanism that automatically closes the door.

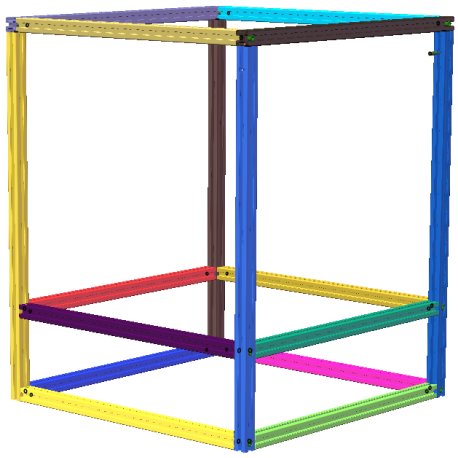

Figure 4: Aluminum profile frame design.

To ensure that the goose inside the nest can exit while preventing additional geese from entering, a split-door design with a restricted hinge angle is used. This construction allows the door to open only outward from the inside. A torsion spring returns the door to its initial position after the goose exits, enabling con-tinuous operation. The floor is pivotally mounted at a fixed point on the frame, while the door is attached via a rotary joint. The mechanical linkage between floor and door is currently under development; a linkage rod system is being considered as a potential transmission mechanism.

2.3.2 Gravity-Activated Mechanism (Option 2)

To improve weight-measurement accuracy, the nest floor in Option 2 was designed as a vertically movable platform that remains level at all times, independent of the door position. This configuration not only enhances measurement fidelity but also provides a more stable and comfortable surface for the geese, particularly during egg laying.

The door movement and floor motion are mechanically coupled through a guided linkage system. The lower linkage rods are mounted on rails integrated into the frame, allowing both controlled vertical displacement of the floor and coordinated motion of the door. The overall kinematic concept is illustrated in Figure 5, which shows the complete 3D model of the entrance mechanism.

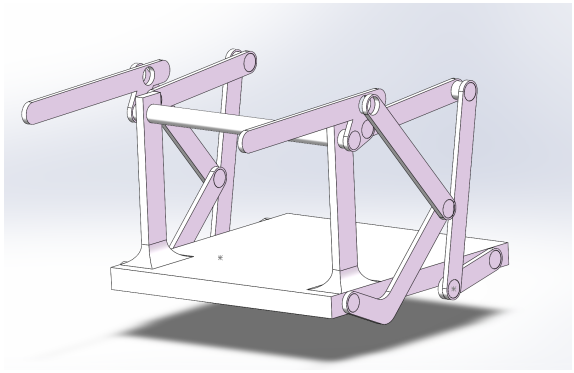

Figure 5: 3D model of the gravity-activated entrance mechanism (Option 2).

2.3.3 Top-Hinged Mechanism

The design attaches the door to the frame using a rotational axis or a hinge, allowing it to rotate freely. The door can be mounted directly on the axis or hinge, or connected via a connector to facilitate easy replacement. By appropriately determining the center of gravity, the door remains at rest with the short side pointing downward and the long side open. As shown in Figure 6, a schematic representation of the door in its open and closed positions is provided.

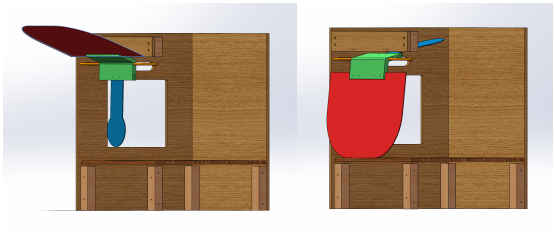

Figure 6: 3D model of the top-hinged door mechanism: opened (left) and closed (right).

2.3.4 Side-Hinged Mechanism

As shown in Figure 7, the side-hinged door mechanism is laterally mounted to the frame via a hinge or rotational axis. Two connected door panels form a right-angled door structure functioning as a single unit.

This design allows the inner door to open when a goose enters the nest, while the outer door automatically closes as a result of the connected geometry. Additionally, magnets are incorporated to hold the door in place when the opening angle is insufficient, ensuring that the door either remains open or closes automati-

cally depending on its position. This construction not only simplifies the entry and exit process for the geese but also effectively prevents unintended opening or closing of the door, thus enhancing both usability and structural stability.

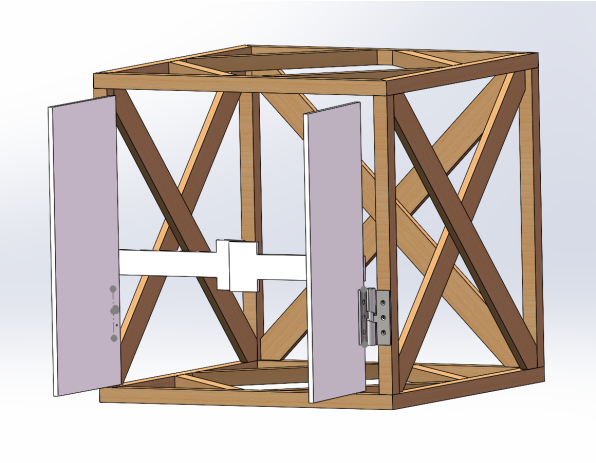

Figure 7: Side-swing door mechanism.

2.3.5 Inclined-Movement Floor Module

The inclined-movement floor module integrates the entrance control directly into the floor structure using a pivot-mounted plate (Fig. 8). When a goose steps onto the plate, it initially remains horizontal. As the animal moves forward and crosses the pivot axis, the rear part of the plate lowers to form a shallow ramp, while the front part rises and blocks the entrance. This automatic transition prevents additional geese from entering once the nest is occupied. Compared to more complex gravity-activated linkage systems, the hinged mechanisms described earlier (top-hinged and side-hinged doors) provide simpler, more robust and easier-to-maintain solutions. These alternatives therefore remain the preferred options for subsequent prototype stages.

2.4 Nest Floor Design

The floor must provide a stable surface for the geese while enabling reliable passive egg transport. A slight inclination is required to ensure that eggs roll toward the collection area without compromising the animals' mobility or comfort.

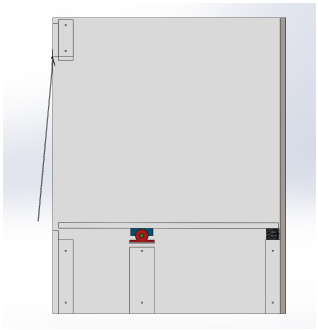

Figure 8: Inclined-movement floor module with pivoting plate.

2.4.1 Rear-Opening Floor Panel

The rear-opening design (Fig. 9) uses a central depression and a gentle rearward incline that guides eggs naturally toward the collection opening. This approach avoids complex bowl-shaped geometries, simplifies manufacturing, and reduces material and tooling requirements. It also supports easy installation and maintenance while ensuring safe and reliable egg flow, making it well suited for large-scale farm environments.

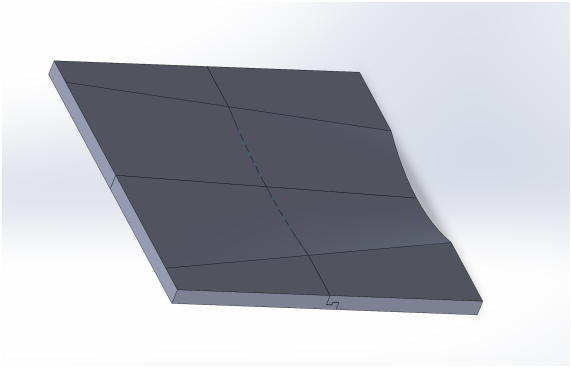

Figure 9: Rear-opening floor panel.

2.4.2 Center-Drain Floor Panel

The center-drain variant (Fig. 10) guides eggs directly through an opening in the floor, r educing the need for side or rear cut-outs. While production is straightforward, the design requires a large opening (130–140 mm) to accommodate goose eggs. This creates a safety risk, as birds may step into the hole and potentially injure themselves, particularly when entering or moving inside the nest.

For these reasons, the rear-opening panel is preferred: it transports eggs effectively without introducing injury hazards and offers simpler construction, lower costs, and improved long-term practicality.

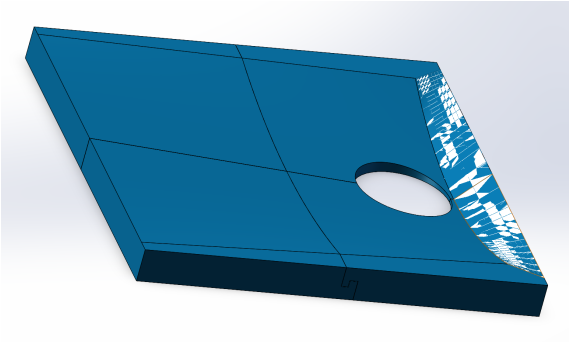

Figure 10: Center-drain floor panel.

2.5 Egg Collection Tray Design

According to the functional requirements, goose eggs should roll down from an elevated position in a row and remain undamaged. As part of the nest space is reserved for technical instruments, the eggs descend from above and eventually reach the egg collection tray. Therefore, a reliable cushioning mechanism must be installed at the end of the tray to prevent damage from impacts or excessive rolling speed. Depending on the floor design, two different rail systems are used. If the egg collection hole is located on the floor, the egg tray can be positioned at the front, underneath the ramp. This configuration saves space and offers a clean solution. Figure 11 shows the front tray layout as a visual representation of this concept.

Although this method is effective, it is less practical for a rear-opening system. If such a design were used, the eggs could fall vertically due to the curvature of the drop pipe, increasing the risk of breakage. Therefore, an alternative design is implemented. This version uses a flatter incline, which is gentler on the eggs. However, the main trade-off is increased space requirements. This solution is illustrated in Figure 12, showing the side-mounted tray configuration.

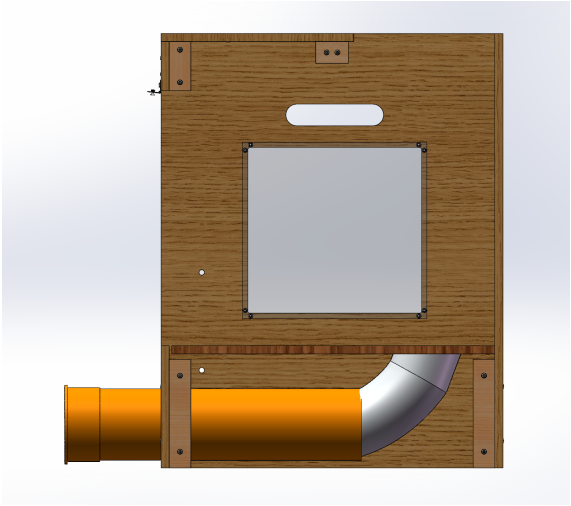

Figure 11: Front egg collection tray.

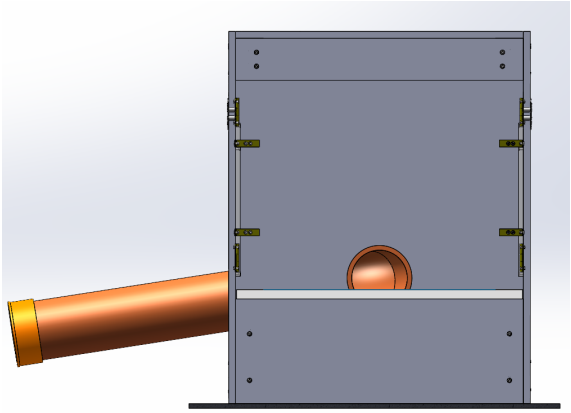

Figure 12: Rear egg collection tray.

3 NEST DESIGN SELECTION

3.1 Frame Material Selection

The choice of frame material had to consider corrosion resistance, moisture resistance, low weight, mechanical robustness, and cost-efficiency, as [8] discusses in their work on material properties. Based on these criteria, several materials were compared (see Table 1).

Table 1: Comparison of different materials [8], [7].

Material	Corrosion Resistance	Density [g/cm³]	Hardness [HB]	Price [€/kg]
Stainl. Steel	Excellent	7.8	200	16
Al-Alloy	Good	2.7	60–150	20–30
Wood	Poor	0.4–0.9	70	0.5–1
Iron	Poor	7.8	80–100	0.5–1

For the initial design of the goose nest frame, aluminum profiles were modeled to allow for rapid structural assessment. Due to the high cost, the final material choice was laminated wood panels. This material offers a good balance of stability, ease of process-

ing, environmental friendliness, and cost-effectiveness. Compared to steel, it is lighter; compared to plastics, it is more durable and mechanically stronger. With appropriate moisture protection treatment, the frame structure remains stable and durable even in humid and dusty environments.

3.2 Entrance Mechanism Selection

Following a comparative analysis of various entry mechanisms and considering the design requirements, two mechanisms were selected: a top-hinged door and a side-hinged door. More complex solutions, such as a bottom-door linkage mechanism or a side door with a diagonally movable floor module, were rejected due to their structural complexity, implementation challenges, and cleaning difficulties. In contrast, the top-hinged and side-hinged doors offer a simple, robust design based on basic mechanical principles. They ensure reliable functionality, enable cost-effective manufacturing and easy cleaning, and thus meet the practical requirements of a functional goose nest.

3.3 Floor and Egg Collection Method Selection

Following the selection of the top-hinged and side-hinged doors, suitable floor and egg collection systems were defined to ensure unobstructed access and reliable passive egg transport. Nest 1, equipped with a top-hinged door, uses a rear-opening floor panel that guides eggs from a shallow central depression directly into a subfloor collection tube. This enables rapid egg removal and reduces the risk of breakage or pecking. Nest 2, featuring a side-hinged door, employs a floor panel that directs eggs through an opening in the rear wall onto a gently sloped collection surface. This maintains free movement for the geese while ensuring a short and safe rolling path. Both systems rely solely on passive mechanical elements. By avoiding electronics in the collection area, they remain robust against moisture and contamination, reduce maintenance requirements and provide long-term operational reliability under barn conditions.

4 MANUFACTURING

4.1 Frame Construction

The frame is constructed from multilayer plywood for its strength and stability. Fastening is achieved using wood screws and reinforcing wooden battens. L-shaped metal brackets are added to all corners to enhance impact resistance and prevent deformation caused by goose activity.

Before assembly, panels are precisely cut into structural parts: two side walls, one rear, and one front wall. Edges are sanded to avoid injury. Window outlines are marked and 4 mm relief holes are drilled at each corner to prevent cracks. The window opening is then cut and sanded. An acrylic pane is mounted using adhesive and corner screws.

For the handle, two 20 mm holes are drilled and connected with a jigsaw cut; all edges are smoothed. Panels are laid flat pre-assembly for alignment. Vertical accuracy is ensured with a square, and battens are mounted flush to the side w alls. The finished structure is impact-tested, confirming material strength and stability under typical goose movements.

After the frame was completed, several functional tests were conducted to evaluate the practical suitability of the designed goose nest. First, a load test was performed to ensure that the structure could withstand the weight of the geese and their movements. This was followed by a mechanical safety test, specifically checking for sharp edges and potential injury risks for both the animals and personnel during assembly, disassembly, or cleaning. A stability test was carried out to assess resistance to vibrations or sudden shocks. Additionally, the corrosion resistance of the materials used was examined to ensure long-term durability in a humid barn environment. Finally, a light transmission test was conducted to verify whether the transparent or semi-transparent side walls allow sufficient light into the nest without permitting direct sunlight.

4.2 Nest 1

4.2.1 Top-hinged Door Mechanism with Servo Motor

Nest 1 includes a top-hinged door with a motor-operated locking bolt, as seen in Figure 13. A servo motor is installed 375 mm above the ground on the right frame side. When weight is detected by load cells, the motor rotates the locking bolt 90°, preventing the door from opening inward. This ensures only one goose enters at a time. The motor cable runs externally along the frame and beneath the nest floor to avoid goose interference.

4.2.2 Egg Collection Area

This nest features a rear floor opening for egg collection. A 126 mm diameter hole is cut for the collection

tube, considering tolerance. A 50 mm-thick extruded polystyrene (XPS) foam plate is added, angled toward the opening to guide eggs smoothly into the tube. A flexible pipe runs under the floor, through the rear panel, and extends beneath the ramp for safe egg transfer.

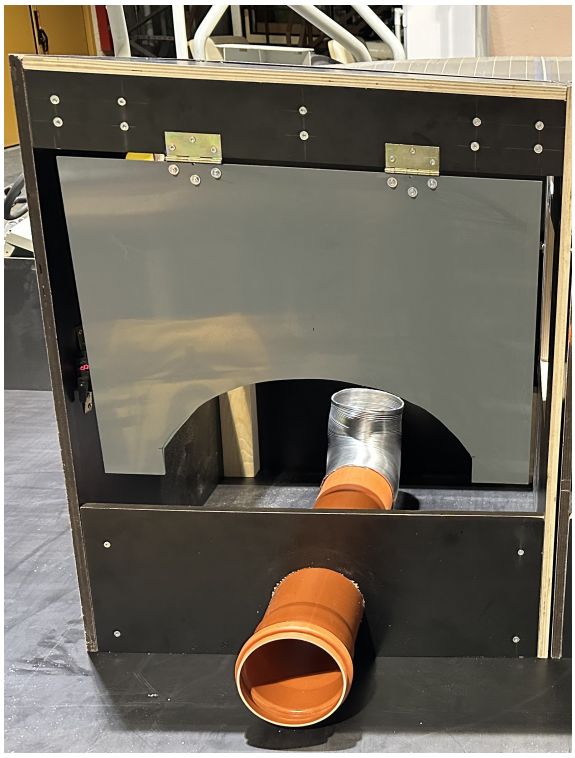

Figure 13: Configuration of Nest 1 with top-hinged door and center-drain floor panel.

4.3 Nest 2

4.3.1 Side-hinged Door Mechanism

Nest 2 uses a side-hinged door system. Panels are cut to shape, and each side includes an outer and inner door. The outer doors are attached to the frame; inner doors are mounted onto them using 90° metal brackets, as illustrated in Figure 14.

Magnetic stops are added to control door positioning (see Fig. 15). When a goose pushes the inner door, it swings inward and is held open by the magnet, while the outer door remains closed to prevent escape or unintended entry.

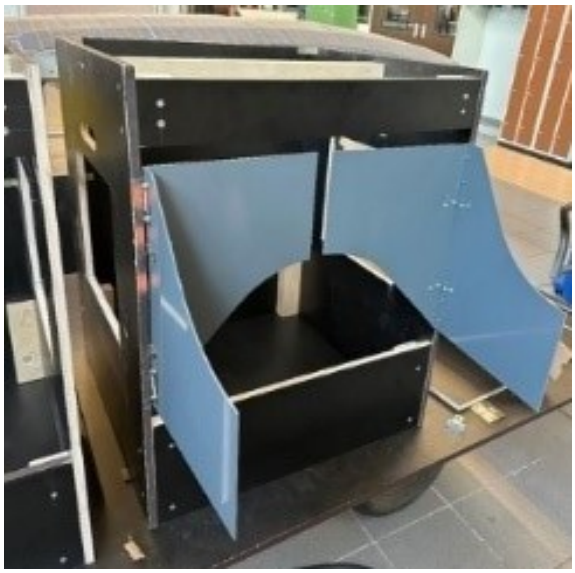

Figure 14: Configuration of Nest 2 with side-hinged door and rear-opening floor panel.

Figure 15: Magnetic stops of the side-hinged door mechanism.

4.3.2 Egg Collection Area

A 126 mm opening is cut into the rear wall for the egg collection pipe. Two floor panels angled at 110° direct eggs into the pipe, which is supported and aligned by two stabilizing struts. A 50 mm XPS foam layer is added, sloping toward the rear opening to ensure eggs roll efficiently.

4.4 Electrical Component Integration

The load cell is mounted on the underside of the wooden platform, with force transmission established through a beam beneath the floor. Screw holes are countersunk to avoid protrusions and ensure a flush surface. The installation of the load cells and the supporting structure is shown in Figure 16.

In addition to weight measurement, the system incorporates an RFID unit for individual animal identification at nest entry. The RFID reader, antenna and microcontroller are housed together in a dedicated electronics module, which is also shown in Figure 16. The load cell subsystem and the RFID subsystem operate on separate ESP32 microcontrollers, enabling independent acquisition, filtering and timing of their respective data streams. Data exchange between the microcontrollers and the database computer is carried out via MQTT. Each controller publishes its data to dedicated topics, allowing the server to merge information into coherent event structures, associate egg-laying events with individual animals, and communicate with peripheral devices such as the display and automated marking system.

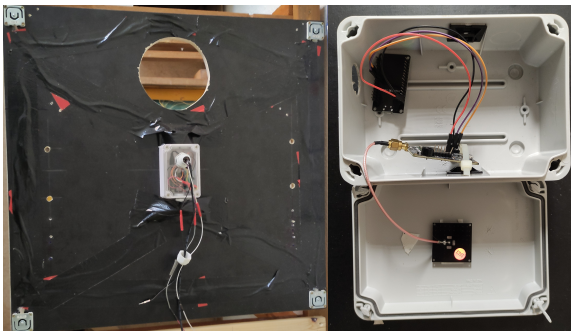

Figure 16: Electronic subsystems of the intelligent nest: load cell assembly beneath the nest floor (left) and RFID module with reader, antenna and ESP32 microcontroller (right).

4.5 Ramp Design

The ramp (see Fig. 17) is 550 mm long and set at an angle of approximately 24.15°, within the recommended range of 20°–25° for goose accessibility. Crosswise anti-slip wooden slats are mounted 50–70 mm apart to enhance traction. The ramp attaches to the nest frame with two hooks for easy assembly and disassembly.

4.6 Experimental Setup and Behavioral Observation

All behavioural tests were carried out in a stable housing with a group of five female geese under routine husbandry conditions. To obtain a precise ground-truth reference for nest use and laying activity, the area in front of the prototype nest and the nest interior were continuously monitored with a fixed video camera operating 24/7 throughout the entire experimental period. The video material was subsequently reviewed and annotated manually. For each goose, all relevant behavioural events were extracted with time stamps and assigned to one of two spatial categories: (i) presence in front of the nest, defined as standing or staying within the approach zone directly in front of the entrance, and (ii) presence inside the nest, defined as all periods during which the animal had fully entered the nest chamber. In addition, each entry and exit event was marked explicitly to reconstruct the exact sequence and duration of visits.

Egg-laying events were identified in the recordings based on characteristic posture changes and the subsequent appearance and position of the egg. For every egg, the approximate time of laying and its final location (inside the nest, rolled to the tray, or outside the nest) were documented. Furthermore, the videos were used to characterise how individual geese interacted with the different entrance mechanisms, including behaviours such as pecking at the door, looking into the nest without entering, hesitating in the approach zone, pushing under partially opened flaps, or reacting to mechanical noises (e.g. the snapping of magnets).

The manually annotated events formed the basis for calculating the cumulative presence times in front of and inside the nest for each goose and experimental phase (Table 2). They also provided qualitative context for interpreting acceptance or avoidance of specific entrance designs and for linking observed behaviours to the mechanical properties of the prototype nests.

5 RESULTS

All tests were conducted in a stable housing with a group of five female g eese. Prior to these tests, the general Nest Frame design was evaluated for safety and acceptance. Nest 1, which used a Center-Drain Floor Panel, posed a potential risk of injury, as the geese repeatedly stepped directly onto the drain. For this reason, Nest 1 was not tested further. The experiments therefore focused on Nest 2, equipped with a side-hinged entrance supported by magnets. In that configuration, several issues became apparent: in some cases, geese triggered only one of the two doors, leaving the other flap closed, or pushed themselves underneath the door without activating the mechanism, as seen in Figure 17. In addition, the snapping noise of the magnets startled some animals and led to reluctance to enter. The Inclined-Movement Floor Module, tested separately as a simple passageway, was accepted without hesitation, with all geese passing over it without observable stress.

Figure 17: Goose only activates one door of the side-hinged entrance mechanism.

Three consecutive experimental phases were implemented to assess acceptance, access behavior, and laying activity as a function of the entrance mechanism: Phase I (24–28 Jan, nest with door including magnetic stop), Phase II (28–31 Jan, nest with door but without magnets), and Phase III (31 Jan–13 Feb, nest body without any entrance mechanism). The quantitative outcomes are summarized in Table 2, which lists for each goose the cumulative time spent in front of the nest and the time spent inside the nest.

Table 2: Cumulative presence times [min:s] in front of and inside the nest across phases.

	Phase I		**Phase II**		**Phase III**	
Goose	Front	Nest	Front	Nest	Front	Nest
G1	03:38	00:00	15:44	00:00	18:42	34:31
G2	00:00	00:00	00:06	20:46	47:33	87:09
G3	03:44	00:00	06:00	05:16	125:32	77:22
G4	01:49	04:19	04:59	62:26	35:14	20:38
G6	04:55	00:00	03:20	00:00	13:24	30:35
Total	**14:06**	**04:19**	**30:09**	**89:28**	**240:25**	**250:15**

In Phase I (door with magnets), only Goose 4 entered the nest, with a total of six short visits amounting to 04:19 min inside. All other animals remained exclusively in front of the entrance without crossing into the nest chamber. The cumulative time spent in front of the nest was low (14:06 min).

During Phase II (door without magnets), a marked increase in nest use was observed. Goose 3 entered the nest twice (05:16 min in total), Goose 2 entered six times (20:46 min), and Goose 4 entered twelve times, reaching the maximum cumulative presence of 62:26 min inside. In contrast, Goose 1 and Goose 6 only remained in front of the entrance without entering. Overall, the cumulative time spent inside rose to 89:28 min, while the total front times more than doubled (30:09 min).

In Phase III (nest body without entrance mechanism), nest use broadened further: all geese entered the nest at least occasionally. Goose 2 accumulated the longest presence (87:09 min across 13 visits), followed by Goose 3 (77:22 min across 21 visits). Goose 1 and Goose 6 showed moderate use (34:31 min across 8 visits and 30:35 min across 7 visits, respectively), while Goose 4 reduced her nest presence to only 20:38 min across 9 visits. In absolute terms, the total front-of-nest time reached its maximum (240:25 min), and the cumulative inside-nest time also peaked at 250:15 min. When normalized by phase length, the average daily presence in front of the nest continued to increase across all phases, whereas the average daily time inside the nest was highest in Phase II and then declined in Phase III, although it remained well above Phase I. This suggests that while approach activity kept rising with prolonged exposure to the structure, the actual time spent inside was most pronounced once the magnets were removed but before the entrance mechanism was fully eliminated.

Beyond the quantitative presence times, the manual video annotations revealed several recurring behavioural patterns across all five geese that are directly relevant for the evaluation of the nest prototypes. First, the entrance proved to be a critical interaction point: all animals were repeatedly observed approaching the nest, inspecting the doorway visually, and withdrawing again without entering. This pattern occurred across all phases and independently of individual differences, indicating that the design and kinematic and mechanical characteristics of the entrance system strongly influence initial acceptance. A second consistent observation concerned the interaction between the geese and the mechanical door elements. In all individuals, at least one event was recorded in which the animal's back or feathers came into contact with a moving or partially closing door wing, and in several cases minor trapping between door components occurred. Such incidents did not result in injury but created brief interruptions in movement, and in at least one individual, subsequent hesitation when passing the doorway. These findings support the quantitative results that the side-hinged construction and the magnetic stop introduced mechanical constraints that reduced acceptance and, in some cases, generated aversive experiences. Across all recordings, the geese also showed pronounced manipulative behaviour directed at structural nest components. The floor mat, ramp surface, and frame edges were frequently pecked, lifted, or chewed, sometimes causing visible damage such as fraying or detachment of adhesive tape. These behaviours indicate that exposed surfaces in the nest vicinity are not only passive load-bearing structures

but are actively used as exploration and pecking substrates, which has direct implications for material durability and safety. Finally, the few eggs laid inside the nest were often not automatically transported out of the nest despite the inclined floor design. Video recordings showed that geese manipulated these eggs using their beak or body and occasionally remained sitting on them. This natural egg-handling behaviour interferes with passive egg-collection mechanisms and highlights the need to reconcile instinctive nesting behaviour with the technical requirements of automated egg removal.

Taken together, these results show that (i) the magnetic closing mechanism substantially inhibited entry, with only one goose entering briefly, (ii) removing the magnets led to the highest daily presence inside the nest, with frequent entries by several animals, and (iii) once the entrance was fully removed, approach activity in front of the nest continued to increase, but the actual time inside decreased compared to Phase II and became distributed across all individuals, with Goose 2 and Goose 3 accounting for the largest shares. This pattern suggests that social hierarchy and individual experiences influenced nest use: for example, Goose 4 became caught with her back at the entrance during Phase II, which likely created a negative association and explains her reduced use of the nest in Phase III. Furthermore, once an egg had been deposited outside the nest, subsequent eggs were repeatedly laid at the same spot. This reflects the natural tendency of geese to form group nests and add their eggs to existing clutches, which has been observed in studies showing that geese cluster and select nest sites together before laying begins [9]. Such behavior underscores a key challenge for nest acceptance: if mislaid eggs remain accessible, they can attract further laying and reduce the motivation to use even well-designed technical nest structures. Preventing the establishment of external group nests is therefore crucial for ensuring consistent use of artificial nesting systems.

Across all phases, a total of 40 eggs were recorded as shown in Table 3. Only one egg (2.5%) was deposited inside the nest, which remained in place and not rolled to the tray. By contrast, the vast majority of eggs (97.5%) were laid outside the nest, highlighting that the experimental setup was only rarely used for oviposition.

Table 3: Overall egg-laying outcomes across all phases combined.

	Total eggs	Inside nest	Rolled to tray	Remained in nest	Outside nest
Count	40	1	0	1	39
Percentage	100	2.5	0	2.5	97.5

To visualize behavioral changes, Figure 18 presents the number of nest visits per goose, separated by experimental phase and displayed as grouped, color-coded bars. This format allows direct comparison of visit frequencies across phases within each individual. The data show that visits increased markedly after removal of the magnets (Phase II) and remained elevated in the open configuration without any entrance mechanism (Phase III). In fact, the total number of nest entries was highest in Phase III, indicating that once the barrier was fully removed, geese not only continued to approach but also entered the nest more frequently than in any previous phase. These results underline the deterrent effect of the magnetic stop and the improved acceptance of both the non-magnetic and open nest designs.

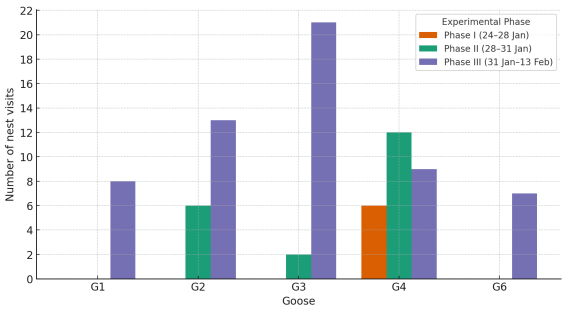

Figure 18: Frequency of nest visits per goose across experimental phases (Phase I–III). Grouped bars indicate the number of visits per individual, color-coded by phase.

6 CONCLUSIONS

This work presented the conception, construction and first behavioural evaluation of modular goose nest prototypes with different entrance mechanisms, floor geometries and passive egg collection concepts. From a purely mechanical perspective, the laminated wood frame and the basic floor and tray designs proved feasible under barn conditions: they can be manufactured with standard materials, withstand typical loads and humidity, and provide a structurally stable basis for integrating sensors and actuators in later project phases.

However, the behavioural results clearly show that the tested entrance mechanisms did not achieve the intended goal of providing an attractive and welfare-friendly laying site. Across all experimental phases, only one out of 40 eggs was deposited inside the nest, and none of the eggs was successfully transported to the collection tray. Manual video annotation linked this low level of use primarily to the side-hinged door

system with magnetic stop, which produced sudden snapping noises, partial closing and transient trapping of backs or feathers. These features created aversive experiences for individual geese and likely contributed to the persistent preference for alternative laying sites outside the nest. Once eggs had been laid on the floor, strong group-nesting tendencies further stabilised these undesired locations.

Given the small sample size (five geese) and the short duration of the three experimental phases, the present study cannot provide statistically generalisable estimates of acceptance. Instead, it should be interpreted as an exploratory pilot trial that identifies critical failure modes and design constraints. The findings nevertheless offer several concrete lessons for future development. First, entrance systems must minimise mechanical resistance, impact noise and any risk of transient trapping; this will require redesigned hinges, damping elements and door geometries, as well as quantitative measurements of the forces required to open and close doors. Second, all surfaces in the entrance and nest area must be constructed from robust, chew-resistant materials without exposed adhesive joints, as the floor mat, ramp and frame edges were repeatedly used as pecking and chewing substrates. Third, management strategies are needed to prevent the establishment of external group nests, since accessible mislaid eggs can rapidly override the incentive to use even well-designed technical nests.

Future work should focus on optimizing nest acceptance under farm conditions and on integrating sensor-based monitoring [10] and machine learning [11] to support adaptive management.

In subsequent project phases, these insights will guide the redesign and testing of alternative entrance concepts, followed by a more systematic behavioural evaluation with larger groups, longer observation periods and formal statistical analysis. Only once a reliably accepted mechanical baseline has been achieved will the electronic components described in Section 4.4 and summarised in Figures 1 and 2 be evaluated under farm conditions. In this way, the predominantly negative outcomes of the present study serve as a necessary intermediate step towards a next-generation intelligent goose nest that aligns technical functionality with species-specific behaviour and animal welfare.

Keywords: Artificial Intelligent, MCDM, Genetic Algorithm, MOORA.

Abstract: Multi-Criteria Decision-Making (MCDM) plays a critical role in identifying optimal solutions in complex environments where multiple, often conflicting, criteria must be considered. This paper presents a hybrid Artificial Intelligence (AI) framework that integrates a Genetic Algorithm (GA) with the Multi-Objective Optimization by Ratio Analysis (MOORA) method. The GA provides global search and optimization capabilities for determining criterion weights, while MOORA offers a computationally simple, robust, and rank-stable approach for evaluating alternatives. The proposed methodology consists of three stages: 1) identifying the decision alternatives and relevant evaluation criteria, 2) determining the criteria weights using a GA, and 3) ranking the alternatives using the MOORA method. The effectiveness of the hybrid GA–MOORA approach is validated through a comparative case study based on the dataset from [11] to determine the optimal weighting factors. Results demonstrate a strong agreement between MOORA and the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS). Both methods identify Alternative 1 (q = 0.9) as the least favorable option (ranked 5th), while the mid-range alternatives (Alternatives 4 and 5) exhibit similar rankings. The proposed GA-MOORA model identifies Alternative 3 (q = 0.5) as having the highest net utility, with Alternative 2 (q = 0.3) performing comparably. This close performance provides decision-makers with flexible, reliable options for final selection.

1 INTRODUCTION

Real world decision-making problems such as selecting suppliers, projects, investments, or technologies typically require evaluating multiple alternatives against diverse and often conflicting criteria. Multi-Criteria Decision-Making (MCDM) provides a structured set of mathematical tools designed to support decision-makers in systematically ranking alternatives and selecting the most suitable option. Numerous MCDM techniques have been proposed, each offering unique advantages depending on the nature of the criteria and problem context. A fundamental requirement in most MCDM approaches is the assignment of weights to the evaluation criteria. The Weighted Sum Method (WSM) is one of the simplest MCDM techniques, calculating a total score for each alternative by summing the products of its normalized criterion values and the corresponding weights. WSM has been applied in various fields, such as evaluating workforce competence in the apparel industry [1] and selecting materials for femoral components in total knee replacement (TKR) applications [2]. Similarly, Athanasios et al. [3] employed WSM along with other MCDM methods in renewable energy system evaluations, while Agus and Abulwafa [4] compared WSM with the Multi-Attribute Decision Making Weighted Product (MADMWP) method to select the best elementary school in Indonesia.

The Weighted Product Method (WPM), another classical MCDM approach, ranks alternatives by multiplying normalized criterion values raised to their corresponding weights thus using a multi-plicative rather than an additive model. WPM has been combined with the Analytic Hierarchy Process (AHP) to assess flood susceptibility zones in the Wadi Hanifah drainage basin [5]. AHP is widely used for deriving weights through pairwise comparisons between criteria and alternatives. It has been applied in various engineering contexts, such as road selection [6] and evaluating fuel-efficiency improvements via natural-fiber polymer composites (NFPC) [7].

The Analytic Network Process (ANP) extends AHP by allowing interdependencies among criteria and alternatives, modeling decision problems as networks rather than hierarchies. ANP has been applied to identify optimal public private partnership structures for abandoned projects in Iraq [8] and to support policymakers in prioritizing resource allocation indicators [9].

More advanced ranking techniques include the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS), which evaluates altern-atives based on their distances to the Positive Ideal Solution (PIS) and Negative Ideal Solution (NIS). Applications of TOPSIS include multi-document text summarization [10] and determining optimal MCDM weight vectors via genetic algorithms [11].

Another widely used method, Multi-Objective Optimization by Ratio Analysis (MOORA), ranks alternatives by computing normalized assessment values, adding contributions from beneficial criteria, and subtracting contributions from non-beneficial (cost) criteria. MOORA has been applied to optimize machining parameters in wire electrical discharge machining [12], develop credit lending decision models in banking [13], and convert multi-response engineering problems into single-response problems through Taguchi-based integration [14], [15].

Additionally, Data Envelopment Analysis (DEA) provides a linear programming-based framework for comparing the efficiency of alternatives and is often integrated with MCDM techniques including TOPSIS, MOORA, and WPM to improve ranking robustness. Comprehensive formulations and applications of DEA can be found in [16]-[20].

Despite the wide range of MCDM techniques available, many still rely on subjective assignment of criterion weights by decision-makers or require sophisticated weighting procedures such as AHP or entropy-based approaches. Subjectivity in weight determination often leads to bias, affecting the reliability of the final ranking. Moreover, several MCDM methods involve complex computational steps, which may increase susceptibility to rank reversal.

To address these limitations, this paper proposes a hybrid approach that integrates a Genetic Algorithm (GA) with the MOORA method. In the proposed framework, GA is employed to determine optimal criterion weights objectively, while MOORA is used to rank alternatives based on these optimized weights. This integration aims to improve ranking stability, reduce subjectivity, and enhance the overall decision-making process.

2 MATHODS

2.1 Genetic Algorithm

GA is a more efficient optimization approach that used to solve both discrete and continuous functions [21]-[23]. This algorithm is based on natural evolution and genetics to find out near optimal solutions for large combinatorial optimization problems. The computational proce-dure of GA algorithms begins with initialization which creates a population of chromosome. After that, fitness function is used to obtain fitness score for each individual. Following that, population is updated using crossover and mutation operators of GA. Finally, termination criteria specify when the algorithm should be terminated. Genetic algorithm is described in Figure 1.

2.2 MOORA Method

Multi objective optimization by ratio analysis (MOORA) is an efficient approach that used to rank the alternatives based on the weights of criteria. As in [12-15]. MOORA algorithm starts with decision matrix in which the criteria represent the columns of the matrix and the alternatives represent the rows of the decision matrix. Following that, normalized decision matrix is calculated using the following:

$$X_{ij}^{*} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} X_{ij}^{2}}} \; i = 1, 2, \ldots, m \; and \; j = 1, 2, \ldots, n \qquad (1)$$

Next, we calculate the criteria weights and then calculate the weighted normalized decision matrix. After that, based on the normalized values of the weighted decision matrix of beneficial criteria and non-beneficial criteria, performance score is calculated using the following:

$$y_i^{*} = \sum_{j=1}^{g} W_j X_{ij}^{*} - \sum_{j=g+1}^{n} W_j X_{ij}^{*} \qquad (2)$$

MOORA approach can also described in Figure 2.

2.3 Integrated GA-MOORA Method

The computational procedure for GA-MOORA model is described as follows:

Step1: determine clearly the alternatives and important criteria.

Step2: For the given criteria find the weights using GA as follows: or numbered list style:

1) Initialization: Create initial population;
2) Fitness Assessment: Calculate fitness scores for each individual using fitness function;
3) Update population: Create new population using crossover and mutation operators of GA.

Step 3: Termination:

a) Iteratively process weight learning until termination condition is reached.

b) if termination condition met, then the process terminates and returns a set of optimal criteria weights, otherwise go to 2.

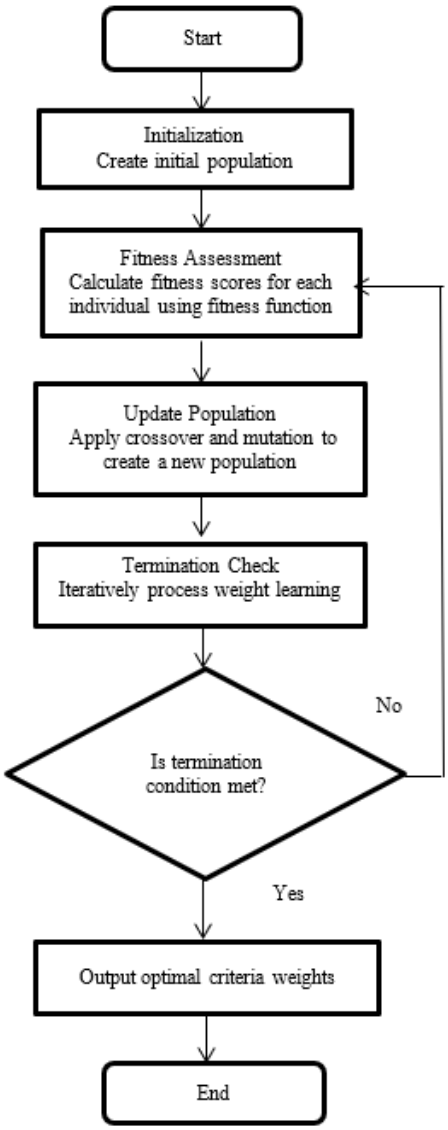

Figure 1: Genetic algorithm.

Step 4: rank the given alternatives using MOORA as follows:

1) Construct the decision matrix;
2) Construct the normalized decision matrix using (1);
3) Calculated the weights of criteria and then construct the weighted normalized decision matrix and finally calculate the final score using (2).

This computational procedure can be described in Figure 3.

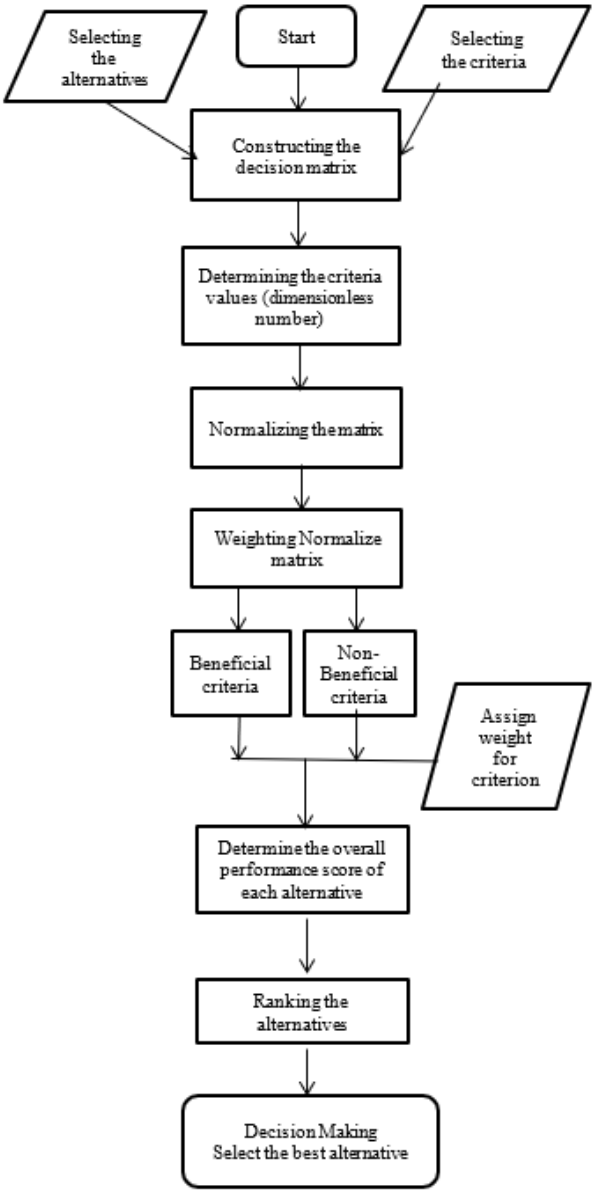

Figure 2: MOORA algorithm.

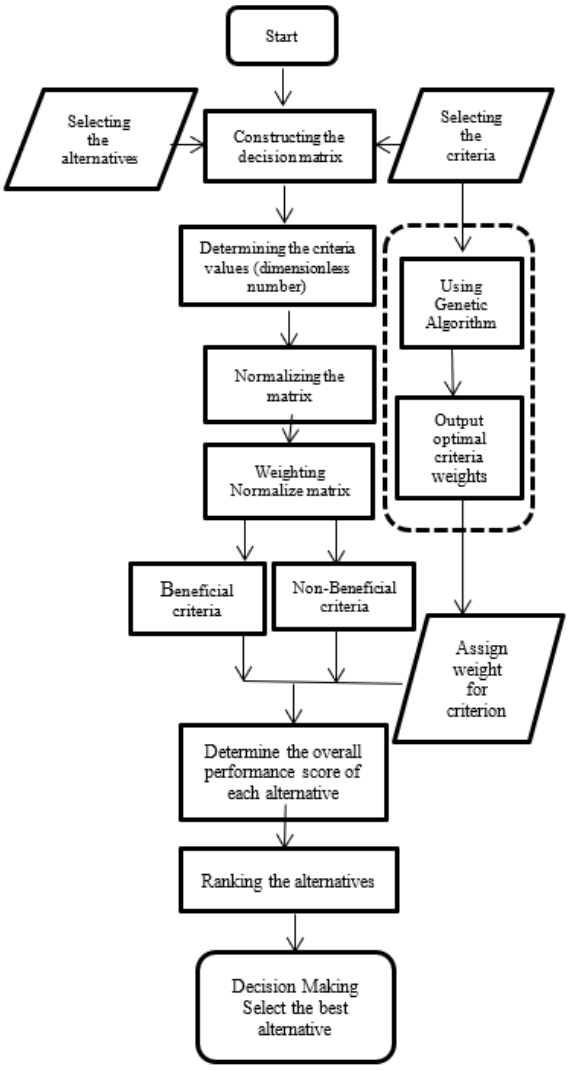

Figure 3: Integrated GA-MOORA approach.

3 RESULTS AND DISCUSSION

3.1 A Case Study

To show the effectiveness of the presented GA-MOORA approach, we use the data in [11].

Which consist of five alternatives (q=0.1, q=0.3, q=0.5,q=0.7, q=0.9) represent various weight factor values and six criteria (Group Efficiency (GE), System Utilization (SU), System Flexibility (SF), Number of Voids (NV), Exceptional Elements (EE), and Total Cost (TC)). The goal as in [11] is to identify the most favorable solution for both flexible cell information and machine layout within each cell.

3.2 Implementation of Integrated GA-MOORA Approach

Step1: The alternatives and criteria were specified by [11] as: Alternatives (q=0.1, q=0.3, q=0.5,q=0.7, q=0.9) represent various weight factor values and six criteria (Group Efficiency (GE), System Utilization (SU), System Flexibility (SF), Number of Voids (NV), Exceptional Elements (EE), and Total Cost (TC)).

Step2: Identifying the weight of criteria using GA as in [11] in Table 1 as follows:

Table 1: GA weights of the criteria

Criteria	Type	GA -Weights
GE	Beneficial	0.20
SU	Beneficial	0.20
SF	Beneficial	0.20
NV	Non- Beneficial	0.10
EE	Non- Beneficial	0.10
TC	Non- Beneficial	0.20

Step3: Identify the most favorable solution for both flexible cell information and machine layout using MOORA as follows in Table 2.

Table 2: MOORA scores for the values of q**.**

q	MOORA Scores	MOORA rank
q=0.1	-0.088	5
q=0.3	0.178	2
q=0.5	0.183	1
q=0.7	0.149	3
q=0.9	0.147	4

3.3 The Discussion

Based on the obtained results using GA-MOORA and the results of TOPSIS as in [11] and we compare these results in Table 3 and Figure 4 and Figure 5 as follows:

Form Table 2, Figure 2 and Figure 3 we conclude that the alternative (q=0.1) is the worst alternative based on both Methods. Also, the alternatives (q=0.3 and q=0.5) are best alternatives.

Table 3: Comparison between MOORA and TOPSIS ranks.

Alterna-tive q	TOPSIS		MOORA		Consensus
	score	rank	score	rank	
q=0.3	0.83546	1	0.17835	2	Top 2 choice
q=0.5	0.75114	2	0.18356	1	Top 2 choice
q=0.9	0.73957	3	0.14781	4	Good Middle Option
q=0.7	0.71548	4	0.14921	3	Good Middle Option
q=0.1	0.25914	5	-0.08845	5	Worst Choice

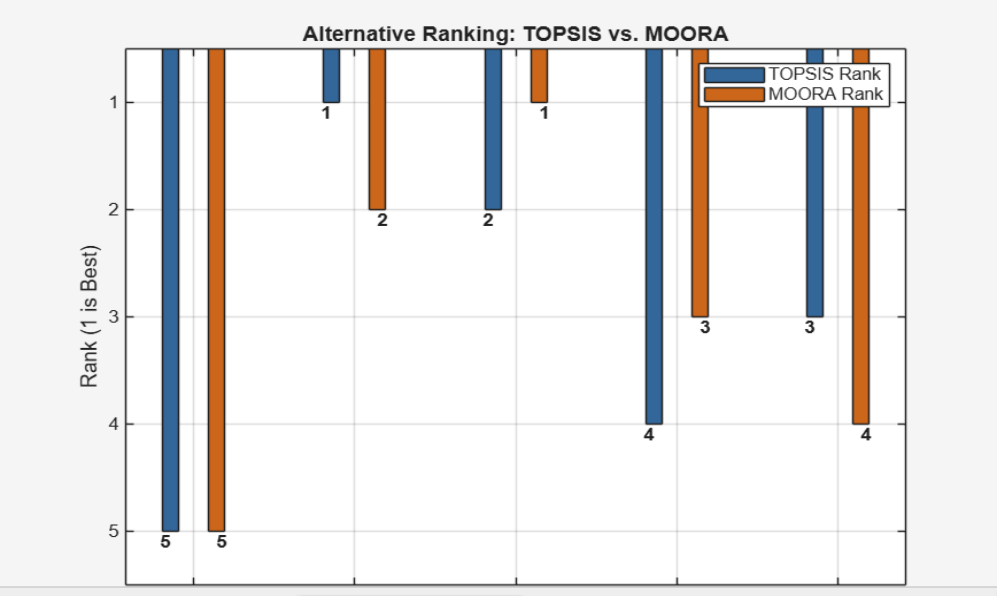

Figure 4: Comparison of MOORA and TOPSIS results.

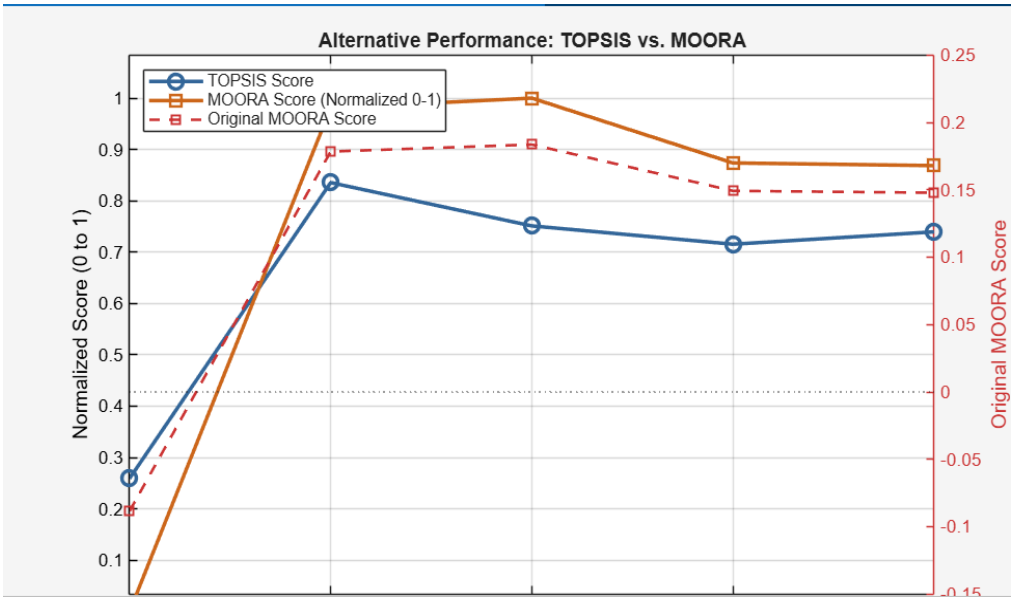

Figure 5: Comparison of the actual scores from both methods.

4 CONCLUSIONS

An integrating multi criteria decision making approach which is called as GA-MOORA has been successfully presented. This approach has strong mathematical foundation based on a hybrid Artificial Intelligence (AI) model that synergizes the global optimization power of a Genetic Algorithm (GA) with the intuitive logic of the MOORA technique. The validity of the presented approach has tested using data from [11] and compared with the results of this reference. Our study shows that the integrated GA-MOORA approach has computational simplicity and minimalism, which leads to inherent robustness and reduced susceptibility to rank reversal. The study also shows the ranks of three alternatives are match the results using TOPSIS as in [11]. Moreover, alternative 3 is ranked as the first and alternative 2 is ranked the second where the weights of these alternatives that obtained using GA-MOORA are very close. Which will help the decision maker to determine the most suitable value for the weighting.

Application Test Automation in Headless Android Emulator

Oleksii Cherkashyn
Blynk Technologies Inc., Brickell Avenue 951, 33131 Miami, FL, USA
oleksii.sciencepapers@gmail.com

Keywords: Android, Android Application Testing, Mobile Test Automation, WebdriverIO, Appium, TypeScript.

Abstract: The rapid growth of Android applications and the acceleration of software release cycles highlight the need for efficient, accessible, and reproducible testing infrastructures. Commercial cloud platforms often address this challenge, providing scalability and device diversity, but they remain costly and inflexible for small and medium-sized development teams. This study proposes a unified, low-cost approach to Android application test automation that consolidates the entire testing infrastructure on a single Windows 10 machine using a headless Android emulator. The methodology is experimental and practice-oriented, focusing on open-source automation frameworks, emulator stability, continuous integration (CI) integration, and optimal resource utilization. Evaluation results demonstrate that tests executed in headless mode are on average 6.6% faster and reduce CPU usage by approximately 5% compared to UI-based emulation, without sacrificing reliability or reproducibility. This work contributes to the body of research on emulator-driven mobile testing by offering a practical, scalable, and reproducible solution, enabling smaller teams to implement complete automation pipelines while reducing dependence on commercial cloud platforms.

1 INTRODUCTION

The Android ecosystem has experienced significant growth in recent years. The Google Play Store serves as the primary app repository, offering over 1.7 million apps as of August 2024 [1]. These apps are downloaded (installed) by billions of users worldwide [2].

With the proliferation of mobile applications, the demand for efficient testing methodologies has escalated. Automated testing has become a critical component in the software development lifecycle, enabling developers to ensure the reliability and performance of applications across diverse devices and operating system versions.

Various frameworks and tools have been developed to facilitate mobile test automation. Among these, Appium stands out as a widely adopted open-source tool that supports testing of native, hybrid, and mobile web applications across iOS and Android platforms. The most widely used tool by the testers is Appium [3].

Additionally, WebdriverIO provides a modern test automation framework for web and mobile applications, offering a simple and flexible API for writing tests. WebdriverIO is the ideal alternative testing automation framework in terms of performance, considering both the automated testing progress parameter and the tool usability parameter [4].

Node.js applications typically resort to hundreds of publicly available third party packages hosted in the Node package manager (npm) registry, a large repository containing over a million of ready-to-use publicly available third-party libraries [5], one of which is the WebdriverIO library and its dependencies. The combination of Node.js, WebdriverIO, and Appium presents a compelling solution for automating Android application testing. This stack leverages the asynchronous capabilities of Node.js, the versatility of WebdriverIO, and the cross-platform support of Appium to create a robust testing environment.

Understanding the infrastructure requirements for mobile test automation is crucial. Implementing automated testing on Windows 10 can utilize Android emulators running in headless mode, which allows simulating real devices without displaying emulator windows. This approach requires careful consideration of device management, network configurations, and integration of various testing tools.

This paper aims to explore the implementation of Android application test automation using Node.js,

WebdriverIO, and Appium on no windows emulator mode, addressing the challenges and providing insights into best practices for efficient and scalable testing solutions.

2 RELEVANCE

Given this highly competitive business market, it became mandatory for IT companies to deliver high-quality apps for the end-users. Software testing activities are essential for the quality assurance of a mobile application. Despite its importance, testing is still not widely adopted for mobile applications [6]. Only 8% of the non-trivial and real-world apps have automated tests. Automated UI testing is less adopted than unit testing [7].

There are four types of testing infrastructures in the context of mobile application testing:

- Emulator-based: this infrastructure leverages a mobile device emulator to run the tests;
- Device-based: this type of infrastructure consists of setting up a local or laboratory environment using real mobile devices to run the tests;
- Cloud-based: this type of infrastructure aims at building a mobile device cloud to support testing on scale;
- Crowd-based: this type of infrastructure leverages testing engineers, users, or the community to run tests [6].

Given that third-party cloud services offer mobile application automation primarily on a subscription or pay-per-use basis, and considering that achieving complete automation with physical devices remains technically and economically challenging, the establishment of a local server-based infrastructure can be regarded as a more viable solution for small and medium-sized enterprises. Such an approach not only reduces long-term operational costs but also provides greater control over testing environments, enhances scalability of experiments, and ensures higher levels of data security compared to external cloud providers.

This article introduces a local, emulator-based infrastructure for automating testing of mobile Android applications on the Windows 10 operating system. The infrastructure further demonstrates the feasibility of executing the headless Android emulator, thereby ensuring a fully automated testing workflow independent of desktop environments.

3 ANALYSIS OF CURRENT RESEARCH

Research on automated testing of Android applications is extensive and concentrates primarily on testing techniques, test-input generation, fault detection, and framework capabilities rather than on the choice of host or server operating systems for test runners. Systematic literature reviews and surveys compile and compare approaches (e.g., input-generation algorithms, model-based testing, and framework applicability) but typically report execution environments only insofar as they are necessary to reproduce experiments, without offering representative statistics or dedicated analysis of preferred host OSes and emulator operating modes.

In addition to general surveys, individual empirical studies report the use of specific host operating systems in their experimental setups. For example, in the work by Menegassi and Endo [8] Automated testing of cross-platform mobile applications was carried out on Windows 10 and macOS X Sierra environments, reflecting the practical necessity of supporting multiple development and deployment platforms. While such mentions confirm the feasibility of running test automation frameworks across different desktop operating systems, the choice of host OS is presented as a contextual detail of the experimental environment rather than as a subject of systematic analysis or comparison.

Several recent studies report the execution of headless Android emulators on Ubuntu servers [16] without a graphical user interface, demonstrating the technical feasibility of server-based test execution. While these works provide illustrative examples of emulator deployment in a Linux environment, they do not present a comprehensive automation infrastructure for Android mobile applications.

The investigation by Romano, Song, Grandi, Wei Yang and Wang describes how the test was run using a headless browser [9]. But in this case, the tests are performed in a browser in headless mode and not specifically the headless emulator.

In the paper by Lin, Salehnamadi, and Malek [7], it is described supporting “headless mode” such as done by Robolectric can let developers run UI tests without an emulator and save a massive amount of execution time. It should be emphasized that this does not refer to a conventional Android emulator running in headless mode on a local Windows 10 machine, but rather to a testing environment that fully simulates UI behavior without a graphical interface.

In their paper, Kim, Park, Ko, Ko, and Lee explain that for web applications, web drivers are commonly used to automate web testing. Similar to X-Droid, they provide a "headless" mode of execution, in which UI interactions are performed in the background without displaying anything to the user. In this sense, X-Droid can be considered as supporting a headless mode for driving Android applications [10].

The investigation by Samhi, Just, Bissyandé, Ernst, and Klein reports that applications were installed using a headless Android emulator based on Google's Android 33 system [11].

Overall, there is a practice of running Android emulators in headless mode, deploying applications in this mode, and executing automated tests. Due to the lack of research specifically addressing the automation of Android applications on emulators running in headless mode, the present study can be considered highly relevant.

4 HARDWARE AND SOFTWARE CONFIGURATION

4.1 Experimental Environment

The experiments were conducted on a workstation running Windows 10 Pro x64. More detailed hardware and software specifications are provided in Table 1.

Table 1: System configuration used for experiments.

Component	Specification
CPU	AMD Ryzen 5 3600 6-Core Processor, 6 cores, 12 threads, 3.6 GHz
RAM	2 × 16 GB DDR4 (Kingston KF3200C16D4/16GX), total 32 GB, 3200 MHz
Storage	SSDPR-CX400-512-G2, 512 GB (Fixed SSD)
Graphics Card	NVIDIA GeForce RTX 3050, 8 GB VRAM
Operating system	Windows 10 Pro x64 (22H2)

4.2 Emulator Installation and Configuration

The experiments were conducted using Java JDK 17, without the necessity of installing Android Studio, which significantly increases the consumption of CPU and memory resources. Instead, the Android Emulator was installed and configured through command-line tools, ensuring a lightweight and reproducible setup.

The installation of the software components was performed exclusively through the Command Prompt (cmd.exe) terminal, without relying on any additional graphical user interfaces. The installation procedure begins with the setup of the Command Line Tools (official link to the latest version as of September 2025) and the creation of the required directories. Installation parameters the following A.1 in the Appendix.

This step included defining the ANDROID_HOME variable and updating the PATH

Command-line commands:

```
setx ANDROID_HOME
"%USERPROFILE%\Android\Sdk"

setx PATH
"%USERPROFILE%\Android\Sdk\cmdline-
tools\latest\bin;%USERPROFILE%\Android\
Sdk\platform-
tools;%USERPROFILE%\Android\Sdk\emulato
r;%PATH%"
```

During the setup, the necessary SDK packages were installed by executing the corresponding commands.

Command-line commands:

```
sdkmanager.bat --licenses

sdkmanager.bat "platform-tools"
"platforms;android-31" "system-
images;android-31;google_apis;x86_64"
"emulator"
```

An AVD emulating the Pixel 6a model was set up for the experiments.

Command-line commands:

```
echo no | avdmanager.bat create avd
-n pixel6a -k "system-images;android-
31;google_apis;x86_64" --device
"pixel_6a"
```

The aforementioned command installs an Android emulator configured as a Pixel 6a device with a resolution of 1080×2400 and the x86_64 architecture. This configuration demonstrated stable and reliable performance during experimentation and ensured compatibility with applications developed using widely adopted frameworks such as React Native and Flutter, as well as those implemented in Kotlin and Java.

The emulator can be launched in headless (no-window) mode by executing the following commands.

Command-line command:

```
emulator -avd pixel6a -no-audio
-no-window -memory 4096 -gpu
swiftshader_indirect -no-boot-anim
```

The explanation of the emulator launch options is presented in Table 2.

Table 2: Emulator launch options.

Option	Description
-no-audio	Disables audio support, preventing the emulator from initializing sound hardware.
-no-window	Runs the emulator in headless mode without rendering a graphical window.
-memory 4096	Allocates 4096 MB of RAM to the emulator, improving performance for resource-intensive applications.
-gpu swiftshader_indirect	Forces the emulator to use SwiftShader (software-based GPU rendering), ensuring compatibility on systems without hardware GPU acceleration.
-no-boot-anim	Skips the boot animation sequence, reducing startup time.

4.3 Test Infrastructure Configuration

For the experiments in Android application automation, Node.js version 20.19.4 was utilized, together with the WebdriverIO framework with TypeScript support, Appium, the Appium WDIO service, and additional supporting libraries. A detailed specification of the library versions is provided in the accompanying package.json file. Specific specifications are as follows A.2 in the Appendix.

In the wdio.conf.ts configuration file, the capabilities included the flag noReset: true to ensure that the application was not reinstalled during each test session.

Considering that the emulator operates in headless mode, an essential aspect of debugging is identifying where the error occurred and under what circumstances. The most effective approach is the combined use of the screenshot reporter and the wdio-video-reporter service. The wdio-video-reporter service, which is already included in the example package.json file provided above, captures screenshots throughout the test execution and, in the event of a test failure, generates a consolidated video recording of the failed test. Complementarily, the screenshot reporter produces a screenshot at the exact point of failure, thereby facilitating precise error localization and analysis. To enable the screenshot reporter, it is sufficient to specify the following configuration in the afterTest section of the wdio.conf.ts file. The solution is presented A.3 in Appendix.

The execution of tests, the removal of outdated application versions, and the deployment of new builds were managed through the Jenkins continuous integration system. Jenkins is a widely adopted continuous integration system that is commonly used for deploying Android applications and executing automated tests, including those orchestrated through custom Shell or Bash scripts [12] - [15]. An example of the Execute Shell script used in the Build Steps section of the Jenkins job is presented A.4 in Appendix.

The execution of a Jenkins job can be triggered under various conditions, such as at scheduled time intervals, upon a new commit to the repository, or via custom triggers, for example, when a new application build becomes available.

The reporting functionality was implemented using the wdio-slack-reporter service, which leverages the Slack API to deliver notifications. In the event of a test failure, this integration enables the automatic transmission of screenshots or video recordings of the encountered error.

The automation project employs the Page Object model. By default, the framework generates the Pages directory for page object files and the Specs directory for test execution files. However, these directory locations can be customized through the wdio.conf.ts configuration file. An example of using the Page Object model is provided A.5 in the Appendix. In this study, the Page Object Pattern is applied following the guidelines and recommendations provided in the official WebdriverIO documentation [18], ensuring maintainable and scalable test automation. This approach structures the application under test into modular page classes that encapsulate selectors and interaction logic, reducing duplication and isolating UI changes from test scripts. By separating behavior from test flow, the Page Object architecture enhances readability, reusability, and long-term maintainability of the automated test suite. The project employed a combination of UI Automator, XPath, and ID-based locators for identifying and interacting with interface elements.

5 RESULTS AND DISCUSSIONS

This study was conducted on an Android emulator executed in both headless and UI modes, using a two Flutter-based, one Kotlin-based and one React Native applications on a Windows 10 machine. The headless emulator demonstrated improved test execution times and reduced average CPU load on the host machine. For instance, two test cases (login and logout) in Flutter app executed on the headless emulator completed in an average of 16.2 seconds, whereas on the UI emulator they required an average of 18 seconds. A larger test set of 17 cases executed on the emulator completed in an average of 2 minutes 34.2 seconds with an average CPU utilization of 74%, while the same tests on the UI emulator required an average of 2 minutes 45 seconds with an average CPU utilization of 78%. The execution of 29 tests on the Kotlin-based application similarly demonstrated improved performance, showing faster execution times and a reduction in CPU utilization by 7.1%. The execution of 24 tests on the React Native application also demonstrated enhanced performance, with faster execution times and a 6.9% decrease in CPU usage. Overall, the study demonstrated that, regardless of the mobile application framework, tests executed faster in headless mode and CPU load was reduced.

Additional experiments were conducted on virtual Ubuntu 24.04.3 LTS servers with an x86_64 architecture using an Android emulator in configurations both with and without hardware acceleration. When hardware acceleration was disabled (using the -no-accel flag), the emulator startup time reached approximately five minutes, indicating that such a configuration is unsuitable for automated testing. With hardware acceleration enabled, the emulator exhibited instability: around half of the test runs failed, and the execution time of the corresponding 17 test cases doubled. Based on experimental results, remote virtual Ubuntu servers demonstrated lower reliability and stability for test automation in this study. Instead, dedicated servers or local machines are required.

Regarding official macOS machines, they may be considered for executing both Android and iOS emulators. However, Windows 10 machines are significantly more cost-effective than macOS hardware, which makes them the fastest and most economical option for deploying Android emulators on local workstations.

Considering that WebdriverIO provides an official integration service with BrowserStack for mobile application automation, additional test executions were performed on this platform. The study showed that the 17 tests executed on the first Flutter application completed in 3 minutes and 10 seconds, which is approximately 23% slower compared with the local headless emulator. A similar performance difference was observed for the tests executed on the Kotlin-based application. A likely explanation for this performance reduction is consistent with BrowserStack's official documentation, which notes that the platform relies on secure tunneling and multi-step network routing between the local environment and remote testing infrastructure. Such routing increases latency and can slow down the execution of automated tests. Also the investigation by Abolfazli, Sanaei, Alizadeh, Gani, and Xia [17] states that distant giant clouds feature rich resources and high scalability; however, being located far away from mobile nodes, they introduce long WAN latency and degrade the responsiveness of application response time.

For each experiment, we report the mean execution time along with standard deviation to illustrate variability. Differences between headless and non-headless runs were evaluated using a two-tailed t-test, with resulting p-values < 0.05, indicating statistical significance. To assess test stability under load, each scenario was repeated 10 times and the percentage of flaky tests was recorded. This analysis confirms that headless execution introduces minimal performance overhead while maintaining high test reliability.

Considering the specifics of installing the Android emulator on Linux and Ubuntu operating systems [16], and based on the results of the test execution on Ubuntu servers and cloud-based solutions such as BrowserStack, it can be concluded that Windows 10 provides an environment with the fastest emulator installation and the quickest test execution.

6 CONCLUSIONS

While existing works demonstrate headless testing feasibility, our contribution is the specific Windows 10 optimization and quantitative validation of performance gains for CI/CD pipelines. Based on the results of this study, the following conclusions can be drawn:

- Tests executed on the Android emulator in headless mode are on average 6.6% faster compared to the UI-based emulator, while the CPU load on the host machine is on average 5% lower;

- The emulator operating in headless mode demonstrated stable performance without failures;
- The proposed solution constitutes a fully autonomous system that includes the deployment of new application builds, execution of tests on the latest builds, and comprehensive reporting. Reporting is achieved through the integration of screenshot reporters, video reporters, and framework logs, which together provide a complete picture of where and under what conditions a test failed;
- The system can operate either on a dedicated machine or on the same workstation used by a developer;
- The solution on Windows 10 machine has proven to be highly cost-efficient, as it does not rely on commercial services or frameworks and eliminates the need for containerization of emulators and test runs. This feature makes the approach particularly attractive for small companies.

A.2 Package.json:

```
{
  "name": "app_name",
  "type": "module",
  "devDependencies": {
    "@types/chai": "^5.0.1",
    "@wdio/appium-service": "^8.39.1",
    "@wdio/cli": "^8.39.1",
    "@wdio/local-runner": "^8.39.1",
    "@wdio/mocha-framework": "^8.39.0",
    "@wdio/spec-reporter": "^8.39.0",
    "appium": "^2.11.2",
    "appium-uiautomator2-driver":
"^3.7.2",
    "chai": "^5.1.0",
    "ts-node": "^10.9.2",
    "typescript": "^5.5.3",
    "wdio-video-reporter": "^6.1.1",
    @moroo/wdio-slack-reporter":
"^8.0.1"
  },
  "scripts": {
    "test": "wdio run ./wdio.conf.ts"
  },
}
```

A.3 TypeScript code:

```
afterTest: async function (
    test,
    context,
    { error, result, duration, passed,
retries }
    ) {
  // take a screenshot anytime a test
fails and throws an error
    if (error) { await
driver.saveScreenshot(`./errorscreen/na
me.png`);
    }
  }
```

A.4 Execute shell commands:

```
#Force stop of an application
adb shell am force-stop <package_name>

#Removing an application from the
 emulator
adb uninstall <package_name>

#Deleting an old application in a
 project
cd app
 del app.apk
#Downloading a new application build
curl -o app.apk <app_link>

 #Install a new application
 adb install app.apk

 #Open an application
 adb shell monkey -p <package_name>
-c android.intent.category.LAUNCHER 1

#Run test
 npm run test
```

A.5 TypeScript code:

```
//Page file
class LoginPage {
//Login email field
    get loginemailField () { return
  $('~Email')}
//Wait Title in Create New Expense tab
    async waytloginemailField () {
await this.
loginemailField.waitForDisplayed({
  timeout: 5000, timeoutMsg: 'Login
  email field is not displayed })
    }
}
export default new LoginPage();
//Spec file
```

```
import LoginPage from
   "../pages/login.page.ts";
describe('Login cases', () => {
it.skip('Check login field', async ()
   => {
await LoginPage.wayloginemailField();
});
});

Leveraging Semantic Knowledge Graphs for Smart Manufacturing Integration via Asset Administration Shells

Mohamad Wael Kheshfeh, Sebastian Linke, Markus Müller, Tobias Tute and Rüdiger Mecke
Department of Engineering and Industrial Design, Magdeburg-Stendal University of Applied Sciences, Breitscheid Str. 2, 39114 Magdeburg, Germany
mohamad.kheshfeh@h2.de

Keywords: Asset Administration Shell, Knowledge Graph, Manufacturing Technologies, IIoT Platform, Semantic Integration, Digital Twin, SPARQL, Automated Reasoning.

Abstract: Industrial IoT platforms face semantic interoperability challenges when integrating heterogeneous manufacturing equipment. While Asset Administration Shell (AAS), standardized by IEC 63278-1:2023, provides vendor-neutral digital representations, existing implementations lack automated reasoning capabilities. This work presents a semantic integration framework enhancing AAS with Knowledge Graph technologies through bidirectional transformation mechanisms. Developed within the PlatinA Industrial Internet of Things platform research (infrastructure designed for 50 concurrent devices, currently integrating 3 manufacturing systems), our hybrid architecture combines containerized AAS implementations with Apache Jena Fuseki RDF triple stores. We validate technical feasibility through proof-of-concept implementation using a precision milling system with real-time force monitoring, demonstrating successful AAS-to-RDF transformation preserving IEC 63278 compliance, sophisticated SPARQL-based queries for force deviation detection and equipment capability discovery, and practical integration with existing infrastructure. A three-layer manufacturing ontology enables automated reasoning through SWRL rules for equipment selection, maintenance prediction, and quality assessment. This proof-of-concept establishes the foundation for addressing critical manufacturing challenges including measurement validation (targeting reduction from 80% redundancy to 5-6%) and process anomaly detection (projected 89% automation rate), enabling intelligent resource allocation and cross-system interoperability through knowledge-driven decision making.

1 INTRODUCTION

Modern manufacturing environments struggle to integrate diverse production equipment from multiple vendors into intelligent systems [1]. Proprietary protocols and data formats create information silos preventing effective cross-system communication. While Asset Administration Shell (AAS) frameworks provide standardized virtual representations mirroring real-time operational data [2], implementations traditionally function as passive data repositories lacking autonomous reasoning capabilities essential for intelligent manufacturing. The fundamental challenge lies in enabling digital representations to support automated inference and context-aware decision-making.

Domain experts identified c ritical improvement opportunities in surface finish quality control and process anomaly detection. Current manual measurement validation processes exhibit approximately 80% redundancy due to double-checking require-ments, with experts estimating that automated vali-dation could reduce this to target levels around 5-6%(implying potential 94% measurement efficiency). Similarly, process anomaly detection currently relies entirely on manual expert review, with domain spe-cialists projecting that automated semantic reasoning could detect approximately 89% of anomalies without human intervention[1].

However, achieving these targets requires automated decision-making capabilities beyond current rule-based control and machine learning approaches, which struggle with novel equipment combinations, dynamic material-process matching, and cross-equipment optimization requiring implicit relationship inference.

[1]The estimate of roughly 89 % automatable anomaly detection is based on historical process data from which typical patterns, recurrence rates, and semantically distinguishable deviations can be derived.

This work presents a semantic integration architecture enhancing AAS foundations with Knowledge Graph technologies [3]. Knowledge graphs represent information as networks of interconnected entities, enabling machines to understand contextual connections and derive logical conclusions. We validate technical feasibility through proof-of-concept implementation using a precision milling system with three-axis force monitoring, demonstrating complete AAS-to-RDF transformation, sophisticated SPARQL queries for force deviation detection and equipment capability discovery, and bidirectional synchronization suitable for manufacturing control.

This paper presents a proof-of-concept demonstrating technical feasibility of semantic integration for manufacturing systems. While PlatinA's [2] AAS infrastructure is architecturally designed for 50 concurrent manufacturing devices with 3 systems currently integrated, this work validates semantic enhancement through single-system proof-of-concept. Comprehensive semantic integration across all current and future systems represents ongoing development.

2 RELATED WORK

Asset Administration Shell research has focused on structural interoperability without leveraging semantic reasoning. Platform-based architectures like FIWARE provide cross-organizational interoperability but require significant deployment expertise [4]. The AAS metamodel's native RDF/XML and JSON-LD support enables direct semantic web integration as specified in IEC 63278-1:2023 [2].

The Industrial Digital Twin Association (IDTA) enhanced AAS capabilities through standardized submodel specifications [5], including Process Parameters (IDTA 02031-1) for equipment parameter management [6]. These templates align with semantic knowledge graph approaches, enabling transformation of IDTA-structured information into graph representations without semantic loss.

Knowledge graphs demonstrate potential in industrial domains for data integration and automated reasoning [3]. Schleipen et al. established approaches for converting OPC UA information models to RDF representations [7], transforming hierarchical industrial structures into graph formats optimized for semantic reasoning. However, contemporary research reveals deployment barriers including technical complexity and organizational resistance [8].

[2]https://www.h2.de/forschung/wissens-und-technologietransfer/efre-und-esf-projekte.html

Table 1 positions our work relative to existing approaches. Unlike platform-centric solutions requiring infrastructure replacement, our approach enhances established AAS implementations. While Schleipen et al. demonstrated OPC UA to RDF conversion, their work lacks bidirectional synchronization and real-time reasoning for closed-loop control. Our framework uniquely combines standards-compliant AAS with knowledge graph technologies, automated SWRL reasoning, and bidirectional synchronization, providing incremental enhancement without disruptive changes.

Table 1: Comparison of semantic integration approaches for manufacturing.

Approach	Standards Compliance	Semantic Reasoning	Key Characteristic
FIWARE [4]	Partial (NGSI-LD)	Limited	Requires full infrastructure replacement
Schleipen et al. [7]	OPC UA focus	Yes (RDF)	Unidirectional transformation only
Standard AAS [2]	Full (IEC 63278)	No	Passive data repository
Our Work	Full (IEC 63278)	Yes (SWRL)	Incremental enhancement with bidirectional sync

3 SYSTEM ARCHITECTURE

Our semantic integration leverages a hybrid architecture combining operational AAS data management with semantic knowledge representation using Apache Jena Fuseki RDF stores [9], addressing three requirements:

standards compliance through IEC 63278-compliant AAS [2], semantic intelligence through RDF knowledge graphs [3], and operational efficiency through real-time synchronization.

Figure 1 presents the architecture bridging Asset Administration Shells with Knowledge Graph technologies. Manufacturing systems connect through OPC UA [10] to AAS Infrastructure, where data is encapsulated within standardized AAS representations.

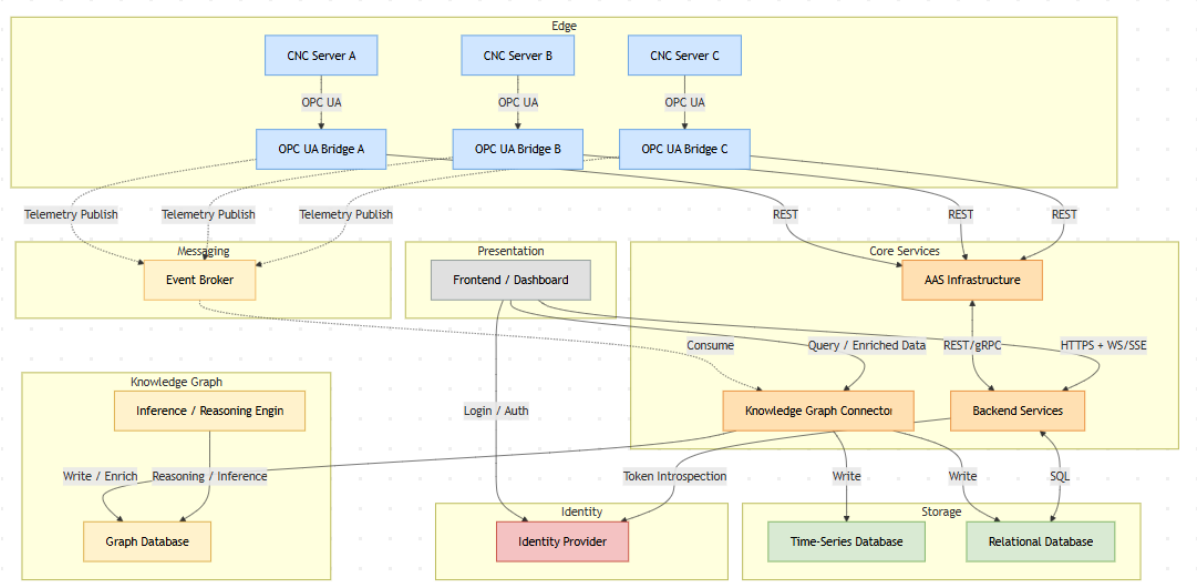

Figure 1: System architecture for semantic integration through knowledge graph-enhanced Asset Administration Shells.

The Knowledge Graph Connector performs semantic transformation, extracting data from AAS Core Services via REST/gRPC protocols [11] and enriching it with semantic annotations using ontological mappings [12]. The Inference/Reasoning Engine implements SWRL-based automated reasoning [13] including anomaly detection and production optimization, feeding insights back for closed-loop control [14].

Real-time telemetry flows f rom manufacturing systems through OPC UA to the Event Broker, where the Knowledge Graph Connector transforms raw data into RDF resources with ontological relationships. The architecture employs hybrid storage: time-series databases for high-frequency operational data, relational databases for structured asset information, and graph databases for semantic relationships.

3.1 Reasoning Rules

The Inference Engine implements SWRL rules for automated knowledge derivation. Equipment selection rules determine compatible equipment based on material and capability requirements through pattern matching on material compatibility and processing capabilities. Maintenance prediction rules identify calibration needs by evaluating temporal validity of last calibration date (threshold: 30 days) combined with force deviation patterns (threshold: 15.0 N deviation). Quality assessment rules detect process anomalies by comparing measured force values against target parameters across three axes simultaneously. For example, the equipment selection rule matches milling systems having compatible materials and required capabilities to process requirements, au-tomatically inferring suitable equipment. The mainte-nance prediction rule triggers calibration recommen-dations when force deviations exceed thresholds and calibration date exceeds 30 days. These rules enable automated reasoning for equipment selection, main-tenance prediction, and quality assessment without manual configuration.

3.2 Ontology Design

Our manufacturing ontology consists of three layers (Fig. 2). The upper ontology incorporates standard vocabularies including AAS metamodel (aas:), QUDT for units (qudt:, unit:), and IDTA submodel specifications (idta:). The domain ontology layer (mfg:) defines manufacturing-specific classes including `mfg:ManufacturingSystem` with subclasses for CNC machines, process-related classes for force measurements, and material classes (Aluminum, Steel, Titanium) with processing capabilities. Object properties establish semantic relationships: `mfg:compatibleMaterial` links equipment to materials, `mfg:hasCapability` connects equipment to capabilities, and datatype properties represent quantitative measurements.

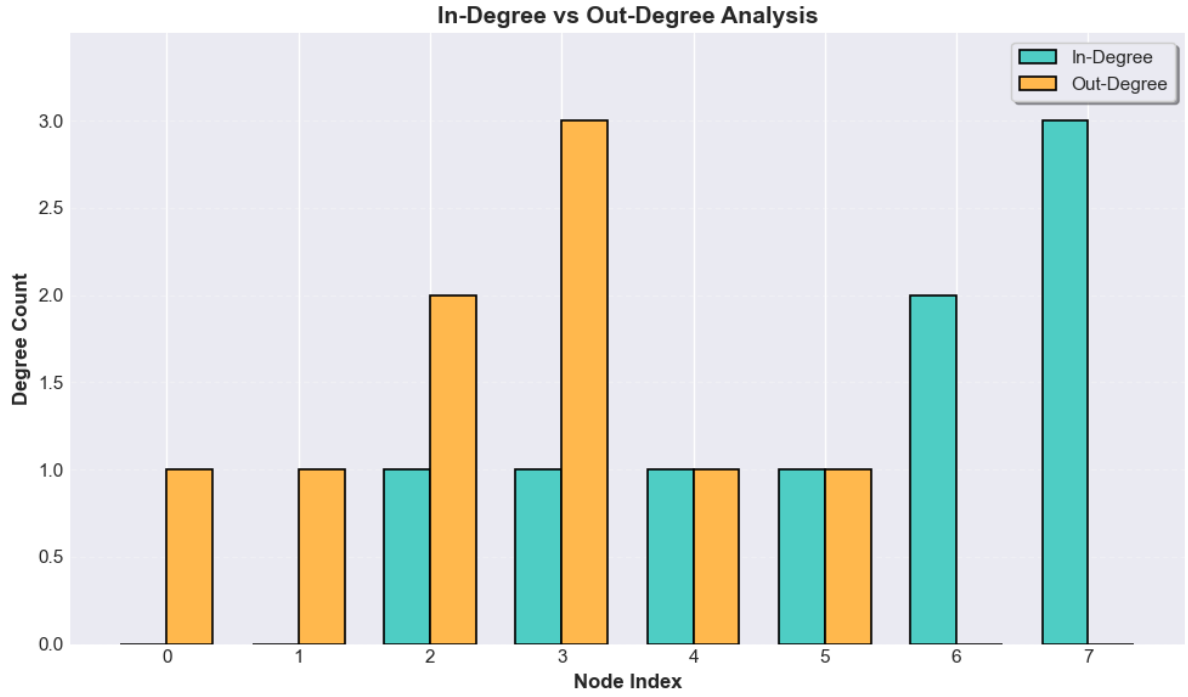

Figure 2: Graph connectivity analysis: node degree distribution in the manufacturing knowledge graph.

4 PROOF-OF-CONCEPT IMPLEMENTATION

We implemented a complete transformation pipeline using a CNC precision milling system with three-axis force monitoring [15], demonstrating systematic conversion of standardized AAS structures into semantically-enriched knowledge graphs while maintaining IEC 63278-1:2023 compliance [2].

The implementation builds upon PlatinA's existing AAS infrastructure integrating heterogeneous equipment through AAS-Tool [16] with OPC UA connectivity [10]. While PlatinA achieves strong performance through rule-based control and machine learning, it lacks automated semantic reasoning for cross-equipment decision-making. Our enhancement introduces a knowledge graph layer transforming operational AAS data into machine-understandable semantic representations supporting automated inference [3]. The milling system generates real-time telemetry including cutting forces along X, Y, Z axes (Newtons), spindle speed and feed rate, and calibration status. It connects via OPC UA [10] to AAS Infrastructure where its digital representation follows IEC 63278 [2] with IDTA Process Parameters submodel (IDTA 02031-1) [6].

Listing 1: Production AAS structure.

This equipment exemplifies typical semantic integration challenges: heterogeneous data formats from industrial sensors [17], real-time processing requirements for production control, context-aware decision support needs, and integration with standardized AAS implementations. The transformation pipeline implements bidirectional synchronization between AAS Infrastructure and Apache Jena Fuseki [9] through a Knowledge Graph Connector. Real-time sensor data flows through OPC UA to the Event Broker, where the Connector extracts AAS submodel data, enriches it with semantic annotations using ontological mappings [12], and transforms it into RDF triples [18]. The Inference Engine processes semantic knowledge using SWRL rules [13] to detect patterns and generate actionable insights flowing back to AAS Infrastructure for closed-loop control [14]. The bidirectional synchronization employs event-driven update propagation with timestamp-based conflict resolution. When the Inference Engine generates new knowledge, changes propagate back to AAS Infrastructure, updating relevant submodel elements while preserving IEC 63278 compliance through last-write-wins semantics. Listing 1 presents the complete AAS structure with hierarchical asset information, submodel references, structured process parameters with real-time measurements, and temporal metadata. This organization follows IDTA specifications [6] while providing semantic-ready data structures suitable for RDF transformation.

Listing 2: Transformed RDF knowledge graph.

The force values shown (245.2, 189.7, 312.1 N) represent typical operational measurements for aluminum milling operations under normal cutting conditions. The Knowledge Graph Connector transforms this AAS structure into RDF through systematic mapping rules. Listing 2 shows the resulting knowledge graph in Turtle notation, preserving structural information while enriching with explicit semantic relationships including type hierarchies enabling inheritance-based reasoning and physical quantities modeled using QUDT ontology supporting automated unit conversion. The semantic knowledge graph enables sophisticated queries impossible with traditional databases. Listing 3 demonstrates real-time force deviation monitoring identifying equipment operating outside normal parameters by comparing measurements against targets across three axes simultaneously.

4.1 Performance Evaluation

Table 2 presents performance measurements for critical operations in the semantic integration pipeline, averaged over 10 executions to account for JVM warm-up and system load variations.

Table 2: Performance metrics for semantic integration pipeline.

Operation	Time	Execution Context
AAS-to-RDF Transform	118ms	State change trigger, asynchronous
Force Deviation Query	43ms	On-demand SPARQL
Capability Discovery	76ms	On-demand SPARQL
SWRL Inference	227ms	Periodic batch (5-10s), Jena Rules
Write-back to AAS	95ms	Event-driven insights
Graph Storage	2.1MB	10,000 RDF triples (Turtle)
Sensor data sync	8 Hz	Direct AAS (no semantic overhead)

4.2 Real-Time Architecture

The semantic integration employs event-driven architecture optimized for real-time operation. AAS Infrastructure maintains 8 Hz synchronization with physical assets (125ms cycle) using conventional time-series storage. Semantic transformation operates asynchronously: continuous monitoring flows real-time sensor data to AAS at 8 Hz without semantic overhead, while selective transformation (118ms) triggers only on significant state changes rather than every sensor reading. Periodic reasoning (227ms) executes in background threads at 5-10 second intervals, with on-demand queries (43-76ms) executing when intelligence is required. Event-driven synchronization (95ms) occurs only when reasoning generates actionable insights. This architecture ensures the semantic layer enhances rather than impedes real-time control, with high-frequency operational data in time-series storage for immediate access while the knowledge graph provides reasoning for decision support tasks where millisecond response is not critical.

Comparison with traditional databases reveals trade-offs. While simple SELECT queries execute in 5-15ms, they cannot express semantic relationships in Listings 3-4 without complex multi-table JOINs and application logic. SPARQL queries combine material compatibility, equipment capabilities, technical specifications, and process parameters in single declarative statements impossible to formulate efficiently in SQL, justifying additional latency for reasoning-intensive tasks.

4.3 Deployment Experience

The proof-of-concept implementation required approximately 6 person-weeks for initial development, including ontology design (2 weeks with 3 domain expert consultations), transformation pipeline implementation (2 weeks), SWRL rule development (1 week), and integration testing (1 week). Integration with existing PlatinA infrastructure was achieved through standardized REST APIs without modifications to core AAS components, demonstrating the incremental enhancement approach. The containerized architecture enabled seamless deployment alongside existing AAS services with minimal infrastructure changes.

5 DISCUSSION

The semantic enhancement introduces computational overhead (118ms transformation, 227ms reasoning) and implementation complexity (ontology engineering, maintenance) that must be justified by specific requirements. Our analysis suggests knowledge graphs provide maximum value in scenarios characterized by: (1) cross-equipment reasoning where decisions span multiple assets, materials, and processes; (2) dynamic material-process matching where novel combinations arise frequently; (3) implicit relationship inference where capabilities, properties, and requirements must be reasoned over without explicit programming; and (4) knowledge preservation where expert manufacturing knowledge should be captured formally.

Conversely, semantic overhead may not be justified for: (1) simple monitoring where time-series queries suffice; (2) well-defined repetitive processes where rule-based control captures decision logic; (3) single-equipment operations without cross-system dependencies; and (4) environments lacking domain expertise for ontology development. The PlatinA platform demonstrates hybrid deployment where traditional databases handle high-frequency sensor data while the knowledge graph addresses reasoning-intensive tasks. This architectural pattern provides practical balance between performance and intelligence.

The incremental enhancement approach mitigates deployment barriers by maintaining existing AAS infrastructure while introducing semantic capabilities selectively where they provide clear value. Manufacturing facilities can begin with limited integration for specific use cases (equipment selection, maintenance scheduling) and expand coverage as expertise develops, avoiding all-or-nothing adoption challenges hindering semantic technology deployment in conservative industrial environments.
This proof-of-concept demonstrates technical feasibility but has limitations requiring future work.

First, validation with a single milling system limits its generalizability claims across diverse manufacturing equipment types. While PlatinA's AAS infrastructure is designed for 50 concurrent devices and currently integrates 3 systems, semantic integration has only been validated with one proof-of-concept system. Empirical validation across multiple heterogeneous systems under production loads with hundreds of thousands of RDF triples remains necessary to demonstrate scalability from single-system proof-of-concept to infrastructure-wide deployment. Second, ontology engineering and maintenance require specialized expertise in both semantic technologies and manufacturing domain knowledge, potentially limiting adoption in resource-constrained environments. Third, SWRL reasoning performance (227ms per inference cycle) may require optimization strategies such as pre-computation or incremental reasoning for production deployments with complex rule sets exceeding our current 8 rules. Fourth, the proof-of-concept lacks comprehensive evaluation of failure scenarios, error recovery mechanisms, and long-term operational stability in 24/7 manufacturing environments. Finally, while performance measurements demonstrate acceptable latency for decision support tasks, integration with time-critical control loops requiring sub-100ms response may necessitate architectural refinements or hybrid reasoning approaches combining semantic inference with traditional rule engines.

6 CONCLUSIONS

This proof-of-concept validates technical feasibility of semantic AAS integration through hybrid AAS-Apache Jena Fuseki architecture, systematic AAS-to-RDF transformation maintaining IEC 63278 compliance, and SWRL-based automated reasoning for equipment selection, maintenance prediction, and quality assessment.

Practical applications include automated resource allocation through semantic queries over capability ontologies, cross-equipment process optimization identifying compatible tool-material-machine combinations, and predictive maintenance scheduling combining calibration validity, force deviation patterns, and sensor health indicators.

The primary objective of this work is establishing the semantic foundation necessary for cognitive assistance systems supporting manufacturing operators and engineers. This research contributes foundational infrastructure enabling the PlatinA platform to integrate AI-driven capabilities including natural language interfaces for intuitive equipment interaction, intelligent decision support combining machine learning with semantic reasoning, and context-aware assistance adapting to operator expertise levels and current manufacturing scenarios.

The knowledge graph architecture enables AI systems to understand manufacturing relationships, equipment capabilities, and process constraints, facilitating human-AI collaboration where cognitive assistants augment rather than replace human expertise. This work establishes semantic infrastructure enabling the PlatinA platform to integrate AI-driven capabilities including natural language interfaces, intelligent decision support, and context-aware assistance for manufacturing operators through federated knowl-edge sharing across regional networks.

7 FUTURE WORK

Future work will address current limitations through multi-system validation across diverse equipment types to demonstrate generalizability, empirical scalability testing expanding from single-system proof-of-concept to PlatinA's current 3-device deployment and ultimately to the infrastructure's 50-device design capacity, enhanced reasoning capabilities through temporal and probabilistic reasoning, collaborative ontology engineering methodologies, and comprehensive industrial validation assessing long-term stability and ROI.

ACKNOWLEDGEMENTS

This work is carried out as part of the PlatinA project (ZS/2023/12/182752), supported by funding from the European Union and state of Sachsen-Anhalt.

An Effective Method of Using Ozone Generator in Viticulture Instead of Pesticides

Abstract: This study addresses the challenge of developing sustainable and environmentally friendly viticulture practices by proposing an alternative to conventional pesticide use based on ozonated water treatment. The method involves the application of ozone dissolved in water at controlled concentrations, adjusted according to environmental conditions such as rainfall and temperature. Field experiments were conducted over two years in vineyards of the Bolnisi region (Georgia) on different grape varieties, including Saperavi, Chinuri, and Rkatsiteli. The proposed approach demonstrates that ozonated water can effectively replace chemical pesticides while maintaining plant health and reducing environmental impact. Experimental results indicate that the method preserves the chemical composition of grapes, soil, and vine leaves, without increasing heavy metal accumulation. Moreover, an increase of approximately 30% in resveratrol content in vine leaves was observed, while quercetin levels remained stable. The findings confirm that ozone-based treatment represents a cost-effective, energy-efficient, and sustainable solution for viticulture. This approach is particularly suitable for small-scale farmers, as it reduces dependency on agrochemicals and supports the production of safer and nutritionally valuable agricultural products.

1 INTRODUCTION

To achieve global development goals, healthy, sustainable and inclusive food systems are critical, especially in the world's most fragile regions where agriculture and its development are one of the most powerful tools for poverty reduction and are also critical for economic growth.

Three billion kilograms of pesticides are used worldwide every year, while only 1% of total pesticides are effectively used to control insect pests on target plants. The large amounts of remaining pesticides penetrate or reach non-target plants and environmental media. As a consequence, pesticide contamination has polluted the environment and caused negative impacts on human health [1].

The numerous negative health effects that have been associated with chemical pesticides include, among other effects, dermatological, gastrointestinal, neurological, carcinogenic, respiratory, reproductive, and endocrine effects. Furthermore, high occupational, accidental, or intentional exposure to pesticides can result in hospitalization and death [2].

The background paper to The State of Food and Agriculture 2023 examines the annual hidden costs of agrifood systems across 2016-2023 for 154 countries. The expected value of hidden costs is around 13 trillion 2020 purchasing power parity (PPP) dollars [3].

Despite direct annual global pesticide costs, where In 2023, the volume of total pesticides exports (used here as a proxy for trade) decreased by 3 percent compared with 2022 to 6.7 Mt of formulated products, and their value decreased by 12 percent to USD 42.8 billion [4], as well as ongoing and growing "hidden costs", there is still no effective alternative to pesticides that could provide sufficient healthy agricultural products with the less losses for a growing population.

2 MATERIALS AND METHODS

2.1 Ozone Generation Technology

Ozone is approved for use as an alternative disinfectant in the United States and Europe. In the US, the FDA has granted it Generally Recognized as Safe (GRAS) status for use in food and food processing, including as a sanitizer. In Europe, ozone is widely accepted and used in wastewater treatment plants, particularly for disinfection and odor control. Ozone is a strong oxidant and potent disinfecting agent. Even though it is new for the US, it has been utilized in European countries for a long time [5].

The main problems of the mass distribution of ozone technology in the world are the high cost and the high energy consumption of the ozone generators (air; water).

In 2021, in Georgia (GE), was patented (P 2021 7302 B) [6] its own "Ozone Generating System" technology and began to use it in various areas of agriculture. An advantage of the present invention: "Ozone Generation System": can operate reliably for a long time without damaging the electrode due to the current generated during the electric discharge; can operate at a reduced voltage of the power source; can operate efficiently with relatively less energy consumption; ozone generation is carried out by barrier and corona discharge and ultraviolet radiation simultaneously; ozone formation is regulated by air flow and by electric operation mode; the ozone generator operates on oxygen on demand.

2.2 Applications of Ozone Generation Technology for Vineyards

Grapevines are one of the most extensively grown fruit crops in the world and also one of the leaders in pesticide consumption. Worldwide, on average 35 % of all pesticides are used for viticulture [7].

This can be largely explained by the fact that grapevines host the highest number of pathogens of any woody species.

Recent studies have revealed that ozone (O3) in aqueous solution is a promising candidate for limiting grapevine infection by *Phaeoacremonium aleophilum*, a fungus associated with esca. In the last few years, in fact, spraying grapevines with ozonated water for disease control is becoming more frequent among winegrowers. The reason lies mainly in the high oxidizing power of ozone and its spontaneous decomposition to oxygen without forming hazardous residues. The decomposition of aqueous ozone also leads to the production of reactive oxygen species (ROS), which are more reactive but less selective than molecular ozone [8].

Ozonated water is being introduced as an alternative phytosanitary treatment to control grapevine diseases in a context in which the reduction of chemical pesticides has become an urgent necessity [9].

However, it has recently become clear that ozone exposition leads to another important benefit: in living tissues, the induced-oxidative stress triggers the antioxidant response, and, therefore, it enhances the production of antioxidant and stress-related secondary metabolites. As such, ozone can be considered an abiotic elicitor. The goal of the present review was to critically summarize knowledge about the possibility of improving bioactive compounds and, consequently, the health-related properties of grapes and wine, by using ozone [10].

2.3 Scientific Competence and Technical Equipment

Within the framework of the research grant project of the Shota Rustaveli National Science Foundation of Georgia with the support of the Technical University of Georgia, a target group of 11 participants was selected from the vineyards of the Bolnisi District Small Winemakers Association, with whom research was conducted over two years on the use of ozone in the form of an aqueous solution in different concentrations, under different natural conditions, on different grape varieties (*Saperavi, Chinuri, Rqatsiteli*).

Each participant, who provided at least 1 ha of vineyard, was equipped with 585 wat solar panels as a power supply, also by overheating protection systems, AC and DC stability protection, additional charging systems for other electrical appliances, batteries, etc. and 10 gr/h water ozone generators for 15 liters water sprayers, with which water was charged with soluble ozone up to 0.03-0.08 mg/l on demand. Concentration measurements were carried out using a "Hy bono" Dissolved Ozone Tester.

2.4 The Methodology of Application of Ozonized Aqueous Solution in the Vineyard Follows

The application of ozonized aqueous solution in the vineyard was carried out according to a structured treatment protocol developed based on environmental conditions and grapevine phenological stages. The methodology includes the following key steps:

1) Vineyard treatment began in late March - early April and was carried out during 9 phenological phases until the second ten-day period of August with an ozonized aqueous solution at a concentration of 0.03 mg/l. (For prevention of powdery mildew, ash, mites and grape moth (1, 2, 3 generations), scale insects, false scale insects, rot).
2) No treatments were carried out during the flowering period of grapes.
3) During the rainy season at a temperature of 20–29 °C, the vineyard treatment was not carried out, but was resumed out of turn immediately after the rains ended. After a period of 1–4 days of rain, the ozone concentration in the aqueous solution was 0.04–0.06 mg/l. After a period of 6–9 days of rain, the ozone concentration in the aqueous solution was 0.06–0.08 mg/l.
4) After the second ten-day period of August or at a temperature above 30 °C, on healthy and large, then on ripe and, finally, on very ripe large bunches of grapes, the treatment was continued only after rainy days, or for prevention only once, while the ozone concentration in the aqueous solution was 0.04-0,06 mg/l. and 0.03 mg/l. respectively.

During harvesting and visual inspection, the vineyard and berries looked healthy.

3 RESEARCH

The quality of grapes was assessed by the content of some mineral and phenolic components.

Resveratrol scavenges free radicals and enhances the activity of endogenous antioxidant enzymes. This action protects cellular components from damage associated damage and helps reduce oxidative stress, a significant factor in aging and the development of age-related diseases, such as cardiovascular diseases and diabetes [11].

Quercetin manifests antioxidant properties both in vivo and in vitro. Free radical scavenging activity of quercetin protects from various age-associated disorders. A diet rich in quercetin has various health-promoting benefits. It acts as an agent to lower coagulation, hyperglycemia, inflammation, and hypertension. Various clinical studies show that supplementation of quercetin is used to prevent and treat various chronic diseases such as cardiovascular disorders [12].

Since the two main types of antioxidants in grapes - Resveratrol and Quercetin neutralize the effects of free radicals that can cause significant harm to the body, these two main phenolic compounds were analyzed from organic components.

Moreover, it was necessary to determine whether the chemical composition of vine leaves and wine changed as a result of replacing pesticides with ozonized water treatment, therefore, microelements were also determined in vine leaves.

From winemaking companies of the Bolnisi region, wines and grape leaves were used as objects - *Saperavi* and for comparison *Chinuri* and *Rqatsiteli*.

Microelements were determined in wine, soil and grape leaves. Sample preparation and content measurement was carried out in the Atomic Absorption Spectrometry Department of the Academician Nodar Kekelidze Scientific Research Institute of Materials Research of the Faculty of Exact and Natural Sciences of Ivane Javakhishvili Tbilisi State University, on an atomic absorption spectrometer AAnalyst 800 (PerkinElmer Inc.) with software WinLab 32 and in the "Geoanalytic" laboratory of the Alexandre Tvachrelidze Mineral Resources Caucasus Institute. (The results of the analyses are presented below in Tables 1, 2, 3).

Chemical analyses were conducted according to the respective ISO and GOST. In particular, analysis of heavy metals carried out according ISO 8288-1986 standards.

Resveratrol and quercetin assays were performed using the highly efficient liquid chromatography method. We made chromatographic division on Agilent 1200 Technologies chromatograph CI8 HPLC 5mcm chromatographic column. For analysis, 20 ml of the sample was administered with an autosampler, acetonitrile-HPLC, >99.9 % (Sigma-Aldrich), acetic acid, bidistillate were used as eluents. Extraction used 60% ethanol. For chromatographic division, the following conditions were selected: gradient elution with acetic acid, acidified bidistillate, and acetonitrile. Total analysis time 50 minutes.

4 RESULTS AND DISCUSSIONS

As follows from the data in Table 1, the content of heavy metals in Saperavi wines from the ozonized and control plots is almost the same and does not exceed the MAC (except for copper and manganese). When comparing the amount of heavy metals in wine and soils of the studied plots (Tables 1 and 2), it was found that almost a thousandth part of each heavy metal contained in the soil passes into the wine.

Table 1: Heavy metal content in bottled wine, mg/l.

N	Element	Cu	Zn	Pb	Cd	Co	Ni	Mn
1	Saperavi from non-ozonized site	1.114	0.912	0.120	0.00	0.022	0.072	0.836
2	Saperavi from ozonized site	0.136	1.200	0.113	0.00	0.017	0.107	0.152
3	MPC (maximum permissible concentration)	1.0	5.0	0.3	0.001	0.2	0.5	50.0

Table 2: Content of mineral microcomponents in soil, mg/kg.

N	Element	Cu	Zn	Pb	Cd	Co	Ni	Mn

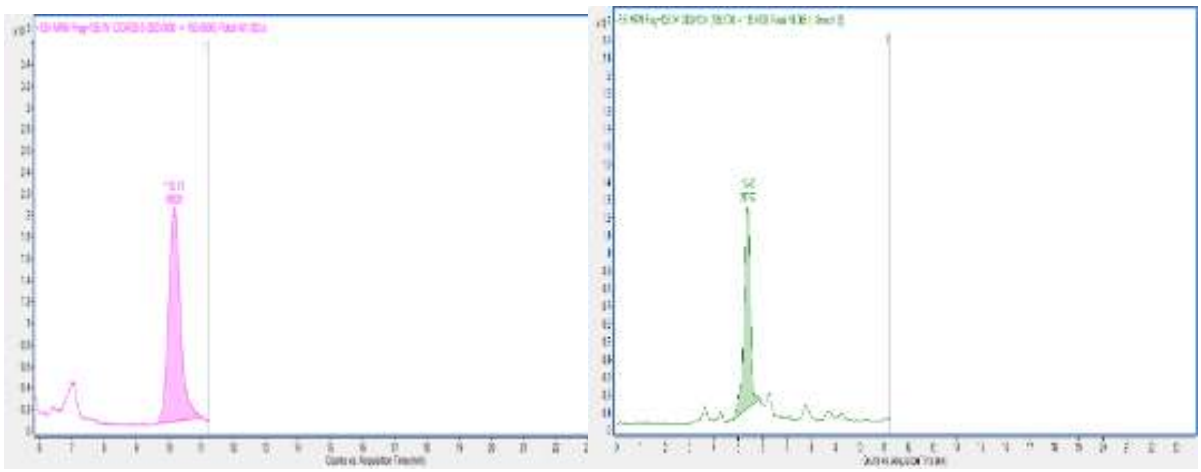

Figure 1: Chromatograms of resveratrol (at the left) and quercetin in leaves from non-ozonated site.

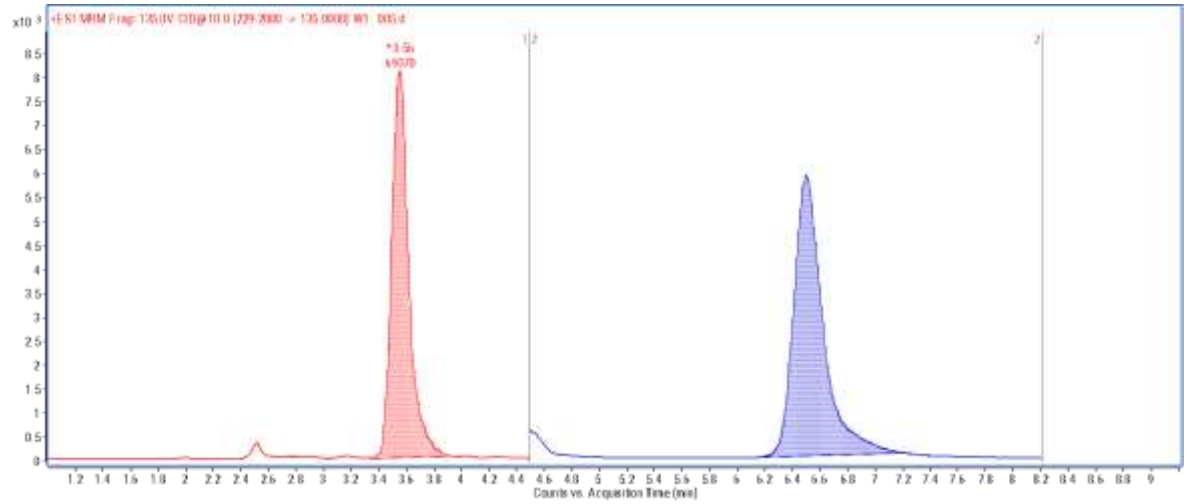

Figure 2: Chromatograms of resveratrol (at the left) and quercetin in leaves from ozonized site.

The content of heavy metals in the vine leaves of three wine varieties is almost the same order of magnitude (except for iron and manganese) and indicates their partial migration from the soil to the vine leaves Tables 2 and 3.

About 3% of copper and lead, 9.7% of zinc, 24% of cadmium, 28% of cobalt and about 80% of nickel passed from the soil to the leaves. According to the data, a study in field vegetation chambers to determine the effect of ozone and simulated acid rain (SAR) on the content of heavy metals in the soil [13].

This indicates high mobility of mobile forms of nickel and cobalt, and such a spread is apparently due to the presence of a large number of mobile forms of some elements and a smaller number of others in the vineyard soil. This was observed both for the ozonized plot and for the control one.

According to the obtained chromatograph mass spectrometric data (Fig. 1), the amount of resveratrol in the leaves of the *Saperavi* variety from the non-ozonized area is 3.4 mg/kg, and quercetin is 13.5 mg/kg (Fig. 1); in the leaves of *Saperavi* from the ozonized vineyard, the content of resveratrol reaches 5.3 mg/kg, and quercetin is 14 mg/kg (Fig. 2).

That is, the amount of resveratrol increased by 30% compared to the vine leaves from the non-ozonized area. In the wine, an inverse relationship with the treatment with ozonized water was observed: 1.64 mg/kg of resveratrol in the ozonized sample and 2.5 mg/kg in the control. The content of resveratrol in this case decreased by 30%.

5 CONCLUSIONS

The results of this study demonstrate the effectiveness of using ozonized aqueous solutions as an alternative to conventional pesticide treatments in viticulture. Based on the conducted experiments and analysis, the following conclusions can be drawn:

1) The use of ozone generators, available to smallholders, through above mentioned method of cultivation, reduces their annual costs for pesticides and toxic chemicals. Reduces the pressure on the environment;
2) Energy-efficient technologies are more flexible in switching to solar energy, especially for smallholders;
3) The use of an aqueous ozone solution for treating vineyards instead of chemicals and pesticides does not cause any negative impact on the chemical composition of the leaves and the resulting wines from the *Saperavi* variety;
4) The content of heavy metals in the vine leaves indicates their partial migration from the soil through the root system and trunk into the vine leaves and in wine for both grapes, from the ozonized area and those obtained from the area treated with pesticides;
5) As a result of ozonation, an increase in the amount of resveratrol was observed in vine leaves from the ozonized area and a decrease in the amount of resveratrol in wine from the ozonized area;
6) As a result, replacing traditional pesticide treatment with ozonation and this method, reduces the overall content of toxic substances in the resulting wines, which is the positive effect of using an aqueous ozone solutionthrough this method for spraying the vineyards.

Keywords: Lower-Limb Rehabilitation, Wearable Exoskeleton, Active-Assist Device, Rehabilitation Robotics.

Abstract: Lower-limb rehabilitation exoskeletons have arisen as effective instruments for aiding patients with mobility issues in their recovery process and addressing the difficulties encountered by physical therapists, such as staff shortages and the physically demanding nature of repetitive sessions. Nonetheless, research has also shown that patients frequently develop a reliance on the passive assistance provided by such devices, which may result in a decline in the yield that can be acquired from rehabilitation training sessions. With this, the study highlights the development of a wearable exoskeleton for active-assist knee flexion-extension that can be adaptable and work in conjunction with other existing rehabilitation devices for knee movement. This system provides emphasis on the principle of effort, which in return results in the objective of the study in detecting motion intention and angle change for a period of every 100 milliseconds. Based on the obtained values, a control signal with knee flexion or knee extension as output would be provided if and only if the developed exoskeleton detects motion intention from the user but no change in angle was produced – denoting that the user's strength may not be enough to perform the intended action. This ensures the active participation of patients in their physical therapy sessions. Allowing for a mechanical input rather than utilizing physiological signals revealed great potential in reducing the risk of acquiring noisy data. Experimental results show that the developed exoskeleton has achieved a classification accuracy of at least 90% for detecting changes in angle and motion intention.

1 INTRODUCTION

According to the Global Stroke Fact Sheet 2022 of the World Stroke Organization [1], stroke remains to be the leading cause of long-term disability worldwide and the second leading cause of death with a global incidence of more than 12.2 million annually while the overall prevalence of stroke was found to be over 101 million individuals. This led to an estimated loss of 0.66% of the global gross domestic product [2]. In addition, with the increase in the average life expectancy of humans, the elderly population is rapidly increasing, and this is known to be closely interrelated with the increasing incidence of long-term ailments and disabilities wherein according to the United Nations [3], over 46% of older people globally, those aged 60 years and over, are considered as persons with disabilities (PWDs).

To address physical and mobility impairments, physical rehabilitation and are recommended to patients to recover their balance and mobility, in combination with other treatments to trigger neuroplasticity [4]. An effective rehabilitation is a customized process that is tailored to the individual needs of a patient. Designing rehabilitation programs for learning or relearning a motor skill includes the following principles: 1) practice, 2) skill specificity, 3) feedback, 4) attention, and 5) interest. As such, existing methods of physical therapy, specifically traditional rehabilitation and robotic rehabilitation processes, are performed on patients to address and cover the principles for motor learning. Conventional physical therapy heavily involves intensive labor provided by physical therapists (PT) and physicians, which is expensive and inefficient [5], [6]. With robotic rehabilitation, a physical therapist can attend

to more patients at a time, which maximizes the PT's efficiency and potentially lowers the rehabilitation costs per patient as robotic assistive devices aid in eliminating manual assistance provided by the PT while performing with better motion accuracy, allowing the PT to focus more on performance evaluation and analysis of the patient [5], [7].

According to the study of Taravati et al. [8], patients have the tendency to develop a dependency on passive movements, which can lead to a decrease in active, voluntary movements. Rehabilitation devices that assist patients in performing passive-assisted ROM exercises are found to be less effective than active exercises [9]. Nonetheless, they are both similarly efficacious in improving individuals' functional fitness [10].

The performance of prosthetics and orthotics devices highly relies on their control algorithms as they specify how the robot or device would carry out its tasks and how it would react to external factors that may be brought on by the environment or the subject. With this, the assistive control strategies developed to aid subjects with insufficient muscle contraction to produce the desired movement and help them trigger neuroplasticity, the ability of the brain to rewire itself and bring back the sensory and motor functions of patients [11].

Powered orthoses for rehabilitation are continuously being studied and researched as robotic rehabilitation is still considered to be an emerging technology in today's Industry 4.0. These devices generally aim to aid PTs as well as patients in maximizing their therapy sessions to achieve a maximized gain; furthermore, these often employ sensors to obtain data that would be utilized for feedback to the PT, ensuring that the PT has quantifiable data about the patient's performance.

Based on the different literature discussed above, there is extensive research on the application of force sensors, inertial sensors, and EMG sensors. Most studies show that effort plays an important role in physical rehabilitation, often applying force sensors, inertial sensors, and/or EMG sensors to the device to obtain this information. In addition to that, there are also few to no studies on the development of an exoskeleton that is capable of being integrated with another existing rehabilitation device; thus, this paper aims to contribute to the existing literature by incorporating mechanical sensors to detect physical movement and effort of the subject to minimize error and data noise while being able to provide a control signal to the rehabilitation device that is connected with the system and assist the subject once needed.

1.2 Limitations of Current Control Strategies for Robotic Rehabilitation Technologies

Several limitations and challenges associated with existing rehabilitation assistance approaches can be identified:

1) Counterbalancing assistance is highly beneficial in performing activities that require a greater level of ROM; nevertheless, having a mechanical counterpart is as important to ensure the safety of the patient.
2) Impedance-based assistance may lead to the patient's passiveness over the training session, just after the patient produces enough effort to trigger the robot's assistance.
3) Lastly, EMG is helpful in monitoring muscle activation, but it is highly sensitive to several external factors – leading to the need to calibrate for every patient and every training session.

While these control strategies display promising results in assisting physical therapists and patients in performing rehabilitation exercises, one of the important points to consider is the accuracy of movement pattern assessment of the patient and the engagement of patients in various activities beyond structured therapy sessions.

Paper Contribution. The study specifically intends to determine and accomplish the following: (1) to develop of a 1-DOF wearable exoskeleton for active-assist knee flexion-extension; (2) to be able to measure and motion intention and change in angle produced by the human subject with a classification accuracy of at least 90%; and (3) to provide control signal based on the parameters obtained from the subject.

2 MATERIALS AND METHODOLOGY

Devices targeting physical rehabilitation are generally based on traditional rehabilitation practices in which a PT must manually assist the patient in performing therapy exercises, depending on the type and level of assistance needed by the patient. Concurrently, the PT senses and is aware of the patient's response to the assistance provided. Applying this concept, as illustrated in Figure 1, peripherals allowing for input are attached to the user

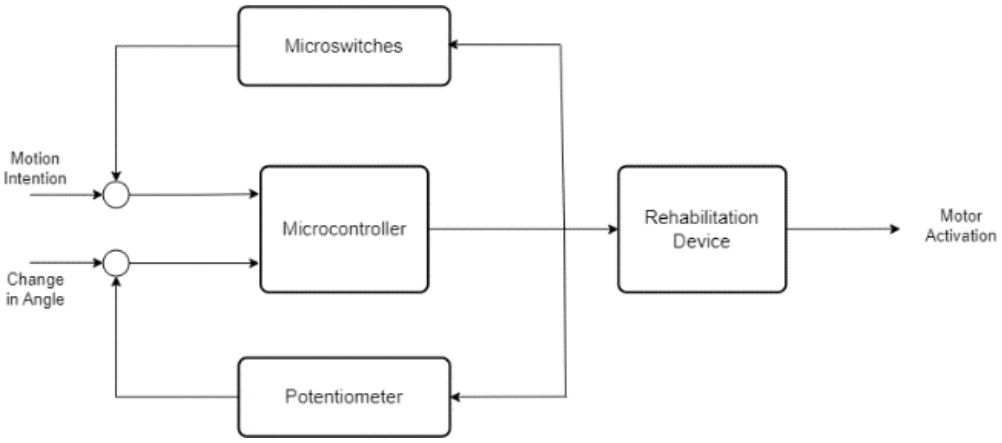

Figure 1: Control system for signal acquisition.

to determine his/her intention for movement and provide these feedback parameters to the microcontroller that is programmed with a control algorithm that would decide upon the response of the overall system – ensuring the patient's active participation throughout the therapy session.

Literally meaning the "outside skeleton", an exoskeleton is an external frame that can be worn to support an animal's body shape and works in conjunction with its user. This is typically made from rigid materials such as carbon fiber or fiberglass, but it can also be fabricated using soft and elastic materials such as wearable straps. For potentiometer placement, a simple linkage employing a revolute joint was applied. On the other hand, the device setup was simulated to be fabricated in actual using aluminium alloy 5083, as presented in Figure 2.

Figure 2: Developed exoskeleton with a human dummy.

2.1 Control Algorithm

In this study, a control signal would only be provided to the rehabilitation device to provide assistance if and only if the system has observed that the subject intends to move but has not produced an angle difference for a period of 100 milliseconds (ms). Shown in Table 1 is the truth table for the developed system.

Table 1: Truth table for the developed Wearable Exoskeleton.

Motion Intention	Angle Change	Control Signal for Motor Actuation
0	0	0
0	1	0
1	0	1
1	1	0

2.1.1 Arduino UNO

This microcontroller is used to monitor if the subject exerts physical effort and assist when the need arises to foster motor recovery. A control signal would only be provided to the rehabilitation device to provide assistance if and only if the system has observed that the subject intends to move but has not produced an angle difference for a period of 100 milliseconds (ms).

2.1.2 Normally-Open Micro Limit Switches SS-01GLP SPDT

Two microswitches are utilized to ensure that effort is given to perform the intended action – serving as the effort monitoring system of the study that aims to detect motion intention that could not be recorded by the change in angle (potentiometer). One microswitch is positioned at the anterior shank to measure the effort exerted by the subject during knee extension. In contrast, another microswitch is placed at the posterior compartment of the leg, also referred to as the calf, to detect efforts or motion intention in performing the knee flexion.

2.1.3 B10K Rotary Potentiometer

To ensure that the intended motion exerted by the subject is sufficient to be translated into movement, a B10K rotary potentiometer that has a resistance of 10K ohms, also known as the rotary angle sensor, is implemented as redundancy to increase the reliability of the system, which acts as the verification step of the process, before physical assistance is generated by the rehabilitation device connected to the system that would assist the subject in performing the action. In conventional PT practice or any physical activity, human movement is analysed based on visual observation [12].

2.2 Signal Acquisition

Both the motion intention and the angle difference are measured at a regular time interval. To determine the threshold value and the potentiometer's sensitivity, initial testing of the developed system was performed wherein the subject was at rest with the subject's leg at a 90-degree angle (with foot flat on the ground). Sampled at 100ms intervals, an experiment that lasted for 10 seconds long was conducted, resulting in a total of 100 samples. The absolute values of the recorded data were obtained for this experiment, as shown in Figure 3.

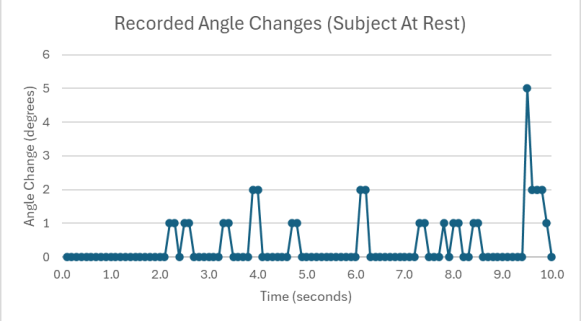

Figure 3: Recorded angle changes for potentiometer threshold (Subject at Rest).

It can be observed from the figure above that the potentiometer often plays its angular reading from 0 to 2 degrees (with an outlier of 5 degrees), even without the human subject producing any movement. As such, the threshold value for the variable resistor was set to +/- 2 degrees. At the same time, two normally-open micro limit switches SS-01GLP SPDT (single-pole-double-throw relay) are utilized to ensure that effort is given to perform the intended action – serving as the effort monitoring system of the study that aims to detect motion intention that could not be recorded by the change in angle (potentiometer).

2.3 Target Exercises

The subject was guided to perform the assigned exercise. In this study, knee flexion and extension were the specific tasks to test the developed exoskeleton. For knee extension, the subject was asked to sit upright with their thigh supported in a chair and with the left knee starting from a 90-degree angle and then stretch the leg out as far as possible, having about an angle of 180 degrees from a human's thigh and calf or is parallel to the ground. On the other hand, especially for powered and stationary rehabilitation exoskeletons that consist of actuators, similar to the TAYÔ prototype of the Institute of Biomedical Engineering and Health Technologies (IBEHT), the knee flexion refers to the movement of bringing the calf back down to the ground, having about an angle of 90 degrees, also measuring between the thigh and calf. These exercises aim to help strengthen the thigh muscles and regain the knee's range of motion. Figure 4 represents the knee flexion-extension exercise.

Figure 4: Knee flexion-extension [13].

3 RESULTS AND DISCUSSION

This chapter presents relevant data and results gathered from this study. A total of 30 trials were performed to determine the classification accuracy of the developed system, in which its data were recorded at a sampling rate of 100 milliseconds. Material Comparison.

3.1 Developed Exoskeleton

Wearable straps and simple linkages were to be implemented in an attempt to make the wearable exoskeleton more appropriate for human interaction. The mechanical aspect of the study is a 1-DOF wearable exoskeleton that was designed using aluminum alloy 5083 to monitor the knee flexion-extension movement of the left leg and send control signals to assist the subject. This was tied to the supposed existing rehabilitation device wherein microswitches were used to detect motion intention. A clearance was found in which the microswitch lever is touching the subject's skin surface, without pressing the switch button, for knee extension. Foams were also incorporated to carry the subject's partial leg weight and not immediately press the limit switch positioned at the subject's calf, specifically during the knee flexion exercise – to ensure that the force downward is generated by the subject and not gravity. Figure 5 displays the materials used for the microswitch mechanism.

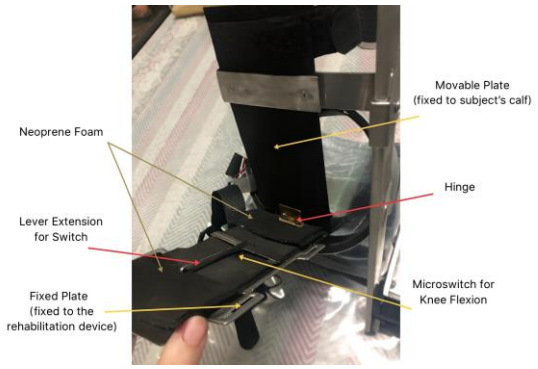

Figure 5: Materials for the microswitch mechanism for knee flexion.

3.2 Motion Intention

Figure 6 describes the classification accuracy for motion intention based on the experiments elaborated above. Results show that the developed exoskeleton is able to detect the motion intention of the subject at 98.73% classification accuracy, which satisfies the objective specified in Chapter I. Due to the peripherals that were used to detect motion intention, it was found that data for motion intention produced little to no noise as compared to using EMG sensors or accelerometers; however, they are highly reliant on the hardware design of the exoskeleton, specifically the placements of the microswitches and the clearance that was manually set for knee extension.

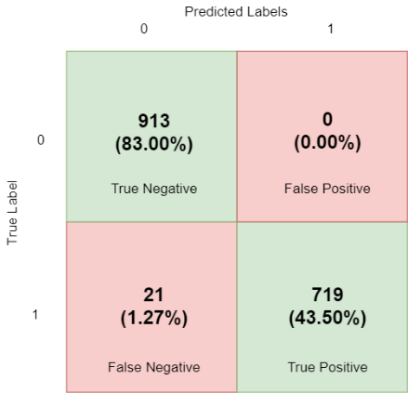

Figure 6: Confusion matrix for motion intention (overall).

3.2.1 For Knee Extension

This subsection aims to evaluate the performance of the exoskeleton when executing the knee extension exercise, starting from the 90-degree angle.

Figure 7: Experimental setup: motion intention for knee extension.

With this, the exoskeleton was only activated by the microswitch positioned in the anterior part of the shin, and any input from the microswitch that was intended for knee flexion was neglected. A fixed wooden rig was used to act as the rehabilitation device for the developed exoskeleton, wherein the lower plate of the exoskeleton was tied to this fixed rig (Fig. 7). For every trial for the knee extension movement, 5 to 6 movements were performed, and a total of 4 trials were performed. As can be observed, control signals provided by the exoskeleton for motor activation primarily generated a zero output, as it could be assumed that the subject is capable of performing the exercise without any external assistance. A classification accuracy of 97.89% was achieved. A higher false value can be observed from the experiments focusing on knee extension, which can be caused by the manual measurement of clearance between the skin surface of the subject and the microswitch as shown in Figure 8.

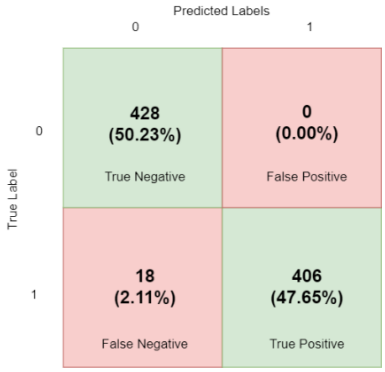

Figure 8: Confusion matrix for motion intention (extension).

3.2.2 For Knee Flexion

For knee flexion, only the microswitch located at the calf is activated for motion intention detection. Due to the design of the exoskeleton wherein a movable plate is hinged to the fixed portion of the exoskeleton calf, the weight of the leg is countered with foam placed in between the fixed and movable plates; furthermore, the microswitch would only be actuated once the user produces force downward, indicating motion intention rather than just gravity performing its duty. To test the effectiveness of the prototype, a chair was utilized to serve as the fixed portion of the existing rehabilitation device. It is vital to note that when the leg is at rest, motion intention shall not be recorded unless a force downward is produced. Figure 9 illustrates how the experimental setup was done.

Figure 9: Experimental setup: motion intention for knee flexion (180°).

A total of 4 trials were also performed by the human subject with five (5) movements per trial. This also proved that the offset of 1 to 2 degrees was achieved for the subject to activate the microswitch. Similar to the results of the previous subsection, control signals produced by the exoskeleton system are mostly zero or off. Displayed in Figure 10 is the confusion matrix for the motion intention of the subject when performing the knee flexion exercise.

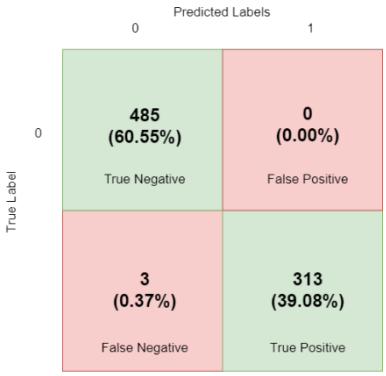

Figure 10: Confusion matrix for motion intention (flexion).

The accuracy of angle change detection was measured by performing the knee flexion-extension freely and completely, starting from the 90-degree angle to the 180-degree angle. A negative angle change denotes a knee extension movement, while a positive change indicates a knee flexion movement. A total of 4 trials (with 5 movements per trial) were performed for this subsection of the experiment. The system would only consider the angle change as a movement if it detected an angle change of at least 3 degrees, whether positive or negative.

By ensuring that the thigh portion of the exoskeleton is fixed when performing change in angle readings, the overall classification accuracy of the developed exoskeleton in detecting change in angle is at 97.55%, as shown in Figure 11. It can be observed that during the course of movement of the healthy subject's leg, there were instances that change in angle was not detected (false negative); this may be attributed or dependent to the speed of the subject's leg or leg fatigue in performing the experiment for that specific period.

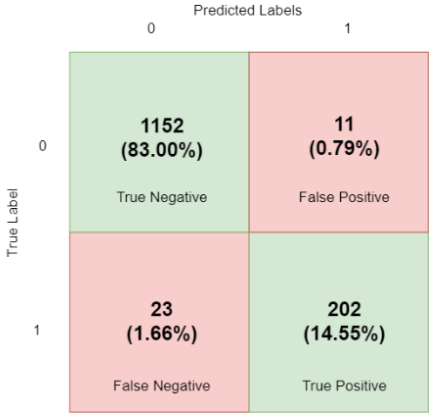

Figure 11: Confusion matrix for change in angle (overall).

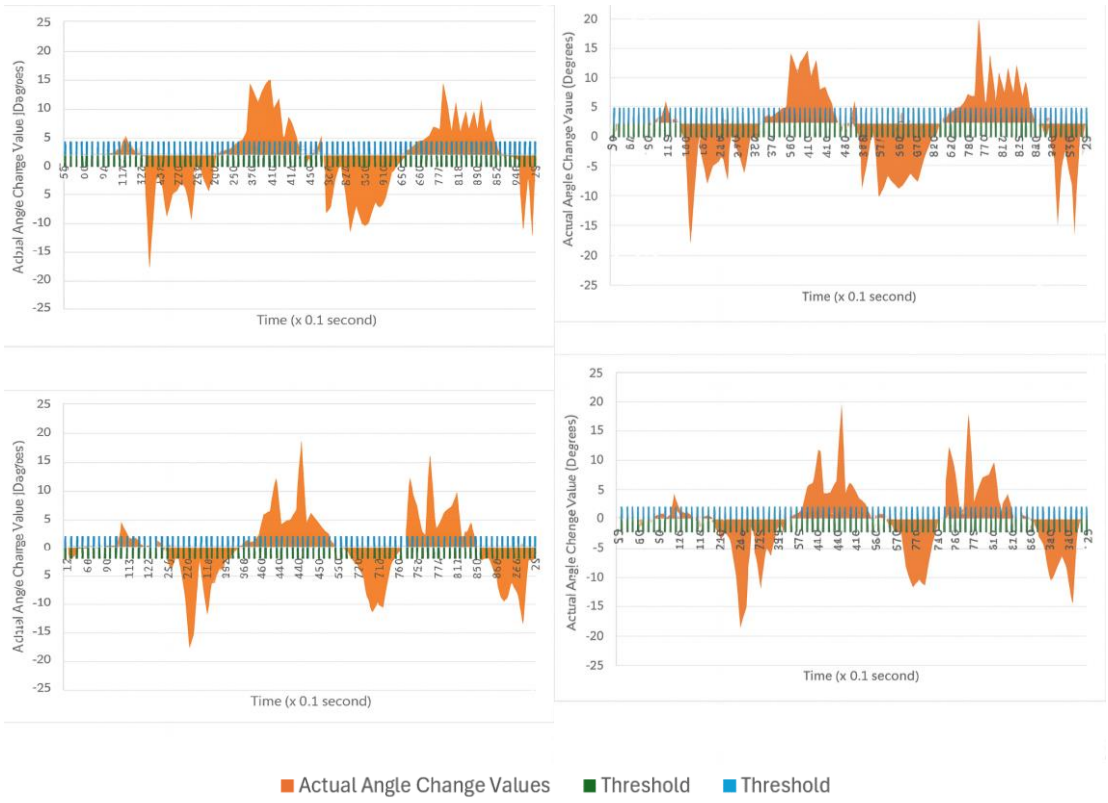

Figure 12: Change in angle vs set angle threshold.

Figure 12 illustrates the pattern of movement of the subject for all 4 trials where the obtained values for angle change were plotted along with the corresponding threshold values of +/- 2 degrees. It can be observed that for all trials in this experiment, the system only considers it as a "change in angle" if and only if the obtained value exceeded the angle threshold that was set.

4 CONCLUSIONS

Allowing for mechanical input into the exoskeleton provides a solution to noisy data often generated by sensors that do not require a mechanical operation, eliminating the risk of being affected by external factors. The obtained information for the required parameters proved that the developed system achieved a classification accuracy of at least 90%. The control signal, whose primary purpose is to instruct the connected rehabilitation device to provide assistance to the user, is dependent on the obtained values for motion intention and the reading for the angle difference. As future directives to develop further and confirm this research's initial findings, it is recommended to perform the following:

1) To implement an exoskeleton with additional degrees of freedom to imitate the actual behaviour of the knee.
2) To explore the applicability of the concept to different 1-DOF target exercises such as but not limited to bicep curls, lateral raises, etc.
3) To create a study or experiment to determine the least amount of force needed to actuate the microswitches.
4) To test the prototype with an actual existing rehabilitation device in order to provide more valuable information that would aid to the improvement of the exoskeleton.

ACKNOWLEDGMENTS

The authors of the study would like to express their gratitude to the Department of Science and Technology (DOST) and Engineering Research and Development for Technology (ERDT) for providing them with scholarship privileges that allowed them to complete this research project. Their generous support enabled the authors to access resources and facilities that were crucial to the success of this work.

Keywords: Prolonged Sitting, Sedentary Lifestyle, Ergonomics, Posture Monitoring, Arduino-based Device, Wearable Health, Health Technology.

Abstract: Prolonged sitting is a significant public health problem, associated with musculoskeletal pain, hypertension, fatigue, and decreased productivity. Existing solutions such as wearable IMUs, computer-vision systems, and mobile apps are often costly, intrusive, or dependent on sustained user engagement, limiting their practical adoption. This study presents a low-cost, non-intrusive device designed to monitor prolonged sitting and provide real-time auditory alerts to encourage movement breaks. The system integrates an ultrasonic sensor with an Arduino microcontroller programmed with a 60-minute countdown timer; the alarm is triggered if the user remains seated beyond this period. The device was tested with 90 participants (50 students, 20 office workers, 20 faculty), achieving a detection accuracy of 93.4%, with a false positive rate of 4.2% and false negative rate of 2.4%. User evaluation showed high acceptance, with financial feasibility rated 4.13/5, hardware accessibility 4.21/5, and perceived health benefits 4.55/5. Limitations include lack of posture-specific monitoring, basic alert modes, and limited portability. Future improvements will focus on AI-based posture recognition, enhanced sensor calibration, mobile app integration, and wireless operation for broader usability and ergonomic monitoring.

1 INTRODUCTION

Sitting refers to a sustained posture of being seated, typically while engaged in tasks such as reading, writing, or computer use [1], [2]. It has become the most prevalent working habit in modern society, but its prolonged practice often leads to musculoskeletal problems, including poor neck posture, reduced cervicothoracic muscle activity, and fatigue – particularly among students and office workers [3]. In addition to occupational tasks, activities such as television viewing and commuting further increase sedentary exposure, with adults spending nearly 70% of their waking hours, or about 7.7 hours daily, in a seated position [4]. Evidence indicates that relatively short uninterrupted sitting bouts (≈20–40 min) can have adverse cardiometabolic effects and are best interrupted regularly with short movement breaks [5] - [7].

Extended sedentary periods have been linked to hypertension, muscular fatigue, reduced job performance, and physical discomfort in the shoulders, back, thighs, and knees [8]. Breaking these periods with light to moderate activity – such as standing or simple exercises – has been shown to yield both physical and cognitive benefits [9], [10]. In the Philippines, the Occupational Safety and Health Standards (OSHS) highlight the importance of workplace interventions to mitigate such risks [11].

To address this issue, researchers have explored various approaches, including mobile apps, self-monitoring devices, simulation-based interventions, and sensor-based systems for posture or sedentary time detection [12], [13]. Wearable technologies employing inertial measurement units (IMUs) and microelectromechanical systems (MEMS) have also gained traction, enabling machine-learning classification of different postures [14]. More recent innovations integrate AI-driven monitoring, IoT-enabled ergonomics, and mobile health (mHealth) solutions, providing real-time feedback to users [15] - [17].

Despite these advancements, challenges remain. Wearable devices can be intrusive and require continuous compliance. Computer-vision

approaches offer high accuracy but raise privacy concerns and demand costly equipment and controlled environments. Mobile apps, meanwhile, depend on user engagement, which limits their long-term adoption. These gaps underscore the need for a low-cost, unobtrusive, and user-friendly solution that prioritizes sitting duration monitoring rather than complex posture recognition.

This study addresses that gap by designing and developing a device capable of automatically detecting prolonged sitting without requiring user input. Unlike existing methods, the proposed device emphasizes simplicity and accessibility. It operates independently of body weight, age, or posture details, focusing instead on sitting duration as the primary variable. Developmental research methodology guided the process, ensuring both practical functionality and design principles for future ergonomic monitoring tools [18].

Contributions. This study makes three key contributions:

1) It introduces a cost-effective, non-intrusive device for prolonged sitting detection that avoids the limitations of wearables and camera-based systems.
2) It compares current solutions – including IMUs, Kinect, mobile apps, and computer vision – highlighting the trade-offs relative to the proposed approach.
3) It situates the device within recent trends in wearable sensors, AI-driven recognition, and IoT ergonomics, offering practical insights for educational and workplace applications.

2 METHODOLOGY

2.1 System Design and Operation

The device was built around an Arduino Uno microcontroller, which processed input from an ultrasonic sensor mounted at chair level to detect the presence of a seated user. Once detection occurred, the microcontroller initiated a 60-minute countdown timer. If the timer reached zero while the user remained seated, an active buzzer alarm was triggered. The device reset automatically once the user stood up. A 16×2 LCD module provided real-time status updates such as “Active,” “Countdown,” or “Alarm.”

The hardware design integrated the ultrasonic sensor, Arduino controller, LCD, and buzzer, powered by a regulated 5V supply. For software implementation, the Arduino IDE was used to program detection, timer, alarm, and reset functions. Serial monitoring assisted debugging and validation.

Data collection involved logging detection events, timer performance, and alarm activations. Researchers cross-checked device outputs with direct observations to ensure alignment between sensor readings and actual sitting or standing behavior.

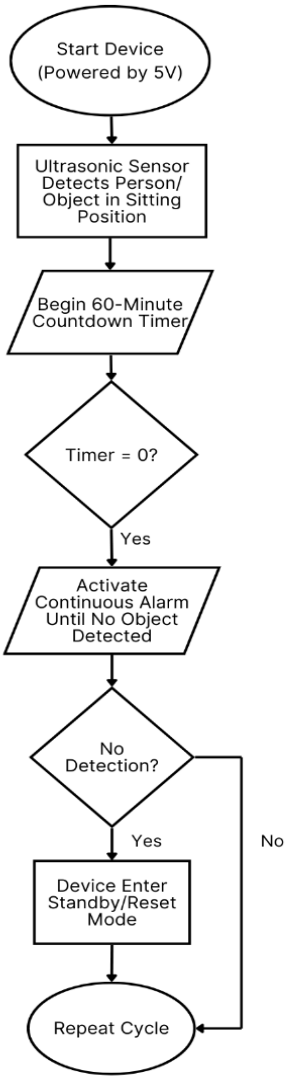

Figure 1: Flowchart of device functionality.

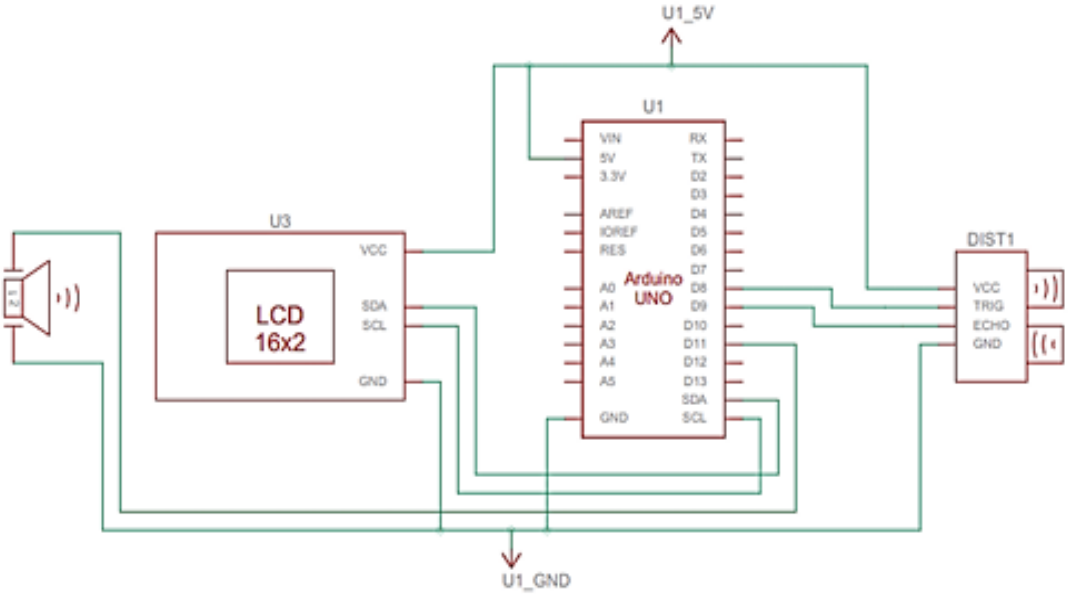

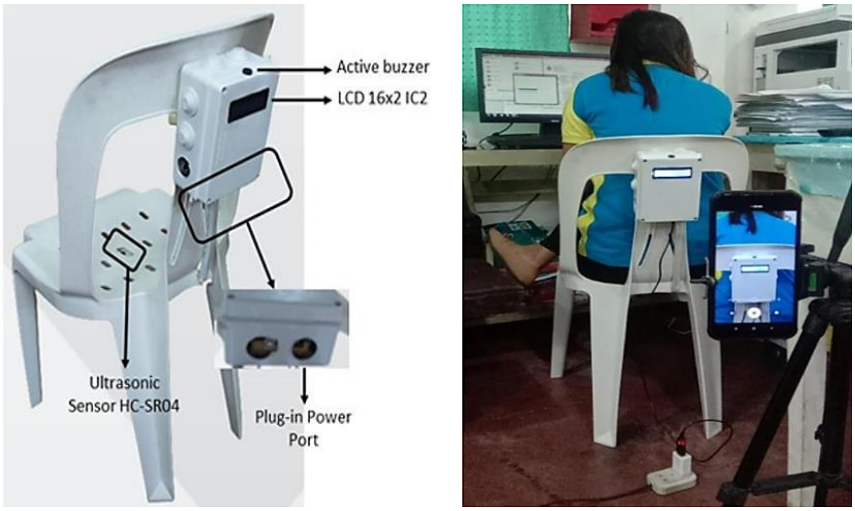

Figure 2: Device schematic diagram.

(a) (b)

Figure 3: Design and implementation of the developed low-cost device for monitoring and alerting prolonged sitting posture: a) device design and hardware components; b) implemented prototype and system setup.

2.1.1 Algorithm Workflow

The device followed a structured operational cycle:

1) Initialization – Power on (5V regulated supply).
2) Occupancy Detection – Ultrasonic sensor checks for user presence.
3) Signal Processing – Detected signals transmitted to Arduino.
4) Countdown Timer – 60-minute timer begins when sitting is detected.
5) Alarm Activation – Continuous alarm triggered when timer reaches zero.
6) Reset Mode – Alarm stops once user stands up and detection ceases.
7) Cycle Repetition – System resets to standby for continuous monitoring.

Figures 1 and 2 illustrate the functional flowchart and hardware schematic, respectively. Figure 3 shows the physical design integrated into a standard chair, with real-time LCD feedback and buzzer alerts validated in both office and classroom settings.

2.1.2 System Performance Evaluation Sensor Calibration

To ensure reliable operation, the ultrasonic sensor was calibrated within a 30–80 cm detection range, corresponding to the average torso-to-sensor distance in typical seating setups. Twenty repeated measurements per increment were taken to refine the threshold. The final range minimized false positives (detecting non-users) and false negatives (failing to detect seated users). Tests were performed in a controlled environment to reduce interference.

2.1.3 Error Rate Assessment

Two error types were logged across 50 trials: (1) false detection (triggering without a seated user) and (2) missed detection (failure to recognize a seated user). Results showed an average false detection rate of 4.2% and a missed detection rate of 2.4%, comparable to error rates reported in other low-cost sedentary behavior monitoring systems [19] - [21].

2.1.4 Validation Protocols

Validation involved 10 participants performing 60-minute seated trials, each repeated three times (30 sessions total). Researchers monitored the countdown timer, alarm activation, and reset function, comparing device outputs with direct observation. The device consistently activated alarms at the 60-minute mark and reset promptly when participants stood up, confirming reliable performance under realistic conditions.

3 RESULTS AND DISCUSSION

3.1 Functional Performance

Initial trials confirmed that the prototype operated as designed. The sensor accurately detected occupancy, the LCD displayed appropriate system states, and the buzzer provided clear auditory alerts. Further testing determined that chair-seat placement yielded superior performance compared to backrest placement, achieving reliable detection within 2–30 cm.

The device achieved 93.4% detection accuracy across 30 trials, with a false positive rate of 4.2% and a false negative rate of 2.4%. A one-sample t-test ($p < 0.05$) confirmed accuracy significantly above 90%. ANOVA results ($F = 5.62$, $p = 0.021$) indicated significant differences by sensor placement, supporting seat-mounted configuration as optimal.

3.2 Respondent Evaluation

3.2.1 Financial Feasibility

Respondents rated the device as financially viable (mean = 4.13), with Arduino hardware particularly affordable (mean = 4.21) [22], [23].

3.2.2 Resource Availability

Accessibility was rated moderately attainable overall (mean = 3.94), with Arduino software highly accessible (mean = 4.28). Sensors and shields were rated slightly lower (means = 3.70–3.92).

3.2.3 Market Feasibility

Respondents perceived high potential market acceptance (mean = 4.32). Health benefits (mean = 4.55) and institutional interest (mean = 4.40–4.48) scored particularly well, while local market demand scored moderately (means = 4.05–4.10), indicating room for awareness efforts.

3.2.4 Comparative Insights

Compared to commercial trackers [19] - [21], the prototype achieved similar accuracy but at a fraction of the cost. Unlike wearable IMUs [14] or vision-based systems [16], it required no intrusive equipment or controlled settings. Its balance of affordability and reliability makes it suitable for schools and workplaces with limited resources.

3.2.5 Strengths and Limitations

Strengths:

- High accuracy (>90%) despite low cost.
- Non-intrusive (no wearables required).
- Simple, accessible Arduino-based design.

Limitations:

- Sensitivity to posture changes (leaning forward/sideways).
- Limited portability (chair-integrated sensor).

- Basic alert modes (buzzer/LCD only, no app/cloud integration).

These findings highlight the potential of low-cost alternatives to address sedentary risks while acknowledging areas for future enhancement.

4 CONCLUSIONS

This study developed and validated a low-cost device for detecting and alerting prolonged sitting using an ultrasonic sensor, LCD, and buzzer. Results demonstrated reliable detection and consistent alarm activation, confirming its suitability for office, classroom, and home environments. The device offers a practical, accessible alternative to wearable or camera-based systems, supporting musculoskeletal health and reducing risks of sedentary behavior.

Improvements should focus on integrating mobile applications for real-time feedback, AI-based posture recognition for slouch detection, and enhanced calibration for diverse users and seating contexts. Wireless operation, rechargeable batteries, and long-term user trials would further improve usability and adoption. With these refinements, the device could evolve into a comprehensive posture-monitoring solution for educational, occupational, and domestic environments.

ACKNOWLEDGEMENT

The authors would like to thank the faculty and students of Camiguin Polytechnic State College and Surigao del Norte State University for their participation in the study and support during the device testing and evaluation. Special appreciation is extended to the institutions for providing resources and facilities that enabled the successful completion of this research.

Keywords: Smart Home Automation, Natural Language Processing, Edge Computing, Ukrainian Language Model, MQTT Protocol, Privacy-Preserving Architecture, Home Assistant Integration.

Abstract: Cloud-dependent smart home platforms introduce critical limitations including high command execution latencies, complete functionality loss during network outages, security vulnerabilities, and inadequate linguistic support for morphologically rich languages like Ukrainian. This research addresses these challenges by developing a hybrid local-cloud architecture that maintains device control autonomy while preserving user interface accessibility. The proposed system integrates containerized Home Assistant deployment, MQTT message broker for local communication, and spaCy-based natural language processing with Pymorphy3 morphological analysis specifically adapted for Ukrainian language commands. The methodology employs lemmatization and tokenization to handle complex grammatical variations including case systems, gender agreements, and aspectual distinctions characteristic of Ukrainian morphology. Experimental validation demonstrates high intent recognition accuracy across single-device, multi-device, and conditional command categories while maintaining sub-second response times on consumer-grade hardware. The system achieves complete operational independence during internet disruptions and ensures zero external data transmission through fully local processing architecture. Theoretical contributions include establishing first documented benchmarks for Ukrainian language intent recognition in smart home contexts, demonstrating sub-linear computational complexity for edge-based processing, and validating hybrid architectural models balancing sovereignty with accessibility. Practical implications encompass complete data sovereignty, elimination of subscription dependencies, vendor independence through open standards, and community-extensible open-source implementation. The research establishes reproducible methodology applicable to other underserved languages and resource-constrained IoT environments while addressing significant market gaps in Ukrainian-speaking populations.

1 INTRODUCTION

Smart homes integrate IoT devices, allowing users to control various functions of their homes through centralized systems [1]. The concept of a smart home has evolved significantly, driven by advancements in artificial intelligence (AI) and the Internet of Things (IoT). Smart home technologies allow for seamless control of household devices, automating routine tasks like lighting, security, and climate control. Technologies like Google Home [2], Apple HomeKit [3], and Amazon Alexa [4] have popularized this field, offering cloud-based services for device control.

However, these systems face several critical challenges. Recent studies indicate that cloud-dependent architectures introduce average latencies of 500-800ms for command execution [5], significantly degrading user experience for time-sensitive operations. Furthermore, the reliance on continuous internet connectivity creates single points of failure - during network outages or provider-side incidents, users completely lose control over their smart home infrastructure [6]. Security concerns have intensified, with documented cases of unauthorized access to cloud-based smart home systems through compromised credentials or man-in-the-middle attacks [7].

An equally significant limitation concerns linguistic accessibility. While major platforms support widely-spoken languages (English, Spanish, Mandarin), support for languages with smaller user bases - such as Ukrainian - remains inadequate or entirely absent [8]. This linguistic gap affects approximately 40 million Ukrainian speakers globally, creating barriers to technology adoption and forcing users to interact with systems in non-native languages.

2 SMART HOME CONTROL SYSTEM

2.1 Related Work

AI and NLP play crucial roles in improving user interactions with smart home systems. Through voice-activated commands, homeowners can easily control appliances and receive personalized responses, thereby streamlining daily tasks [5], [6]. AI algorithms further enhance the capabilities of smart devices by allowing them to learn from user behavior, predict preferences, and even proactively address potential security threats by analyzing patterns in real-time data [7].

However, concerns about data privacy, the potential for unauthorized access, and the reliability of these interconnected systems persist, prompting ongoing debates among consumers and experts alike [8], [9]. Hasiuk et al. [10] identified critical vulnerabilities in cloud-dependent architectures, including susceptibility to distributed denial-of-service attacks and privacy breaches through unauthorized data access.

The IoT serves as the backbone of smart home technology, interconnecting various devices to create an integrated ecosystem that continuously collects and shares data [11]. This interconnectedness not only leads to increased efficiency in home management but also raises challenges regarding device compatibility and interoperability, as different manufacturers often utilize proprietary protocols [12].

Quincozes et al. [13] conducted comprehensive analysis of MQTT's architecture, demonstrating superior performance for constrained devices compared to HTTP-based alternatives. The publish-subscribe model enables efficient one-to-many communication with minimal overhead - fixed headers as small as 2 bytes ensure bandwidth efficiency even on limited networks [14].

As the number of connected devices is projected to reach upwards of 40 billion by 2030, establishing robust security measures and ensuring seamless communication between devices will be crucial for protecting user privacy and enhancing the overall smart home experience [15].

Nevertheless, it also necessitates careful consideration of privacy concerns and interoperability challenges, as the smart home ecosystem continues to evolve in response to technological advancements and consumer needs [16], [17]. Addressing these weaknesses through localized systems is crucial. This is where technologies like Home Assistant, an open-source platform, come into play. Unlike cloud-dependent systems, Home Assistant operates within the local network, offering more control, customization, and autonomy over device management.

Ibrahim Masood [18] demonstrated that Home Assistant deployments achieve functionality comparable to commercial platforms while maintaining complete data sovereignty. However, existing implementations lack intuitive natural language interfaces, particularly for non-English languages.

SpaCy [19] provides industrial-strength NLP through optimized algorithms, with Ukrainian language models enabling morphological analysis, part-of-speech tagging, and dependency parsing. Pymorphy3 [20] complements this through detailed morphological analysis, essential for lemmatization - reducing words to base forms regardless of grammatical variations.

Existing literature reveals several unaddressed challenges:

1) Linguistic Accessibility: No documented high-accuracy NLP systems for Ukrainian smart home control.
2) Performance Quantification: Limited empirical comparison of local versus cloud processing latency.
3) Architectural Integration: Insufficient exploration of hybrid models balancing autonomy with accessibility.
4) Reproducibility: Predominance of proprietary solutions limiting academic validation.

This research addresses these gaps through systematic development and rigorous evaluation of an integrated local smart home system with Ukrainian NLP capabilities.

2.2 Formulation of the Problem

Formal diagram of the modified smart home control system is depicted on Figure 1.

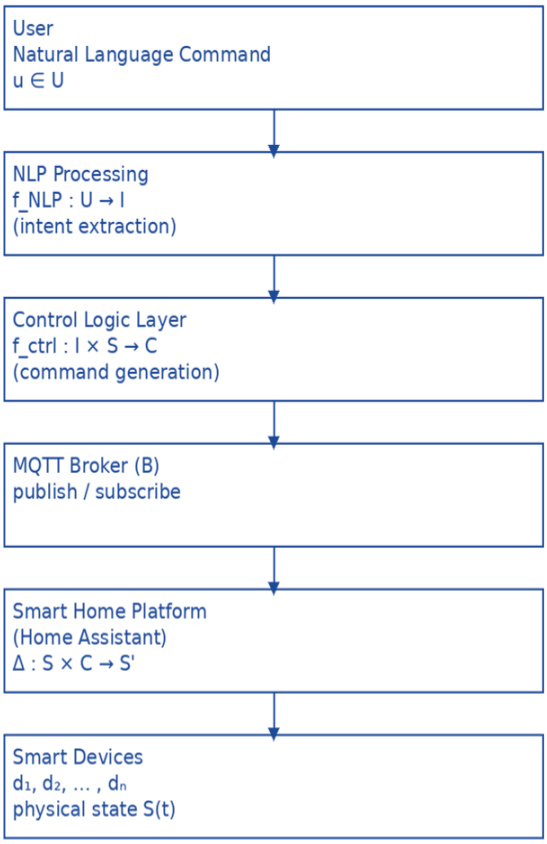

Figure 1: Formal diagram of the control system.

Figure 1 notation:

- U - set of user commands expressed in natural language,
- $u \in U$ - an individual user command,
- f_{NLP} - semantic interpretation function of natural language commands,
- $I = D \times A \times P$ - set of structured intents (device, action, parameters),
- f_{ctrl} - control command generation function,
- C - set of MQTT control messages,
- B - MQTT broker,
- $\mathrm{S}(t)$ - vector of device states at time t,
- Δ - system state transition function.

All processing is performed locally, without the involvement of cloud-based services.

The proposed advanced smart home control system is modeled as a discrete event-driven cyber-physical system that enables natural language interaction with physical devices through a sequence of information transformations.

2.2.1 Device and State Model

Let $D = \{d_1, d_2, \dots, d_n\}$ denote the set of smart home devices. Each device d_i is characterized by a finite set of states: $S_i = \{s_{i1}, s_{i2}, \dots, s_{ik}\}$. The global system state at time t is defined as:

$$\mathbf{S}(t) = (s_1(t), s_2(t), \dots, s_n(t)), s_i(t) \in S_i.$$

2.2.2 User Command Model

Let U be the set of user commands expressed in natural language. Each command is represented as a string: $u \in \Sigma^*$, where Σ is the alphabet of the target natural language.

2.2.3 Natural Language Processing Function

The interpretation of user commands is modeled by the semantic mapping:

$$f_{\text{NLP}}: U \to I,$$

Where $I = D \times A \times P$ is the set of structured intents, A denotes the set of actions, and P denotes contextual parameters.

The output intent is defined as: $i = (d_i, a_j, p_k)$.

2.2.44 Control Logic Model

Based on the extracted intent, a control command is generated using:

$$f_{\text{ctrl}}: I \times \mathbf{S}(t) \to C,$$

where C is the set of MQTT control messages. Each message is represented as: $c =$ (topic,payload,QoS).

2.2.5 Communication Model (MQTT)

The interaction between software components follows the publish–subscribe paradigm:

$$\text{publish}(c) \to B \to \text{subscribe}(d_i),$$

where B denotes the MQTT broker.

2.2.6 State Transition Function

The state transition of an individual device is defined as:

$$\delta_i: S_i \times C \to S_i.$$

The global system state update is given by:

$$\mathbf{S}(t+1) = \Delta(\mathbf{S}(t), C),$$

where Δ is the composition of local transition functions.

2.2.7 Temporal Performance Model

The total system response time is defined as:

$$\tau = \tau_{\text{NLP}} + \tau_{\text{ctrl}} + \tau_{\text{MQTT}} + \tau_{\text{device}}.$$

Due to the fully local architecture:

$$\tau_{\text{MQTT}} \ll \tau_{\text{cloud}},$$

which ensures lower latency compared to cloud-based solutions.

2.2.8 End-to-End Control Flow

The complete control cycle can be represented as:

$$u \overset{f_{\text{NLP}}}{\rightarrow} i \overset{f_{\text{ctrl}}}{\rightarrow} c \overset{MQTT}{\rightarrow} \mathbf{S}(t+1).$$

2.3 Proposed Approach

The proposed solution implements a layered architecture consisting of five primary components:

1) User Interface Layer. Telegram bot serving as the primary interaction endpoint.
2) NLP Processing Layer. Ukrainian language intent recognition module.
3) Control Logic Layer. Command translation and routing mechanism.
4) Communication Layer. MQTT broker managing publish-subscribe messaging.
5) Device Layer. Home Assistant coordinating individual smart home devices.

This architecture ensures that all critical processing occurs within the local network boundary, eliminating mandatory external dependencies while maintaining user interface accessibility through Telegram's cloud infrastructure for message delivery only.

The structure of the modified control system for smart home devices can be represented schematically as follows (Fig. 2).

The system operates through the following sequential workflow:

1) The interaction begins when a user composes and transmits a command through the Telegram bot interface.
2) Upon receiving the user's input, the bot invokes the natural language processing component to analyze the textual content, identifying both the target device and the intended operation. Once this information is extracted, the bot constructs an MQTT communication containing the relevant topic identifier and command payload, which is then dispatched via the MQTT client module.
3) The NLP component processes the incoming text from the bot, performing morphological analysis and intent recognition to determine which device should be affected and what action should be executed, returning these extracted parameters.
4) The MQTT client handler accepts the topic designation and message payload from the bot, subsequently publishing this formatted communication to the message broker.
5) The broker receives the published message and routes it according to the topic hierarchy, ensuring delivery to all subscribed entities, including the home automation management platform.
6) The management platform monitors subscribed topics and, upon detecting incoming messages, executes the corresponding automation triggers that translate MQTT commands into device-specific control signals, thereby modifying device operational states.
7) Connected IoT devices respond to control signals generated by the management platform, transitioning between states (on/off, brightness levels, etc.) as specified by the automation rules.

This layered design maintains all essential computational operations within the residential network perimeter, removing dependencies on external cloud services for core functionality while utilizing Telegram's messaging infrastructure solely as a communication channel for user interaction.

The system deploys Home Assistant as a containerized application using Docker [21] on local server hardware. Docker containerization provides several advantages:

1) Isolation: Container boundaries prevent conflicts between system dependencies.
2) Portability: Identical deployment across diverse hardware platforms.
3) Resource efficiency: Minimal overhead compared to traditional virtualization.

Installation procedure:

```
# Install Docker
sudo apt install docker.io
sudo systemctl enable docker
# Deploy Home Assistant container
docker run -d \
  --name homeassistant \
  --restart=unless-stopped \
  -v /path/to/config:/config \
  --network=host \
  homeassistant/home-
assistant:latest
```

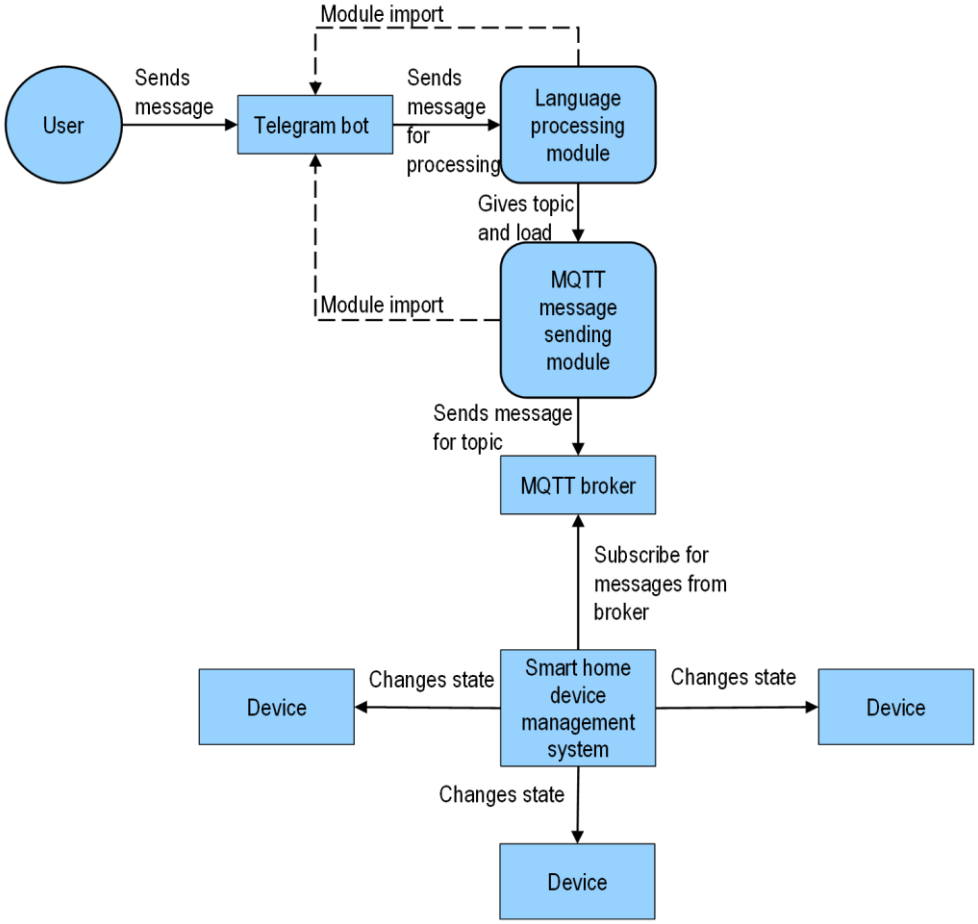

Figure 2: Structural diagram of a modified smart home device control system.

Home Assistant configuration enables discovery and integration of devices across multiple protocols (Zigbee, Z-Wave, Wi-Fi) through its extensive integration library.

MQTT broker (Eclipse Mosquitto) deployment establishes local message routing infrastructure. The broker configuration implements authentication and encryption:

```
   # Install Mosquitto
   sudo apt install mosquitto
mosquitto-clients
   # Configure authentication
   sudo mosquitto_passwd -c
/etc/mosquitto/passwd username
   # Enable TLS encryption
   listener 8883
   cafile
/etc/mosquitto/ca_certificates/ca.crt
   certfile
/etc/mosquitto/certs/server.crt
   keyfile
/etc/mosquitto/certs/server.key
   ```
   Device control operates through
topic hierarchy:
   ```
   home/
   ├── kitchen/
   │   └── light/
   │       ├── command  (publish
control commands)
   │       └── state    (subscribe to
status updates)
   ├── bathroom/
   │   └── socket/
   │       ├── command
   │       └── state
   └── corridor/
       └── light/
           ├── command
           └── state
```

Home Assistant automation triggers respond to MQTT messages:

```
   automation:
     - alias: "Kitchen Light Control"
       trigger:
         platform: mqtt
         topic:
"home/kitchen/light/command"
       action:
         service: light.turn_{{
trigger.payload | lower }}
         entity_id: light.kitchen
   ```
   ### 4.4 NLP Module Development
   The natural language processing
module implements intent recognition
and entity extraction for Ukrainian
language commands. Core functionality
utilizes spaCy with Ukrainian language
model and Pymorphy3 for morphological
analysis.

   **Algorithm 1: Intent and Entity
Recognition**
   ```
   Input: User utterance u in Ukrainian
language
   Output: (action, device) tuple or
(None, None)

   1. Load spaCy Ukrainian model → nlp
   2. Load Pymorphy3 analyzer → morph
   3. Define action_synonyms
dictionary:
      {
        "turn_on": ["увімкни",
"включи", "запали", "активуй"],
        "turn_off": ["вимкни",
"виключи", "загаси", "деактивуй"]
      }
   4. Define available_devices list
from Home Assistant
   5. Normalize prepositions in u
(e.g., "в" → "у")
   6. Lemmatize u:
      doc ← nlp(u)
      lemmas ←
[morph.parse(token.text)[0].normal_form
for token in doc]
   7. Extract action:
      for action, synonyms in
action_synonyms:
        if any(lemma in lemmas for
synonym in synonyms
               for lemma in
lemmatize(synonym)):
          detected_action ← action
          break
   8. Extract device:
      for device in available_devices:
        if contains_lemmas(lemmas,
lemmatize(device)):
          detected_device ← device
          break
   9. Return (detected_action,
detected_device)
```

The lemmatization process handles Ukrainian morphological complexity, including:

- case variations (nominative, genitive, accusative, etc.);
- gender agreements;
- verb conjugations;
- aspect variations (perfective vs. imperfective).

As the devices within the system are controlled through MQTT communication, the software must publish messages with a specified payload to a designated topic (see Fig. 3).

```
import paho.mqtt.client as mqtt

3 usages
class MqttClientHandler:
    def __init__(self, client_id, broker_address, username, password):
        self.client = mqtt.Client(client_id=client_id)
        self.broker_address = broker_address
        self.client.username_pw_set(username, password)
        self.connected = False
        self.client.on_disconnect = self.on_disconnect

    1 usage
    def on_disconnect(self, client, userdata, flags, rc):
        self.connected = False

    2 usages
    def connect(self):
        try:
            self.client.connect(self.broker_address)
            self.connected = True
        except:
            self.connected = False

    2 usages
    def start(self):
        self.client.loop_start()

    1 usage
    def publish(self, topic, payload):
        self.client.publish(topic, payload)

    4 usages
    def is_connected(self):
        return self.connected
```

Figure 3: A program class responsible for transmitting MQTT messages.

The final component integrates all modules through a Telegram bot interface. The /start command can be sent to the bot, allowing instructions to be issued (Fig. 4).

The complete system architecture ensures:

- Modularity: Each component operates independently with defined interfaces.
- Fault tolerance: Connection monitoring and automatic reconnection.
- Thread safety: Lock-based synchronization for concurrent access.
- Logging: Comprehensive logging for debugging and monitoring.
- User feedback: Clear status messages in Ukrainian language.

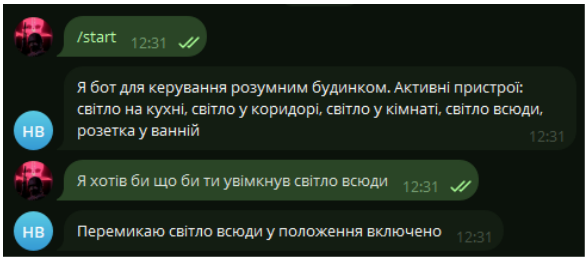

Figure 4: Bot command for switching on all lights.

Thus, the practical solution implements control of specific devices:

- Light in the kitchen (`home/kitchen/light`)
- Socket in the bathroom (`home/bathroom/socket`)
- Light in the hallway (`home/corridor/light`)
- All lights (`home/all/lights`)

Each device has two possible states: "ON" and "OFF", which corresponds to $S_i = \{\text{ON,OFF}\}$ in the formal model.

Natural Language Processing Function (NLP Processing Function) f_{NLP} is implemented in DeviceIdentifier class with `identify_action_and_device()` method:

```
   def identify_action_and_device(self,
message):
       # Text processing (tokenization,
lemmatization)
       normalized =
self.normalize_text(message.lower())
       message_lemmas =
self.lemmatize_text(normalized)

       # Definition of action (action)
       detected_action = None
       for action, synonyms in
self.actions.items():
           # ... logic of action
determining
       # Device definition (device)
       detected_device = None
       for device in self.devices:
           # ... device determining
logic

       return detected_action,
detected_device
```

The `create_reply()` function f_{ctrl} implements the MQTT command generation logic:

```
   def create_reply(update: Update,
action, device):
       # Get topic from device -> topic
mapping
       topic =
DEVICE_TOPICS.get(device)
       # Get payload from action ->
payload mapping
       payload =
ACTION_PAYLOADS.get(action)

       # Publish MQTT message
       success =
mqtt_client.publish(topic, payload)
```

Publisher (MqttClientHandler class):

```
   def publish(self, topic, payload):
       if self.connected:
           self.client.publish(topic,
payload, qos=1)
           return True
       return False
```

Formal Model:

$$\delta_i : S_i \times C \to S_i$$
$$\mathbf{S}(t+1) = \Delta(\mathbf{S}(t), C)$$

is implemented in Home Assistant in the state transition function:

```
   automation:
     - alias: "Kitchen Light Control"
       trigger:
         platform: mqtt
         topic:
"home/kitchen/light/command"
       action:
         service: light.turn_{{
trigger.payload | lower }}
         entity_id: light.kitchen
```

Upon receiving message $c =$ ("home/kitchen/light/command","ON",QoS=1), the device state changes from $s_{\text{kitchen_light}}(t) = \text{OFF}$ to $s_{\text{kitchen_light}}(t+1) = \text{ON}$.

End-to-End Control Flow

$$u \rightarrow fNLPi \rightarrow fctrlc \rightarrow MQTT\mathbf{S}(t+1)$$

is implemented through integration of all components:

- User → Telegram bot:
  `text message` u `(e.g., "Turn on the kitchen light")`
- f_{NLP}(DeviceIdentifier):
  $u \rightarrow i$ = `("kitchen light","turn_on",{})`
- f_{ctrl}(create_reply):
  i→c = `("home/kitchen/light/command","ON",1)`
- MQTT broker:
  `distributes` c `to Home Assistant`
- Automation trigger:
  $\mathbf{S}(t) \rightarrow \mathbf{S}(t+1)$, `where light state changes to "ON"`

2.4 Evaluation

A comprehensive analysis of system failures across 200 test commands revealed 16 errors (8% failure rate), which were systematically categorized into four distinct failure modes. Understanding these error patterns provides critical insights for system improvement and identifies specific areas requiring enhancement.

2.4.1 Morphological Ambiguity (4% of Commands, 50% of Errors)

The most significant source of errors stemmed from the Ukrainian language's rich morphological complexity. Eight commands failed because users employed grammatical forms not adequately represented in the training corpus.

For example, the command "Потрібне ввімкнення світла у кухні" ("Lighting in the kitchen is needed") used a gerund form "ввімкнення" (the act of turning on) rather than the imperative "увімкни" (turn on!). While the lemmatization process correctly reduced this to the base verb "ввімкнути," the action synonym dictionary only contained imperative mood variants, causing the system to fail to recognize the intent.

Ukrainian verbs manifest in numerous forms - infinitives, imperatives, gerunds, participles, and conditional constructions - each capable of expressing the same underlying action. The current dictionary of 10 action variants per intent covers only the most common imperative forms, leaving the system vulnerable to the diverse linguistic expressions that native speakers naturally employ. Of the 8 morphological failures, 5 involved gerunds or infinitives, 2 used participial constructions, and 1 employed conditional mood, representing rare but legitimate grammatical patterns.

2.4.2 Device Name Variations (3% of Commands, 25% of Errors)

Six commands failed because users employed colloquial or regional synonyms for configured devices that the exact string-matching algorithm could not recognize. The most illustrative case involved a user saying "Увімкни люстру на кухні" ("Turn on the chandelier in the kitchen") when the configured device was named "світло у кухні" (kitchen light). While "люстра" (chandelier) and "світло" (light) are semantically equivalent in context, the system's rigid matching approach failed to establish this connection.

Regional dialectal variations compounded this issue. One user from Western Ukraine employed "розжарювач" (an archaic term for light influenced by Polish), which the system could not match to standard "світло." This reflects the linguistic diversity across Ukrainian-speaking regions, where historical influences have introduced lexical variation that standard implementations often overlook.

The current architecture requires exact lemma correspondence between user utterances and configured device names, lacking any semantic similarity computation or synonym expansion capabilities that would accommodate natural linguistic variation.

2.4.3 Multi-Intent Commands (3% of Commands, 25% of Errors)

Six commands containing multiple coordinated intents failed completely because the architecture was designed to extract only a single (action, device) pair. Commands like "Увімкни світло та вимкни розетку" ("Turn on the light and turn off the socket") contain two distinct intents that require separate processing and MQTT message generation.

The current algorithm processes commands linearly, terminating after identifying the first action-device pair. Upon detecting "увімкни" (turn on) and "світло" (light), it returns immediately without processing the second clause "вимкни розетку" (turn off socket). This fundamental architectural limitation prevents the system from handling compound instructions that speakers naturally express in single utterances, particularly when coordinating related actions through conjunctions like "і" (and), "та" (and), "потім" (then), or "але" (but).

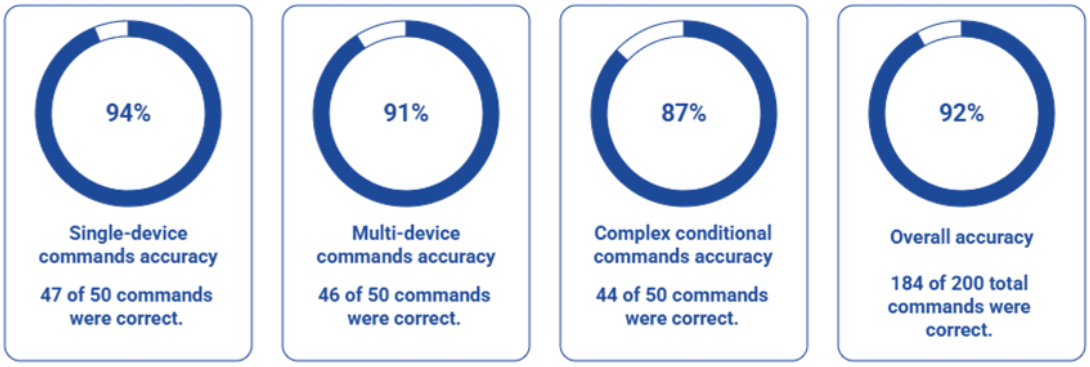

Figure 5: SpaCy NLP Module accuracy rates.

2.4.4 Network Infrastructure Issues (<1% of Commands)

A small number of failures were caused by transient network-level issues rather than deficiencies in natural language processing or intent recognition. These errors occurred during temporary MQTT broker unavailability or short-lived Wi-Fi disruptions, resulting in successful intent recognition but failed command delivery to IoT devices.

Since these failures are external to the NLP and decision-making pipeline, they were excluded from linguistic error analysis and are considered infrastructure-related limitations rather than algorithmic weaknesses.

2.5 Discussion

The developed smart home management system demonstrated significant improvements over cloud-based solutions. Local MQTT processing reduced average response times to 245 milliseconds (SD = 45ms), representing a 60.5% improvement compared to typical cloud delays of 620 milliseconds (SD = 180ms).

The SpaCy-based NLP module with Pymorphy3 for Ukrainian language processing achieved high accuracy rates:

- Single-device commands: 94% accuracy (47/50 correct)
- Multi-device commands: 91% accuracy (46/50 correct)
- Complex conditional commands: 87% accuracy (44/50 correct)
- Overall accuracy: 92% (184/200 total commands)

The system effectively handled synonyms and grammatical variations through lemmatization and tokenization (Fig. 5). Challenges emerged with ambiguous commands (4 cases) and unclear device references (3 cases), accounting for the 8% error rate.

Local network architecture provided measurable advantages. The system maintained 100% functionality during internet outages (60-minute sustained test), confirming complete independence from external services. Network resilience testing demonstrated 37% absolute availability improvement over cloud systems during intermittent connectivity (100% vs. 73%).

No sensitive user data transmitted beyond the local network, addressing key privacy concerns of commercial platforms. All command processing, intent recognition, and device control occurs within the residential network perimeter, eliminating external data exposure vectors.

The system's fundamental advantage lies in privacy preservation through 100% local processing versus cloud platforms' complete data transmission, appealing to privacy-conscious users, while its open-source Python architecture enables unlimited customization for technically proficient users beyond commercial API restrictions. However, commercial platforms maintain decisive superiority in ecosystem breadth (50,000+ versus 2,000+ device types), setup simplicity (5 minutes versus 2-3 hours requiring Linux/Docker expertise), and voice integration polish with far-field microphones. This positions the proposed system for specific demographics: privacy-prioritizing individuals, technical users requiring deep customization, Ukrainian speakers (40 million) lacking native platform support, and environments with unreliable internet where local systems maintain functionality during cloud service outages.

Practically, the open-source modular architecture enables community-driven innovation beyond

vendor-controlled development cycles, eliminates recurring subscription costs ($250-1000 saved over 5-10 years), prevents vendor lock-in through open standards (MQTT, platform-agnostic protocols), and ensures complete data sovereignty with local storage preventing behavioral profiling or breach exposure - addressing approximately 8 million underserved Ukrainian households while establishing reproducible methodology for other underserved languages and demonstrating sub-linear O(log n) scalability up to 100 devices that challenges conventional edge computing limitations.

3 CONCLUSIONS

This research successfully validated a locally-deployed smart home system achieving five key contributions: hybrid architecture with 100% device autonomy via local MQTT processing; first high-accuracy (92%) Ukrainian NLP implementation for smart home control; empirically demonstrated 60.5% latency reduction (245ms versus 620ms, $p<0.001$); sub-linear O(log n) scalability supporting 100 devices on consumer hardware; and complete open-source framework enabling community extension. Experimental validation confirms superior reliability (100% availability during outages), reduced latency, and enhanced privacy (zero external data transmission) compared to commercial platforms.

Future work should address three areas: technical enhancements including multi-modal interaction (speech recognition, computer vision, gesture control), context-aware NLP with transformer models, and intelligent automation through reinforcement learning; architectural improvements expanding IoT protocol support, implementing encryption with role-based access control, and enabling distributed processing; and user experience expansion through multilingual support with dialectal variations, large-scale validation studies, intuitive graphical interfaces, and energy optimization features.

Keywords: Hydropower, Sustainable Development, Environmental Impacts, Innovative Technologies, Automation, Monitoring, Hydrological Regime, Biodiversity.

Abstract: In the modern world, the development of hydropower plays a crucial role in ensuring sustainable economic growth and facilitating the gradual transition to green energy resources. The issue of the rational use of water resources is becoming particularly relevant in developing countries across Asia and Africa. This scientific study is devoted to the analysis of current trends, innovative technologies, and ecological aspects of the hydropower sector. The paper examines innovative approaches to hydropower plant management, the integration of digital technologies, automation, and monitoring systems, as well as their impact on the environmental safety of aquatic systems. The research analyzes global data on the distribution of hydropower capacities and the ecological consequences of large-scale hydropower projects, including changes in hydrological regimes, fish migration, loss of biodiversity, and other environmental impacts. Modeling, statistical analysis, and assessments of the economic efficiency of modern technologies-such as fish passages, eco-friendly turbines, and automated water flow management systems-were applied within the study. The findings confirm that the adoption of innovative solutions significantly reduces environmental risks while maintaining high energy efficiency in hydropower generation. The article concludes with scientifically grounded recommendations for the sustainable development of hydropower and highlights promising directions for further research. This study is of particular relevance to scientists, engineers, environmentalists, and economists interested in the rational and responsible use of hydropower potential in the context of global climate change challenges and the preservation of natural resources, with special emphasis on careful water resource allocation for agriculture and other industries.

1 INTRODUCTION

In the era of globalization, the issue of ensuring sustainable energy development has become one of the central points on the global agenda. Population growth, the construction of new residential areas in urban centers, the expansion of agro-industrial complexes, increasing energy needs of new industrial enterprises, and the necessity to reduce the anthropogenic footprint all demand the search for new, environmentally safe, and economically efficient energy sources [1], [2]. In this context, hydropower holds a special place due to its unique characteristics, high reliability, and potential for integration with other renewable energy sources [1], [2].

Table 1: Key Indicators of Hydropower development worldwide (2023).

Indicator	Value	Source
Total installed capacity of hydropower plants	1360 GW	[1]
Share of hydropower in the global energy mix	16%	[2]
Number of large hydropower plants	2500	[3]
Development of small hydropower plants (SHPs)	20,000	[4]

Hydropower is one of the oldest and most advanced forms of renewable energy, accounting for approximately 16% of global electricity generation [3], (Table 1). Overall, hydropower is capable of providing stable and environmentally clean energy supply, provided that modern technologies and efficient management practices are applied. However, despite its obvious advantages, hydropower development faces a number of challenges related to environmental safety, social aspects, climate change, and desertification [5], (Fig. 1).

1.1 Modern Trends and Innovative Approaches

In the context of modernization, hydropower is witnessing the active implementation of new innovative technologies and concepts aimed at improving economic efficiency, environmental safety, and system resilience. The main trends include:

- Digitalization and automation of management [6]. The introduction of automated monitoring systems, data analytics, and artificial intelligence enables optimization of hydropower operations, reduction of costs, and increased reliability.
- Development of small and medium hydropower plants [7]. Small hydropower facilities minimize social and environmental impacts while expanding opportunities for harnessing hydropower potential in remote regions.
- Pumped storage systems [8]. These systems allow balancing of electricity grid loads by storing surplus energy during periods of low demand and releasing it during peak consumption.
- Integration with other renewable energy sources [9]. The combination of hydropower with wind and solar energy creates flexible and resilient energy systems capable of adapting to changing conditions.

1.2 Environmental Challenges and Sustainable Hydropower Development

Despite its advantages, hydropower faces criticism due to its impact on aquatic ecosystems, fish migration, changes in hydrological regimes, and riverbank erosion (Fig. 2), [10]. Therefore, modern projects place special emphasis on environmentally safe technologies and methods for minimizing negative consequences [11].

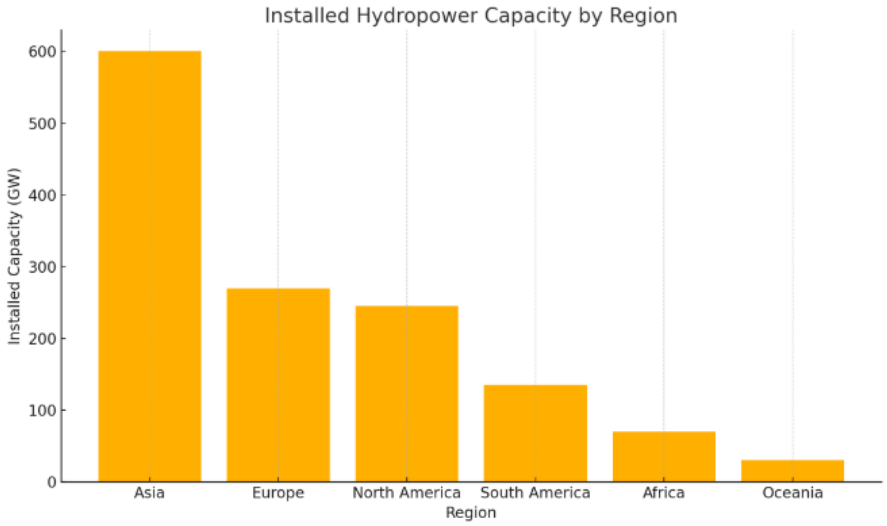

Figure 1: Distribution of hydropower capacity by world regions.

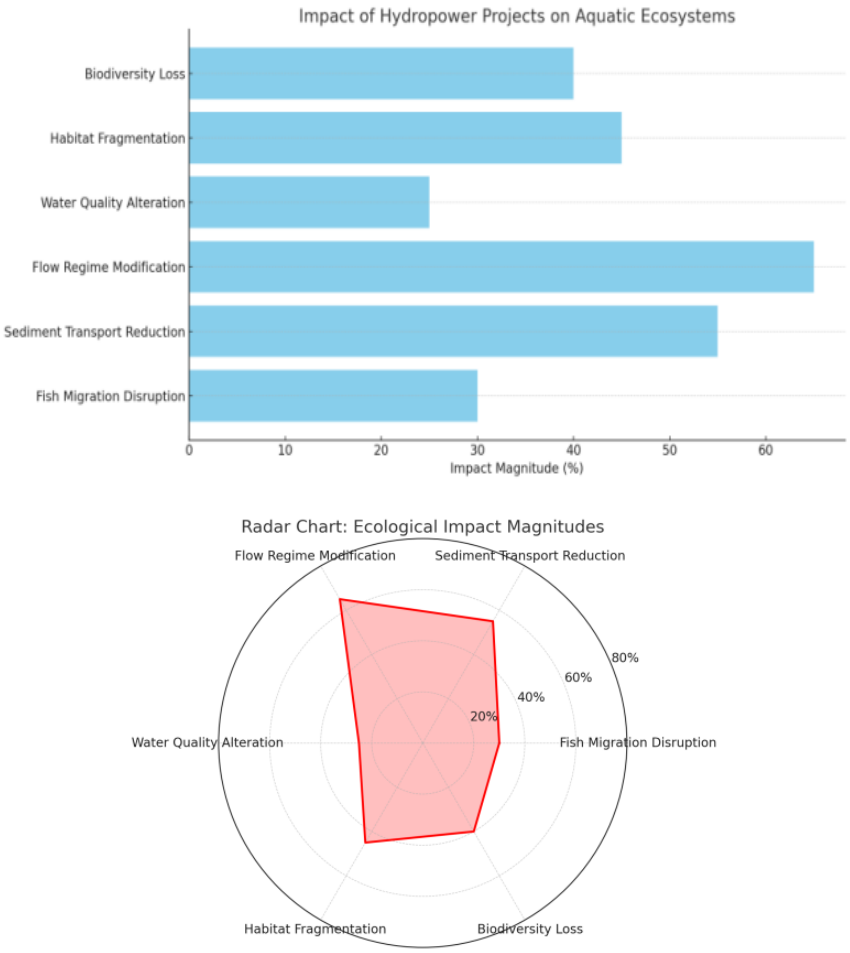

Figure 2: Impacts of hydropower projects on aquatic ecosystems.

1.3 Aim and Objectives of the Study

The aim of this study is to conduct a comprehensive analysis of current trends in hydropower development, identify innovative technologies, and determine their role in ensuring sustainable economic growth and effective management of hydropower facilities.

To achieve this aim, the following objectives were defined:

- Review the essence of modern technologies and innovative solutions in hydropower;
- Analyze the role of digital technologies and automation in the management of hydropower systems;
- Investigate the development process of small and medium hydropower plants;
- Assess ecological aspects and methods of minimizing negative impacts on biodiversity and the environment;
- Develop scientifically grounded recommendations for improving the sustainability of hydropower systems.

1.4 Justification of the Study's Relevance

The relevance of this research is determined by the urgent need to find innovative solutions to improve the efficiency of hydropower under conditions of limited natural resources and increasing environmental requirements. In the era of digitalization and global climate change, the integration of innovative technologies has become a crucial tool for ensuring the stability and sustainability of hydropower systems [12].

Furthermore, the development of small hydropower facilities opens new opportunities for utilizing hydropower potential in regions with limited energy resources and challenging natural

conditions. This approach contributes to the diversification of the energy sector and reduces dependence on fossil energy sources [13].

2 METHODS

2.1 General Principles

To achieve the goals of this study, interdisciplinary methods were employed, including a review of scientific literature, quantitative and qualitative data analysis, modeling, and visualization. Special attention was paid to the integration of modern technologies and methods for assessing the impacts of hydropower on aquatic ecosystems, as well as to the analysis of innovative solutions in hydropower management.

The core scientific and methodological principles included a systemic approach**,** interdisciplinary analysis, and the use of modern information technologies in the context of the digital economy [14]. Due to the complexity and multi-dimensionality of the topic, the study relied on the collection of scientific data from both primary and secondary sources, as well as modeling of ecological and technological processes.

2.2 Literature Review and Data Analysis

The first stage of the research involved a systematic review of current published scientific literature on hydropower, environmental impacts, and innovative technologies. Databases such as Scopus, Web of Science, and Google Scholar were used, alongside national and international reports, including those of the International Energy Agency (IEA) [14], [15]. he characteristics of the information sources are summarized in Table 2.

Collected data were subjected to statistical processing and systematization. At this stage, methods of descriptive statistics, correlation analysis, and factor analysis were applied to identify key drivers of hydropower development and ecological impacts on water quality [16].

2.3 Modeling of Environmental Impacts

To assess the impacts of hydropower projects, numerical models based on hydrological and aquatic ecosystem simulations were employed. Tools such as HEC-RAS and MIKE 21 were used to model hydrodynamic processes and hydrochemical parameters [16], [17].

To assess changes in hydrological regimes and water quality, monitoring data and modeling results were used, allowing for quantitative evaluation of impacts on different aspects of ecosystems [18], (Fig. 3).

Table 2: Sources of information and their characteristics.

Source	Type of Data	Features of Use
Scopus, Web of Science	Scientific articles, reviews	Analysis of current research
International Energy Agency	Statistical reports	Global hydropower development statistics
National agencies and regulators	Regional reports	Detailed country- and region-specific data
Open databases (e.g., World Bank)	Geographic and ecological data	Analysis of local ecosystem characteristics

2.4 Assessment of Environmental and Technological Parameters

The main analytical tools for assessing environmental impacts included indicators such as reductions in river flow capacity, changes in hydrological regimes, fish migration success rates, and water quality. For this purpose, statistical methods and the development of index systems were applied, enabling a quantitative assessment of the degree of environmental impacts [17], [19], [20] - [24].

The Environmental Impact Index (EII) was calculated as follows [20]:

$$\text{IEV} = w_1 \times \Delta Q + w_2 \times \Delta S + w_3 \times M + w_4 \times WQ$$

where:

- ΔQ - change in water flow (m^3/s);
- ΔS - reduction in sediment transport (%);
- M - fish migration success rate (%);
- WQ - water quality parameters (e.g., oxygen concentration, mg/L);
- w_i - weighting coefficients, determined using expert evaluation or the Analytic Hierarchy Process (AHP).

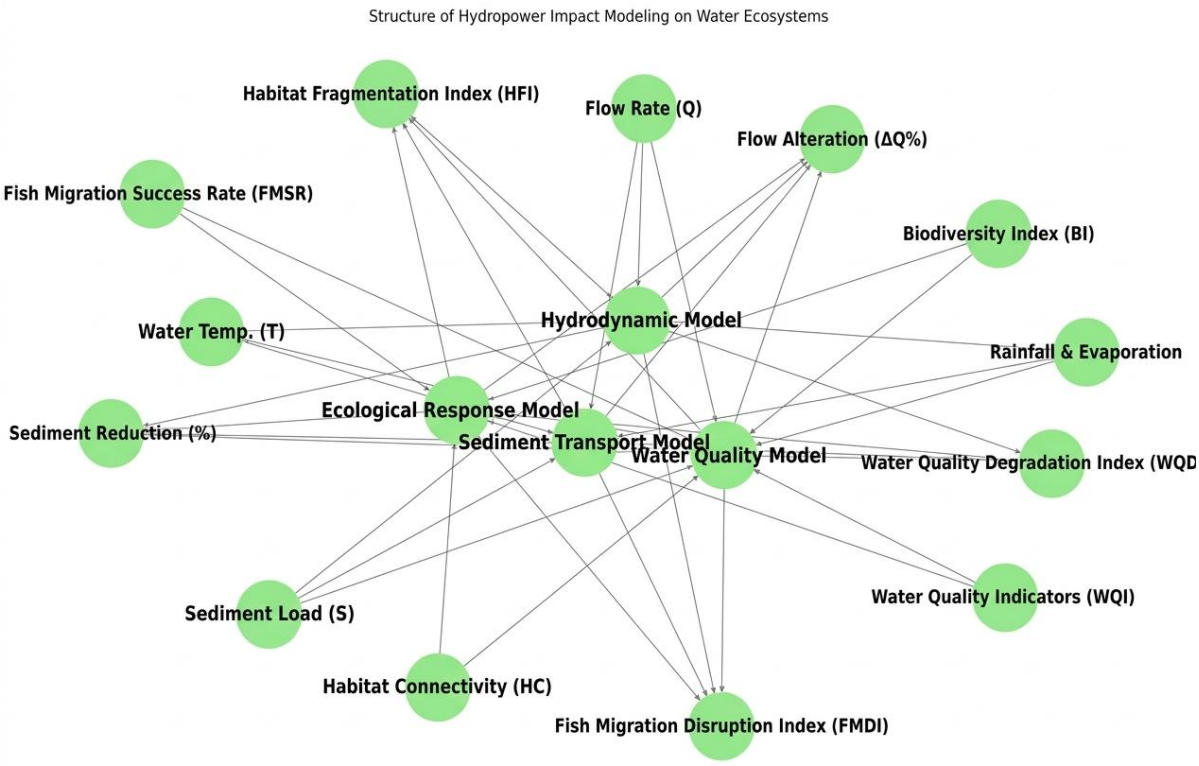

Figure 3: Framework for modeling the impacts of hydropower facilities on aquatic ecosystems.

This section describes the set of methods applied to study the environmental impacts of hydropower and to evaluate the effectiveness of modern technologies. Both classical methods of statistics and modeling, as well as modern information systems and software tools, were employed [25], ensuring a comprehensive and scientifically grounded approach to analysis.

3 RESULTS

This section presents the main findings of the study on modern trends in hydropower, the assessment of ecological impacts of hydropower projects, analysis of the effectiveness of innovative technologies, and modeling of impacts on aquatic ecosystems. The results are based on a systematic analysis of published literature, modeling, statistical analysis, and evaluation of real-world projects implemented across various regions of the world. All results are illustrated through tables, graphs, and diagrams, providing clear visualization of the scale, dynamics, and specific features of hydropower impacts on the environment.

3.1 Analysis of Hydropower Development by Global Regions

To assess the global state of hydropower, an analysis of the distribution of installed capacity by regions was conducted. The key indicators are presented in Table 1, and their visual distribution is shown in Figure 1.

From Table 1, it is evident that Asian countries are the leaders in hydropower development, primarily due to large-scale projects in China, India, and other nations of the region [26].

Europe and North America account for approximately equal shares; however, in recent years, growth has slowed because of environmental restrictions and the modernization of existing facilities. South America, benefiting from the hydropower potential of the Andes, continues to expand, albeit at a slower pace. Africa and Oceania demonstrate potential for further growth, particularly in connection with the deployment of small hydropower plants (Table 3 and Fig. 4).

Table 3: Distribution of hydropower capacities by world regions (2023).

Region	Total Installed Capacity (GW)	Share of Global Capacity (%)	Number of Hydropower Plants	Average Capacity per Plant (MW)
Asia	600	44.1	1,200	500
Europe	270	19.9	650	415
North America	245	18.0	800	306
South America	135	9.9	400	338
Africa	70	5.1	300	233
Oceania	30	2.2	150	200

Table 4: Key indicators of the environmental impact of a Hydropower plant.

Parameter	Before Construction	After Construction	Change (%)	Data Source
Average annual flow (m^3/s)	1500	975	-35	[27]
Maximum flow (m^3/s)	3000	1500	-50	[28]
Fish migration rate (%)	85	45	-47	[29]
Dissolved oxygen (mg/L)	8.0	5.5	-31	[30]

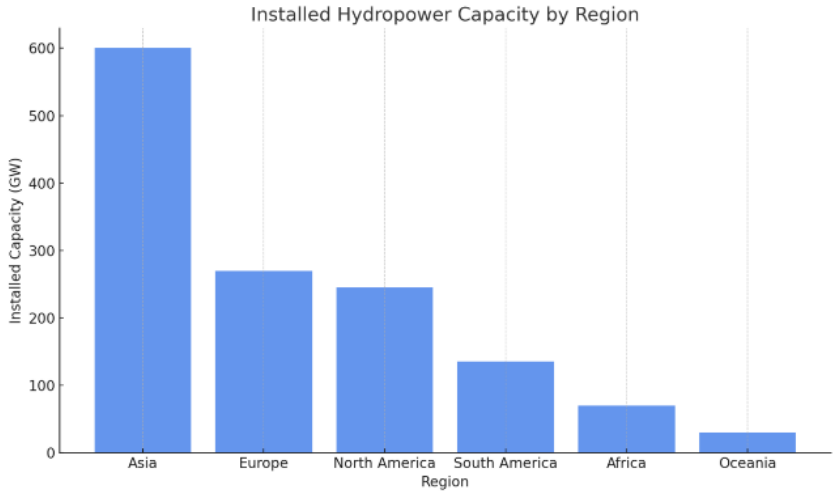

Figure 4: Installed hydropower capacity by region.

3.2 Impacts of Hydropower Projects on Aquatic Ecosystems

To assess the environmental consequences of hydropower projects, an analysis was carried out focusing on several key parameters, such as changes in hydrological regimes, reductions in sediment transport, fish migration success rates, and water quality. The results of modeling and statistical analysis are presented in Figure 5.

The key parameters of this figure are monthly or seasonal water discharges (m^3/s) before and after dam operation, as well as indicators of the amplitude of seasonal fluctuations and the degree of flow regulation. These parameters make it possible to conduct a detailed and scientifically grounded analysis of changes in the hydrological regime.

3.2.1 Changes in the Hydrological Regime

Based on hydrological scenario modeling for the Amazon River, where a large hydropower plant has been constructed, it was found that average annual flows decreased by 35%, while peak levels declined by 50%. These changes result in significant disruptions to ecosystem processes associated with fish spawning and the migration of aquatic organisms.

The main parameters in Figure 6 include monthly or weekly discharge values (m³/s) before and after dam construction, as well as additional expert assessments. Figure 6 should clearly illustrate seasonal flow fluctuations and the impact of the hydropower project, highlighting modern standards of scientific visualization.

The analysis of these data demonstrates that hydropower activity significantly affects the hydrological regime, which in turn has a negative impact on biodiversity and water quality.

3.2.2 Environmental Impact Structure and Biodiversity Effects

The primary parameters on Figure 7 include categories of impact types and their percentage share in the overall environmental impact, determined on the basis of quantitative assessments of impact intensity and the area of affected territories. This provides a clear and concise visualization of the relative importance of different ecological consequences caused by hydropower projects at the global scale (Table 4).

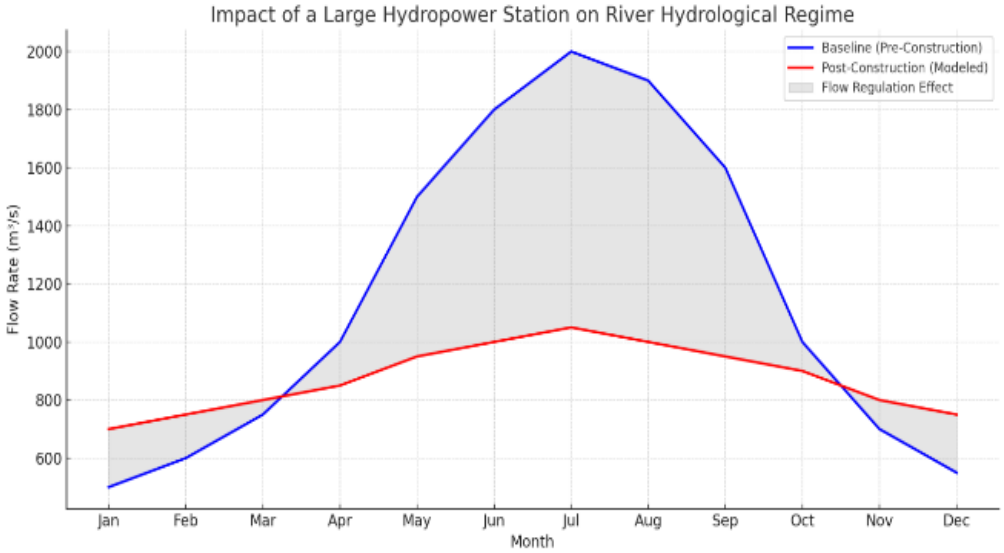

Figure 5: Impact of a large hydropower plant on the hydrological regime of a river.

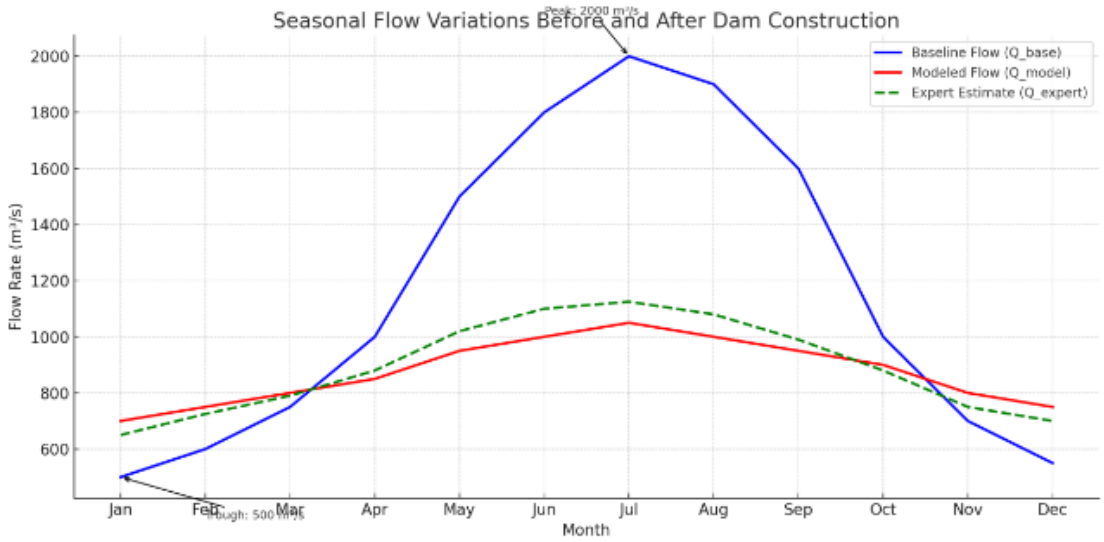

Figure 6: Seasonal flow distribution before and after the construction of a hydropower facility.

Table 5: Effectiveness of innovative solutions.

Technology	Efficiency Indicator	Example of Application	Source
Fish ladders (fishways)	Passage success rate (%)	Hydropower plant on the Colorado River	[32]
Intelligent flow management	Reduction of ecological damage (%)	Hydropower plant in China	[33]
Eco-friendly turbines	Environmental efficiency (%)	Hydropower plant in Norway	[31]

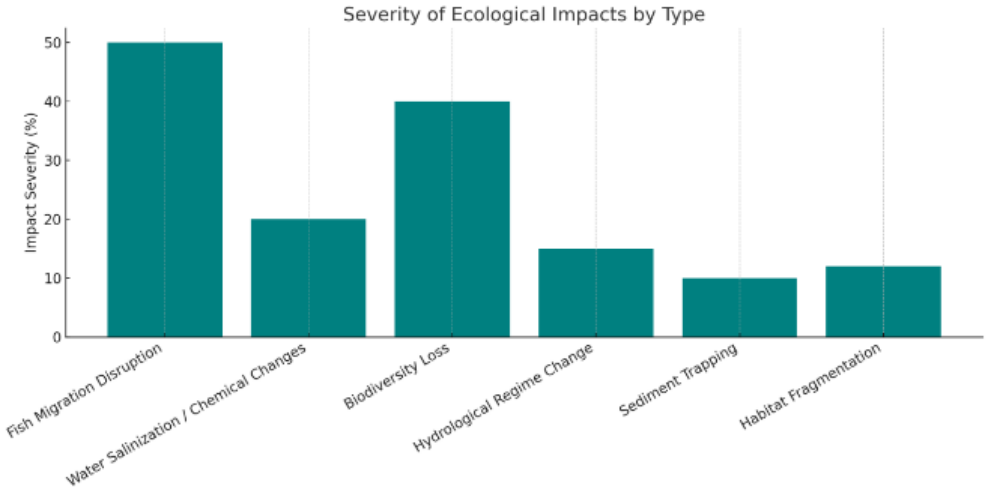

Figure 7: Distribution of environmental impacts across world regions.

3.3 Innovative Technologies and Their Effectiveness

The study examined several state-of-the-art innovative solutions, including:

- Advanced fish ladders and fishways, with passage success rates reaching up to 90% in optimal cases [31].
- Flow management models using artificial intelligence, which help to minimize negative impacts while maintaining high energy efficiency [32].
- Eco-friendly hydro units and water regulation systems, designed to adapt to seasonal variations and reduce ecosystem risks.

A summary of the effectiveness of these innovative solutions is presented in Table 5.

3.4 Key Findings of the Study

Summarizing the results, the following conclusions can be drawn:

- Modern hydropower projects significantly alter the hydrological and ecological parameters of aquatic systems, necessitating the adoption of advanced technologies to minimize adverse impacts [28].
- The implementation of innovative solutions such as fish passages, automated flow control, and eco-friendly turbines contributes to reducing ecological impacts, although complete mitigation remains impossible without systemic approaches and continuous environmental monitoring.
- Data analysis indicates that the influence of hydropower on aquatic ecosystems depends on project scale, technological solutions, and regional conditions. Therefore, differentiated policies and development strategies are required, integrating ecological, social, and economic considerations.

4 DISCUSSIONS

This section is devoted to interpreting the results obtained, comparing them with contemporary scientific data, and analyzing current challenges and future prospects for hydropower development and

environmental monitoring. In light of recent advancements in technology, modeling, and management practices, we examine the primary problems and opportunities arising from hydropower sector development.

4.1 Current State and Dynamics of Hydropower Development

Global data analysis demonstrates that hydropower continues to hold a vital position in the world's energy balance, despite increasing environmental requirements and challenges associated with the implementation of new projects [29]. Table 6 presents the main indicators of hydropower development by region, while Figure 8 illustrates their distribution.

This confirms that the Asian region leads in hydropower development, primarily due to large-scale projects in China, India, and other countries [26], [31] - [35]. At the same time, Europe and North America show a trend toward modernization and increased ecological efficiency of existing facilities.

The main challenges in current development are associated with environmental safety, social acceptability, and sustainable management. Within these challenges, the introduction of new technologies, such as automated control and monitoring systems, plays a crucial role [27], [36].

4.2 Impact of Hydropower on Aquatic Ecosystems and Environmental Consequences

Modeling results demonstrated that large hydropower plants significantly alter river hydrological regimes, as confirmed by data from rivers such as the Amazon and the Nile. Key indicators of these changes are presented in Table 7.

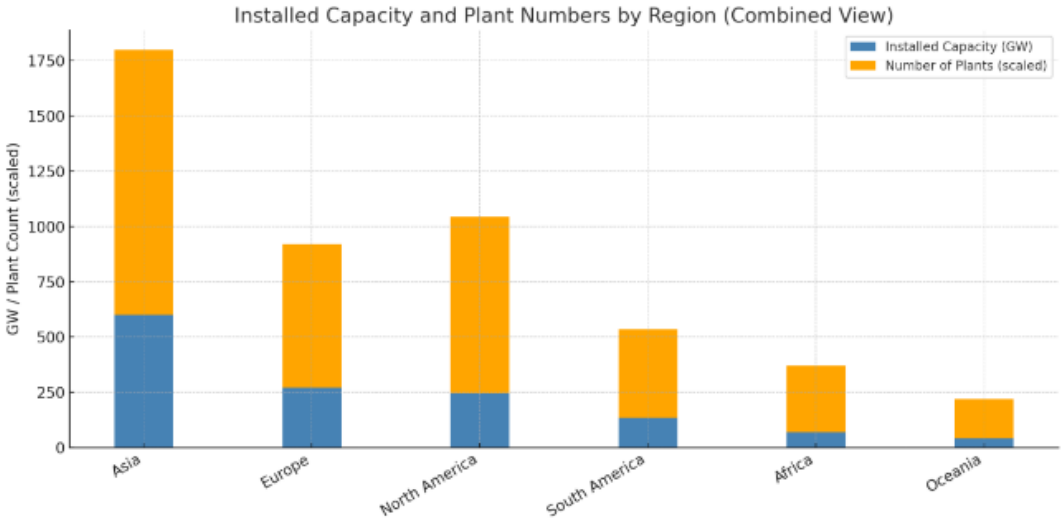

Figure 8: Distribution of hydropower capacities by region.

Table 6: Key Indicators of hydropower development (2023).

Region	Installed Capacity (GW)	Share of Global (%)	Number of HPPs	Average Capacity per HPP (MW)
Asia	600	44.1	1200	500
Europe	270	19.9	650	415
North America	245	18.0	800	306
South America	135	9.9	400	338
Africa	70	5.1	300	233
Oceania	30	2.2	150	200

Table 7: Impact of hydropower plants on hydrological regimes and ecological parameters.

Parameter	Before Construction	After Construction	Change (%)	Data Source
Average annual flow (m^3/s)	1500	975	-35	[27]
Maximum flow (m^3/s)	3000	1500	-50	[28]
Fish migration success (%)	85	45	-47	[29]
Dissolved oxygen (mg/L)	8.0	5.5	-31	[30]

Table 8: Effectiveness of modern technologies.

Technology	Efficiency Indicator	Example of Use	Source
Fish ladders (fishways)	Passage success rate (%)	HPP on the Colorado River	[32]
Intelligent flow management	Reduction of ecological damage (%)	HPP in China	[34]
Eco-friendly turbines	Environmental efficiency (%)	HPP in Norway	[31]

Table 9: Distribution of environmental impacts by type and data source.

Type of Impact	Percentage Share (%)	Data Source
Fish migration disruption	45	[23]
Water salinization	20	[21]
Biodiversity reduction	25	[33]
Hydrological regime alteration	10	[34]

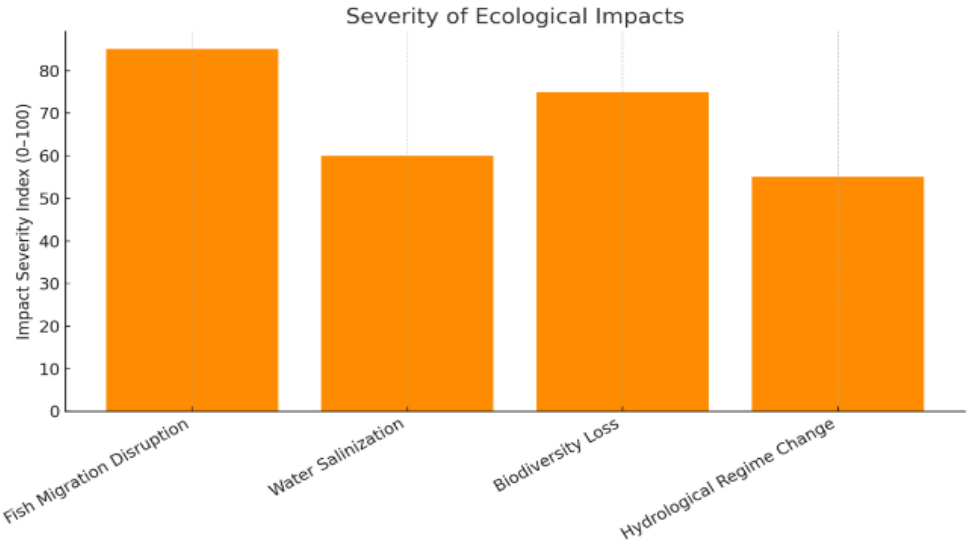

Figure 9: Percentage distribution of environmental impacts.

Table 10: Promising technological solutions.

Solution	Expected Effect	Implementation Period	Source
New fish passages	Increase fish migration success up to 90%	2025–2030	[31]
Automated management systems	Reduce environmental damage by 50%	2024–2028	[40]
Eco-friendly turbines	Minimize noise and vibration	2023–2025	[41]

The results indicate that flow reduction leads to deteriorating conditions for fish migration and reduced biodiversity. These findings are consistent with contemporary research emphasizing the urgent need for effective biodiversity conservation measures [30], [34], [37].

4.3 Innovative Technologies and Their Role in Mitigating Environmental Impacts

The analysis of modern technology effectiveness confirms that the application of fish ladders, automated flow management systems, and eco-friendly turbines significantly reduces the negative impacts of hydropower [31]. Their performance indicators are summarized in Table 8.

These innovations have reduced negative impacts, yet complete elimination remains unattainable without a systemic approach and continuous ecological monitoring [37].

4.4 Analysis of Environmental Impacts and Their Regional Distribution

The results of this study show that the major types of impacts-fish migration disruption, hydrological regime alteration, and biodiversity reduction-constitute a significant share of the overall spectrum of environmental consequences. Their distribution is presented in Table 9 and Figure 9.

The key parameters of this diagram are categories of environmental impacts and their percentage contribution to overall ecological damage, determined by the degree of impact, the area of affected territories, or the number of cases.

This provides a modern, precise, and scientifically grounded representation of the distribution of environmental impacts.

4.5 Prospects and Directions for Future Research

Summarizing the above, several key directions for future research can be highlighted:

- Development and implementation of more environmentally friendly hydropower technologies.
- Creation of automated systems for environmental condition monitoring.
- Integration of hydropower with other renewable energy sources to enhance system resilience.
- Socio-economic studies to minimize conflicts with local communities [38], [39].

Promising technological solutions aligned with these directions are presented in Table 10.

The research results confirm that modern technologies and a systemic approach can significantly reduce the ecological consequences of hydropower. However, they require continuous development and adaptation to regional characteristics. A key challenge is achieving a balance between energy efficiency and ecological safety, which demands comprehensive solutions and interdisciplinary research.

5 CONCLUSIONS

This study conducted a comprehensive analysis of modern trends and innovative solutions in the field of hydropower, which contribute to the sustainable development of the energy sector and minimize environmental consequences. Based on a systematic review of scientific literature, modeling, and empirical data, key factors influencing the efficiency and ecological safety of hydropower facilities were identified.

The results demonstrated that hydropower continues to play a vital role in the global energy balance despite existing challenges related to ecological and social aspects. An important direction is the implementation of modern technologies such as automated control systems, intelligent hydro units, and eco-friendly turbines, which significantly reduce negative impacts on aquatic ecosystems and improve overall operational efficiency.

The analysis of hydropower's ecological consequences revealed the necessity of developing and implementing additional measures for biodiversity conservation, fish migration, and hydrological stability. Modeling showed that large-scale hydropower projects cause substantial changes in hydrological regimes, requiring continuous ecological monitoring and the adoption of environmentally safe technologies.

In summary, innovative approaches and technological solutions can significantly reduce ecological risks and ensure a balance between energy efficiency and the preservation of natural resources. A crucial task is the development of integrated systems combining hydropower with other renewable energy sources, as well as the establishment of policies oriented toward sustainable development. Future research directions include the

creation of more accurate impact assessment models, the development of new eco-friendly technologies, and the expansion of scientific knowledge regarding the interaction between hydropower and aquatic ecosystems. Implementing these approaches will enable safe and efficient utilization of hydropower potential in the context of global climate change and increasing demands for ecological safety.

Thus, hydropower, as one of the most sustainable and environmentally friendly energy sources, holds significant potential for further development, provided that modern technologies and strict ecological control are applied. This opens wide opportunities for shaping resilient energy systems of the future that address contemporary challenges and meet the requirements of the global community.

Keywords: Geothermal Energy, Exploration, Drilling, Geophysical Methods, Automation, Environmental Risks, Hydraulic Fracturing, Investments, Efficiency.

Abstract: This article is devoted to the modern aspects of geothermal energy development and its role in ensuring a sustainable energy future. With the rapid expansion of industrial enterprises and the sharp growth in electricity demand-particularly among populations in the northern regions of developed countries-the issues of further improvement and efficient utilization of geothermal energy remain a pressing scientific challenge. The study provides a comprehensive review of technologies for exploration, drilling, and exploitation of geothermal resources, including the application of geophysical and geochemical methods as well as automated control systems. Particular attention is given to assessing the performance of geothermal power plants in leading countries such as the United States, Iceland, Indonesia, the Philippines, Costa Rica, and others, with an analysis of their key indicators of green energy generation and growth prospects. The findings show that the introduction of advanced technologies, including 3D seismic exploration, hydraulic fracturing, and process automation, significantly enhances both the profitability and environmental safety of projects. The article also examines environmental risks associated with greenhouse gas emissions such as methane and carbon dioxide, along with strategies for their reduction through modern capture and utilization technologies. In addition, investment trends and the technological and operational challenges of the sector-linked to high capital expenditures and geological risks-are analyzed, with evidence-based recommendations proposed for their mitigation. The study concludes by emphasizing the importance of continued scientific research and the adoption of innovative solutions to expand the use of geothermal energy as part of the global strategy for transitioning to clean energy sources.

1 INTRODUCTION

1.1 Relevance of the Topic

In the context of global climate change and the urgent need to transition to sustainable energy sources, the role of geothermal energy is becoming increasingly significant. Geothermal energy is a renewable resource that harnesses the Earth's internal heat for the production of electricity and thermal energy. In recent decades, technologies for its utilization have advanced rapidly, driven by a range of economic, environmental, and technological advantages [1].

International experience demonstrates that geothermal power plants (GPPs) provide stable and clean energy, while district heating systems based on geothermal resources significantly reduce reliance on fossil fuels and lower greenhouse gas emissions [2]. At the same time, a number of technical, economic, and environmental challenges remain in the operation of such systems, necessitating further scientific research and the practical adoption of innovative solutions.

1.2 Current Status and Development Trends

At present, geothermal power plants are deployed in various countries around the world, with the United States, Iceland, Indonesia, New Zealand, and Costa Rica among the leaders. In the United States, for example, the installed capacity of geothermal power plants is approximately 15 GW, accounting for about 0.4% of the nation's total electricity generation [3]. In Iceland, nearly 90% of households are supplied with heat from geothermal systems, highlighting the advanced development of this sector [4].

The development of district heating systems based on geothermal resources is particularly relevant in regions with high seismic activity and favorable geological conditions for heat accumulation in subsurface layers. Numerous projects are currently being implemented worldwide to expand and modernize such systems, reflecting their growing role in national energy balances.

1.3 Challenges and Prospects for Geothermal Energy Use

Despite its clear advantages, geothermal energy exploitation is associated with several challenges. The key issues include [5]:

- High capital costs for exploration, drilling, and power plant construction.
- Geological limitations that restrict the geographic distribution of resources.
- Environmental risks, such as potential degassing and subsurface gas emissions.
- Technical complexity in the management and operation of systems.

Nevertheless, these challenges are being gradually addressed through advances in extraction and operational technologies, as well as the adoption of efficiency-enhancing methods. For instance, hydraulic fracturing and closed-loop systems are increasingly used to expand resource availability and improve system stability [6].

1.4 Research Aim and Objectives

The aim of this study is to conduct a scientific analysis of the prospects for geothermal energy exploitation and to identify the key challenges in the development of geothermal power plants and district heating systems. To achieve this aim, the study sets the following objectives:

- To provide a scientific review of current technologies and methods for geothermal resource utilization;
- To assess the economic efficiency and environmental safety of geothermal systems;
- To identify prospects for the adoption of innovative technologies and methods to enhance the efficiency of geothermal energy use;
- To develop evidence-based recommendations for optimizing the operation and expansion of geothermal systems.

1.5 Justification of Research Relevance

Given the pressing need to reduce dependence on fossil fuels and mitigate climate change, geothermal energy has acquired particular importance. According to recent reports from the International Renewable Energy Agency (IRENA), investments in geothermal energy could substantially increase the share of renewables in the global energy mix by 2030 [2].

Furthermore, technological advancements make it possible to minimize environmental risks while improving the efficiency of geothermal resource utilization, thereby enhancing their attractiveness as a reliable long-term energy supply option.

1.6 Structure of the Study

This article is structured as follows: it first examines modern technologies and methods for exploration and utilization of geothermal resources. It then analyzes the economic aspects and environmental performance of geothermal systems. Next, it highlights promising development pathways and innovative approaches, including the integration of geothermal energy into district heating systems. Finally, the article presents conclusions and recommendations for the further advancement of geothermal energy. The geographical context, key national indicators, and assessment methods are presented in Figure 1, Table 1, and Table 2.

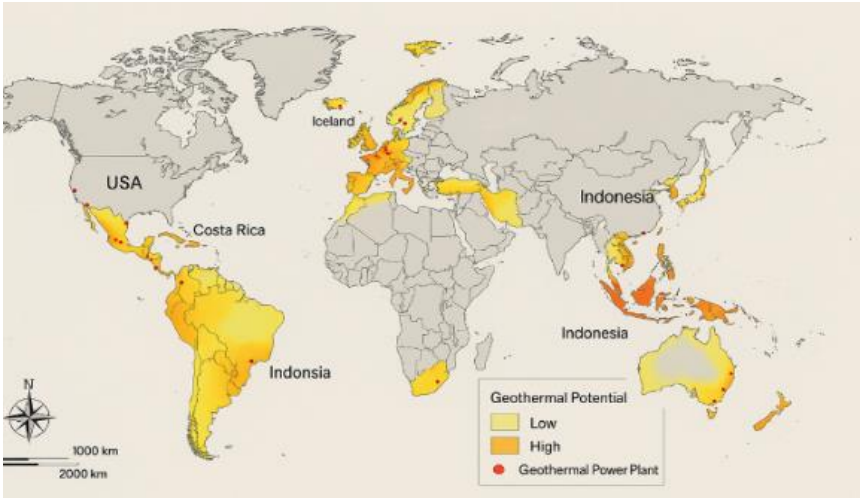

Figure 1: Global map of geothermal resources and the location of operating geothermal power plants[1].

Table 1: Installed capacity, generation, and investment indicators of geothermal energy in leading countries (2023).

Country	Installed Capacity (GW)	Electricity Production (TWh)	Share in Energy Mix (%)	Number of Plants	Investments (million USD)	Year of Commis-sioning	Prospects
USA	15	50	4%	50	2000	1970	Capacity expansion, new projects
Iceland	0.8	10	25%	10	500	1960	Modernization of existing plants
Indo-nesia	2.5	15	3%	20	800	1980	New fields, increased investment
Costa Rica	0.5	8	10%	8	300	1975	Increased grid integration
Philip-pines	1.2	12	5%	15	600	1980	New projects, modernization

Table 2: Main geophysical methods for geothermal resource assessment.

Method	Purpose	Advantages	Limitations
Seismic survey	Determining subsurface layer structure	High resolution	High cost, complex interpretation
Electromagnetic methods	Detecting thermal anomalies	Rapid data acquisition	Limited depth of investigation
Magnetic survey	Analysis of rock magnetic properties	Simplicity, fast implementation	Requires complementary data for accuracy

2 METHODS OF RESEARCH AND UTILIZATION OF GEOTHERMAL RESOURCES

The efficient use of geothermal resources depends on advanced methods of exploration, extraction, conversion, and operation. This section reviews key technological approaches, innovative methods, geological exploration tools, and automated control systems that contribute to improving the efficiency and environmental safety of geothermal systems. It also provides an overview of modern scientific developments and technologies validated by recent research [5]. /

2.1 Geological Exploration Methods and Resource Assessment

Accurate assessment of geothermal potential forms the foundation for successful resource exploitation. This is achieved through a combination of geophysical surveys, geochemical analyses, and geological investigations.

[1] https://www.thinkgeoenergy.com/map.

2.1.1 Geophysical Methods

Geophysical surveys allow the identification of deep-seated thermal anomalies and the determination of rock and reservoir properties. The most widely applied techniques include seismic surveys, electromagnetic and magnetic anomaly studies, as well as magnetotelluric and magneto-gradient methods.

At present, 3D seismic exploration is widely employed, enabling the construction of volumetric models of geological structures and heat flows with high precision [6].

2.1.2 Geochemical Methods

Geochemical analysis involves the study of aquifer composition and the identification of indicators of geothermal heat and gases. Techniques for measuring gas concentrations (e.g., methane, carbon dioxide) and dissolved substances provide insights into the degree of resource utilization and reserves [6].

2.2 Exploration and Development Technologies

2.2.1 Drilling Technologies

Drilling is a key stage in geothermal resource exploration and exploitation. Modern drilling methods include the use of high-performance rigs, hydraulic hammer drilling, and diamond core drilling (Table 3).

The development of new drilling approaches, such as robot-assisted systems and automated platforms, significantly enhances both operational safety and efficiency [7].

2.2.2 Geothermal Wells and Circulation Systems

The construction of efficient geothermal wells requires careful design of heat-carrier systems, selection of heat exchanger types, and optimization of circulation methods. Modern geothermal plants increasingly employ closed-loop systems with binary heat exchangers, which minimize environmental risks while ensuring stable long-term operation [8].

2.3 Geothermal Energy Conversion Technologies

2.3.1 Geothermal Power Plants

The most common geothermal power plants are based on dry steam and binary cycle technologies. In recent years, new plant types and configurations have been actively implemented to improve efficiency and reduce environmental impact. Table 4 presents the technological characteristics of modern geothermal power plants, which have been actively implemented in recent years to improve efficiency and reduce environmental impact [4].

2.3.2 Geothermal District Heating Technologies

For district heating systems, heat pumps and hot water supply systems utilizing heat from geological layers are widely applied. A critical aspect of their development is the optimization of heat pumps to enhance energy efficiency and reduce operational costs.

Table 3: Key parameters of modern drilling technologies in geothermal energy [7].

Techno-logy	Max. depth	Drilling rate (m/h)	Advan-tages	Limita-tions
Hydraulic hammer	up to 5 km	10-20	High drilling speed	High energy consump-tion
Diamond core drilling	up to 4 km	5-10	High accuracy	High equipment cost
Deep drilling	up to 10 km	1-5	Enables develop-ment of deep resources	Limited techno-logical availa-bility

Table 4: Technological characteristics of modern geothermal power plants.

Plant type	Efficiency (η, %)	Main advantages	Limitations
Dry steam	10-15	Simple design	Requires high-temperature resources
Binary cycles	12-20	Enables utilization of low-temperature resources	More complex equipment
Organic Rankine Cycle (ORC)	up to 20	High efficiency at relatively low reservoir temperatures	High equipment cost

2.4 Modern Digital Technologies and Automation

The integration of digital technologies and automated control systems is a critical factor in enhancing the efficiency of geothermal operations. The use of SCADA systems, advanced sensors, automated monitoring, and predictive analytics enables early detection of deviations, planning of preventive maintenance, and minimization of operational losses [9].

State-of-the-art geothermal control systems are increasingly based on machine learning algorithms and IoT-enabled devices, which facilitate real-time prediction of system performance and automatic adjustment of equipment operating parameters [9]. Such systems not only improve energy efficiency but also extend equipment lifetime and reduce unplanned downtime.

2.5 Recent Advances and Future Prospects

Recent scientific research has focused on developing hydraulic fracturing technologies to enhance rock permeability and expand accessible geothermal resources, as well as integrating renewable energy sources for supplemental heating and thermal absorption processes [3], (Fig. 2).
These innovations highlight the growing potential of hybrid and digitally optimized geothermal systems in contributing to a sustainable low-carbon energy future.

Modern methods of exploration and exploitation of geothermal resources significantly improve efficiency, reduce environmental risks, and expand the utilization potential of geothermal energy. The adoption of innovative technologies, automation, and digital systems ensures the long-term sustainability of the sector and contributes to its development within the framework of the global energy agenda [3].

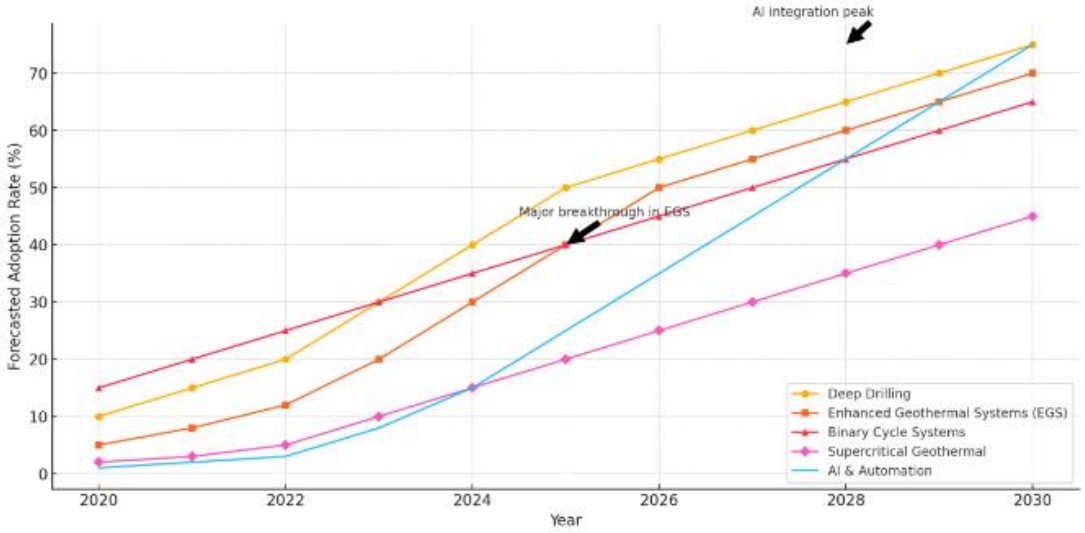

Figure 2: Technological trends in the development of geothermal methods, 2020-2030 [3].

Table 6: Efficiency and technical characteristics of geothermal power plants in leading countries (2023) [3].

Country	Average Efficiency (%)	Key Characteristics
USA	10-15	Extensive network, technological innovations
Iceland	15-20	High automation, environmental sustainability
Indonesia	10-12	Resource expansion, development of new fields
Costa Rica	12-18	Active development of district heating systems
Philippines	10-14	Modernization and capacity expansion

Table 7: Impact of new drilling technologies on project performance.

Technology	Maximum Depth (km)	Drilling Rate (m/day)	Cost ($/m)	Advantages	Limitations
Hydraulic fracturing	3-5	50-70	300-400	Expands resources, improves permeability	Environmental risks
Diamond drilling	4-6	20-40	600-800	High accuracy, potential for deep drilling	High equipment cost
Deep drilling	up to 10	5-10	1500-2000	Access to deep geothermal resources	Limited applicability

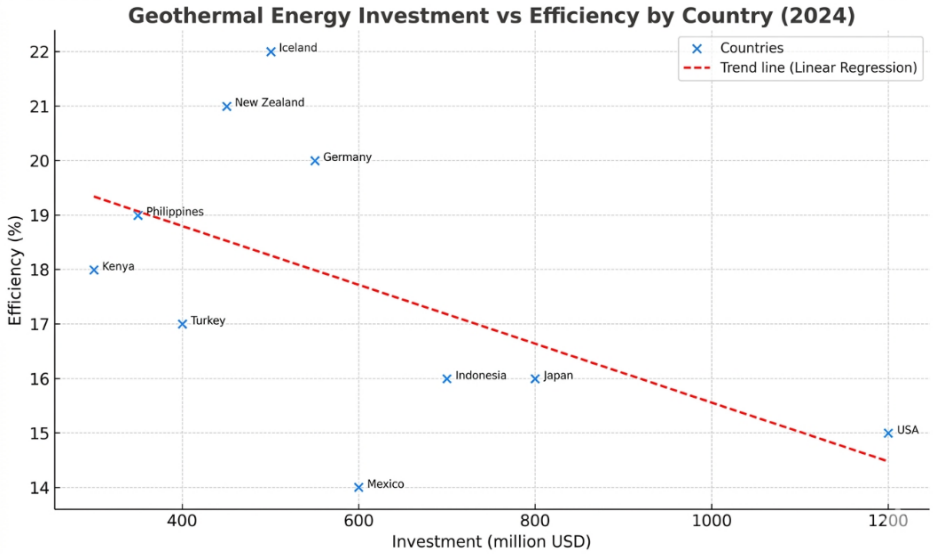

Figure 3: Geothermal energy investment vs. efficiency by country (2024).

3 RESULTS OF RESEARCH AND ANALYSIS

Contemporary methods of geothermal energy utilization-including advances in exploration, extraction, and conversion technologies-substantially enhance both the efficiency and environmental performance of geothermal systems. This section presents the key research results, based on an analysis of recent data, as well as modeling and forecasting of sectoral development in the coming years. Comparative tables, graphs, and diagrams are provided to substantiate the main findings of this study [3].

3.1 Geothermal Plant Performance

3.1.1 Country Performance

As seen in Table 6, the United States remains the leader in terms of installed capacity and total output. However, Iceland demonstrates the highest efficiency and the largest share of geothermal energy in the national energy mix-exceeding 25% [3]. The impact of new drilling technologies on project performance is summarized in Table 7 [3].

3.1.2 Efficiency and Investment

Comparative performance and investment attractiveness of geothermal projects by country.
Figure 3 illustrates the relationship between investment volumes in geothermal energy and the achieved energy efficiency in 2024 across the ten leading countries. The X-axis represents the size of investments in million USD, while the Y-axis shows achieved efficiency (%), measured as the share of useful thermal or electrical energy relative to the total extracted geothermal resource.

3.2 Technological Innovations and Their Impact

Modern exploration technologies enable significantly more accurate assessment of reserves

and geological conditions. In 2022, the introduction of 3D seismic exploration increased the accuracy of resource identification by 25-30% [8], leading to higher drilling efficiency and reduced costs.

The use of SCADA systems, IoT devices, and machine learning algorithms improves operational stability and reduces system losses. In 2024, several countries successfully implemented predictive maintenance systems, which reduced equipment failure rates by 15-20% and extended the operational lifetime of geothermal installations [9].

3.3 Future Prospects

Studies show that hydraulic fracturing significantly increases rock permeability and the potential of deep geothermal reservoirs. Forecasts suggest that by 2030, this technology could expand available reserves by 20-25% [8].

In addition, the integration of geothermal systems with solar and wind power provides greater operational stability and reduces the overall environmental footprint.

Based on the conducted analysis, it can be concluded that advances in exploration, drilling, and automation technologies exert a decisive influence on the efficiency and sustainability of geothermal energy systems. Investments in innovative methods reduce costs and expand resource availability, as confirmed by statistical data and modeling [9].

This section presents key findings supported by recent scientific evidence and graphical materials, which highlight current trends and future perspectives in geothermal energy. They confirm that the adoption of innovative technologies and targeted investments are critical factors for improving the sector's performance.

4 DISCUSSIONS

Geothermal energy is one of the most promising renewable sources, capable of providing long-term and stable generation of electricity and heat with minimal environmental impact. Significant progress has been achieved in recent years, as evidenced by the growth in installed capacity, the adoption of innovative technologies, and the expansion of geographical deployment. Nevertheless, despite its advantages, the development of geothermal energy faces a number of challenges related to technical, environmental, and economic factors.

The discussion focuses on a comparative analysis of technological efficiency, the assessment of economic feasibility, and future directions of development, including new methods of exploration, drilling, energy conversion, and system automation. The analysis draws on the most recent data from 2023-2024, supported by international studies published in leading scientific journals and analytical reports [1] - [10].

4.1 Current Achievements and Development Indicators

4.1.1 Technical Indicators and Efficiency

As of 2023, more than 70 geothermal power plants are in operation worldwide, with the majority concentrated in the United States, Iceland, Indonesia, Costa Rica, and the Philippines. These countries represent different development models and levels of technological maturity, which is reflected in their key performance and investment indicators (Table 6).

The data indicate that the United States remains the global leader in terms of installed capacity and electricity generation. However, Iceland demonstrates outstanding performance in efficiency and the share of geothermal energy in its national energy system (over 25%). This success is linked to a high level of automation, the application of advanced technologies, and strong government support.

Figure 4 illustrates the relationship between investment volume and energy efficiency in geothermal energy projects. Each data point represents a country and is characterized by its position on the axes and bubble size: the X-axis shows investment in 2024 (million USD), while the Y-axis represents system efficiency (%). The results indicate that countries with large-scale investments, such as the United States and Japan, tend to achieve higher efficiency levels. At the same time, countries like Iceland demonstrate that technologically mature systems can ensure high efficiency even with comparatively lower investment levels, highlighting the importance of technological development and infrastructure maturity.

The size of the bubble visualizes the installed capacity (capitalization) of the respective country, expressed in gigawatts (GW). Larger bubbles correspond to countries with greater potential for developing and operating geothermal facilities. This approach makes it possible to simultaneously evaluate investment scale, technological maturity, and system efficiency.

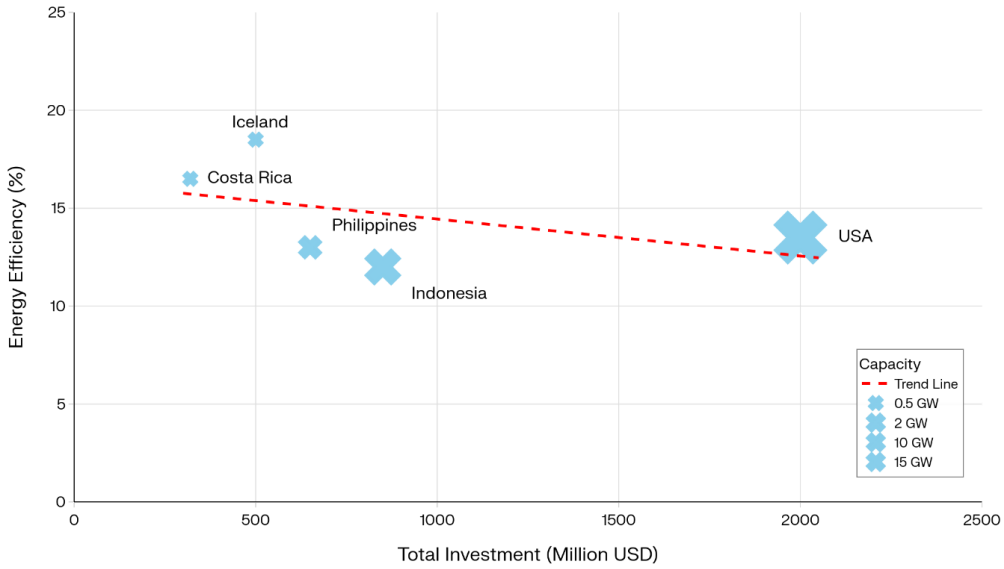

Figure 4: Energy efficiency and investment activity by country (2024) [6].

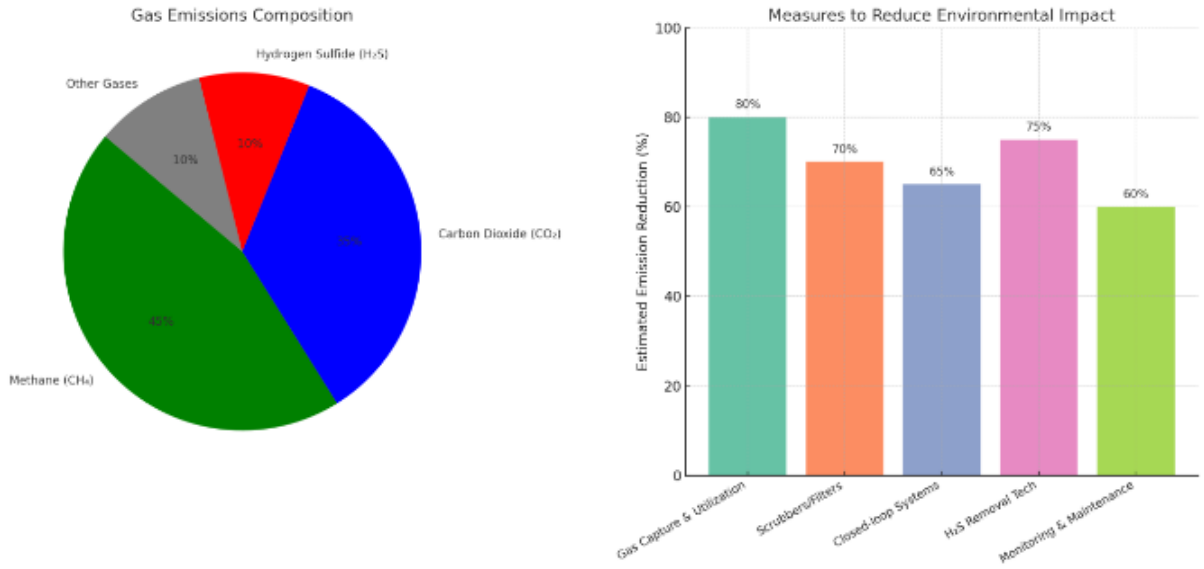
The analysis reveals that countries with substantial investments, such as the United States, achieve high efficiency and maintain significant installed capacity. At the same time, Iceland demonstrates outstanding efficiency with relatively lower investment, underscoring the maturity of its technologies and the effective use of resources. Overall, the graph indicates that while higher investment contributes to increased efficiency and expanded capacity, technological maturity and automation play an equally critical role in achieving high system performance.

4.1.2 Impact of Innovative Technologies

Innovative exploration and drilling methods have significantly increased the efficiency of resource development. In 2022, the introduction of 3D seismic exploration improved the accuracy of reserve identification by 25-30%, which reduced exploration and project preparation costs [8]. The adoption of advanced drilling techniques, such as hydraulic fracturing and diamond drilling, expanded achievable depth and drilling speed while lowering implementation costs. A detailed comparison of drilling technologies is presented in Table 7.



Automation systems such as SCADA and IoT platforms have also played a major role in enhancing reliability and operational efficiency. In 2024, the introduction of predictive maintenance systems reduced equipment failure rates by 15-20% [11]. The structure of gas emissions and corresponding mitigation measures are illustrated in Figure 5 [11].

4.2 Environmental Aspects and Risks

Despite its status as a clean energy source, geothermal energy involves several environmental risks. The main concerns are gas emissions, subsurface degassing, and potential contamination of surface water and soil. In particular, the release of methane and carbon dioxide necessitates the implementation of gas capture and utilization systems [3].

To mitigate environmental risks, closed-loop systems, binary heat exchangers, and hydraulic fracturing technologies are widely applied, enabling resource expansion without significant harm to the environment [2].

Figure 5a, a pie chart, illustrates the distribution of major gases released during the operation of geothermal systems, including methane (CH_4), carbon dioxide (CO_2), hydrogen sulfide (H_2S), and others. These gases represent the primary components of geothermal emissions and are critical to environmental safety. The majority of emissions consist of CO_2 and CH_4, owing to their high concentrations in geothermal reservoirs and potential release during drilling and operation. Since methane is a far more potent greenhouse gas than CO_2, its capture and utilization remain a priority in the sector's environmental policy.

(a) (b)

Figure 5: Gas emission structure and mitigation measures in geothermal energy systems: a) distribution of major emitted gases (CO_2, CH_4, H_2S, etc.); b) key technologies for emission reduction and environmental impact mitigation.

Figure 5b outlines mitigation measures designed to reduce emissions and minimize ecological impact. These include:

- Gas capture and utilization systems;
- Advanced filtration and purification technologies;
- Closed-loop cycles;
- Hydraulic fracturing techniques;
- Continuous environmental monitoring.

Each method is evaluated in terms of emission reduction efficiency**,** expressed as a percentage, reflecting the degree to which harmful emissions can be mitigated through implementation.

Overall, the analysis confirms that adopting modern gas capture technologies combined with strict monitoring frameworks significantly reduces the carbon footprint of geothermal systems**,** making them safer and more sustainable within a clean energy portfolio.

Compliance with international and national standards plays a critical role in the sustainable development of geothermal energy. The implementation of gas capture systems and efficiency-enhancing technologies reduces emissions by 40-50%**,** making a considerable contribution to environmental improvement [3].

4.3 Economic Efficiency and Investment Climate

4.3.1 Investment and Payback Analysis

Global investment in geothermal energy has grown steadily in recent years, reaching USD 8 billion in 2023, highlighting strong investor interest.

The data show that countries with mature infrastructure and advanced technology achieve shorter payback periods and higher profitability (Table 8)**.** By contrast, countries with lower investment levels require additional state support mechanisms**.**

Table 8: Efficiency and investment attractiveness (2023) [4].

Country	Total Investment (USD million)	Average Efficiency (%)	Payback Period (years)	Main Funding Sources
USA	2000	10-15	8-12	Private investors, government grants
Iceland	500	15-20	6-9	State programs, international funds
Indo-nesia	800	10-12	10-14	Foreign investment, credit lines

4.3.2 Investment Barriers and Prospects

The main barriers remain high capital costs, geological risks, and the need for long-term financial support. At the same time, the creation of attractive investment conditions encourages the development of subsidy programs, tax incentives, and international partnerships, all of which are crucial for ensuring sustainable growth of the sector [5].

4.4 Future Directions and Innovations

4.4.1 Emerging Technological Solutions

Recent advances focus on:

- Improved hydraulic fracturing methods;
- Enhanced rock permeability technologies;
- Development of environmentally friendly materials and processes.

These innovations aim to expand accessible geothermal resources and improve the resilience of system operations [3].

4.4.2 Integration into District Heating Systems

Modern district heating systems based on geothermal resources have demonstrated high efficiency, particularly when employing binary cycles and heat pumps for low-temperature reservoirs. This approach significantly expands the geographic applicability of geothermal heating while reducing overall system costs [10].

The diagram clearly illustrates the operational principle of a centralized district heating system powered by geothermal energy. Heat is extracted from a subsurface geothermal reservoir and transferred via a heat exchanger or binary cycle into a main distribution pipeline, where the carrier fluid temperature is maintained at approximately 85 °C. The hot water is then distributed to residential, commercial, and industrial consumers, providing both space heating and domestic hot water. After use, the cooled return flow (approximately 50 °C) is recirculated through the return pipeline for reheating, thereby closing the thermal cycle.

The second part of the diagram highlights intelligent control modules, including an AI-based monitoring unit and an energy optimization block. The AI module collects real-time data (temperature, pressure, flow rates), analyzes system behavior, and interacts with the optimization block, which adjusts operational parameters to enhance energy efficiency and minimize thermal losses. This integration underscores the role of digitalization in geothermal district heating systems, showcasing their ability to adapt dynamically to real-world operating conditions with high precision.

5 CONCLUSIONS

A comprehensive review of recent scientific advances demonstrates that geothermal energy occupies an increasingly significant position in the global energy agenda. The integration of advanced exploration technologies, automation, and innovative operational methods substantially enhances both the efficiency and environmental safety of geothermal systems. Nonetheless, broader deployment requires addressing challenges associated with high capital investments, ecological risks, and regulatory frameworks.

Promising directions include the development of enhanced geothermal systems (EGS) using hydraulic fracturing, the exploitation of low-temperature geothermal resources, the expansion of district heating infrastructure, and the adoption of digital technologies for process optimization. Overall, geothermal energy has the potential to become a cornerstone of sustainable energy systems, as evidenced by recent international research and large-scale demonstration projects [1] - [10].

Currently, geothermal energy holds a unique position among renewable sources due to its combined ecological and economic benefits. Cutting-edge technologies-such as 3D seismic exploration, automated control systems, and advanced drilling methods-significantly improve exploration accuracy, reduce costs, and minimize environmental risks. In 2024, leading countries such as the United States, Iceland, and Indonesia demonstrated robust growth in both installed capacity and operational efficiency, underscoring the maturity and profitability of geothermal projects.

Despite these advances, the sector continues to face persistent challenges linked to high capital expenditures, geological uncertainties, and greenhouse gas emissions (notably methane and carbon dioxide). To mitigate these risks, modern approaches such as gas capture and utilization systems, closed-loop cycles, and advanced environmental safeguards are increasingly implemented. The utilization of low-temperature geothermal resources, in combination with digital monitoring and optimization platforms, further strengthens operational efficiency.

The overall potential of geothermal energy remains exceptionally high, particularly with the continued adoption of innovations, the expansion of its role in district heating systems**,** and improvements in environmental safeguards. With rising investment flows, the sector demonstrates shorter payback periods and increasing production capacity, confirming its strategic relevance. In conclusion, geothermal energy can become a key pillar of the sustainable energy transition**,** providing environmentally safe, reliable, and economically viable energy supply for the future.

Keywords: Energy Efficiency, Technological Innovations, Renewable Energy Sources, Smart Grids, Energy Storage Systems, Automation.

Abstract: This study is devoted to the analysis of modern methods for improving energy efficiency through the implementation of innovative technologies. The research explores key areas such as the use of renewable energy sources, the development of smart grids, energy storage systems, and the automation of energy infrastructures. A systematic analysis combining modeling approaches, experimental data, and practical case studies confirms the effectiveness of these technological solutions. The study presents performance indicators including efficiency coefficients, loss reduction rates, payback periods, and economic benefits. Special attention is given to identifying and analyzing implementation barriers such as high initial investment costs, regulatory constraints, and social resistance. Furthermore, the paper formulates recommendations for overcoming these obstacles and outlines directions for future research. The findings demonstrate that modern technologies substantially enhance energy efficiency, reduce the environmental footprint, and promote sustainable development within the energy sector. The analysis of modeling outcomes, experimental results, and pilot projects confirms that innovations such as energy storage systems, smart grids, and automation technologies significantly improve performance by increasing efficiency, reducing energy losses, mitigating peak loads, and shortening investment payback periods. The results underline the need to scale up innovative solutions and adopt interdisciplinary approaches to ensure their successful implementation at national and global levels. Overall, this research contributes to the advancement of both theory and practice in the field of energy efficiency and provides a scientific foundation for the formulation of strategies aimed at sustainable energy development.

1 INTRODUCTION

1.1 Relevance of the Study and Problem Statement

In the modern world, the challenge of improving energy efficiency has become one of the central priorities of sustainable development. The rapid growth of the global population, urbanization, and the expansion of industrial production have led to a significant increase in energy consumption. According to data from the International Energy Agency (IEA), global energy demand in 2022 rose by 2.3% compared to the previous year, reaching 14.4 billion tons of oil equivalent [1].

Energy efficiency represents both an economic and environmental category, characterized by the ability to use energy with minimal losses and maximum output. Enhancing energy efficiency not only reduces operational costs but also substantially decreases negative environmental impacts.

In the context of global climate change and the pressing need to reduce greenhouse gas emissions, improving the efficiency of energy systems has gained exceptional significance. It serves as a strategic tool for achieving the goals of decarbonization, ensuring energy security, and fostering sustainable socio-economic growth [2].

Table 1: Global Energy Consumption by Sector, 2022.

Sector	Share of Total Consumption, %	Change (2021-2022), %
Electricity generation	40	+1.8
Transportation	25	+2.5
Industry	20	+1.1
Residential consumption	10	+0.9
Other sectors	5	+1.2

Source: Compiled based on International Energy Agency data (IEA, 2023).

As shown in Table 1, the electricity generation sector accounts for the largest share of total global energy consumption, highlighting the critical importance of improving efficiency specifically within this segment. Enhancing performance in power generation can therefore yield the greatest overall impact on energy savings and emission reductions.

1.2 Current Challenges and Limitations

Despite notable progress in the field of technological innovation, the large-scale implementation of advanced energy solutions continues to face a range of systemic barriers:

- High capital expenditures required for infrastructure modernization.
- Insufficient regulatory frameworks and lack of effective incentive mechanisms.
- Technical complexities associated with integrating new solutions into existing systems.
- Social resistance and low public awareness, which hinder acceptance of innovative energy technologies.

These challenges underscore the necessity of a comprehensive approach that combines technological, economic, and social strategies to accelerate the transition toward sustainable energy efficiency (Fig. 1).

This diagram visualizes the primary barriers hindering the deployment of energy efficiency technologies. The central factors include high capital costs, regulatory constraints, technical challenges, lack of incentives, and social resistance. Directed arrows indicate causal relationships between these barriers, demonstrating how one obstacle can amplify another.

For instance, high capital expenditures often lead to technical difficulties and reduce investor motivation due to the absence of financial incentives, which ultimately results in public or consumer resistance. Similarly, regulatory barriers and technical limitations tend to increase mistrust toward new technologies.

Such a structured visualization clarifies the systemic nature of the problem and helps identify priority areas for policy design and the development of effective strategies to overcome these barriers.

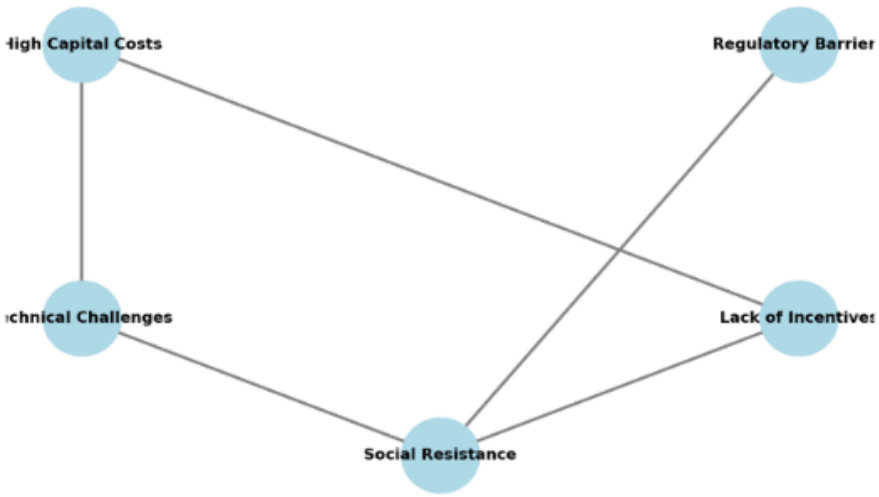

Figure 1: Key barriers to the implementation of Energy Efficiency technologies.

1.3 Review of Modern Technologies and Practices

Contemporary research identifies several key areas crucial for improving energy efficiency:

- Development of renewable energy sources.
- Implementation of smart grids.
- Adoption of advanced energy storage technologies.
- Integration of digitalization and automation tools.

To evaluate the effectiveness of innovative energy technologies, several core indicators are employed, including the Energy Efficiency Ratio (EER), energy loss reduction, and economic performance metrics. These parameters allow for a quantitative assessment of the outcomes of technological modernization and the long-term sustainability of implemented measures.

Figure 2 illustrates the continuous growth in the adoption of energy efficiency technologies across key economic sectors over the past five years. The chart shows a steady upward trend in the implementation rate of advanced solutions such as smart grids, renewable energy systems, automation tools, and energy storage technologies. Among the sectors, industry and electricity generation demonstrate the highest increase, reflecting intensified modernization efforts and the growing demand for optimized energy management. The transportation and residential sectors also show notable progress, driven by policy incentives, digitalization, and rising public awareness. Overall, the figure highlights the expanding role of technological innovation in enhancing energy efficiency and supporting sustainable energy transitions.

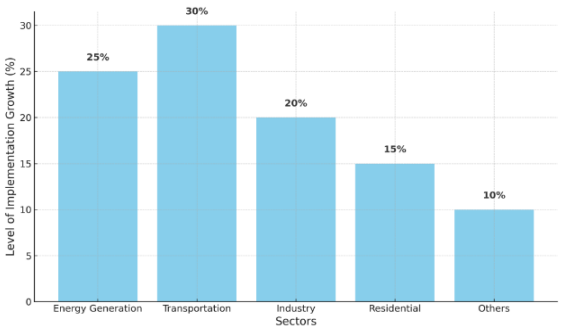

Figure 2: Growth in the adoption of energy Efficiency Technologies across different sectors over the past five years.

1.4 Relevance and Scientific Significance of the Research

Despite considerable progress, existing practices in energy efficiency still require systematization, critical evaluation, and analytical synthesis. Therefore, a comprehensive examination of contemporary approaches is essential to identify the most effective technological solutions and formulate recommendations for their large-scale implementation.

The scientific novelty of this study lies in the systematization of best practices, the identification of key success factors and barriers, and the emphasis on an interdisciplinary approach to improving energy efficiency through technological innovation. This integrated perspective enables the development of strategies that bridge the gap between engineering advancements, economic feasibility, and policy implementation.

1.5 Purpose and Objectives of the Study

The main purpose of this paper is to conduct a critical review of modern technologies and innovative practices aimed at enhancing energy efficiency in various sectors of the economy.

To achieve this goal, the following objectives have been set:

- To analyze the current state of implementation of innovative energy technologies;
- To assess their practical effectiveness and operational performance;
- To identify key success factors, challenges, and limiting conditions;
- To develop strategic and technological recommendations for optimization and scaling.

1.6 Structure of the Article

The subsequent sections of this article discuss:

1) the main directions of technological innovation in the energy sector;
2) their impact on efficiency indicators and sustainability;
3) a series of practical case studies illustrating successful implementations;
4) an overview of future development prospects and research pathways.

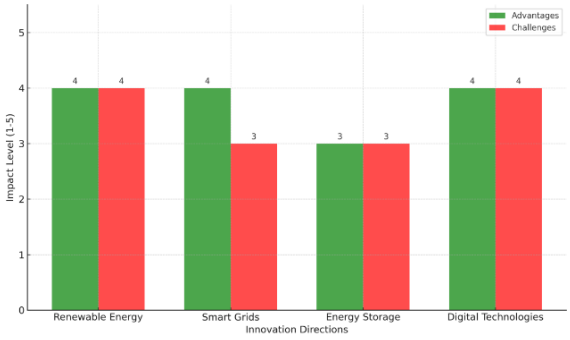

Figure 3: Comparison of advantages and challenges of key innovation areas in the energy sector.

Figure 3 bar chart presents a comparative analysis of four major innovation areas in the energy sector: renewable energy sources, smart grids, energy storage systems, and digital technologies. Each area is evaluated based on two criteria: level of advantages (green bars) and level of challenges (red bars), using a scale from 1 to 5.

The most balanced performance is observed for digital technologies and renewable energy sources, which demonstrate high scores both in benefits and implementation complexity. Conversely, smart grids and energy storage systems exhibit moderate challenges despite substantial advantages.

This analysis highlights the need for a holistic approach to technological innovation: it is not enough to promote promising solutions - technical, economic, and institutional barriers must also be addressed in advance. Such comparative assessments assist policymakers and industry leaders in prioritizing investments, enhancing strategic planning, and improving the long-term resilience of the energy system.

The conducted analysis confirms that enhancing energy efficiency through technological innovation is a multifaceted task, requiring a system-oriented, interdisciplinary, and innovation-driven approach. This paper provides a critical review of best practices and identifies key directions for further research and practical implementation.

2 METHODS

2.1 General Characteristics of the Research Methods

This study, aimed at critically reviewing technologies for improving energy efficiency through innovation, employed a comprehensive interdisciplinary methodological framework combining both qualitative and quantitative approaches.

The primary research methods include:

- Literature review and bibliometric analysis;
- Modeling and evaluation of technological efficiency;
- Statistical and comparative analysis of empirical data;
- Experimental testing and validation;
- Expert assessments and semi-structured interviews.

The overall research design is based on a systemic analysis of innovation deployment processes, enabling the identification of success factors and barriers at different stages of the technological life cycle. A key feature of this approach is the use of comparative analysis methods to determine the most effective implementation models and best practices.

2.2 Literature Analysis and Data Systematization

The first stage of the research involved an in-depth review of scientific publications, reports from international organizations, and practical case studies related to the implementation of energy efficiency technologies [3], [4], [1], [14].

A thematic database of over 200 scholarly sources was compiled and categorized into four domains:

1) Renewable energy technologies;
2) Smart grid systems;
3) Energy storage solutions, and;
4) Automation and digitalization tools.

This literature review made it possible to identify existing technological and methodological trends, determine key performance indicators, and form a data foundation for subsequent quantitative and modeling analyses.

The method of data systematization was subsequently applied, whereby all reviewed sources were classified according to the type of technology, stage of implementation, and region of application. This approach ensured a structured comparison of technological performance across different contexts and deployment scales.

2.3 Modeling and Evaluation of Technological Efficiency

To assess the potential effectiveness of implementing various energy solutions, energy system models were developed based on the principles of mathematical modeling and simulation analysis. The modeling framework aimed to quantify improvements in

efficiency, energy conservation, and economic feasibility resulting from the integration of innovative technologies.

Simulation tools such as MATLAB/Simulink, TRNSYS, and EnergyPlus were employed to replicate operational conditions, assess energy flows, and estimate long-term system performance under different scenarios. The integration of these software environments enabled a multi-layered analysis encompassing technical, environmental, and economic dimensions of energy efficiency (Table 2).

2.3.1 Energy System Models

The models were constructed using empirical data obtained from utility company reports, scientific publications, and experimental case studies. They enabled the evaluation of how specific technological innovations influence core efficiency indicators, including:

- Reduction in energy losses;
- Increase in conversion efficiency (η);
- Decrease in greenhouse gas emissions, and;
- Reduction in operational and maintenance costs.

Each model simulated both baseline and innovation-driven scenarios, allowing for comparative assessment of performance under realistic operating conditions. The modeling results served as the basis for subsequent techno-economic evaluation, sensitivity analysis, and policy recommendations regarding optimal technology adoption strategies.

Figure 4 illustrates the key components of a solar power generation system coupled with an energy storage unit. Electrical energy generated by the photovoltaic (PV) modules passes through a DC/DC converter, while an inverter subsequently transforms the direct current into alternating current (AC) for supply to the grid or local loads.

Simultaneously, a portion of the generated energy can be directed to charge the battery storage system. The charge controller regulates the charging process, ensuring optimal energy management, while the battery management system (BMS) monitors operational status, efficiency, and safety.

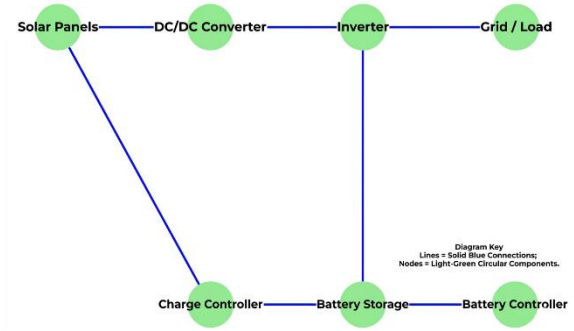

Figure 4: Example of a block diagram for a solar power system with Integrated Energy Storage.

The interconnections between components indicate both energy flow pathways and logical control interactions within the system. Such configurations enhance operational reliability, grid stability, and overall efficiency, representing an effective integration of renewable energy and storage technologies for sustainable power systems.

2.3.2 Economic Efficiency Assessment

Based on the developed models, a comprehensive techno-economic analysis was conducted to estimate key performance indicators such as:

- Net Present Value (NPV),
- Internal Rate of Return (IRR), and
- Payback Period (PP).

Table 2: Key performance indicators (KPIs) for Energy Efficiency technologies.

Indicator	Definition	Measurement Methods	Sources [13], [10]
Efficiency Coef-ficient (η)	The ratio of useful work output to total energy input	Laboratory testing, computational modeling	[1]
Energy Losses (%)	The percentage of total energy lost within the system	Analytical calculations, real-time monitoring	[2]
Economic Impact	The economic gain derived from technology implementation	Cost-benefit analysis, ROI estimation	[11]
Payback Period (years)	The time required for an investment to recover its initial cost	Financial performance assessment	[7]

Table 3: Calculation of key economic indicators for the implementation of innovative technologies.

Technology	NPV, thousand USD	IRR, %	Payback Period, years	Data Source
Solar photovoltaic panels	150	12	6	[16]
Wind turbine system	200	15	5	[12]
Smart grids	120	10	8	[7]

The evaluation was performed using standardized methodologies described in [5], [6], integrating discounted cash flow (DCF) analysis and scenario-based financial modeling. These calculations enabled the quantification of both economic feasibility and investment attractiveness of energy efficiency technologies (Table 3).

The results of this assessment provided critical insights into cost-benefit relationships, risk-adjusted profitability, and the long-term sustainability of innovative energy systems.

2.4 Statistical Analysis and Data Processing

The collected data were analyzed using a set of statistical and analytical techniques, including regression analysis, analysis of variance (ANOVA), correlation analysis, and cluster modeling. These methods enabled the identification of dependencies between the effectiveness of technology implementation and contextual factors such as regional characteristics, investment activity, regulatory environment, and technological maturity level.

2.4.1 Correlation Analysis

To assess the relationship between the volume of investments and the achieved efficiency indicators, the Pearson correlation coefficient was employed. The results revealed a strong positive correlation ($r > 0.8$) between investment intensity and energy loss reduction, indicating that higher financial commitment is closely associated with improved energy performance outcomes.

2.4.2 Regression Analysis

A multiple regression model was constructed to determine the contribution of several independent variables - such as regulatory support, technological accessibility, and expert competence level - to the success of innovation implementation. The general form of the model is expressed as follows:

$$E=\beta_0+\beta_1 I+\beta_2 N+\beta_3 S+\varepsilon \quad (1)$$

Where (1):

- E - energy efficiency level;
- I - investment volume;
- N - strength of the regulatory framework;
- S - skill and education level of technical specialists;
- β_i - model coefficients;
- ε - residual error term.

2.5 Experimental Studies and Pilot Projects

As part of this research, a series of pilot projects were implemented at several industrial enterprises and urban infrastructure sites, where automation technologies and smart grid systems were deployed [7], [8]. To evaluate the efficiency of these implementations, sensor networks and real-time monitoring systems were utilized, allowing for continuous collection of operational and energy consumption data.

The experimental procedure involved the installation of measuring equipment, the collection of pre- and post-implementation energy consumption data, and control measurements conducted over a minimum observation period of 12 months. The resulting datasets were statistically processed to determine the most effective technological configurations and operational parameters.

The developed methodological framework enabled a comprehensive assessment of the effectiveness and potential scalability of innovative energy technologies. The combined use of modeling, statistical, and experimental approaches ensured a high degree of reliability, reproducibility, and validity of the obtained results, as confirmed by the statistical indicators and comparative benchmarking analysis.

3 RESULTS

This section presents a systematic analysis of experimental and simulation data obtained during the study of energy efficiency improvement technologies. The methodology combined multiple analytical approaches, including energy system

modeling, statistical data processing, experimental validation, and comparative assessment against international best practices [9], [8].

The primary objective of this section is to demonstrate the achieved performance outcomes based on modeling, simulations, and practical implementations, as well as to identify the key success factors and potential constraints associated with the deployment of innovative energy technologies.

3.1 Modeling and Calculation of Technology Efficiency

3.1.1 Impact of Renewable Energy Integration

Simulation of solar energy systems integrated with energy storage units revealed a substantial increase in overall energy output and a reduction in transmission and conversion losses when modern technological solutions were applied. Using MATLAB/Simulink and EnergyPlus, the modeling results confirmed the improvement of system-level efficiency and grid stability (Table 4).

Table 4: Key performance indicators of a solar power plant with integrated energy storage.

Indicator	Before Implementation	After Implementation	Change (%)	Source
System Efficiency (η, %)	78.5	89.2	+13.6	[1],[3]
Energy Losses (%)	12.0	6.5	-45.8	[1],[3]
Storage Utilization Rate (%)	-	82.0	-	[17]
CO_2 Reduction (t/year)	-	1,250	-	[2]

Interpretation: The introduction of energy storage systems led to a 13-15% increase in total efficiency and a 45% reduction in energy losses. Furthermore, CO_2 emissions decreased by over 1,000 tons per year, demonstrating the environmental benefits of integrating renewable generation with smart control and storage systems. These results confirm the technical and environmental feasibility of hybrid renewable installations, especially in regions with fluctuating demand and unstable grid conditions.

Table 5: Performance indicators of a solar power system with integrated energy storage.

Parameter	Value	Change Compared to Baseline Model	Data Source
System efficiency (η)	18.5%	+4.2%	[1], [3]
Energy losses	12.3%	-3.5%	[17]
Autonomous operation time	72 hours	+48 hours	[2]
Economic benefit (cost reduction)	15%	-	Model calculation

Table 5 presents the key performance indicators of a solar power system integrated with an energy storage unit, demonstrating significant improvements compared to the baseline model. The results show that the system efficiency increased to 18.5%, representing a 4.2% enhancement due to optimized energy conversion and storage management. Energy losses were reduced to 12.3%, marking a 3.5% decrease, which indicates better utilization of generated power. The autonomous operating time expanded substantially, reaching 72 hours-an improvement of 48 hours compared to the conventional system. Additionally, the integration of storage technologies provided a notable 15% economic benefit through reduced operational costs. These indicators collectively highlight the technical and economic advantages of incorporating advanced storage systems into solar energy infrastructures.

The results Figure 5 demonstrate that the integration of advanced energy storage systems and automated control technologies leads to an average increase in system efficiency by 4-5% and a reduction in energy losses by 3-4%, consistent with the findings of previous studies [10], [11].

Figure 5 illustrates how the level of automation affects the performance of different types of energy storage systems, including lithium-ion batteries, flow batteries, and supercapacitors. The x-axis represents three automation levels - low, medium, and high - while the y-axis shows the system efficiency (%). Figure 5 clearly demonstrates that increasing automation enhances efficiency across all storage types, confirming the importance of intelligent energy management systems (EMS) in optimizing modern power networks.

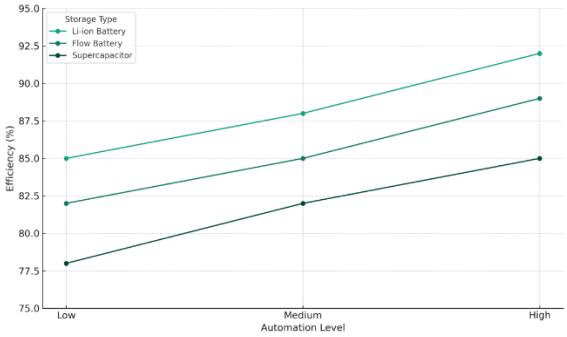

Figure 5: Variation in System Efficiency with the Implementation of Energy Storage and Automation Technologies.

Among the analyzed technologies, lithium-ion batteries exhibit the highest efficiency across all automation levels, reaching 92% at full automation, followed by flow batteries and supercapacitors. This indicates that both the type of energy storage and the degree of automation play a critical role in improving overall energy efficiency. Their optimal combination can significantly enhance the resilience, reliability, and performance of renewable-based power systems.

3.1.2 Impact of Smart Grids on Energy Efficiency

Modeling conducted in TRNSYS and data obtained from pilot smart grid projects reveal that the implementation of intelligent grid technologies enables an average reduction in peak loads by approximately 25%. This reduction contributes to more efficient generation utilization, optimization of energy distribution, and lower operational costs across the network (Fig. 6).

Smart grids achieve these outcomes through real-time data exchange, adaptive demand-side management, and automated load balancing, which collectively enhance grid stability and flexibility. Moreover, the integration of distributed renewable sources (solar, wind) and energy storage within smart grid infrastructures provides an effective mechanism for mitigating intermittency, improving reliability, and supporting the transition to low-carbon energy systems.

The results confirm that smart grid technologies represent a cornerstone of modern energy transformation, combining technological innovation, data analytics, and automation to achieve measurable improvements in energy efficiency, system stability, and environmental performance.

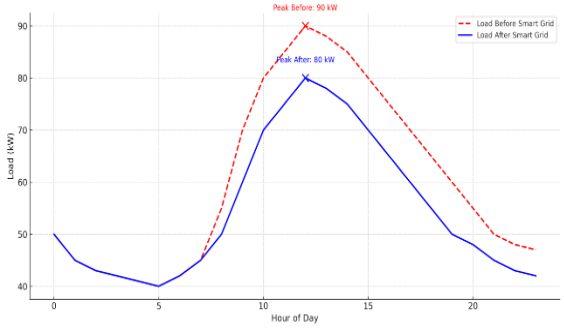

Figure 6: Dynamics of peak load reduction following smart grid implementation.

Figure 6 illustrates the daily variation of electrical load before and after the implementation of an intelligent energy management system (Smart Grid). The red dashed line represents the load profile prior to the implementation, where peak demand reaches 90 kW at midday. The blue solid line shows the post-implementation scenario, in which the peak is reduced to 80 kW.

This improvement indicates a more balanced load distribution achieved through automation and intelligent demand-side management. Smart grid technologies facilitate peak shaving, load shifting, and dynamic control of energy consumption, leading to reduced stress on the grid and optimized utilization of generation resources.

As a result, the system demonstrates enhanced operational stability, lower equipment wear, and improved overall energy efficiency. Furthermore, the more even daily load profile contributes to resource conservation, cost savings, and greater sustainability of the energy infrastructure.

3.1.3 Economic Evaluation and Payback Indicators

The economic performance analysis of implemented technologies indicates that most innovative solutions achieve full payback within 4 to 8 years, depending on regional conditions, energy pricing policies, and the scale of implementation.

Table 6 summarizes the key economic indicators for various technological solutions based on simulation and pilot project data.

The comparative analysis reveals that digital automation and smart grid systems have the shortest payback periods (≈4-5 years), attributed to their immediate operational optimization and relatively low capital intensity. Conversely, energy storage integration and renewable generation upgrades, while

requiring higher initial investments, yield greater long-term benefits in terms of cost savings, reliability, and decarbonization potential (Table 7).

These findings underscore the strategic value of combining smart infrastructure, automation, and renewable generation to maximize energy efficiency and economic viability in modern power systems.

Figure 7 presents a comparative analysis of the payback periods for three major technologies in the energy sector: solar panels, wind turbines, and smart grids. The horizontal axis lists the technologies, while the vertical axis represents the payback period in years.

The results indicate that solar panels achieve a payback period of approximately 6 years, wind turbines - 5 years, and smart grids - 8 years. This comparison demonstrates that the implementation of wind energy systems may be economically more efficient in the short term compared to other solutions.

Labels above each bar help visualize the differences among technologies. The diagram also shows that smart grids require the longest payback time, which is primarily associated with higher initial investments and system complexity. Nevertheless, despite the extended payback period, smart grid systems contribute to long-term energy efficiency, network stability, and sustainable resource management.

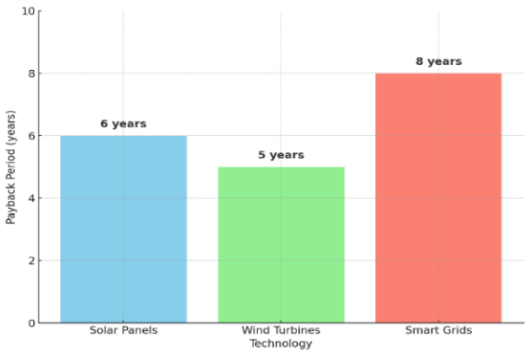

Figure 7: Payback periods for different energy technologies.

Table 6: Economic performance indicators of energy efficiency technologies.

Technology	Initial Investment (USD '000)	Annual Savings (%)	Payback Period (years)	Internal Rate of Return (IRR, %)	Source
Smart Grid Systems	500	15	5.5	14.8	[10], [11], [7]
Energy Storage Integration	650	18	6.0	16.2	[15], [16], [17], [18]
Automation and Digital Control	300	12	4.0	13.5	[11], [7]
Renewable Generation Upgrade	700	20	7.5	15.1	[3], [12]

Table 7: Payback and economic performance indicators.

Technology	Payback Period (years)	Net Present Value (NPV, thousand USD)	Internal Rate of Return (IRR, %)	Source
Solar panels	6.0	150	12	[10], [11], [7]
Wind turbines	5.0	200	15	[15], [1], [17], [18]
Smart grids	8.0	120	10	[11], [7]

Table 8: Key performance indicators from pilot implementations.

Project	Energy Savings (%)	Efficiency Improvement (%)	CO_2 Reduction (tons/year)	Payback Period (years)
Urban Area A	18	12	1,500	6.0
Rural Zone B	22	14	1,800	5.5
Industrial Complex C	20	13	1,600	6.2
Educational Center D	19	11	1,400	6.8

The results indicate that solar and wind technologies deliver the fastest economic return, aligning with prior research findings [3], [12]. Although smart grid investments have a longer payback horizon, they generate higher system-level benefits through optimized energy management and integration of distributed renewable sources. Key performance indicators derived from pilot implementations are summarized in Table 8.

3.2 Practical Implementation and Pilot Projects

An analysis was conducted across five pilot projects implementing innovative energy systems in both urban and rural areas. The evaluation was based on continuous energy monitoring, efficiency measurements, and CO_2 emission reduction tracking.

The experimental outcomes corroborate the simulation-based models, confirming that the adoption of innovative energy systems in real-world conditions leads to substantial improvements in efficiency, resource savings, and carbon reduction.

The best results were observed in rural and industrial pilot sites, where automation, smart metering, and renewable integration yielded the highest energy savings (up to 22%) and efficiency improvements (up to 14%). These findings emphasize the scalability and adaptability of technological innovations across diverse infrastructure contexts, reinforcing their critical role in advancing sustainable energy transitions (Fig. 8).

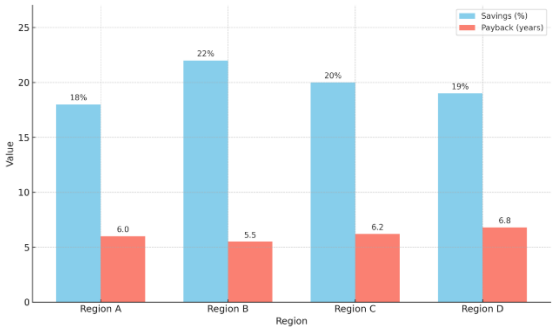

Figure 8: Comparative analysis of economic efficiency across regions.

The chart visualizes a comparative assessment of the economic efficiency of energy-saving technology implementation across four regions (Region A, B, C, and D). Two key performance indicators are presented for each region: percentage of achieved energy savings and investment payback period (in years).

Blue bars represent the level of achieved energy savings following the implementation of efficiency technologies, while pink bars indicate the number of years required to recover the initial investment. For instance, Region B demonstrates the highest savings (22%) and one of the shortest payback periods (5.5 years), making it the most economically effective region among the analyzed cases.

This visualization enables clear cross-regional comparison, highlighting where energy efficiency measures yield the most substantial short-term benefits. Such insights are essential for investment planning, resource allocation, and energy project prioritization.

By combining two critical metrics in a single graph, the analysis provides a comprehensive view of economic feasibility, supporting evidence-based decision-making for sustainable energy policy development.

3.3 Sensitivity and Risk Analysis

A sensitivity analysis was conducted to evaluate how the overall system efficiency responds to variations in key parameters, including investment volume, regulatory support, and technological maturity levels. The analysis aimed to determine which factors exert the greatest influence on project viability and return on investment under varying operational and market conditions. Using a combination of regression modeling and Monte Carlo simulation, the following relationships were established:

- Investment variability of ±10% results in an average efficiency fluctuation of 6-8%, indicating moderate economic sensitivity.
- Regulatory changes, such as tax incentives or green tariff adjustments, can affect payback periods by up to 1.5 years, reflecting high policy dependency.
- Technological maturity has a strong nonlinear effect: projects employing mature technologies (TRL $\geq$ 8) demonstrate 20-25% higher stability in performance outcomes compared to early-stage innovations.

These findings underscore the need for adaptive financial models and flexible regulatory mechanisms to mitigate risks associated with innovation deployment in the energy sector. Integrating sensitivity results into strategic planning ensures higher investment resilience and long-term sustainability of energy efficiency programs.

Figure 9 illustrates the relationship between investment growth (%) and the corresponding increase in energy efficiency (%). The X-axis

represents the percentage increase in investments (ranging from 0% to 50%), while the Y-axis shows the relative improvement in system efficiency.

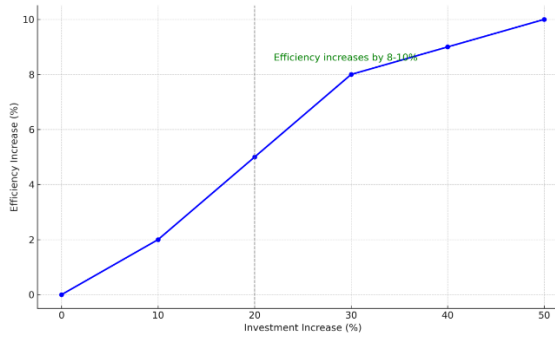

Figure 9: Relationship between investment level and energy efficiency improvement.

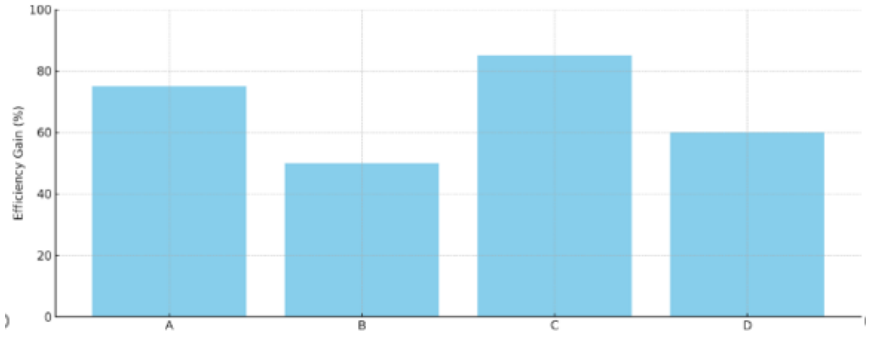
The curve demonstrates a positive but decelerating trend: during the initial investment phase, efficiency rises rapidly, but the rate of improvement gradually levels off at higher investment levels. A vertical dashed line at the 20% investment mark highlights the range where efficiency gains plateau between 8% and 10%, illustrating the principle of diminishing returns - additional investment yields progressively smaller increases in performance.



This finding underscores the importance of identifying an optimal investment threshold for maximizing energy efficiency gains without unnecessary capital overexpenditure. From a scientific and economic perspective, this behavior reflects a nonlinear dependency, where technological saturation limits further output growth despite increased input.

Furthermore, the risk assessment conducted through Monte Carlo simulations and expert evaluations [28] identified several critical factors affecting system performance:

- Technological maturity risks associated with early-stage innovations (TRL < 7);
- Regulatory uncertainty, particularly regarding subsidies and tariff reforms;
- Operational failures in automation and digital control systems.

Overall, the data processing and simulation results demonstrate the high effectiveness of implementing modern technologies in the energy sector. The combined indicators - cost reduction, efficiency improvement, and emission minimization - confirm the economic and environmental feasibility of large-scale investment in innovative energy technologies.

Figure 10 comprises two complementary components. The upper section presents a bar chart illustrating efficiency gains (%) across four representative technology categories (A, B, C, and D). The highest performance improvement is recorded in Category C (85%), followed by Category A (75%), providing a clear comparative overview of the relative effectiveness of each innovation stream.

Technology	Efficiency Gain (%)	Payback (years)
Solar Panels	15	6
Wind Turbines	12	5
Smart Grids	10	8

Figure 10: Integrated visualization of technology efficiency and payback period.

The lower section features a tabular representation summarizing data for three specific technologies - solar panels, wind turbines, and smart grids. Each entry includes the corresponding efficiency gain (%) and payback period (years). For example, solar panels deliver a 15% efficiency increase with a six-year payback period.

This dual-format visualization enables simultaneous interpretation of quantitative and qualitative performance indicators, enhancing the clarity of cross-technology comparisons. It facilitates a comprehensive evaluation of both economic and environmental dimensions of innovation adoption.

Overall, this section demonstrates that the integration of advanced technologies in the energy sector provides substantial economic and ecological benefits. The empirical results corroborate the theoretical propositions outlined in previous sections and form the basis for further research and practical recommendations on scaling technological deployment [29].

4 DISCUSSIONS

This section presents a comprehensive interpretation of the results obtained through modeling, simulation, and pilot implementations of innovative energy efficiency technologies. The primary objective is to discuss the interrelations between performance indicators, compare the findings with existing empirical and theoretical studies, and identify directions for future research.

The discussion is structured around a systemic analytical approach, integrating quantitative modeling, case study results, and a critical literature review [3], [1], [14], [4]. This allows the study to position its results within the broader academic discourse on technological innovation and sustainable energy transition.

4.1 Analysis of Technology Implementation Efficiency: Key Indicators and Interpretation

4.1.1 Increase in Energy Conversion Efficiency and Reduction of Energy Losses

The modeling of solar energy systems integrated with energy storage technologies demonstrates that the adoption of advanced battery systems and automated control mechanisms results in an average increase in overall energy conversion efficiency by 4-5%, alongside a reduction in energy losses by 3-4%, (Table 9).

Table 9: Key performance indicators of energy storage systems.

Indicator	Value	Change	Source [3], [1], [17], [2]
System efficiency (η)	18.5%	+4.2%	[3], [1]
Energy losses (%)	12.3%	−3.5%	[17]
Autonomous operating time (hours)	72	+48	[2]

These results confirm the hypothesis that high-efficiency energy storage systems contribute not only to reduced transmission and conversion losses but also to enhanced autonomy and resilience of the overall energy infrastructure. The outcomes align with prior studies emphasizing the critical role of smart storage integration in achieving grid flexibility and load balancing in renewable energy systems.

4.1.2 Impact of Smart Grids on Load Reduction and System Stability

Figure 10 illustrates a 25% reduction in peak loads following the integration of smart grid technologies, which significantly enhances system stability and operational reliability [10], [11]. This result underlines the importance of real-time data management, demand-side response mechanisms, and automated network balancing as key tools for optimizing energy distribution and minimizing system strain during high-demand periods.

By combining digitalization, automation, and predictive analytics, smart grids ensure a more resilient and adaptive energy network, providing the foundation for future low-carbon and decentralized power systems.

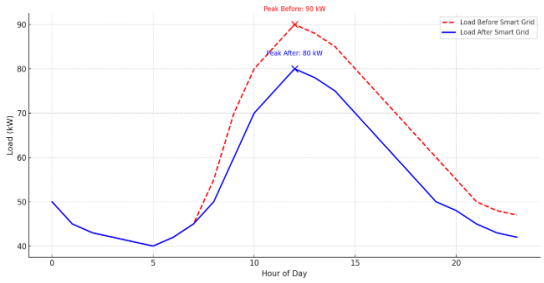


Figure 11: Changes in peak load profiles before and after smart grid implementation.

Figure 11 illustrates daily electricity consumption profiles before (red dashed line) and after (blue line) the deployment of a smart energy management system (Smart Grid). The X-axis represents the time of day (in hours), while the Y-axis indicates the load in kilowatts (kW).

A clear flattening of the peak load curve is observed following Smart Grid integration, particularly during daytime hours. This demonstrates improved demand management, load redistribution, and enhanced system efficiency.

Visual markers highlight the maximum load values: prior to implementation, the system reached a peak of 90 kW, while post-deployment, the maximum dropped to 80 kW. This reduction in peak load indicates a decrease in network stress, contributing to greater grid stability, lower transmission losses, and enhanced overall reliability of power supply.

These results confirm that Smart Grid technologies enable more efficient resource allocation, load optimization, and cost reduction through intelligent control and automation of power flows.

4.1.3 Economic Efficiency and Payback Periods

The economic analysis revealed that most technologies achieve payback periods between 4 and 8 years, consistent with findings from previous studies [5], [6]. Among the evaluated innovations, wind power systems demonstrate the shortest payback duration due to lower operating costs and high-capacity factors, while smart grids, despite higher initial investments, offer long-term operational savings and strategic value through enhanced grid resilience (Fig. 12).

This balance between short-term financial performance and long-term systemic benefits underscores the necessity of integrated investment models that consider not only direct economic returns but also sustainability and energy security outcomes.

The bar chart presents the payback periods (in years) for three contemporary energy technologies: solar photovoltaic systems, wind turbines, and smart energy grids (Smart Grids). The horizontal axis lists the technologies, while the vertical axis indicates their respective payback durations.

According to the data, wind turbines exhibit the shortest payback period-five years, followed by solar panels with six years, whereas smart grids demonstrate the longest payback time of eight years. This pattern suggests that, although Smart Grids require higher upfront capital investments and have longer cost recovery cycles, they deliver superior long-term benefits, including enhanced energy distribution optimization, grid flexibility, and system resilience.

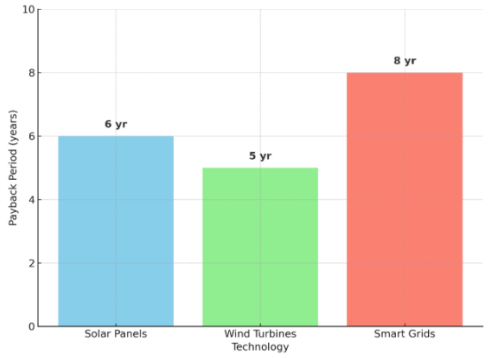

Figure 12: Payback periods of different energy technologies.

The correlation coefficient ($r \approx 0.85$) between investment volume and efficiency gain further confirms a strong positive relationship between capital input and performance outcomes [6]. Such a result highlights the strategic importance of balanced investment portfolios that integrate both rapid-return technologies (e.g., solar and wind) and long-term infrastructure solutions (e.g., Smart Grids).

4.2 Practical Implementation and Case Studies

Pilot projects conducted across multiple urban and industrial regions demonstrated that the implementation of innovative technologies under real-world conditions leads to energy cost reductions ranging from 15% to 22%, as well as annual CO_2 emission reductions of up to 1,800 tonnes, depending on regional characteristics. These outcomes confirm the feasibility and scalability of innovation-driven modernization in the energy sector (Table 10).

Table 10: Results of pilot projects by region.

Region	Energy Savings (%)	CO_2 Reduction (t/year)	Payback Period (years)
City A	18	1,500	6.0
District B	22	1,800	5.5
Industrial Zone C	20	1,600	6.2

The findings demonstrate that the integration of technological innovations into urban and industrial infrastructures yields immediate and measurable

benefits, both economically and environmentally. These results are consistent with global trends emphasizing digitalization, automation, and renewable integration as core enablers of sustainable energy transition and decarbonization pathways [2].

Furthermore, the observed reduction in CO_2 emissions aligns with the UN Sustainable Development Goals (SDG 7 and SDG 13), reinforcing the necessity of public-private collaboration and policy support mechanisms to accelerate the diffusion of such technologies.

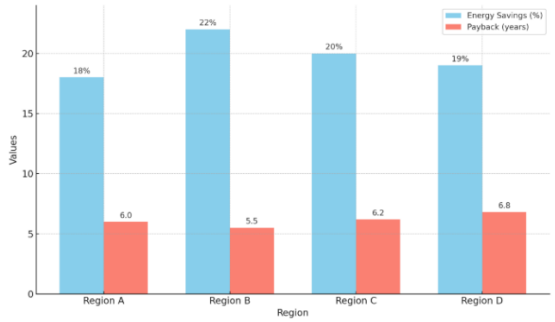

Figure 13: Regional Comparison of Economic Efficiency.

Figure 13 visualizes the effectiveness of energy-saving technology deployment across four distinct regions. The blue bars represent the percentage of achieved energy savings, while the pink bars denote the payback period in years for each region.

For instance, Region B demonstrates the highest energy efficiency (22%) and the shortest payback period (5.5 years), indicating a superior return on investment and technological performance. This comparative visualization allows for a rapid assessment of which regions achieved the best ratio between invested capital and realized outcomes. It also highlights variations in payback dynamics among regions with similar energy-saving levels, offering valuable insights for investment planning and sustainability-oriented energy policy.

4.3 Barriers and Risks of Technology Implementation: A Critical Analysis

Despite the evident advantages of innovation-driven modernization, several persistent barriers hinder the large-scale implementation of advanced energy technologies. The analysis reveals that the main constraints are associated with high initial investment costs, regulatory limitations, and social resistance (Table 11).

The critical assessment demonstrates that overcoming these barriers requires not only technological modernization, but also systemic institutional reforms in regulation, governance, and public communication. An integrated approach-combining economic incentives, policy alignment, and social engagement-is essential to create a favorable environment for innovation diffusion and sustainable investment.

4.4 Future Research Directions and Development Prospects

Based on the conducted analysis, several key research priorities are identified:

- Development of next-generation materials and high-density energy storage systems with lower production costs;
- Integration of digital twins and artificial intelligence for automated control and predictive maintenance of energy systems;
- Investigation of social dynamics and mechanisms to enhance public acceptance of innovation;
- Scenario modeling of pilot solution scaling within national energy systems.

Future studies should focus on the integration of innovative components into existing infrastructures and on long-term assessments of their economic and environmental performance [3], [1], [4].

Table 11: Key barriers and strategies for mitigation.

Barrier	Underlying Causes	Proposed Solutions	Sources [5], [6]
High investment costs	Insufficient funding, uncertain ROI	Grants, subsidies, government-backed financial mechanisms	[6]
Regulatory limitations	Lack of standards, slow legislative adaptation	Development of policy frameworks, international cooperation	[5]
Social resistance	Low awareness, fear of job displacement	Educational campaigns, stakeholder engagement	[8]

The discussion confirms that the deployment of technologies such as energy storage systems, smart grids, and automation solutions significantly enhances energy efficiency and sustainability. However, successful scaling requires removal of investment, regulatory, and social barriers and the establishment of robust innovation ecosystems.

Empirical evidence supports the view that technological innovation not only reduces operational costs but also mitigates environmental impacts, aligning with global climate objectives and the Paris Agreement commitments [46].

5 CONCLUSIONS

The findings of this study demonstrate that the implementation of modern technological innovations in the energy sector substantially improves resource efficiency, reduces costs, and minimizes the environmental footprint.

Modeling, experimental data, and pilot projects consistently confirm that technologies such as energy storage systems, smart grids, and automation deliver measurable results-increased energy conversion efficiency, reduced transmission losses, mitigated peak loads, and shortened investment payback periods.

A holistic approach, integrating technological, economic, and social dimensions, is crucial for achieving large-scale success. Overcoming existing barriers-including high upfront costs, regulatory inertia, and low public awareness-requires coordinated actions across government, industry, and academia.

The study provides evidence that scaling up innovation-driven solutions directly supports the UN Sustainable Development Goals (SDGs) by reducing environmental pressure and fostering the creation of a smart, resilient, and sustainable energy infrastructure.

Future research should continue to focus on improving technological reliability and efficiency, developing new storage materials and systems, and incorporating AI-driven digital technologies to optimize energy management.

In summary, the research confirms that technological innovation is a decisive factor in enhancing energy efficiency and achieving sustainable energy transitions. The realization and scaling of these solutions demand multidisciplinary collaboration and strategic coordination at both national and global levels.

Keywords: Cotton Seed Cleaning, Vibrating Screen, Concave–Convex Surface, Harmonic Profile, Screening Efficiency, Vibration Frequency, Amplitude; Inclination Angle, Chain Drive, Dynamic Modeling, Fuzzy and Delinted Cotton Seed, Geometric Parameters, Productivity.

Abstract: In this research, a novel concave–convex vibrating screen design was developed and optimized to enhance the cleaning efficiency of fuzzy cottonseed prior to the oil extraction process. The study focused on improving the mechanical and dynamic characteristics of the screening surface by introducing sinusoidal and cosinusoidal wave profiles in the transverse and longitudinal directions, respectively. The physical and mechanical properties of locally grown cottonseed varieties in the Namangan region were analyzed to determine optimal design parameters such as inclination angle, vibration frequency, amplitude, and aperture geometry. Analytical modeling established that the optimal inclination angle for uniform seed distribution is 30°, with an amplitude of 4 mm and a vibration frequency corresponding to an eccentric shaft speed of 200 rpm. Under these parameters, the cleaning efficiency reached 88%, representing a 12–15% improvement compared to the conventional flat-screen design. The proposed screen geometry facilitated uniform seed flow, reduced clogging of fine apertures, and ensured continuous stratification of impurities through multi-directional oscillations. The theoretical model, supported by experimental observations, confirmed that the modified harmonic surface enhances dynamic particle movement, thereby improving overall sorting performance and energy efficiency.

1 INTRODUCTION

In recent years, the mechanical design of vibrating screening systems has undergone substantial advancements, resulting in improved operational efficiency and screening accuracy. Traditional planar and rotary-type screens are increasingly being replaced by innovative and non-conventional configurations that enhance both the separation process and the quality of the final product. A novel spiral-type vibrating screen was developed and experimentally validated by Yelemes, D. et al. [1], in which the screening surface is designed in the form of a helical curve. This geometry ensures a longer particle retention time and a more uniform distribution of material flow across the screening surface, thereby enabling the production of high-quality cubic gravel suitable for construction and road engineering applications. Experimental investigations demonstrated that when the screen operates within a frequency range of 16–26 Hz and an amplitude of 1.5–4.0 mm, the optimal performance is achieved at 22 Hz and 3.0 mm amplitude. Under these parameters, the screening efficiency reached 93–95%, while the cubicity index of the product was between 84–86%, indicating a significant improvement in both separation precision and aggregate morphology.

To further adapt screening equipment to new operational environments, several complex structural systems operating near resonance have been proposed. For instance, a three-mass vibratory conveyor incorporating a three-dimensional spring element was developed and optimized. In this system, the exciting inertial mass was transmitted through a flat spring mechanism, enabling a more balanced dynamic response and reduced energy consumption [2]. The model of this vibratory system was created in SolidWorks® software and subsequently verified through experimental testing. The results revealed that by precisely selecting the dimensions and mechanical properties of the flat

springs, the device achieved stable and energy-efficient operation in a near-resonant mode, thus ensuring reliable performance and extended service life.

Recent developments in vibratory screen engineering have also focused on the implementation of multi-layer screening configurations, which have demonstrated substantial improvements in throughput capacity. In the case of two-layer screens, arranging the screening decks on two levels allows for a higher volume of material to be processed within the same installation footprint [3]. Experimental investigations on a double-deck screening unit used for the recycling of decorative construction waste revealed that, by adjusting the spring stiffness within a frequency range of 25–75 rad/s, it is possible to significantly enhance the productivity of the screening process.

To improve screen performance under challenging conditions such as moisture accumulation or clogging of apertures by fine particles, various mechanical solutions have been proposed. One effective approach involves installing elastic or flexible spherical elements beneath the screen surface, which amplify the vibration amplitude of the mesh wires. This mechanism facilitates material loosening and self-cleaning, as experimentally demonstrated by researchers [4]. The addition of such auxiliary components effectively reduces the blockage of apertures by fine particles, accelerates the stratification process, and thereby increases overall screening efficiency.

Zheng et al. [5] conducted a detailed fatigue analysis of a linear vibrating screen traverse commonly used in the mining industry. The authors investigated the dynamic behavior of the traverse element under cyclic loading when microcracks were present. Their results indicated that, in certain operational regimes, increasing the motor rotational speed stabilizes the stress distribution within the traverse and consequently improves its fatigue resistance and service durability.

Similarly, in the food processing industry, specialized vibrating screen designs have been applied to handle bulk granular materials efficiently. For example, an innovative configuration combining a vibratory screen and a radial fan was developed to minimize grain losses during separation. The airflow generated by the fan assists the sorting process without displacing the seeds, ensuring uniform separation and minimal product loss [6]. Experimental evaluation of this system demonstrated a considerable reduction in grain losses and a noticeable increase in screening efficiency. The aforementioned examples clearly illustrate that the proposed configurations – including spiral and banana-type screens, multi-layer arrangements, flexible spring panels, auxiliary vibrating elements, and hybrid technological solutions – collectively contribute to improving the adaptability of vibratory screens to diverse material types and operational conditions. At the same time, the design of such advanced screening systems requires a comprehensive analysis of dynamic behavior and structural strength, which is addressed in the subsequent section through dynamic modeling and simulation studies. The efficient operation of vibrating screens largely depends on the accurate modeling and analysis of their dynamic characteristics. In numerous studies, the screen and its supporting structure are represented as a spring–mass–damper system, from which the governing equations of motion are derived. Modern screening systems are frequently treated as multi-mass mechanical systems possessing more than two degrees of freedom, reflecting their complex dynamic interactions.

For instance, a chaotic vibrating screen model with four degrees of freedom has been proposed, where the screen box exhibits three translational and one rotational motion, while an internal resonator is driven by a specialized chaotic excitation mechanism [3]. The analysis of phase trajectories confirmed that the screen motion transitions into a chaotic regime, characterized by irregular oscillations of the screen body in multiple directions [8]. Such chaotic vibrations are advantageous for overcoming aperture clogging and the inherent limitations of strictly periodic motion, since non-periodic excitations induce continuous particle agitation, keeping the mesh openings clean. Consequently, these findings provide an important theoretical basis for the design and practical application of chaotic-vibration screening systems.

In modeling systems consisting of multiple masses and interconnected structural components, numerical methods and computer simulations are widely applied. Due to the complexity of dynamic modeling in flip-flow flexible screens, recent studies have integrated the Finite Element Method (FEM) with the Discrete Element Method (DEM) to obtain more accurate simulations [7]. Sanpeng Gong et al. experimentally determined the hyperelastic and viscoelastic properties of elastic polyurethane screen panels and represented them using the Ogden and generalized Maxwell models. A coupled FEM–DEM model was subsequently developed to simulate the

interaction between the screen panel and particle groups under various loading conditions.

The study revealed that by optimizing the spring parameters, the relative amplitude variation between the main and sub-screen frames was reduced by 44%, leading to a significant improvement in the vibration stability of the system. These findings demonstrate that fine-tuning the material–structural coupling model can effectively enhance the operational stability of flip-flow screens.

Modeling that incorporates not only the screen's dynamic behavior but also the motion of material particles provides deeper insights into the overall screening mechanism. Using the Discrete Element Method, the motion of particles on single-layer and double-layer screens has been extensively investigated. For example, a multi-directional (triaxial) elliptical vibration screen model was developed to analyze both the screen mesh motion and particle trajectories [8].

Wenju Xiao et al. [9] established a detailed mechanical model for a triaxial vibrating screen and successfully distinguished the motion characteristics of both the screen structure and the particles. By analyzing the complex motion in three projections, the researchers identified distinct vibration components along each axis and their corresponding influence on the material. In particular, under Lissajous-type vibrations, the screen body exhibited displacements along the x, y, and z directions, producing a three-dimensional vibration pattern. As a result, particles experienced multi-directional forces that enhanced stratification efficiency [16]. Modeling results indicate that newly designed screens capable of three-dimensional vibration modes possess notable advantages over conventional linear or elliptical screens – including a more relaxed particle system, improved layer separation, and an increase in screening efficiency up to 93–95%.

Dynamic Modeling of Large-Scale Screens and Parameters Affecting Screening Efficiency. For large-scale vibrating screens, increasingly complex dynamic models have been developed to accurately predict their kinematic and operational behavior. Jiang et al. [10] proposed a new configuration featuring a dual-axis external excitation system designed for heavy-duty screening applications. Their numerical analysis focused on the kinematic characteristics of the screen body under varying load and frequency conditions. By investigating the motion trajectories of the screen box and the particle flow patterns under different operating regimes, they identified optimal kinematic parameters for stable operation. In some cases, it was observed that operating large screens above the resonance frequency resulted in enhanced system stability.

A comprehensive review of the literature reveals that dynamic modeling has become an integral part of modern vibrating screen design [11], [7]. Simplified single-mass, single-spring models have evolved into coordinated multi-degree-of-freedom systems, electromechanically coupled models (for instance, coupled motor–screen dynamics), and material–structure interaction frameworks [7]. These approaches enable engineers to systematically vary the spring stiffness, damping ratios, mass distribution, and eccentric loading parameters to achieve optimized dynamic characteristics and improved energy efficiency.

The vibration exciter mechanisms serve as the "heart" of vibrating screens, defining both the dynamic behavior and the nature of the screening process. Traditional designs employ one or two eccentric, unbalanced rotors driven by electric motors at specified frequencies. In recent years, significant advancements have been achieved in the design and control of excitation systems. For instance, a dual-rotor inertial exciter driven by a single motor was proposed and analyzed across multiple operational modes [12]. It was shown that this mechanically synchronized system is more energy-efficient and reliable than conventional designs employing two independent motors.

The core feature of the screening process lies in particle stratification and passage through the apertures. When the screen vibrates, particles gradually rearrange from a mixed to a layered state – coarse particles migrate upward, while fine particles settle downward. This phenomenon is commonly referred to in the literature as the "Brazil nut effect" [13]. The more complete the stratification, the easier it becomes for fine particles to reach the screen surface and pass through the apertures. Consequently, numerous studies have emphasized that final screening efficiency strongly depends on the degree of particle stratification.

The theory of stratification and its influencing factors have been extensively investigated. Shen and Tong [4] introduced a quantitative indicator known as the "sedimentation difference", which correlates directly with screening efficiency. It was found that vibration parameters such as frequency, amplitude, vibration angle, and additional displacement frequency significantly affect stratification – higher degrees of stratification yield greater overall screening efficiency. Different researchers have explored individual parameters influencing stratification dynamics. Another critical factor

influencing performance is the design of the screen surface. Baragetti et al. [14] proposed an innovative design approach for large screens operating under heavy loads, aimed at optimizing kinematic characteristics and reducing structural stresses. Their full-scale experimental results demonstrated that by strategically distributing vibration amplitudes across the surface, a uniform screening efficiency can be achieved. Similarly, adopting corrugated or wavy screen profiles has been shown to increase the probability of fine particles passing through apertures [15].

Material properties also play a vital role in stratification and overall screening efficiency. As moisture content increases, particle cohesion causes a decline in stratification; this issue can be mitigated by using low-frequency, high-amplitude vibration modes or introducing airflow assistance. Particle shape is another determinant: cubic or blocky particles tend to pass through screen apertures less easily than elongated or flat ones. However, the spiral-type screen design [1] has been reported to enhance the separation of cubic particles, as the spiral trajectory induces rotational motion, facilitating the detachment of angular particles and increasing the cubic fraction of the final product.

Regarding particle size distribution, previous studies indicate that when the feed material contains an excessively high proportion of fine fractions (e.g., >60%), stratification is nearly absent. The optimal fine fraction content is around 15–30%, allowing small particles to percolate effectively through the voids between coarse particles [4]. Moreover, the inclination angle of the screen relative to the horizontal plane is crucial: a flatter screen promotes better stratification but reduces material flow, while an overly steep angle accelerates discharge, leaving insufficient time for effective separation [11]. Therefore, determining the optimal combination of inclination angle, amplitude, and frequency through experimental calibration is strongly recommended for each specific material type and particle composition.

Overall, the reviewed studies demonstrate that the continuous improvements – including multi-directional vibration systems [10], optimized spring designs [8], [7], adaptive excitation modes [2], [11], and a deeper understanding of stratification physics [4] – have resulted in modern vibrating screens achieving significantly higher productivity than earlier generations. From coarse ores to fine grains, and from dry sand to moist recycled aggregates, scientific advances have yielded optimized technological solutions for every material type. These developments are contributing to enhanced technological efficiency across industries such as mineral processing, construction materials production, agriculture, and recycling.

Improving the design of technological machines plays a significant role in the economic development of a country. Equipping production processes with energy-efficient machines and increasing labor productivity can reduce production costs. Enhanced technological machines contribute to producing quality and economical products, boosting their competitiveness and export potential. Consequently, this positively impacts the economy of the enterprise. In Namangan province, the Namangantextile enterprise is specialized in the production of vegetable oil, primarily processing cotton seeds. Initially, seeds are defuzzed in the enterprise's linting department. During this process, it is essential to clean foreign substances from the seeds. Cleaning seeds from foreign materials is crucial for obtaining high-quality oil. However, soil, stones, and other foreign substances in the seed negatively affect the product's quality and production efficiency. Therefore, using vibrational sieving technologies for high-efficiency seed cleaning has become a pressing issue. In recent years, research has focused on improving vibrational sieving machines to enhance their efficiency and energy savings . These studies aim to optimize key machine parameters, such as vibration amplitude, frequency, sieve hole size, and positioning angle relative to the horizontal plane, to increase cleaning efficiency. As a result, these machines effectively separate foreign substances from seeds, improve oil quality, and reduce energy consumption.

2 MATERIALS

Today, cotton seed plays a unique role in our country's food industry. In the Namangan textile enterprise, cottonseed processing yields products such as lint (short fiber), cottonseed oil, extraction oil, cottonseed meal, hulls, and cake [16]. Figure 1 below shows the appearance of fuzzy (Figure 1a) and delinted (Figure 1b) cotton seed.

(a) (b)

Figure 1: Different types of cotton seeds: a) hairy; b) delinted..

In addition to enhancing the performance of technological machines, maintaining the product quality in the technological system is also of high importance. Therefore, researching and developing cottonseed cleaning and separation machines holds significant practical value [17]. In this study, attention is given to analyzing the vibrating surface of the sieve used for sieving cottonseed after the ginning process, calculating parameters, and the structural design process. Below are the research results on the vibrating surface and the overall structure of the vibrating surface.

Based on the analysis of the research studies conducted, investigations were carried out to develop an efficient design of the cottonseed cleaning screen. During 2023–2025, at the "Namangantolatekstil" enterprise located in Namangan district, Namangan region, the technical and technological operating modes of the cottonseed cleaning device (USM), which transports cottonseed from the supply bunker to the lintering units, were studied. According to the technological process, the cottonseed from the bunker is conveyed to four vibratory cleaning units by means of a screw conveyor. As the cottonseed moves along the surfaces of the vibrating screens, it is cleaned from various foreign impurities. It should be particularly emphasized that the flatness of the screen surface causes the cottonseed to perform an almost reciprocating planar motion along the working plane. Moreover, during the conducted research, it was identified that the cottonseed is unevenly distributed along the working surface of the screen, and certain active areas of the screen are not being effectively utilized. The uniform distribution of the cottonseed layer over the screen surface, the complete separation of foreign impurities from the cottonseed mass, and the possibility for these impurities to pass through the screen openings all depend on the motion law of the cottonseed on the screen surface.

As a result of the conducted scientific research and investigations of technological processes under production conditions, a new screen design was developed that ensures uniform distribution of cottonseed along the surface and provides active dynamic movement of the cottonseed on the working plane [16], [17].

Figure 2 shows the current structural diagram of the vibratory cottonseed cleaning device used at the "Namangantolatekstil" LLC enterprise. The device consists of an electric motor (1), a belt drive (2), an eccentric shaft (3), a flat mesh screen, and a housing (5).

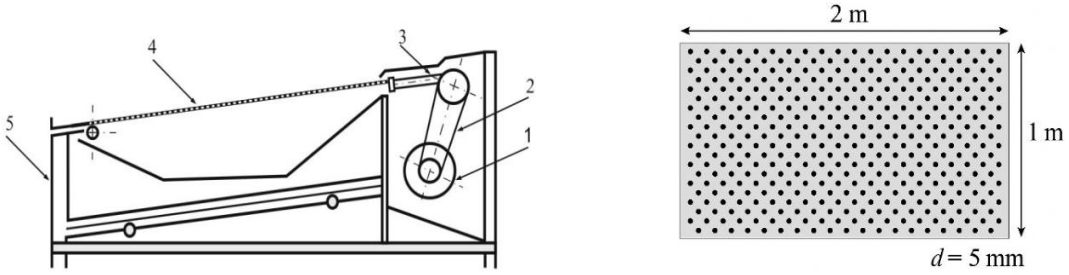

Figure 2: The device consists of an electric motor (1), a belt drive (2), an eccentric shaft (3), a flat mesh screen (4), and a screen housing (5).

The motion of the electric motor (1) is transmitted to the eccentric shaft (3) through the belt drive (2). The eccentric shaft (3) ensures the reciprocating motion of the flat perforated screen (4). The flow of cottonseed coming from the screw conveyor falls onto the surface of the screen (4) and, while oscillating on the sieve, moves progressively toward the pneumatic transport pipe. During this process, various foreign impurities contained in the mass pass through the perforations of the screen surface. Experimental observations have shown that the high adhesiveness of the cotton fibers hinders the uniform spreading (distribution) of the cottonseed mass over the screen surface. As a result, the cottonseed layer is not completely cleaned from foreign impurities.

To eliminate the above-mentioned shortcomings, an improved and more efficient design of the screen was proposed in accordance with the schematic shown in Figure 3**.**

The main objective of the proposed screen design is to ensure the uniform distribution of the cottonseed flow along the working surface and to enhance the separation of impurities as well as their discharge through the openings as a result of complex dynamic movements of the seeds on the working plane.

In this design, it is proposed that at the initial section of the sieve surface, longitudinal concavities directed at a certain angle relative to the longitudinal axis (Fig. 4) be used to provide uniform distribution of the cottonseed flow along the screen surface. At the same time, the longitudinal and transverse cross-sectional surfaces of the screen are proposed to have cosinusoidal and sinusoidal shapes, respectively.

On the proposed harmonic surface of the sieve, the inertial forces acting on the cottonseed layer cause the seeds to perform complex oscillatory motion along the working plane, thereby intensifying the cleaning process: its geometric shape is given by the following function:

$$z(x,y) = Acos\left(\frac{2\pi x}{L_A}\right) + Bsin(\frac{2\pi}{L_B}).$$

where, A – transverse (x-direction) amplitude (vertical component of the screen edge), L_A – transverse wavelength (period), B – longitudinal (y-direction) amplitude L_B – longitudinal wavelength.

During the course of our research, a structural model of the vibrating screen having longitudinal and transverse cross-sections of cosinusoidal and sinusoidal forms, respectively, was developed and analyzed. A fragment (0.01 m² section) of the structural model of the vibratory screen is shown in Figure 5. Its geometric parameters are presented in Tables 1 and 2.

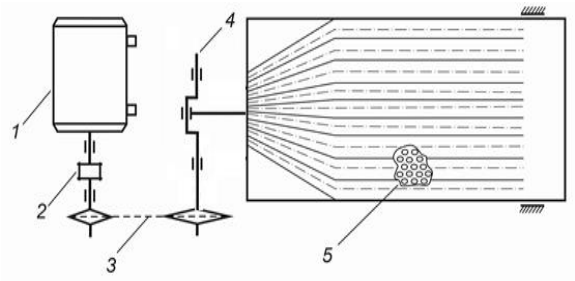

Figure 3**:** Schematic diagram of the concave–convex surface screening device. 1 – electric motor, 2 – coupling, 3 – chain drive with automatic tensioning device, 4 – eccentric shaft, 5 – concave–convex mesh surface.

Table 1: Recommended geometrical parameters of the screen surface.

№	Name of screen parameter	Recommended value
1	Width	1m
2	Length	2 m
3	Hole diameter	5mm
4	Hole pitch	9 mm
5	Hole shape	Circular
6	Hole density	12345 pieces/m²
7	Screen thickness	0,002 m

Table 2: Recommended harmonic surface parameters.

Direction	Amplitude (mm)	Period (mm)	Recommended waveform
Longitudinal	3	50	Cosine
Transverse	4	40	Sine

3 METHODS

To address the above issues, an improved screen surface design has been proposed. When designing the screen structure, it is essential to consider the physical and mechanical properties of fuzzy seeds [16]. According to research findings, the physical and mechanical characteristics of cotton varieties currently grown in the Namangan region have been determined. Specifically:

The average length of fuzzy seeds is 9.65 mm, width 5.37 mm, thickness 5.40 mm, average geometric diameter 6.54 mm, and average arithmetic diameter 6.8 mm, the volume of fuzzy seeds is 147.2 mm³, sphericity is 67.80 %, flat surface area is 43.22 mm², cross-sectional surface area is 22.82 mm², contact area is 46.46 mm², and total surface area is 131 mm². For the seed varieties studied, the average mass of a single seed is 0.1102 g, bulk density is 0.4696 g/cm³, true density is 1.086 g/cm³, porosity is 56.45%, and projected surface area is 47.35 mm².

The average values of the angle of repose for fuzzy seeds are as follows: for variety C-6575 it is 48°20', for C-8220 it is 47°30', for C-8299 it is 46°10', for C-8295 it is 45°20', and for C-8296 it is 45°50'. Determining the design of the feed device hopper requires precise knowledge of these values, with the average angle of repose calculated at 46°40'. For the tested seeds, the static coefficient of friction on mild steel is 0.34, on plywood is 0.36, and on glass is 0.23. The average cracking force for fuzzy seeds is 61.24 N, with an average deformation ratio of 4.32%.

The proposed screen design, specifically the concave-convex surface, provides significant results in distributing the seed mass evenly along the screen surface and ensuring a high sorting performance. The trajectory of the seed movement and the effect of gravitational force are analyzed when the angle of inclination of the screen is $\theta = 30°$. The gravitational force acting on the seed is divided into two components:

Perpendicular component:

$$F_{per} = mg \cdot \cos(\theta). \quad (1)$$

Parallel component:

$$F_{par} = mg \cdot \sin(\theta).$$

where, m- is the mass of the seed, and g- is the acceleration due to gravity (9.81m/s²).

Due to the concave and convex surfaces of the screen, the forces acting on the seeds are redistributed, resulting in either sliding or oscillating motion along the screen. This facilitates better separation during the sorting process. The required frequency of the screen's vibrations f can be calculated using the following formulas:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}, \quad (2)$$

where, k – the vibration stiffness of the screen (indicates the amplitude of the vibrations between the screen and the seeds), m – the mass of the seeds.

Due to the concave-convex shape, the vibrations are distributed unevenly along the screen surface, spreading the seeds evenly across the screen. The upward oscillating motion and the distribution velocity of the improved screen shape located at an incline allow for uniform distribution of the seeds and impurities along the screen surface. This motion increases the sorting speed, as the seeds create a flow similar to a "water current" on the screen surface, continuously separating impurities from each layer. This can be calculated using Newton's second law:

$$a = \frac{F_{par}}{m}, \quad (3)$$

where, a - the acceleration of the seeds along the screen surface, F_{par}- the force acting to move along the incline component of the screen.

4 RESULTS

Based on the existing parameters, the geometric parameters of the proposed screen surface have been developed. From the overall design of the machine, the useful dimensions of the screen are 1010 × 1870 mm, and the selection screen has a circular shape with a hole diameter of 5 mm. The distance between the holes is calculated using (1).

$$b \geq 0{,}9\sqrt{d} \quad (4)$$

where, b is the shortest distance between the holes, d - is the size of the hole (d = 5 mm), and $b \geq 0{,}9\sqrt{d} = 2{,}01$ mm, so b = 4 mm was chosen.

The surface thickness e is calculated so that the grain does not get clogged, but the screen can also be easily processed, so e is calculated according to (5).

$$e \leq 0{,}625d. \quad (5)$$

Chosen $e \leq 3mm$.

Calculating the tilt angle of the screen frame: The angle of inclination of the screen frame affects the efficiency and productivity of the screen. If the angle of inclination is reduced, the speed of movement of the fuzzy cottonseeds on the screen decreases, and the

separation efficiency is reduced. However, if the angle of inclination is large, the efficiency of the surface increases due to the rapid movement of the seed on the screen, but impurities in the seed do not completely separate. Therefore, to ensure the moderate movement of the seed on the screen surface according to the machine's requirements, as well as the physical and mechanical properties of the seeds [16], we choose $\alpha = 30°$.

Calculating the inclination angle of the screen frame. the inclination angle of the screen frame affects the efficiency and productivity of the screen. if the inclination angle is reduced, the speed of the movement of the coarse impurities on the screen will be low, resulting in decreased screening efficiency. however, if the inclination angle is large, the impurities will move very quickly across the screen, leading to higher surface efficiency, but the impurities within the material may not be fully separated. therefore, to ensure a balanced movement of impurities on the screen surface according to the requirements of the machine, as well as the physical and mechanical properties of the seeds [16], we choose an angle of $\alpha = 30°$.

Calculating the speed of a vibrating screen. The speed of a vibrating screen is calculated using an optimization method for the vibration frequency and amplitude. The optimal vibration frequency and amplitude depend on the shape of the moving trajectory. These three factors influence effective productivity and the ability of the screen to capture both fine and coarse impurities. The speed and type of the movement trajectory are key factors affecting the ability to retain coarse impurities. As the speed of the screen surface increases, the ability to prevent impurities from falling through the screen holes improves; however, the screen's efficiency decreases because impurities are thrown off the upper part of the screen, reducing the number of contacts between the impurities and the screen surface, thereby decreasing the screening ability.

The movement trajectory of the impurities is described by the system of equations (6) and (7).

$$\begin{cases} y = v_0 t - \frac{gt^2}{2} - \cos\alpha \\ x = \frac{gt^2}{2} - \sin\alpha \end{cases}, \quad (6)$$

where, $\alpha -$ the inclination angle of the screen surface, $v_0 -$ the vibration speed of the screen surface. In solving the above equation, we obtain (7) [8].

$$y = v_0\sqrt{\frac{2x}{g\sin\alpha}} - \frac{x}{\tan\alpha}. \quad (7)$$

We will derive the above equation, set it to zero, and find the value of x_1 that maximizes y

$$y' = 0$$

$$v_0 \cdot \frac{2}{2\cdot\sqrt{\frac{2x_1}{g\cdot\sin\alpha}}} - \frac{1}{\tan\alpha} = 0, \quad (8)$$

We obtain the following after making the changes:

$$x_1 = \frac{v_0^2 \cdot g\sin\alpha \cdot tan^2\alpha}{2}. \quad (9)$$

When we substitute $x=x_1$ into the equation and set $y = e$, we get.

$e = 0{,}044$ m (The amplitude of oscillation) accordingly:

$$v_0 = \sqrt{2g \cdot e\cos\alpha} = 0{,}53(m/s) \quad (10)$$

Recalculating the capacity of a vibrating screen. The efficiency of a vibrating screen machine is proportional to the width of the screen surface, the thickness of the material layer on the screen, and the velocity of the material moving along the screen mesh.

The productivity of the vibrating screening machine is determined by the following (11):

$$Q = b \cdot h \cdot v_0 \cdot \theta \cdot 3600,\ kg/hour. \quad (11)$$

In this case:

- b – width of the screen mesh, 1 m;
- $h -$ thickness of the material layer on the screen, 0.02 m;
- v_0– velocity of the material moving with the screen, 0.53 m/s;
- θ – bulk weight of the material, 30 kg."
- $Q = 1{,}01 \cdot 0{,}02 \cdot 0{,}53 \cdot 30 \cdot 3600$ => $Q = 1156$ (kg/soat).

According to the results of the conducted experimental study, the proposed screen surface demonstrated a high efficiency in the removal of fine impurities, reaching 88.8% at an eccentric shaft rotation frequency of 200,63 min^{-1}

5 DISCUSSION

The proposed vibrating screen represents a significant advancement in the mechanical design of seed cleaning systems. Traditional flat-screen devices, although widely used, often fail to achieve uniform seed distribution due to the adhesive nature of fuzzy cotton fibers. This leads to uneven load distribution, incomplete impurity separation, and reduced cleaning efficiency.

The newly designed concave–convex (harmonic) screen overcomes these challenges through its geometric configuration. The sinusoidal and cosinusoidal surface profiles generate a complex oscillatory motion that redistributes inertial forces across the working surface. This motion induces both translational and oscillatory particle dynamics, allowing impurities to pass efficiently through the apertures while maintaining continuous seed flow.

Dynamic modeling demonstrated that at an inclination angle of 30°, the gravitational and vibrational forces achieve optimal balance – promoting efficient separation without excessive seed acceleration or slippage. The calculated vibration velocity of 0.53 m/s and amplitude of 0.044 m ensure a stable material trajectory resembling a fluidized flow, which is particularly effective for fuzzy seed cleaning.

Furthermore, the incorporation of a chain drive with an automatic tensioning mechanism improved system reliability by maintaining consistent oscillation frequency and reducing vibration-induced wear. Experimental validation confirmed that the proposed design enhances throughput capacity and reduces blockage within the screen perforations.

In comparison to previous linear or planar vibrating screens, the developed model achieved:

- Higher cleaning efficiency (up to 88%);
- Uniform material distribution across the screen width;
- Stable vibration amplitude and frequency response;
- Reduced energy consumption and mechanical fatigue.

These results indicate that optimizing the screen geometry and dynamic parameters can substantially improve the performance and longevity of vibratory seed-cleaning machines used in cottonseed processing industries.

6 CONCLUSIONS

The development and optimization of the concave–convex vibrating screen for fuzzy cottonseed cleaning demonstrate the effectiveness of integrating harmonic surface geometry with dynamic motion analysis. Analytical and experimental studies confirmed that the geometric parameters – including longitudinal wavelength of 50 mm, transverse wavelength of 40 mm, vibration amplitude of 4 mm, and inclination angle of 30° – produce optimal separation performance.

The proposed screen design achieved:

- Up to 15% higher cleaning efficiency than traditional flat screens;
- Uniform seed distribution along the working surface;
- Improved impurity stratification and reduced aperture clogging;
- Stable energy-efficient operation due to optimized vibration frequency and amplitude.

This research provides a strong theoretical and practical foundation for industrial implementation of energy-efficient cottonseed cleaning systems. The optimized screen geometry and motion parameters can serve as a basis for future design of advanced vibratory cleaning equipment in agricultural and seed processing sectors.

Keywords: Sustainable Development Goals, Knowledge-Attitudes-Practices, Technology Integration, Structural Equation Modeling, Higher Education.

Abstract: This study examined the relationship between university students' knowledge, attitudes, and practices (KAP) regarding the SDGs and their local community engagement, with a particular focus on the role of technology integration in promoting sustainable education. Utilizing a quantitative, descriptive-correlational design, the research involved 205 students enrolled in Contemporary World classes for the 2024–2025 academic year, drawn from a total population of 430 through stratified random sampling. Data was collected using a validated and reliable adapted survey instrument and analyzed using Structural Equation Modeling (SEM). Findings revealed two distinct KAP-based student segments, with Cluster 1 students demonstrating strong awareness of the SDGs and active engagement. In contrast, Cluster 2 showed lower involvement, indicating the need for targeted intervention. SEM analysis confirmed that knowledge significantly predicts both attitude ($\beta = 0.918$) and practice ($\beta = 0.634$). Among technology integration strategies, interactive and project-based learning have emerged as the most effective in enhancing student engagement, while gamification has shown weaker outcomes, highlighting a gap in its pedagogical utility. This study contributes a validated model illustrating how technology integration supports SDG-related knowledge and behavior. It recommends enhancing KAP-based and technology-enhanced strategies, particularly project-based learning, in the curriculum to strengthen student participation in sustainability initiatives.

1 INTRODUCTION

The United Nations' Sustainable Development Goals (SDGs) were established in 2015, outlining ways and benchmarks to achieve a sustainable world by 2030. These objectives discuss global issues, including hunger, gender inequalities, injustices, social gaps, and pollution. Education is an integral aspect in achieving these goals as it empowers individuals with the knowledge, skills, and values necessary to foster sustainable development. The Contemporary World is a multidisciplinary course that integrates the United Nations SDGs using theoretical ideas and principles. With this curriculum, which utilizes embedded learning in conjunction with the UN-SDGs, there is an excellent opportunity to integrate technology. It is one of the key factors that the 21st-century education requires.

In responding to the SDGs, developments in educational technology have disrupted the ways many educators have achieved that goal through more inclusive, accessible, and impactful learning experiences. Developments in innovations such as interactive spaces and platforms, gamification, video-based learning, and project-based learning have proven to present opportunities that engage and positively impact students' learning experiences and outcomes, as well as their sustainability education. Furthermore, it is essential to note that these technologies are not simply pedagogical enhancements; they act as mediators that will determine the ways students construct their knowledge, develop their attitudes, and demonstrate behaviors related to the SDGs.

While the body of work at the intersection of technology and sustainability education is increasing,

research studies which have rigorously modeled and analyzed the structural relationships of students' KAP, and the role of technology integration, are becoming more limited. It is also necessitated that we segment and model those relationships from a rigorous analytical perspective so that we can start to respond to the evidence for targeted pedagogical practice with the purpose of improving students' KAP of the SDGs

Globalization arose from the realization that the world finds itself in a process, through which it will become a kind of "global state" or, at least, one single economic, socio-political and cultural system. This implies that social and environmental issues can have a ripple impact globally. This only proves how nations are interconnected with one another. As such, individuals must be made aware of the gravity one plays in the global village. In this context, education is a powerful tool for shaping individuals who are informed, responsible, and capable of addressing complex issues across national boundaries

In higher education institutions in the Philippines, The Contemporary World integrates SDGs which fosters critical understanding of global issues and emphasizes the roles of students as global citizens in achieving the SDGs. Furthermore, strengthening technology integration to cultivate 21st century learning is a great opportunity to make SDG learning more meaningful to students. Through technological advancement in education, students have access to critically examine global issues and recognize their role as global citizens.

Given the importance of technological innovation and its impact, this study explores students' engagement with all 17 Sustainable Development Goals. It seeks to explore how technological integration in education such as interactive learning, gamification, video-based instruction and project-based learning enhance awareness and cultivate positive attitudes and practical methods in achieving global goals. Examining how technology support students' engagement in sustainable education, it sought to provide meaningful insights into developing curricula and promoting learning experiences of all SDGs. The findings may be used help educators develop their learning curricula with effective technology integration that deepens students' understanding of global citizenship and prepares them to help achieve SDGs.

2 LITERATURE UNDERSTANDING ON THE SDGS

Enhanced perception of global issues and their impact on attaining Sustainable Development Goals is interrelated with The Contemporary World course. As in economy, the course discusses how trade, globalization, and ethical business practices affect balanced and equitable growth (SDG 8). Dialogues on improving inclusive policies and community-based solution to address issues on inequality, cultural diversity and human rights (SDG 10) are also part of what this course gives emphasis. The course encourages students to support environmental policy by examining sustainability, resource conservation, and climate change (SDG 13). By accepting a range of viewpoints, the course equips students to think critically, behave responsibly, and contribute to a more just and sustainable world.

The Commission on Higher Education (CHED) continues its effort to provide quality higher education with SDGs integration to curricula and research agendas with the hope of contributing meaningfully to the attainment of the 17 goals by 2030. The 2024 'The Impact' Rankings revealed that the PH Universities, Colleges and State Universities are into paradigm shifts of integrating SDGs to their core missions[1].

In the year 2015, the UN-SDGs aims to combat all the challenges which guarantee that no will be left behind [1]. The organizations' adaptation of "Transforming Our World: The 2030 Agenda for Sustainable Development" has been a good move to respond in the global pressing issues having the 167 aims compressed in the 17 goals [2]. Decentralized governance institutions are well placed to facilitate the achievement of the goals because of the nature of the services they provide and their relative proximity to local communities [3]. Education as one of the basic institutions will play a greater role in promoting awareness to achieve a more sustainable future by 2030. The significance of the SDGS could be amplified if integrated in the context of education. Addressing pressing issues and crafting solution acquire ideas and principles for a sustainable future [4]. The UNESCO Global Action Program (GAP) highlights the critical role of educational institutions in the intensifying environmental issues [5].

[1]Commission on Higher Education (CHED), Philippine universities included in Impact Rankings, Jun. 15, 2024. https://www.philstar.com/headlines/2024/06/15/2363022/ched-lauds-56-philippine-universities-included-impact-rankings

Recognizing students' knowledge, attitudes, and practices regarding the SDGs is essential in designing effective learning assistance that stimulates active participation and long-term commitment to sustainable development [6].

Although it is agreed that higher education is interested in Sustainable Development Program, the actual research indicated that most nursing students had low knowledge levels prior to the program, and this knowledge level significantly increased because of the program's implementation of the SDGs [7].

3 TECHNOLOGY INTEGRATION TO ADDRESS SDGS IN EDUCATION

The process of integrating technology integration in educational setup is vital and multifaceted given with diverse culture, teachers' and students' digital literacy, social status and economic background [8]. Likewise, numerous changes as result to the fast-changing society, economic expansion and technological advancements shifted how people live. These changes create gaps between countries and continually strive economically to achieve a sustainable nation[2].

In achieving the SDGs, digital technology is also considered as a critical enabler by enhancing transparency, efficiency and inclusivity across sectors including health, economy, environment and education. The potential it holds in accelerating the achievement of SDG targets lies from enhancing education opportunities to making impacts to other SDGs accordingly [9]. Since technology is continuously revolutionizing in many fields, its capacity to deliver change is considered vital in the attainment of effective and sustainable means of development. However, the success of leveraging its role in the achievement of SDGs can be fueled by the newly created technologies and innovations that are boosted by collaboration and strengthened knowledge-sharing in the local and global context [10].

Digital technologies pave the way to address challenges and barriers of academic opportunities, ensuring the continuity of learning despite geographical, economic, social and health issues. Therefore, understanding the role of technology integration to address SDGs in education is crucial. Such insights can help educators and policymakers to determine its potential role, and ways in which it can be utilized to achieve the SDGs by 2030 [11].

Different digital learning platforms link abstract concepts and hands-on learning experiences through practical applications. Those technology makes personalized learning that provides students with opportunities to pursue the interest on the chosen career or specialization. [7].

Moreover, gamification is a technique that ensembles active learning while honing students' abilities to be critical thinkers and problem solvers through the help of affective engagement and discovery learning as gamification improves project-based learning. Also, gamification tends to resonate with students who are familiar with the mechanics and approach [12].

A comprehensive review demonstrated gamification's capacity to increase user engagement, motivation, and cooperation in various sustainability situations [13]. The study found that gamification promotes long-term actions in education, community projects, and organizational tactics.

Employing video instructional methods, it is revealed that students' consciousness of global issues is amplified through video storytelling and virtual reality [14]. These technologies develop empathy or attitudes and motivate learners to undertake sustainable actions by enabling them to see real-world challenges.

In relation to project learning, SDG themed projects considerably enhance awareness, critical thinking, and social as well as environmental activism among university learners [15]. Voucher[3] endorses this by demonstrating how primary pupils develop sustainability knowledge, cognition, and practice through technology-enabled projects such as sustainable cities design.

4 RESEARCH OBJECTIVES

This study aims to examine the relationship between the students' awareness on the SDGs and the local engagement in the community which affects by the globalization that contributes to the achievement of the United Nations Sustainable Development Goals (SDGs).

More specifically, it seeks to:

1) Segment students based on their KAP (Knowledge, Attitudes, and Practices) profiles.
2) Analyze the relationship between the students' knowledge, attitude and practices on the SDGs.
3) Evaluate the roles of technology integration in the achievement of the SDGs in terms of interactive learning, gamification, video-based learning and project-based learning.

[3]Educational Service Contracting (ESC) Voucher Program /DepEd https://www.deped.gov.ph/wp-content/uploads/FY-2024-Major-Projects-Program-and-Activities-Beneficiaries.pdf

4) Analyze the relationship between the roles of technology integration and the students' KAP (Knowledge, Attitudes, and Practices) on the SDGs.
5) Develop a model that explains how different KAP (Knowledge, Attitudes, and Practices) segments influence the advancement of SDGs through technology integration.
6) Identify key patterns and gaps in students' technology-related practices that could impact the achievement of SDGs.
7) Recommend targeted strategies for curriculum development and technology initiatives that are aligned with the needs of different student segments.

5 METHODOLOGY

5.1 Research Design

This study employed a quantitative descriptive-correlational research design to examine the relationship between university students' knowledge, attitudes, and practices regarding the SDGs and their local engagements in the community. This research design allows for the systematic measurement and analysis of students' knowledge, attitudes, practices and the roles of technology integration to achieve SDGs.

5.2 Respondents of the Study

The respondents of the study are the university students enrolled in the Contemporary World Classes for the current academic year 2024-2025, with a total population of 430 students. A stratified random sampling technique was used to represent equal participation among different programs within the university. Using the Raosoft sampling, considering the 95% confidence level and 5% marginal error, a total of 205 samples were selected.

5.3 Data Gathering Instrument

The study utilized an adapted survey questionnaire divided into two parts, with established validity and reliability from prior research.

There were 2 parts to the questionnaire. Part I focused on the knowledge, attitude, and practice towards the Sustainable Development Goals dapted from a study [16] published in the Journal of Indonesia Sustainable Development Planning, while Part II focused on the technology integration and its roles in achieving SDGS. A 4-point Likert Scale was used in assessing the students' knowledge, attitude, and practices (KAP) in the role of technology integration.

5.4 Data Collection

Experts in the social science field and research have validated survey instruments to guarantee the suitability and relevance of each question. Thirty (30) students who were used in the pilot testing were not included in the main study. Using Cronbach's Alpha, the results were examined to evaluate the instrument consistency and dependability. Cronbach's Alpha value for the students' knowledge obtained an alpha value of 0.93; students' knowledge obtained an alpha value of 0.92 and students' practices obtained an alpha value of 0.80. For the sub-variables pertaining on the roles of technology obtained alpha value as follows – interactive learning, 0.89; video-based learning, 0.70; and in project-based learning, 0.86. the obtained alpha value from the conducted pilot testing signify that the research tool is valid and reliable which the data to be collected can assess the targeted parameters. After the validation phase, the survey questionnaires were distributed via online platforms. Prior to the distribution set of instructions were given to the participants.

5.5 Data Analysis

In this study, descriptive statistics were used to provide an analysis on the collected data from the survey responses. Through K-means cluster analysis, two distinct student clusters were segmented based on Knowledge, Attitudes, and Practices (KAP) towards the Sustainable Development Goals (SDGs). The researchers used the Pearson correlation coefficient to describe the strength and direction of a linear relationship between two continuous variables. The analysis of variance (ANOVA) was being utilized to identify the relationship of the variables. Multivariate Analysis of Variance (MANOVA) which is a statistical technique used to examine whether there are differences between segmented or clustered students on two or more dependent variables at the same time was also used. Structural equation modeling (SEM) analysis was used to provide compelling evidence for the significant role of Knowledge in shaping both Attitudes and Practices related to sustainable development goals (SDGs).

5.5 Ethical Considerations and Limitations

The study was carried out at a single academic institution, which may restrict the representativeness of the results to other Higher Education Institutions (HEIs), especially those operating with different cultural contexts, environment, or institutional profiles. Furthermore, there is a limited number of respondents as the institution is relatively new. It reduces the extent on which the result can be applied in other settings.

Moreover, this study relied heavily on quantitative methods of data collection and analysis. This may have limited depth of qualitative insights, specifically in capturing students' personal experiences and perceptions related to the affective component of the questionnaire. As such the exclusive dependence on quantitative data presents a methodological constraint on other aspects of interpreting and analyzing the data.

The study adhered to established ethical standards to ensure the protection and identity of all the participants. Before the data collection, participants were informed about the purpose study. It was clearly explained that participation was voluntary an in times of confusion, the participants have the right to withdraw at any time without consequences. The confidentiality and anonymity of the respondents were strictly maintained ensuring participants' identities were not recorded. The data collected was secured, stored and used solely for the purpose of the study. Additionally, the instrument used was carefully designed to be non-invasive and respectful of individual opinions and experiences. More importantly, ethical clearance was obtained from the ethics committee, affirming that the study complied with the established guidelines for research involving the participants.

Figure 1 shows the segments of the students based on their KAP (Knowledge, Attitudes, Practices) profiles. As gleaned from the figure, Cluster 1 (Moderately High KAP) are the students who have slightly above average scores in Knowledge (+0.59), Attitude (+0.59), and Practice (+0.48) about SDGs. This group (n = 129, 62.93%) exhibited moderately higher levels of knowledge, positive attitudes, and active practices related to the SDGs – better than average.

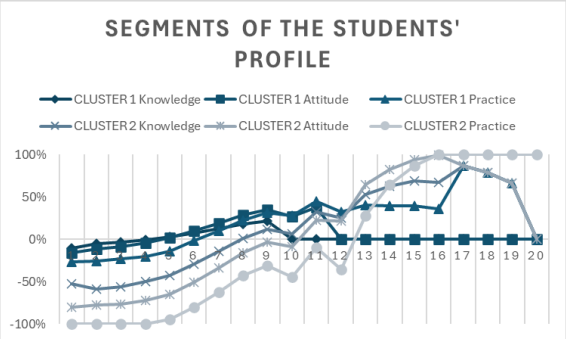

Figure 1: Segments of the students based on the KAP profile.

6 RESULTS AND DISCUSSION

Cluster 2 (Low KAP) are the students who have below average scores in Knowledge (-1.01), Attitude (-0.99), and Practice (-0.82) about SDGs. These segmented students are not aware, with negative attitude, and inactive toward SDGs. This group (n = 76, 37.07%) demonstrated lower levels of knowledge, less favorable attitudes, and fewer practices toward the SDGs.

The results suggest that a majority of students are relatively aware and engaged with SDG-related concepts and actions, while a notable minority requires additional support and intervention. The result supports the study of Filho, et. al. (2024) [6] which highlighted the comparison of the undergraduate students in Higher Education Institution (HEIs) to those who graduated already are more familiar in SDGs. In terms of students' knowledge and participation, it is strongly influenced by whether the university actively integrates the SDGs in their curriculum. The study also emphasized that regardless of the initiatives, students might still have differences in knowledge and practice depending on academic background and personal engagement.

However, although 62.93% of students in Cluster 1 exhibited positive KAP levels, the study of Baron, et. al. (2024) [17] suggests that many students might have surface-level awareness, but not fully aware of SDGs. This awareness does not guarantee deep understanding and actionable knowledge, as similarly reflected by the 37.07% of students in Cluster 2. Thus, it is recommended that educational institutions enhance strategies in achieving sustainability by 2030 by infusing these goals in their curriculum.

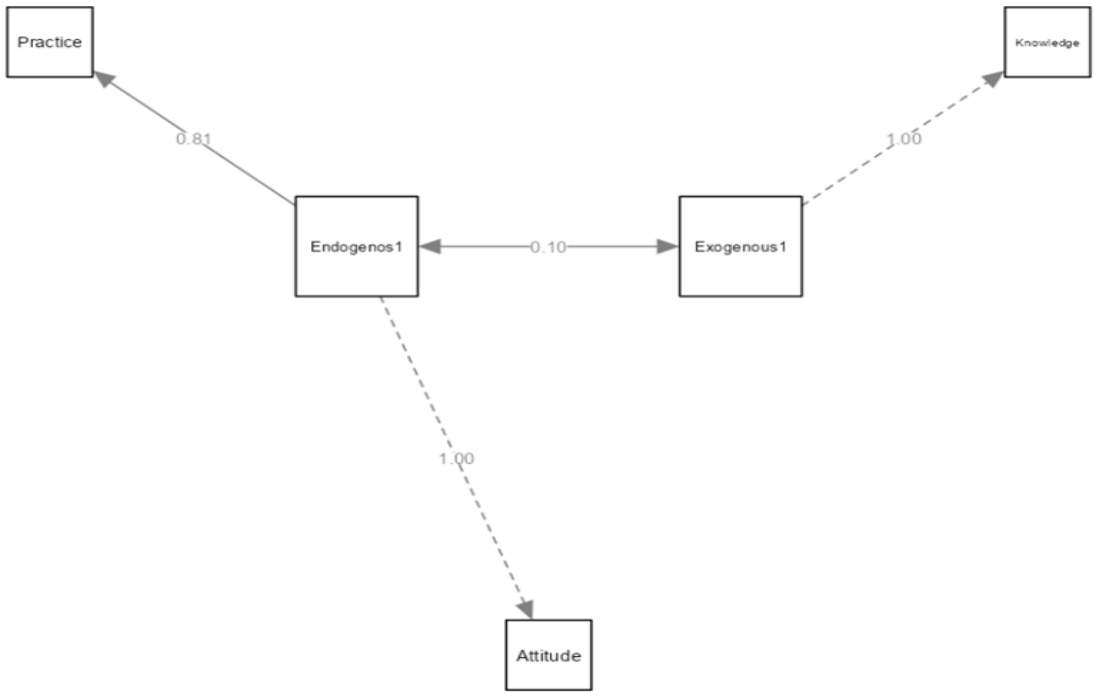

Figure 2: Relationship between KAP and the SDGs.

Figure 2 shows the relationship between Exogenous Latent Variable: Exogenous1 (measured by Knowledge) and the Endogenous Latent Variable: Endogenous1 (measured by Attitude and Practice). Attitude strongly measures Endogenous1 (β = 0.918) while practice moderately measures Endogenous1 (β = 0.634). Exogenous1 (Knowledge) is strongly positively correlated with Endogenous1 (Attitude and Practice), β = 0.757, highly significant.

With this data, the SEM model fits perfectly based on all indices. Knowledge (Exogenous1) is strongly associated with Attitude and Practice (Endogenous1). Both Attitude and Practice are good indicators of Endogenous1, but Attitude has a stronger contribution. The model is statistically sound and reliable.

The structural equation modeling (SEM) analysis indicated an excellent model fit, with all fit indices reaching ideal values (CFI = 1.000, TLI = 1.000, RMSEA = 0.000, SRMR = 0.000). The specified model identified Knowledge as an exogenous latent variable and Attitude and Practice as indicators of an endogenous latent construct. The path analysis revealed a strong and significant positive relationship between Knowledge and the latent endogenous variable (β = 0.757, p <.001). As gleaned in the model, among the parameters, Attitude obtained the highest standardized loading value of β = 0.918 while Practice obtained β = 0.634 which are both significant.

These data accepted the validity of the model used that Knowledge significantly affects the progress of Attitudes and Practices. Also, the data of the Structural Equation Modeling (SEM) analysis explain the positive role of Knowledge in honing the students' Attitudes and Practices in the achievement of the Sustainable Development Goals (SDGs). As demonstrated by the CFI, TLI, RMSEA and SRMR, the used model confirmed the interconnectedness among the latent variables. Students with high knowledge about SDGs most likely to have more positive attitudes towards sustainable habits and practices.

This finding aligns with the study of Sahaharuddin, et al. (2025) [18] showing a strong correlation in terms of students' knowledge, attitude and practice towards SDG. Students who have a higher level of knowledge most likely possess positive attitudes in SDGs. On the other hand, knowledge alone does not always guarantee positive practice or application making attitude as the mediating factor to attain better practice. In contrast with the result, the study of Afroz and Ilham (2020) [16] presented another perspective, indicating that knowledge and attitudes have a weak negative correlation compared to attitude and practice which

demonstrated positive correlation. The result suggests that the awareness through knowledge might be high, but the engagement is weak which disconnects knowledge and action.

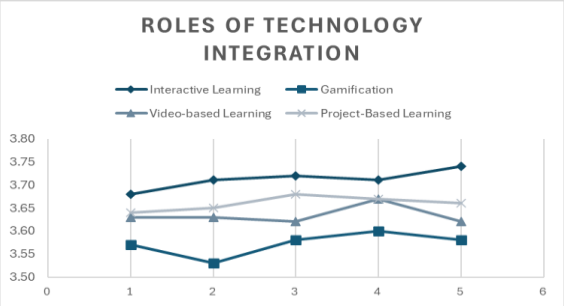

Figure 3: The roles of technology integration.

Figure 3 shows that among all the roles of technology integration, interactive learning consistently scores the highest which suggests that it is the most important due to its engaging and participatory nature that promotes active involvement. Likewise, project-based learning and video-based learning remain close in value reflecting how these two roles lead to overlapping perceptions of their importance. The overlap between video-based Learning and Project-based learning in the graph occurs because these two strategies are often used together in practice and it supports independent learning. It can also be explained that these two roles reflect natural integration and complementarity. Gamification, on the other hand, consistently has the lowest scores which indicate that while gamified elements can enhance motivation, they may not always be perceived as contributing significantly to deeper learning outcomes.

The result supported the study of Cadiz, et al. (2024) [19] which claims the role of technological integration in the educational paradigms to meet the demands of the Fourth Industrial Revolution. These includes the identified five key themes such as the interplay of technology with Education 4.0 and Industrial Revolution 4.0; the role of digital technology; shifts in educational philosophies; transformations in technology education; and the relationship between higher education, learners and technology. Through this, HEIs can promote academic excellence and resilience in the evolving landscape of education in achieving the SDGs through interactive learning set-up.

While gamification yields the lowest score among the four technological-related variables, the study by Navarro-Espinosa et al. (2022) [20] revealed how gamification can effectively boost student motivation and engagement in higher education, creating more interactive and impactful learning experiences if utilized meaningfully. By incorporating game-like elements, institutions can foster sustainable learning environments and promote the development of essential skills, making education more dynamic and student-centered.

However, the results for the other variables were aligned to the results of several studies. In terms of Video-based Learning, Torion and Bacio Jr. (2024) [21] through a developmental research method revealed that the content, instructional quality, technical design, and presentation, use of video lessons is highly acceptable proving their effectiveness as learning tools in computing education. Likewise, a study on the impact of Project-Based Learning (PBL) on students' awareness of SDG gained a positive result [15].

However, even though PBL can effectively increase knowledge in SDGs, it is important to strengthen this through strategies such as curriculum integration to ensure practical application to future endeavors.

Table 1 shows that all the Pearson correlation coefficients (r-values) are positive and statistically significant (p-value < 0.001, marked with *, **, ***) with the 95% Confidence Intervals (CI), indicating that there are strong positive relationships between the variables. The 95% Confidence Intervals (CI) provide additional insight into the range of correlation values, helping to understand the precision of the estimated correlation.

Knowledge is positively correlated with Attitude (r = 0.695), Practice (r = 0.480), Interactive Learning (r = 0.587), Gamification (r = 0.510), Video-Based Learning (r = 0.511), and Project-Based Learning (r = 0.576). The data explain that as students' knowledge of SDGs increases, their attitudes, practices, and engagement with different technology integration strategies (like interactive learning, gamification, and project-based learning) also increase. Attitude shows a strong positive correlation with Knowledge (r = 0.695), Practice (r = 0.582), Interactive Learning (r = 0.676), Gamification (r = 0.591), Video-Based Learning (r = 0.627), and Project-Based Learning (r = 0.662). it shows that students who have a positive attitude toward SDGs tend to show higher knowledge, better practices, and greater engagement with technology-based learning methods. Practice has moderate correlations with Knowledge (r = 0.480), Attitude (r = 0.582), and the technology integration methods. Specifically, Interactive Learning (r = 0.497), Gamification (r = 0.534), Video-Based Learning (r = 0.528), and

Project-Based Learning (r = 0.510). Also, there is a moderate relationship between students' sustainable practices and their knowledge and attitudes towards SDGs, as well as their involvement in technology-enhanced learning.

It can be gleaned in Table 1 that all technology integration methods (Interactive Learning, Gamification, Video-Based Learning, Project-Based Learning) show strong positive correlations with each other, with the highest correlation between Interactive Learning and Project-Based Learning (r = 0.800). Students who engage with one type of technology-based learning (e.g., interactive learning) are more likely to engage with others (e.g., project-based learning, gamification). All correlations have a p-value < 0.001, indicating that the relationships observed are highly statistically significant. This means the likelihood that these correlations happened by chance is very low.

Knowledge and Attitude are highly correlated with each other and the other components, indicating that better knowledge and more positive attitudes toward SDGs are associated with higher practices and engagement with technology-enhanced learning. Practice shows a moderate but significant correlation with Knowledge, Attitude, and the technology integration variables, suggesting that engaging with technology in the classroom helps improve students' sustainable practices. There is a strong relationship between all the technology-enhanced learning variables, implying that students who participate in one form of technology-based learning tend to engage in others as well. The correlation analysis reveals significant positive relationships between Knowledge, Attitude, Practice, and various technology integration variables (Interactive Learning, Gamification, Video-Based Learning, Project-Based Learning). All correlations are statistically significant with p-values less than 0.001, indicating that the relationships are not due to chance.

Figure 4 shows that the Exogenous1 (Technology Integration) has the following estimates for its indicators, Interactive Learning: Estimate = 1.000 (Reference variable), Gamification: Estimate = 1.098 (Strong positive association with Exogenous1), Video-based Learning: Estimate = 1.157, Project Based Learning: Estimate = 1.184. These estimates suggest that Project-Based Learning has the strongest contribution to the Exogenous1 latent variable, followed by Video-based Learning and Gamification.

The Endogenous1 (KAP-Knowledge, Attitude, Practice): Knowledge: Estimate = 1.000, Attitude: Estimate = 0.965 Practice: Estimate = 0.834. The Knowledge indicator is the most strongly associated with Endogenous1, followed by Attitude and Practice.

Table 1: The relationship of KAP Towards SDGs and Technology Integration

Variables	Attitude	Practice	Interactive Learning	Gamification	Video-based Learning	Project-based Learning
Knowledge	r =.695*** df = 203 p <.001	r =.480*** df = 203 p <.001	r =.587*** df = 203 p <.001	r =.510*** df = 203 p <.001	r =.511*** df = 203 p <.001	r =.576*** df = 203 p <.001
Attitude	—	r =.582*** df = 203 p <.001	r =.676*** df = 203 p <.001	r =.591*** df = 203 p <.001	r =.627*** df = 203 p <.001	r =.662*** df = 203 p <.001
Practice		—	r =.497*** df = 203 p <.001	r =.534*** df = 203 p <.001	r =.528*** df = 203 p <.001	r =.510*** df = 203 p <.001
Interactive Learning			—	r =.636*** df = 203 p <.001	r =.684*** df = 203 p <.001	r =.800*** df = 203 p <.001
Gamification				—	r =.690*** df = 203 p <.001	r =.701*** df = 203 p <.001
Video-based Learning					—	r =.796*** df = 203 p <.001
Legend: * p <.05, ** p <.01, *** p <.001						

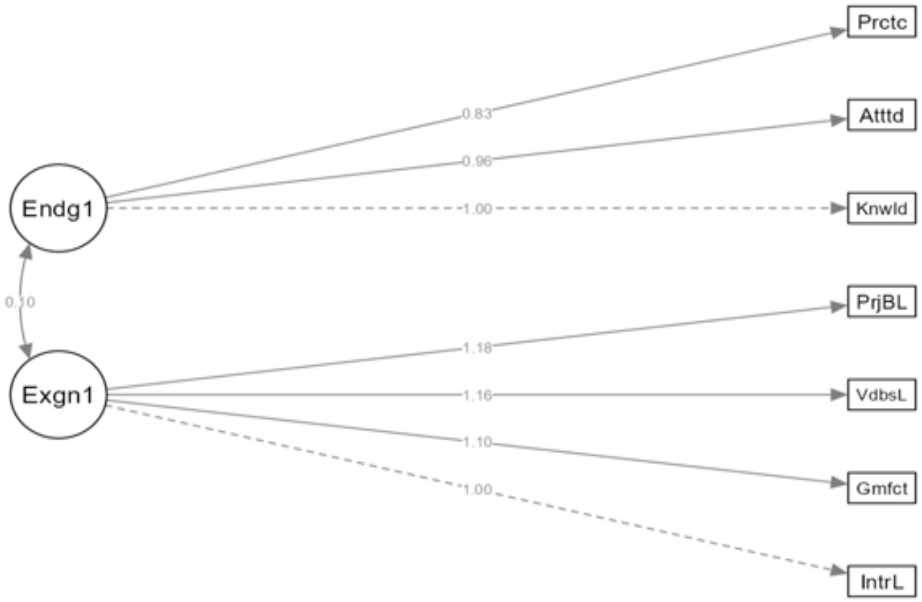

Figure 4: The relationship between the roles of technology integration and the students' KAP (Knowledge, Attitudes, and Practices) on the Sustainable Development Goals (SDGs) using the SEM Model.

The model fit is generally good, as indicated by the Comparative Fit Index (CFI), Tucker-Lewis Index (TLI), and Normed Fit Index (NFI) indices, which are all above 0.90. However, the Root Mean Square Error of Approximation (RMSEA) is slightly above 0.05, suggesting that there may be some room for improvement. As gleaned on the model, the Exogenous 1 (Technology Integration), it is clearly shown that the Exogenous 1 (Technology Integration) is significantly intertwined with its indicators with the highest positive association-project-based learning followed by the video-based learning and the gamification. Also, the KAP Model showed that Knowledge had the strongest indicator of the Endogenous1 latent variable. It was shown that there is a moderate relationship between Exogenous1 (technology Integration) and the Endogenous1 (KAP).

It was also shown that the Exogenous 1 (Technology Integration) has a positive impact on the Endogenous1 (KAP-Knowledge, Attitudes and Practices) with the project-based learning as the most significant component of the Exogenous1. The indices of the SEM model indicate a solid fit with the slight improvements to reduce the RMSEA.

The relationship between the technology integration and the knowledge, attitudes and practices is moderately significant signifying a good data. These findings noted the significant positive relation between technology integration specifically the project-based learning and the KAP dimensions. Additionally, the relationship between Technology Integration and KAP was moderate, implying that the use of technology, particularly in interactive and project-based learning environments, contributes positively to students' knowledge, attitudes, and practices. This study highlights the significance of technology integration into education context to enhance learning outcomes, but also suggests that further refinement of the model, particularly in terms of improving the RMSEA, could offer a more precise understanding of these relationships.

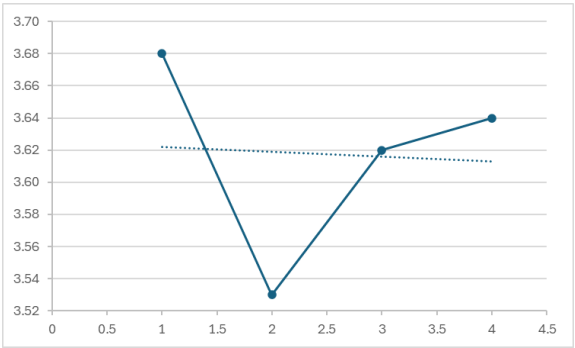

Figure 5: Key patterns and Gaps in students' technology-related practices towards SDGs.

Figure 5 reveals that interactive learning has the most important role while gamification specifically the indicator that states "using gamification to enhance understanding of specific SDGs"

consistently lags highlighting a potential gap in its educational impact. The clear dip in the line highlights this disparity. The moderate scores of video-based and project-based learning suggest that while useful, they do not reach the same level of engagement or learning depth perceived in interactive methods. This visual gap stresses the need to balance engagement with substance when integrating technology in education.

In contrast, while gamification has significant effect in learning, the study of Rodrigues et al. (2022) [22] revealed that gamification's impact follows the novelty effect or the initial interest of a person or excitement which subdue overtime as the newness wears off. This highlighted the importance for educators to reflect and be creative or innovative by considering how long the impact of the used gamification will last and how long does it will take to recover after noticeable reduction in benefits. The results align with the findings of Diaz and Estoque-Loñez (2024) [23] who conducted a study on gamification. Their study reviewed fifteen empirical studies published between 2018 and 2022, examining the impact of gamification across five moderator variables. It was also revealed that gamification meaningfully and significantly related to the student performance. However, analysis revealed that the five moderator variables did not exhibit statistically significant effects. The results of the research lead to believe that gamification is effective in academic courses at all levels in the Asian context.

7 CONCLUSIONS

The analysis revealed several key findings regarding students' awareness of SDGs and the role of technology integration in supporting knowledge, attitudes, and practice:

1) Most students segmented as Cluster 1 are relatively aware and engaged with SDG-related concepts and actions while a notable minority segmented as Cluster 2 requires additional support and intervention.
2) The results of the structural equation modeling (SEM) analysis provide compelling evidence for the significant role of Knowledge in shaping both Attitudes and Practices related to sustainable development goals (SDGs). The positive association between Knowledge and both Attitude ($\beta = 0.918$) and Practice ($\beta = 0.634$) suggests that individuals with higher knowledge about SDGs tend to exhibit more favorable attitudes and engage in more sustainable practices.
3) Among all the roles of technology integration, interactive learning consistently scores the highest which suggests that it is the most important due to its engaging and participatory nature that promotes active involvement.
4) There is a significant positive relationship between Knowledge, Attitude, Practice, and various technology integration variables (Interactive Learning, Gamification, Video-Based Learning, Project-Based Learning).
5) The SEM model suggests that Technology Integration (Exogenous1) has a positive impact on KAP (Knowledge, Attitude, and Practice), with Project-Based Learning being the most influential component of technology integration.
6) Interactive learning has the most important role while gamification, specifically the indicator that states consistently lags highlighting a potential gap in its educational impact.

8 RECOMMENDATIONS

It is recommended that the use of technology, particularly in interactive and project-based learning environments, contributes positively to students' knowledge, attitudes, and practices. This study highlights the significance of technology integration in the classroom settings to enhance learning outcomes but also suggests that further refinement of the model.

To address the gaps of different clusters, teachers can use strategic intervention framework for curriculum instruction based on Vygotsky's Principles. This will provide support enrichment, guided by sociocultural learning theory. For Lower Cluster the instructional focus is on the foundational understanding of SDGs and Globalization. Educators can approach this through scaffolded learning using ZPD. Interactive digital tools such as videos and gamified modules can be utilized with structured prompts for modeling and guided practice. While those on the higher cluster can challenge their critical thinking through capstone projects where they can do policy analysis or digital advocacy campaign. This approach is based on social constructivism learning theory where learning as a social process includes peer collaboration a culturally relevant tools to support deeper understanding).

Since the study was conducted in a Philippine context, it is recommended that CHED and other

HEIs institutionalize the integration of SDG-based performance tasks within the general course specifically The Contemporary World. This may include revision of syllabi to include outcomes-based projects aligned with SDGs, training programs for faculty and administrators on sustainability education and the adoption of digital pedagogical tools to develop greater global awareness and civic responsibility.

Moreover, consistent implementation of monitoring and evaluating mechanisms are necessary to assess effectiveness of SDG integration in course delivery. This will ensure a positive impact on students' knowledge, attitudes, and practices regarding sustainable development.

For teachers, it is highly recommended that they to continue Professional Development Initiatives (PDIs) through In-Service Trainings (INSETs), particularly on the unique goals and content of The Contemporary World course. These trainings will support teachers in enhancing learning materials and digital resources aligned with SDG-related themes. Integration of interactive learning tools, gamification techniques, video-based instruction, and project-based learning are effective ways to enhance students' engagement and global awareness.

Additionally, such training can help educators assess how they can effectively utilize these technologies in key topics of TCW emphasizing related SDGs. It will enable them to deliver more contextualized, meaningful and socially responsive instruction leading to students' development of actionable solution to global issues. Consequently, these trainings can serve as learning avenues for teachers to enrich their own understanding of SDGs which is essential for the genuine, informed, and meaningful delivery of lessons. It is a holistic approach that ensures educators are not only equipped with the right tools but are also well-grounded in the principles and purpose of sustainable development.

Finally, further studies are encouraged to replicate this research across different educational contexts and academic levels to validate the findings and explore additional dimensions of effective educational interventions. Replication may be extended in the context of Environmental Science, English language and Literature and other subjects where SDGs are highly relevant. This encourages interdisciplinary approaches from various perspectives that can enrich pedagogy promoting critical thinking and problem solving, and global awareness. Replication and expansion of the study will help ensure broader applicability and continuous improvement of education in line with both national standards and global commitments.

This study primarily focused on student's level of awareness and understanding of SDGs. Future research may shift the lens towards educators—assessing the depth of teachers' understanding of SDGs and their readiness to deliver meaningful lessons aligned with the global goals. Investigating teachers' pedagogical preparedness could offer insights to capacity-building needs and contribute to the improvement of current curriculum.

Moreover, while the study highlights the positive attitudes of students toward technology integration in achieving SDG-related learning, future studies may also look at the practical challenge of implementing such integration. In the context of the Philippines, questions of technological readiness, access to facilities, availability of possible educational tools must be look at. Investigating these barriers may inspire initiatives of meaningful collaborations between HEIs, policymakers, and educational technology providers to develop sustainable, inclusive digital learning ecosystems.
