Keywords: Fair Payment Systems; Smart Contracts; IPFS (Interplanetary File System); Off-Chain Storage; Decentralized Storage.

Abstract: Blockchain-based fair payment systems have gained considerable attention due to their potential to facilitate transparent, secure, and automated transactions. However, managing large-scale digital assets directly on-chain is impractical due to blockchain scalability constraints, high transaction fees, and limited storage capacities. Existing solutions often employ centralized cloud-based storage services for off-chain data, introducing trust dependencies, censorship risks, and undermining core decentralization objectives. This paper presents a preliminary exploration into integrating the InterPlanetary File System (IPFS) a decentralized, peer-to-peer storage protocol with blockchain smart contracts to enable fully decentralized off-chain storage for fair payment systems. We propose a conceptual model leveraging IPFS to ensure verifiable data delivery, automated dispute resolution, and trustless payment settlements. Preliminary qualitative analysis and comparative evaluations highlight substantial improvements in decentralization, transparency, and resilience compared to traditional cloud-based approaches. Our results demonstrate the feasibility and potential advantages of employing IPFS in blockchain payment frameworks, paving the way for truly decentralized digital asset management and exchange systems.

1 INTRODUCTION

Blockchain technology has profoundly reshaped digital transactions, enabling trustless, transparent, and secure payment processes without relying on central authorities or intermediaries [1], [2]. Decentralized payment systems, leveraging blockchain smart contracts, have gained significant attention for their potential to automate financial exchanges, eliminate fraud, and enhance transparency in various digital economies. However, one persistent challenge in realizing truly decentralized blockchain-based applications (dApps) is efficiently managing the storage and distribution of substantial digital assets, as direct on-chain storage remains impractical due to inherent scalability constraints, limited block sizes, and high transaction costs [3], [4].

To work around on-chain limits, many "decentralized" payment systems quietly park their off-chain data in a regular cloud bucket think S3 or GCS while the chain stores only a pointer or hash [5]. It's hard to argue with the convenience: elastic storage, global CDNs, familiar APIs, and a bill that (usually) makes finance happy. But the trade-offs are familiar, too. A single account suspension, a region hiccup, or an ACL misconfiguration can take data offline. Takedown requests and policy changes can nudge toward de-facto censorship. And unless versioning and audit trails are enforced and actually monitored subtle tampering may slip by [6], [7]. All of that sits uneasily with what blockchains were supposed to buy us. These central points of control and failure appear to undercut resilience, fairness, and the neutrality we expect from a decentralized payment system. The approach works, yes – but it bends the architecture back toward the very trust assumptions it set out to avoid.

Decentralized off-chain storage most visibly IPFS has been gaining traction as an alternative to parking data in a single cloud account. IPFS runs over a peer-to-peer network and uses content addressing: every file is referenced by a CID (essentially the hash of its bytes), so if the content changes, the CID changes too. That setup makes tampering easy to spot and, in many cases, hard to get away with; it also appears to blunt

platform-level takedowns since copies can live on independent nodes rather than one provider [8], [9]. It isn't magic, though. Availability depends on pinning and who's actually hosting the data – teams often pin to a couple of providers and keep a local node as a backstop. Even with those caveats, recent work has used IPFS for decentralized sharing, archival records, and computation pipelines, reporting advantages over traditional cloud models in integrity checks and resilience to outages [10], [11]. However, few studies systematically integrate IPFS with blockchain-based payment protocols, particularly regarding automated payment settlement and dispute resolution, thus leaving critical gaps unresolved.

Motivated by these considerations, this paper presents a novel approach that integrates IPFS as decentralized off-chain storage with blockchain-based smart contracts to establish an end-to-end fair payment system. The proposed framework aims to ensure trustless verification, transparent settlement, and automated dispute management while eliminating reliance on third-party storage providers. Specifically, this research provides the following key contributions:

- A detailed conceptual model demonstrating how IPFS can be integrated seamlessly with blockchain-based payment mechanisms.
- Qualitative analysis highlighting the advantages, feasibility, and potential limitations of the proposed decentralized storage approach compared to traditional cloud-based solutions.
- A preliminary scenario illustrating dispute resolution processes within the IPFS-based fair payment system, supported by conceptual diagrams and comparative tables.

The remainder of the paper is structured as follows: Section II defines the problem context and motivation, Section III reviews related literature, Section IV describes the proposed architecture and methodology, Section V presents preliminary findings and analysis, and Section VI concludes with future directions.

2 PROBLEM DEFINITION

Blockchain-based payment systems have attracted considerable attention due to their potential to enable transparent, secure, and automated financial transactions without reliance on central intermediaries [1], [2]. Nevertheless, decentralized applications (dApps), particularly those designed for fair payment and digital asset management, frequently require storing and managing large-scale or complex data. Directly storing such data on-chain is impractical due to blockchain limitations such as restricted block sizes, limited scalability, and prohibitive transaction costs [3], [12]. As a result, existing decentralized payment systems typically utilize centralized cloud services for off-chain storage to alleviate these constraints and reduce blockchain-related expenses as depicted in Figure 1 [5] [13].

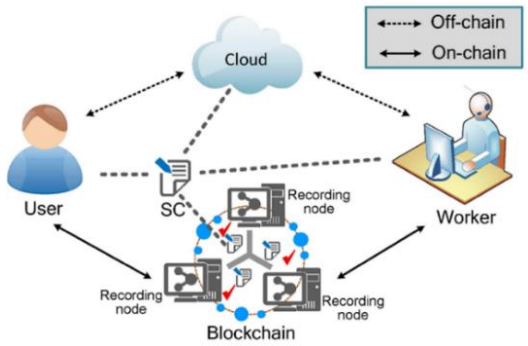

Figure 1: Decentralized payment systems relying on centralized cloud services for off-chain storage.

Cloud services scale nicely and are easy to use, but leaning on a single provider sits awkwardly with the goals of decentralization, transparency, and minimizing trust [14]. A suspended account, a misconfigured bucket policy, or a regional outage can knock data offline; takedown requests and shifting terms can amount to soft censorship [15]. You also inherit new trust anchors provider admins, access keys, internal ACLs the very stuff blockchains try to avoid. And while clouds promise high durability, they don't, by default, give you content-addressed proofs or independently reproducible audit trails; long-term integrity, availability, and verifiability become policy claims rather than cryptographic facts. That gap complicates disputes and appears to leave fair-payment flows exposed to manipulation missing files, swapped blobs, or back-dated uploads are hard to rebut without external evidence [16].

There's still a stubborn gap: an off-chain storage layer that preserves the same decentralization, censorship resistance, and minimal trust that blockchains promise on-chain. To chip away at that gap, we explore wiring IPFS a decentralized, peer-to-peer, content-addressed protocol directly into smart contracts [17], [18]. The idea is simple enough. Let the chain commit to CIDs while the actual bytes live off-chain. Verification then boils down to fetching the content for that CID and checking a signature, which

appears to give a practical, scalable, and easily verifiable path for settling payments without leaning on a single provider. Two caveats are worth flagging. Availability hinges on pinning and replication policies, and access control usually comes from encryption and key management rather than IPFS itself. Even with those reservations, the approach keeps the trust budget small and the system closer to the decentralization we set out to maintain.

3 RELATED WORK

Blockchain-based fair-payment schemes have become a go-to way to keep exchanges transparent and automated without leaning on a trusted middleman. The proposals cover a lot of ground: payment atomicity via conditional transfers or HTLC-style locks, stronger security with verifiable proofs, and fee cuts through batching or off-chain channels. A representative example is Zhang et al. [16]. Their protocol made the payment flow harder to break and, on paper, more dependable. Still, the design parked outputs in a centralized cloud bucket (think S3 or GCS) while the chain stored only references. That choice is understandable it's cheap and widely supported but it also nudges the system back toward a single provider and, by extension, appears to dilute the decentralization the blockchain layer is supposed to guarantee.

To sidestep the chain's storage ceiling, a lot of recent work parks off-chain data in regular cloud services – think S3 buckets or GCS blobs while the blockchain keeps only a pointer or hash [16], [19]. It's convenient and cheap, sure, but it appears to smuggle trust back in: an account suspension, a regional outage, or a sloppy bucket policy can take data offline; takedown requests can edge into soft censorship; and "integrity" often boils down to provider logs rather than cryptographic facts [18]. These cracks suggest we still need to look harder at decentralized, durable off-chain storage that fits blockchain assumptions systems where availability comes from replication, integrity comes from content addressing, and long-term verifiability doesn't hinge on a single company's dashboard.

Recent works have explored decentralized storage technologies such as the IPFS and Swarm to mitigate these challenges. Kumar et al. [4] presented an in-depth analysis of IPFS and Swarm, highlighting their compatibility with blockchain systems, especially emphasizing immutability and secure storage. Similarly, Benisi et al. [17] conducted a comparative assessment of IPFS and Swarm, emphasizing blockchain interoperability and the ability to guarantee data integrity in decentralized contexts.

Researchers have started leaning on decentralized storage mainly IPFS and, in some settings, Swarm to get around the obvious limits of parking data with a single provider. Kumar et al. [4] take a close look at both systems and argue they line up well with blockchain assumptions: content addressing helps you spot tampering, and data can live on multiple nodes rather than one vendor. Benisi et al. [17] offer a side-by-side comparison and come to a similar place, stressing interoperability with on-chain logic and the ability to verify that what you fetched is exactly what was written. That said, neither system is plug-and-play perfection. Availability still depends on who pins or incentivizes storage, and real-world latency can wobble with network churn. Even so, these studies appear to suggest that IPFS and Swarm are a better fit for decentralized workflows than a lone cloud bucket, especially when integrity and auditability matter.

Casino et al. [7] take a hard look at what "immutability" really buys you in decentralized storage and where it can bite. Freezing content by hash doesn't stop abuse; it can, in some cases, make takedowns messy. Once a harmful CID circulates, anyone can repin it, gateways may block inconsistently, and legal accountability gets murky. The authors highlight issues like malicious content dissemination, "poisoned" hashes used for harassment or denial-of-service, and the awkward linkability of CIDs to sensitive material. They also sketch practical mitigations: encrypt data client-side and manage keys off-chain; apply clear pinning policies; maintain gateway deny-lists with transparent audit logs; and design incentives that discourage hosting flagged content on IPFS-style networks. The bigger lesson appears to be that pairing decentralized storage with blockchains doesn't make safety a given you still need to engineer for abuse cases, compliance, and the tension between permanence and the need to remove harmful material.

Moreover, not all next-generation peer-to-peer data networks have embraced blockchain integration, due to concerns such as scalability and latency. Naik and Keshavamurthy [20] provided a general review of modern peer-to-peer (P2P) networks, analyzing the evolution of classical systems (e.g., BitTorrent, Chord) and newer models, with particular attention to their performance characteristics under node churn conditions. Notably, their classification categorizes IPFS as a classic P2P network. However, other recent perspectives suggest IPFS and similar technologies have significantly evolved, incorporating incentive

mechanisms and decentralized data management techniques that extend beyond traditional P2P models [9].

In terms of incentive mechanisms specifically designed for decentralized storage and delivery, Tit-for-Token (2023) presented peer incentivization protocols for IPFS-based systems, introducing economic models to foster resource sharing and fair compensation among peers [11]. Similarly, FileInsurer (2022) proposed mechanisms layered atop IPFS to enhance reliability through economic guarantees and deposit-based compensation models for data availability [21].

Despite the breadth of existing work, comprehensive solutions integrating decentralized off-chain storage with automated, blockchain-based fair payment remain limited. Few studies explicitly tackle challenges around dispute resolution, verification mechanisms, and persistent data availability when employing decentralized storage like IPFS. Thus, a gap remains in systematically combining these critical elements to form robust, decentralized payment systems.

We tackle the gap with a single, end-to-end path: wire IPFS directly into smart contracts so the chain commits to CIDs while the bytes live off-chain. That way, anyone can check what was stored (and when), payments settle under rules you can actually audit, and disputes run as code timeouts, bonds, compact proofs instead of going through a help desk. The aim is straightforward: keep trust out of the critical path, scale with rising job counts, and stay resilient when parts of the network wobble. It won't solve everything pinning policies and key management still matter but this unified approach appears to move fair-payment systems closer to the decentralization they promise, with verifiable storage, transparent settlement, and automated dispute handling that's practical in the real world.

4 IPFS AS OFF-CHAIN STORAGE

Much of the recent literature OBFP [13] and EFP [5] are typical keeps the bytes in a cloud bucket (think S3 or GCS) and writes only a hash or pointer to the chain to dodge storage fees. Pragmatic? Absolutely. It scales, ops teams know how to run it, and the bill is predictable. But the fit with blockchain's goals is shaky. Handing availability to a single provider quietly brings back a trusted third party: account suspensions, region outages, or an ACL slip can make data vanish, and takedown requests can act like soft censorship. Integrity, too, becomes a matter of provider logs and policies rather than end-to-end cryptographic proofs. That appears to undercut the very properties these payment systems claim to prioritize trustlessness, transparency, and resilience. None of this means clouds are "wrong" in every case; a hybrid setup (e.g., dual-cloud storage with periodic on-chain anchoring) may ease operations. Still, for fair-payment designs that aim to be genuinely decentralized, reliance on centralized infrastructure looks like a step back, not forward.

To tackle this limitation, we use IPFS as the off-chain storage layer, following the direction of Rani et al. [22], and Ma et al. [23]. The goal is straightforward: keep storage trustless and hard to censor while still scaling to real job sizes. With content addressing, the chain commits to a CID and the bytes live off-chain; if the file changes by even a single bit, the CID flips, which makes tampering obvious. Practically, this appears to cut our reliance on any single provider and helps with availability when multiple parties pin the same data (e.g., worker, client, and a small pinning service). It also shifts weight off the blockchain CIDs and small receipts on-chain, large artifacts on the P2P network which is likely to lower fees and keep state growth in check. Cloud buckets (S3/GCS) can be faster in some regions and are undeniably convenient, but they reintroduce a trust anchor we're trying to avoid. There are a few knobs to get right. IPFS doesn't do access control by itself, so sensitive outputs are typically encrypted client-side and keys managed off-chain. Pinning and replication policies matter, too; without them, availability can drift. Even with those caveats, replacing centralized off-chain storage with IPFS strengthens resilience and censorship resistance, and by distributing data across peers improves scalability and cost efficiency without bloating the chain.

The contribution of integrating IPFS into decentralized payment systems is a principled model for off-chain data management that advances trustlessness, transparency, and system autonomy. Conventional models often handle only the payment process on-chain while depending on centralized or semi-centralized repositories for off-chain data, introducing single points of failure, potential censorship, and weaker integrity guarantees. In the proposed design, IPFS serves as the off-chain storage layer that complements smart contracts managing fair payments. When a provider generates digital content or service outputs, the data are uploaded to IPFS, which fragments and distributes them across the peer-to-peer network. IPFS assigns a unique content hash (CID) that acts as an immutable, verifiable identifier; the provider then submits this CID to an on-chain

smart contract. The client can independently retrieve and verify the content from IPFS, ensuring it has not been altered. Figure 2 illustrates data availability in IPFS; reliable access depends on file pinning by one or more network nodes. Overall, the proposed approach not only mitigates the weaknesses of traditional off-chain storage models but also enhances the reliability, security, and efficiency of decentralized payment systems for outsourced service providers.

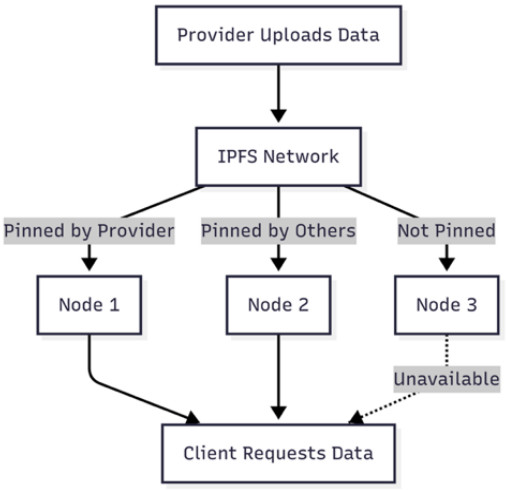

Figure 2: Illustration of data availability in IPFS that upload by service provider.

5 RESULTS AND DISCUSSION

This study presents a preliminary exploration of integrating IPFS as an off-chain storage solution within decentralized fair payment systems. Given the conceptual and prototype nature of the work, the results focus on the qualitative assessment of system behavior, feasibility, and anticipated advantages over traditional cloud-based approaches.

5.1 Feasibility and System Behavior

Through a prototype implementation and scenario analysis, the proposed model demonstrates several critical improvements. By leveraging the content-addressed architecture of IPFS, the system ensures data integrity and tamper-evidence without the need for trusted third parties. In the illustrative scenario of digital asset exchange, the provider uploads content to IPFS and submits the resulting hash to a blockchain smart contract. The client retrieves the file directly from IPFS using the hash, verifies its authenticity, and only then triggers payment release through the contract. This workflow depicted in Figure 3 confirms the model's capacity to automate fair settlement and transparent data verification.

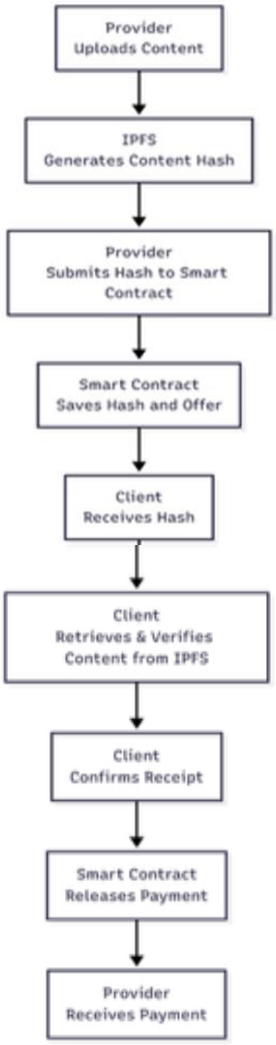

Figure 3: Automated fair settlement and transparent data verification workflow using IPFS and blockchain smart contracts.

5.2 Comparative Analysis

A qualitative comparison with conventional cloud-based off-chain storage models is presented in Table 1. The analysis highlights that, unlike centralized solutions, the IPFS-based model eliminates single points of failure and enhances censorship resistance. Furthermore, payment settlement and content verification are entirely automated and transparent via the smart contract,

significantly reducing operational risks. However, challenges remain regarding persistent data availability on IPFS, which depends on effective pinning and incentivization strategies. Retrieval latency was also identified as a variable factor, suggesting the need for further optimization in production-scale deployments.

Table 1: A qualitative comparison with conventional cloud-based off-chain storage models is presented and IPFS-Based Model.

Feature/Aspect	IPFS-Based Model (Proposed)	Cloud-Based Off-Chain Storage
Decentralization	Fully decentralized, peer-to-peer	Centralized (single/multi-cloud)
Data Integrity	Guaranteed by content hash (immutable)	Depends on provider
Payment Settlement	Automated via smart contract, trustless	Relies on third party logic
Censorship Resistance	High (difficult to remove data)	Low (provider can censor/delete)
Scalability	High, distributed across many nodes	Limited by provider infrastructure
Storage Cost	Minimal on-chain cost, pay for pinning	Pay-per-use or subscription
Data Availability	Requires persistent pinning/incentives	Guaranteed by provider SLAs
Transparency/Auditability	Fully transparent on blockchain	Limited to provider's reporting

5.3 Conceptual Findings

The conceptual results indicate that the integration of IPFS addresses key limitations of previous architectures. Specifically, the system:

- Reduces reliance on centralized infrastructure and trusted intermediaries.
- Guarantees data authenticity through content-addressed storage.
- Supports automated, trustless payment and dispute resolution.
- Provides robust transparency and auditability for all transactions.

5.4 Dispute Scenarios

The proposed IPFS-based fair payment model anticipates several principal dispute scenarios and incorporates dedicated resolution mechanisms to address each case, as detailed in Table 1. For instance, if data is not accessible on IPFS, the smart contract is designed to withhold payment and automatically trigger a refund or invoke timeout logic to protect the client. In cases where the content hash does not match the expected data, payment is withheld, and the client may explicitly reject the transaction or initiate a dispute process [18]. The system also addresses scenarios where a user falsely claims non-delivery by requiring explicit confirmation of receipt, with provisions for auditor intervention when necessary (Table 2), [24]. Additionally, slow or intermittent data retrieval is managed through timeout policies, allowing users to retry or abort the transaction as appropriate. Figure 4 show Dispute resolution process Payment is only released upon client confirmation of data retrieval, with timeouts and optional auditor intervention for unresolved cases. Finally, any attempt by the provider to submit a fake or malicious hash is counteracted by robust content hash verification within the contract, ensuring transparency and auditability using the algorithm shown in Figure 5. Collectively, these mechanisms provide an automated, fair, and trustless approach to dispute resolution, significantly enhancing the security and reliability of the decentralized payment framework.

Table 2: Common dispute scenarios and resolution mechanisms in the proposed IPFS-based fair payment model [18], [24].

Dispute Scenario	Model's Resolution Mechanism
Data not accessible on IPFS	No payment released; refund or timeout logic triggers
Content hash does not match expected data	Payment withheld; client can reject or trigger dispute
User falsely claims non-delivery	Requires explicit confirmation; possible auditor check
Data retrieval is slow or intermittent	Timeout policy; user may retry or abort transaction
Provider submits fake or malicious hash	Content hash verification prevents payment; transparency for auditing

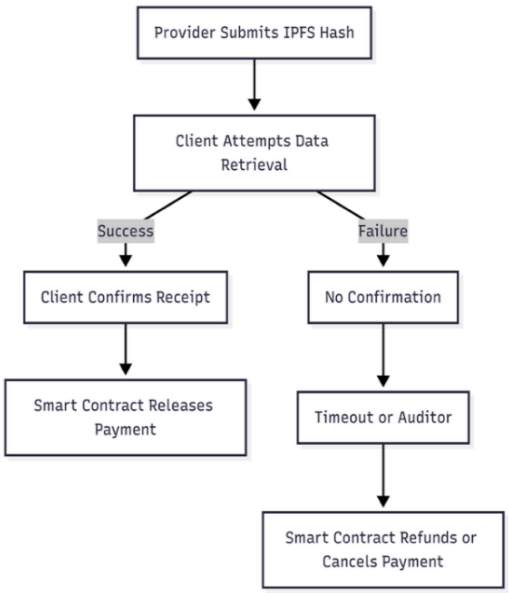

Figure 4: Workflow of dispute resolution process in the IPFS-based fair payment model.

```
Algorithm 1: Dispute Resolution in IPFS-
Based Fair Payment System

Input:
    ipfs_hash      // Content hash provided
by Provider
    timeout        // Maximum time for client
confirmation

1:  Provider submits ipfs_hash and initiates
payment via SmartContract

Client after timeout
15:     end if
16: end if

17: SmartContract logs dispute and
resolution status on-chain
```

Figure 5: Pseudocode Representation of the Dispute Resolution Mechanism in the Proposed IPFS-Based Model.

We deployed a minimal escrow contract on Ethereum Sepolia and integrated it with IPFS for off-chain asset addressing. Using the CID QmPtUE…K44j, contract deployment consumed 978,042 gas (5.57 s), while the createDeal and confirmAndPay functions required 186,418 gas (10.85 s) and 61,843 gas (11.51 s), respectively. Complementary local IPFS measurements for ~1 MB assets showed sub-0.03 s upload and ~0.005 s retrieval times with SHA-256 verification. These results, summarized in Table 3, demonstrate efficient content-addressed storage and verifiable retrieval, supporting the feasibility of automating fair settlement conditioned on IPFS-based data verification, with on-chain costs concentrated in the initial deployment and escrow creation steps.

Table 3: Experimental results of escrow contract deployment and IPFS integration.

Operation	Resource/Asset	Gas Used	Time (s)
Contract Deployment	Escrow contract on Sepolia	978,042	5.57
CreateDeal	CID QmPtUE…K44j	186,418	10.85
ConfirmAndPay	CID QmPtUE…K44j	61,843	11.51
IPFS Upload	~1 MB asset	–	0.03
IPFS Retrieval	~1 MB asset	–	0.005

Figure 6. End-to-end prototype: (1) client uploads asset to IPFS and obtains CID; (2) escrow smart contract records CID and funds; (3) client verifies asset off-chain; (4) on successful verification, confirmAndPay releases payment; otherwise, a dispute/timeout path halts payout.

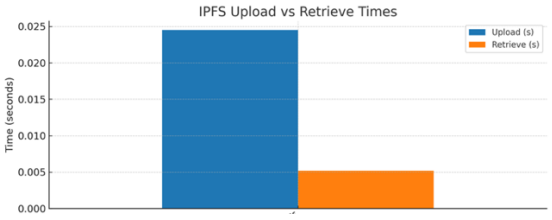

Figure 6: End-to-end prototype of upload and retrieve times.

Nevertheless, it is acknowledged that practical deployment will require additional mechanisms to ensure reliable long-term storage and efficient access, particularly for large or highly dynamic datasets. In summary, these findings support the conclusion that integrating IPFS with blockchain-based payment logic is a promising pathway for building scalable,

transparent, and fully decentralized fair payment systems. Future work will focus on quantitative performance benchmarking, incentive designs for storage reliability, and broader evaluation across diverse application scenarios.

6 CONCLUSIONS

This paper has presented a preliminary exploration of integrating the IPFS as a decentralized off-chain storage solution within blockchain-based fair payment systems. By addressing the limitations of centralized cloud storage, the proposed model leverages IPFS's content-addressed, peer-to-peer architecture to enhance data integrity, transparency, and censorship resistance. The integration of blockchain smart contracts with IPFS enables automated, trustless settlement and robust dispute resolution without reliance on third-party intermediaries. Qualitative analysis and scenario-based evaluation demonstrate that the model effectively mitigates common dispute scenarios and delivers substantial improvements in decentralization and security compared to conventional approaches. The study demonstrates the important and effective role of IPFS as off-chain storage approach in scalable the reach of blockchain applications to make them fully decentralized and trustless. Future work will focus on quantitative performance evaluation, large-scale prototype deployment, and the development of advanced incentive and persistence strategies to further strengthen reliability and practical applicability in real-world decentralized payment systems.

Keywords: Smart Power Grid, Intrusion Detection, AdaBoost Algorithm, Particle Optimization Algorithm.

Abstract: In recent years, cyber-attacks targeting the physical infrastructure of modern power systems have significantly increased, posing serious risks to society and critical services. This study investigates intrusion detection in smart grids using a hybrid approach based on Particle Swarm Optimization (PSO) and the AdaBoost ensemble classifier. To enhance detection performance, data preprocessing techniques, including handling missing values and normalization, were applied. Subsequently, PSO was utilized for feature selection, reducing the original feature set from 40 to 30 optimal attributes. These selected features were then used as input to the AdaBoost classifier. The ensemble learning mechanism of AdaBoost combines multiple weak learners to improve classification reliability by focusing on misclassified instances and aggregating their outputs. This approach enhances detection capability compared to individual classifiers. Experimental results demonstrate that the proposed method achieves an accuracy of 92.9% on the test dataset, outperforming the baseline method by approximately 3%, which confirms the effectiveness of combining feature optimization with ensemble learning for smart grid intrusion detection.

1 INTRODUCTION

Smart grids represent a cyber-physical infrastructure in which communication networks are tightly integrated with physical power systems to enable efficient monitoring, control, and energy distribution [1], [2]. While this integration enhances operational efficiency, it also increases exposure to cyber-attacks that may result in severe physical, economic, and social consequences [3]. Unlike conventional communication networks, cyber intrusions in smart grids can directly affect power availability, system stability, and public safety [4].

Traditional security mechanisms such as firewalls, encryption, and authentication play an essential role in protecting communication infrastructures; however, they are insufficient to address sophisticated and previously unknown cyber threats [5], [6]. Consequently, Intrusion Detection Systems (IDSs) have become a critical component of smart grid security architectures, aiming to monitor system behavior and identify malicious activities that bypass preventive defenses [7], [8].

Despite their importance, the effectiveness of IDSs in smart grid environments is often limited by high-dimensional data, redundant features, and increased false alarm rates, which reduce detection reliability in real-world operational settings [9], [10]. To overcome these limitations, several detection paradigms have been proposed, including signature-based, anomaly-based, and description-based intrusion detection methods that focus on modeling normal system behavior [11], [12], [13].

In recent years, ensemble learning techniques have attracted increasing attention due to their ability to improve classification robustness by combining multiple weak learners [17], [18]. Among these techniques, AdaBoost has demonstrated effectiveness in reducing classification errors and variance. Nevertheless, the performance of ensemble classifiers remains highly dependent on feature quality and dimensionality, making feature selection

a critical step in intrusion detection systems [16], [19].

To address these challenges, this study investigates a hybrid intrusion detection approach that integrates Particle Swarm Optimization (PSO) for feature selection with the AdaBoost ensemble classifier [16], [20]. PSO is employed to select a reduced and informative subset of features, which is then used as input to the AdaBoost classifier to enhance detection accuracy while reducing false alarms. The effectiveness of the proposed approach is evaluated using the NSL-KDD benchmark dataset.

2 CONTRIBUTIONS OF THIS STUDY

The main contributions of this study can be summarized as follows:

- This study proposes a hybrid intrusion detection framework for smart grid environments by integrating Particle Swarm Optimization (PSO) for feature selection with the AdaBoost ensemble classifier.
- The proposed approach demonstrates that reducing the feature space prior to classification improves intrusion detection accuracy and reduces false alarm rates.
- An experimental evaluation is conducted using the NSL-KDD benchmark dataset, providing insight into the effectiveness and limitations of optimization-based ensemble learning for smart grid intrusion detection.

3 RELATED WORKS

Previous studies explored signature-based IDSs, which are effective for known attacks but limited in detecting unknown threats [13], [25]. Anomaly-based IDSs have been developed to be capable of detecting novel intrusions but are prone to high false alarms [12], [22]. Recent advancements introduced description-based IDSs to model system behaviors in detail [15].

In smart grids, IDSs have been classified into Host-based (HIDS), Network-based (NIDS), and Distributed architectures [14], [27]. Studies employing machine learning and optimization techniques, including neural networks, decision trees, and whale optimization algorithms, highlight the promise of hybrid approaches [28], [18], [19]. However, limitations remain in scalability, accuracy, and adaptability [29], [30], [31].

In the last few years, cyber-attacks on the physical infrastructure of smart electricity systems have increased [3], [20]. If such attacks are carried out successfully, they can cause many problems in people's lives. The prevalence of such attacks has raised concerns about the security of sensitive infrastructure [9], [10]. Therefore, despite these attacks, the use of intrusion detection in smart electrical systems has become necessary [7], [8]. If intrusion detection is performed in a network using more than one method, it will detect new attacks and reduce the rate of incorrect and false alarms of one detection method by using another detection method [17]. According to the mentioned cases, in order to detect intrusion in the power grid, we employed the AdaBoost algorithm and the particle swarm optimization algorithm.

4 METHODOLOGIES

AdaBoost was employed as an ensemble classifier to combine multiple weak learners, where each learner focused on misclassified instances from previous iterations. This approach improved detection stability after feature reduction using PSO [16], [17].

In this work, it is proposed to use the AdaBoost classifier to achieve the goal of increasing detection accuracy in order to detect intrusion in smart grids. The advantage of this approach over other methods is that this algorithm is an ensemble learning method. In ensemble learning algorithms, an example is classified using several different classifiers, and the result of the classification is intelligently combined with each other, and the final result is determined for that specific example [26]. The accuracy and performance of this algorithm is higher compared to traditional and deep classification algorithms, because the general result is obtained from several classifiers. This algorithm has reduced the error and variance of training data.

In ensemble learning algorithms, each classifier is trained with a randomly selected subset of all samples. With the formation of several different classifiers, the final classifier, which is the result of a collective view, contains more efficiency [17]. Also, to increase the efficiency of this classifier, we intend to select the best features using the particle swarm optimization algorithm, and then the selected features will be provided to the classifier as input [16].

5 PROBLEM STATMENT

Smart power grids are a very important issue in order to meet future energy needs [1]. In order to achieve higher efficiency, which is the goal of energy distribution networks of future generations, it is necessary to create a centralized energy source by integrating various distributed power plants, and to continuously manage and monitor energy production and consumption [23], [24]. In order to successfully accomplish this, it is very important to use special network monitoring techniques and utilize specialized application software [2].

Smart grid is a term that includes various aspects of modern electric power transmission and distribution networks [1]. In order to become familiar with the basic concepts of the smart grid, we will state some definitions that have been provided by reliable institutions:

The European Smart Grid Task Force and the SG European Technology Platform define smart grids as follows: electric grids that efficiently monitor the operation of all users of this grid, including generators, consumers, and production and consumption systems, in order to ensure high economic efficiency, stability of a powerful network with the lowest losses and the highest quality, security, and convenience of energy production [23].

In the United States, the U.S. Department of Energy's Power Transmission and Distribution Administration defines the future energy grid as: a network of digital technology used to increase the reliability, security, and efficiency of electric power systems [23]. This action is possible by using information exchange, distributed generators, and energy storage resources. These systems are created by using two-way communication technology and complex computer processes [2], [24].

According to the above definitions, telecommunication technology and information systems are very important in smart grids. For example, computer-based remote control, monitoring processing, industrial automation, two-way communication between producer and consumer, and smart meters are among its components [1], [2]. Therefore, it can be stated that the smart power grid is actually a vast telecommunication and communication network that deals with energy production, transmission systems, and small and large networks located at the end of the line.

As with any communication network, network security is one of the important requirements in the communication infrastructure of smart networks, and it can be considered one of the biggest challenges of implementing smart power grids [3], [9]. Whenever the security of these networks is compromised, all the components of this smart network will be at risk and the provision of its services will be difficult [4], [10]. A problem in providing service in a part of smart networks means the power outage of several houses, factories, or even a city and several power plants being out of service. Considering the role that electricity has in people's lives, this issue has many serious consequences [1], [20].

6 DISCUSSIONS

The experimental results obtained in this study indicate that integrating PSO-based feature selection with the AdaBoost ensemble classifier enhances intrusion detection performance in smart grid environments [16], [17]. Reducing the feature set from 40 to 30 features eliminated redundant and less informative attributes, enabling the classifier to focus on the most discriminative traffic characteristics.

The ensemble learning nature of AdaBoost played a key role in improving classification stability by combining multiple weak learners, which reduced variance and mitigated misclassification errors [17]. This behavior is particularly beneficial in smart grid systems, where reliable and timely detection is critical due to the close interaction between cyber and physical components [15], [30].

Although the achieved accuracy of 92.9% demonstrates the feasibility of the proposed approach, the results should be interpreted in the context of the employed dataset and experimental setup. The findings confirm that optimization-based feature selection can effectively support ensemble classifiers in intrusion detection tasks, while also highlighting the importance of balanced evaluation beyond accuracy alone [17], [31].

7 LIMITATIONS AND FUTURE WORK

Despite the promising results achieved in this study, several limitations should be acknowledged. First, the experimental evaluation was conducted using a single benchmark dataset, which may not fully capture the complexity and diversity of real-world

smart grid traffic [29], [30]. Second, the proposed intrusion detection framework was evaluated in an offline setting, without considering real-time constraints or deployment challenges [7], [8]. Additionally, the PSO-based feature selection process prioritizes optimization performance over feature interpretability, making it difficult to directly associate selected features with specific attack behaviors [16].

Future work will focus on evaluating the proposed approach using real-world smart grid datasets [11], [18], extending the framework to multi-class attack scenarios [19], and investigating lightweight or adaptive optimization techniques suitable for real-time intrusion detection in large-scale smart grid infrastructures [28], [31].

8 RESULTS

The reported accuracy should be interpreted in the context of the NSL-KDD dataset and limited baseline comparisons. While the results demonstrate the feasibility of combining PSO with AdaBoost, broader comparisons with additional modern methods are left for future work. To check the effectiveness of the proposed method, we compared the results obtained from the test dataset of the proposed method with other methods reported in the baseline article, as summarized in Table 1. It should be noted that the dataset used in this work is the same as the dataset used in the baseline paper.

Table 1: Comparing the results of different methods with the proposed method.

Method	Accuracy	Precision
XGBOOST	89,15%	80,27%
LSTM_XGBOOST	89,21%	82%
AdaBoost+PSO	92,9%	88%

9 DATA SET USED

To evaluate the performance of the proposed intrusion detection system, accuracy, precision, and recall were employed as evaluation metrics [17], [31]. Accuracy was used to assess the overall effectiveness of the proposed PSO–AdaBoost framework in correctly classifying both normal and intrusive traffic. Precision was considered essential due to the critical nature of smart grid environments, where excessive false alarms may lead to unnecessary operational interventions [10], [30]. Recall was used to measure the system's ability to correctly detect actual intrusion instances, ensuring that malicious activities were not overlooked. These metrics were jointly analyzed to provide a balanced assessment of detection capability and system reliability [31].

10 CONCLUSIONS

The increasing dependence on electricity and the growing complexity of smart power grids highlight the critical importance of ensuring their security. Smart grids rely heavily on communication networks that enable two-way data exchange and integration of various system components. However, this interconnected and distributed structure also introduces new vulnerabilities, making such systems attractive targets for cyber-attacks. The integration of SCADA and ICT technologies further increases exposure to potential cyber risks.

To address these challenges, this study proposed a hybrid intrusion detection approach that combines Particle Swarm Optimization (PSO) for feature selection with the AdaBoost ensemble learning algorithm. After applying preprocessing techniques, including data cleaning and normalization, PSO was used to identify the most informative subset of 30 features from the original 40 features. The reduced feature set was then used to train the AdaBoost classifier, improving detection efficiency and reducing redundancy.

The results demonstrate that the proposed approach achieves a classification accuracy of 92.9%, outperforming the baseline method by approximately 3%. These findings confirm that integrating optimization techniques with ensemble learning can significantly enhance intrusion detection performance in smart grid environments.

Overall, the study highlights the potential of combining feature selection and ensemble methods as an effective solution for improving the security and reliability of modern smart power systems.

Keywords: Dynamic Systems, State-Space Models, Similarity Transformations, Scaling Methods, Electric Vehicles, Model Reduction, Control-Oriented Modeling.

Abstract: The increasing complexity of electric vehicle (EV) powertrains – integrating multi-domain interactions among traction motors, battery packs, and power electronics – demands mathematically rigorous yet computationally efficient modeling frameworks. This paper presents a structured review of the mathematical foundations for modeling and scaling of dynamic systems, with emphasis on EV applications. Three core analytical tools are examined in depth: 1) state-space representation as a unified multi-domain modeling formalism; 2) similarity transformations for complexity reduction while preserving essential system invariants such as eigenvalues, characteristic polynomials, and transfer functions; and 3) scaling techniques, including dimensionless parameterization and transfer function normalization, for cross-platform simulation efficiency. A structured mapping links these methods to specific EV subsystems: traction motors (4th–8th order systems), battery packs (2nd–10th order equivalent circuits), and power inverters (3rd–6th order systems), identifying the most appropriate scaling strategy for each. The reviewed framework supports scalable simulation, model-based diagnostics, and control system design, bridging high-fidelity physics-based models and computationally efficient representations required for real-time embedded applications. This paper serves as a foundational methodological resource for researchers and practitioners in EV engineering and control systems.

1 INTRODUCTION

The rapid global expansion of electromobility, driven by environmental regulation and the broader transition to sustainable energy, has substantially increased the engineering complexity of electric vehicle (EV) powertrain systems. Modern EVs integrate tightly coupled subsystems – traction motors, power electronic inverters, electrochemical battery packs, and mechanical drivetrains – each operating across different physical domains and timescales [1]. The co-simulation of these subsystems within a single unified framework represents a fundamental challenge in contemporary systems engineering.

Effective analysis, design, and validation of such multi-domain dynamic systems require mathematical modeling tools that are simultaneously expressive, computationally tractable, and scalable across a range of component sizes and operating conditions. Three methodological pillars have emerged as particularly relevant in this context: state-space representation, similarity transformations, and signal scaling techniques.

State-space models provide a compact and general formalism for representing linear and nonlinear dynamic systems of arbitrary order, enabling systematic treatment of controllability, observability, and stability [2]. Unlike transfer-function approaches restricted to single-input single-output (SISO) descriptions, state-space methods naturally accommodate multi-input multi-output (MIMO) configurations typical of EV powertrains, where cross-coupling between flux, torque, voltage, and current dynamics must be explicitly captured [3].

Similarity transformations constitute a second essential tool. By applying invertible coordinate changes in the state space, it is possible to decompose complex high-order systems into canonical or

decoupled forms, substantially simplifying analysis and controller synthesis while guaranteeing the preservation of fundamental dynamic invariants [4]. For EV motor models, this allows independent treatment of flux and torque channels; for battery models, it enables the isolation of dominant electrochemical modes.

Scaling and dimensionless parameterization form a third indispensable layer of the framework. When the same control algorithm must be deployed across motors of different rated powers, or when battery models must generalize across different cell chemistries, re-deriving the full mathematical model for each configuration is computationally prohibitive. Scaling techniques allow systematic reformulation of system equations into normalized forms, from which platform-specific models can be recovered by simple parameter substitution [5].

The integration of intelligent monitoring and condition-based diagnostics into EV operation further amplifies the need for scalable dynamic models. Real-time fault detection – whether based on spectral analysis, wavelet decomposition, or data-driven approaches – relies on efficient model representations that can be executed on embedded control hardware [6], [7]. Providing such representations without sacrificing physical fidelity is a central open problem in applied systems modeling.

This paper reviews the mathematical foundations underpinning these three modeling paradigms and demonstrates their structured applicability to EV components. Section 2 develops the theoretical framework, covering state-space models, the matrix exponential solution, transfer functions derived via the Laplace transform, and the formal theory of similarity transformations. Section 3 presents scaling methods and their canonical dimensionless formulations. Section 4 discusses the practical mapping of these methods to specific EV subsystems, supported by a comparative summary table. Section 5 concludes with recommendations for future research directions. This study reviews mathematical approaches to modeling and scaling of dynamic systems, with particular attention to their applicability in electric vehicle (EV) powertrain analysis.

2 MATHEMATICAL FRAMEWORK

2.1 State-Space Representation of Dynamic Systems

A continuous-time linear time-invariant (LTI) dynamic system is described in state-space form as:

$$\dot{x}(t) = Ax(t) + Bu(t),\ y(t) = Cx(t) + Du(t) \quad (1)$$

where $x(t) \in \mathbb{R}n$ is the state vector, $u(t) \in \mathbb{R}m$ is the input, $y(t) \in \mathbb{R}p$ is the output, and A, B, C, D are real system matrices of appropriate dimensions. Electrical, mechanical, thermal, and electrochemical subsystems of an EV.

2.2 Solution of the State Equation

The homogeneous solution $\dot{x} = Ax$ with initial condition $x(0) = x_0$ is derived from the power-series ansatz:

$$x(t) = \sum_{i=0}^{\infty} K_i t^i x_0 \quad (2)$$

Substituting into the differential equation and matching coefficients yields $K_i = A^i/i!$, so that the solution takes the form of the matrix exponential:

$$x(t) = e^{At}x_0 = \lim_{k\to\infty} \left(I + \frac{At}{k}\right)^k x_0 \quad (3)$$

In the discrete-time approximation with sampling interval h, this becomes:

$$x(t+h) \approx (I + Ah), x(t), x(0) = x_0 \quad (4)$$

Equation (4) constitutes the basis for numerical integration of state-space models and is directly implemented in simulation environments such as MATLAB/Simulink for real-time EV control applications [2].

2.3 Transfer Function Derivation via the Laplace Transform

Applying the Laplace transform to (1) under zero initial conditions yields the algebraic system:

$$sX(s) = AX(s) + BU(s), Y(s) = CX(s) + DU(s)$$

Solving for $X(s)$ and substituting:

$$\mathrm{Y}(s) = [C(sI - A)^{-1}B + D]\mathrm{U}(s) = \mathrm{G}(s), \mathrm{U}(s) \quad (5)$$

The matrix $G(s) = C(sI - A)^{-1}B + D$ is the transfer function matrix of the system. For a stable system driven by a harmonic input $u(t) = ae^{j\omega t}$, the Cauchy integral formula yields the steady-state frequency response:

$$\tilde{y}(t) = C(j\omega I - A)^{-1}B, \tilde{u}(t) \quad (6)$$

so that the matrix frequency transfer function takes the form:

$$G(j\omega) = C(j\omega I - A)^{-1}B \quad (7)$$

Each scalar entry $g_{ki}(j\omega)$ of this matrix establishes the relationship between the i-th harmonic input and the k-th output component of the steady-state response:

$$\tilde{y}k(t) = |gki(j\omega)|, a\cos(\omega t + \phi), \quad \phi = \arg g_{ki}(j\omega) \tag{8}$$

This frequency-domain characterization is the analytical basis for vibro-acoustic and spectral diagnostics of EV drivetrain components [6].

2.4 Similarity Transformations

A similarity (coordinate) transformation $x = T\tilde{x}$, where $T \in \mathbb{R}^{\mathbb{m}\times\mathbb{m}} with \det T \neq 0$, maps the original system matrices to an equivalent representation:

$$\tilde{A} = T^{-1}AT, \quad \tilde{B} = T^{-1}B, \quad \tilde{C} = CT, \quad \tilde{D} = D \tag{9}$$

The following four properties are invariant under any similarity transformation [4]:

1) Eigenvalues of A: $\lambda_i(\tilde{A}) = \lambda_i(A)$;
2) Determinant: $\det(\tilde{A}) = \det(A)$;
3) Trace: $(\tilde{A}) = (A)$
4) Transfer function: $\tilde{G}(s) = C(sI - A)^{-1}B + D = \tilde{C}(sI - \tilde{A})^{-1}\tilde{B} + \tilde{D}$.

These invariance properties ensure that similarity transformations yield a physically equivalent – but mathematically simpler – description of the system. A canonical choice of T leads to the companion (Frobenius) form, in which matrix A takes the structure:

$$A = \begin{matrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \lfloor -a_n & -a_{n-1} & -a_{n-2} & \dots & -a_1 \rfloor \end{matrix} \tag{10}$$

The characteristic polynomial of A_c is:

$$\phi(\lambda) = \det(\lambda I - A_c) = \lambda^n + a_1\lambda^{n-1} + \dots + a_{n-1}\lambda + a = \sum_{i=0}^{n} a_i\lambda^{n-i}, \quad a_0 = 1 \tag{11}$$

The companion form (10) is particularly useful for order reduction: by truncating states associated with fast, weakly observable or weakly controllable modes, a reduced-order model is obtained that preserves the dominant dynamics of the original system [5].

3 SCALING METHODS FOR DYNAMIC SYSTEM MODELS

3.1 Motivation for Scaling

When a mathematical model of an EV subsystem must be reused across configurations that differ in rated power, voltage, or capacity, direct reuse of the original model is generally not possible without re-identification of all parameters. Scaling provides a systematic methodology for normalizing system variables and equations, enabling the derivation of dimensionless models that are configuration-independent [5].

3.2 Signal Scaling and Dimensionless Parameterization

Consider the original (dimensional) input-output description of a controlled process:

$$\hat{y} = \widehat{G\hat{u}} + \widehat{G_d\hat{d}}, \hat{e} = \hat{y} - \hat{r} \tag{12}$$

where $\hat{u}, \hat{d}, \hat{y}, \hat{e}, \hat{r}$ are, respectively, the control input, disturbance, output, error, and reference signals, all in physical (dimensional) units. Introducing diagonal scaling matrices $D_{,}D_{,}D$ such that the normalized signals

$$d = D_d^{-1}\hat{d}, u = D_u^{-1}\hat{u}, e = D_e^{-1}\hat{e}, r = D_u^{-1}\hat{r} \tag{13}$$

have unit magnitude bounds, the system is transformed into the dimensionless form:

$$y = Gu + G_d d, e = y - r \tag{14}$$

where the scaled transfer matrices are given by:

$$G = D_e^{-1}\hat{G}, D_u, G_d = D_e^{-1}\widehat{G_d}, D_d \tag{15}$$

The dimensionless formulation (14)–(15) is particularly advantageous for MIMO control system design, since all variables are of comparable magnitude, improving the numerical conditioning of matrix operations such as singular value decomposition and H_∞ norm computation [3], [5].

3.3 Scaling of Elementary Dynamic Links

Any *n*-th order LTI system with a single input and single output can be decomposed into a block diagram containing only amplifying (gain), integrating, and summing elements. The state-space matrices of such a decomposition can be obtained directly from the

companion form (10) via similarity transformation, allowing systematic construction of scaled block diagrams for EV subsystems of arbitrary order.

For systems with serial, parallel, or feedback interconnections of elementary dynamic links Σ_1 and Σ_2, the composite state-space matrices can be derived analytically [2]:

Series connection:

$$A = \begin{bmatrix} A_1 & 0 \\ B_2 C_1 & A_2 \end{bmatrix}$$

Parallel connection:

$$A = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix}$$

Feedback connection: composed via the standard well-posedness conditions on the feedback loop.

These compositional rules enable modular construction of multi-domain EV powertrain models from independently validated subsystem models.
Scaling is especially effective when designing control systems for complex dynamic objects of the MIMO class.

4 APPLICATION TO ELECTRIC VEHICLE SYSTEMS

4.1 Structured Mapping of Methods to EV Components

Table 1 provides a structured mapping of the mathematical methods reviewed in Sections 2 and 3 to the principal dynamic subsystems of an electric vehicle powertrain. For each subsystem, the typical model order, the recommended scaling approach, and supporting references are indicated.

Table 1: Application of scaling and transformation methods to EV powertrain components.

EV Component	System Order	Scaling Method	Reference
Traction motor	4–8	State-space similarity transformation	[7]
Battery pack	2–10	Dimensionless parameterization	[20]
Power inverter	3–6	Transfer function scaling	[21]

4.2 Traction Motor Modeling

A permanent magnet synchronous motor (PMSM) or induction motor (IM) is typically represented in the synchronously rotating $d-q$ reference frame as a 4th to 8th order LTI system, with state variables comprising the d- and q-axis flux linkages (or currents), rotor speed, and, in higher-order formulations, mechanical oscillation modes of the drivetrain [7]. The state-space form is:

$$\dot{x_m} = A_m x_m + B_m u_m, y_m = C_m x_m$$

where $x_m = \left[i_d, , i_q, , \omega_r, , \theta_r\right]^\top$ for a 4th-order PMSM model. The application of a similarity transformation T that block-diagonalizes A_m allows independent tuning of the flux-weakening and torque-production channels, forming the analytical basis of field-oriented control (FOC) [7].

4.3 Battery Pack Modeling

Battery packs are commonly represented by equivalent circuit models (ECM) consisting of an open-circuit voltage source, an ohmic resistance, and one or more RC parallel branches capturing diffusion dynamics. A second-order (1-RC) ECM takes the state-space form with $x_b = [V_{RC}, , \mathrm{SoC}]^\top$, while higher-order (up to 10th order) models include additional RC branches and thermal states. Dimensionless parameterization is obtained by normalizing voltages by the nominal open-circuit voltage V_0 and currents by the rated capacity Q_n, yielding a normalized model in the form of (14)–(15) that is independent of cell chemistry and applicable across battery chemistries via parameter re-identification alone [20].

4.4 Power Inverter and Control Unit

A three-phase voltage source inverter (VSI) with its PWM controller is typically characterized by a 3rd to 6th order transfer function model, capturing the effects of switching delays, LC filter dynamics, and current control loop bandwidth. Transfer function scaling – achieved by normalizing frequencies to the inverter switching frequency ω_{sw} and gains to the DC-link voltage V_{dc} – enables a single normalized controller design to be deployed across inverters of different power ratings by straightforward rescaling of gains, without altering the control structure [21].

4.5 Interconnection and Scalable Simulation

The modular interconnection rules described in Section 3.3, combined with the scaled subsystem models of Sections 4.2–4.4, enable the construction of a full-vehicle powertrain model of controllable complexity. By selecting the appropriate truncation level in the companion form (10) for each subsystem, a hierarchy of models – from detailed design models (high-order) to real-time embedded models (low-order) – can be derived within a unified mathematical framework. This approach is directly supported by MATLAB Control System Toolbox and Simulink environments [2], [20].

5 DISCUSSION

5.1 Comparative Evaluation of Scaling Approaches

The three scaling paradigms reviewed in this paper – similarity transformation, dimensionless parameterization, and transfer function normalization – are complementary rather than competing. Similarity transformations operate on the internal representation of the system and are best suited for analytical tasks such as decoupling, controllability decomposition, and order reduction. Dimensionless parameterization, by contrast, operates on the external signal variables and is most effective when the same model structure must be reused across a family of physically similar but differently sized components, as in battery pack scaling across different cell counts. Transfer function normalization occupies an intermediate position, making it particularly appropriate for controller synthesis tasks where frequency-domain performance specifications (bandwidth, gain margin, phase margin) are defined in normalized units.

5.2 Implications for Model-Based Diagnostics

The framework presented here has direct implications for real-time condition monitoring and fault diagnosis in EV systems. Scalable state-space models provide a natural basis for observer design (Kalman filters, Luenberger observers) that can track the evolution of internal states – such as battery state-of-charge (SoC), state-of-health (SoH), or motor winding temperature – without direct measurement [6]. Deviations of the observer-estimated states from the actual measured outputs serve as residuals for fault detection [12]. The use of dimensionless parameterization ensures that the same observer algorithm can be applied across EV variants of different rated capacities, which is a significant practical advantage in fleet-level diagnostics.

Furthermore, when combined with spectral and wavelet analysis of motor current or vibration signals, the state-space framework supports the extraction of diagnostic features that are directly linked to the physical parameters of the mathematical model – such as changes in inductance due to winding faults or changes in the RC time constants of a battery equivalent circuit due to aging [17], [18].

5.3 Limitations and Future Directions

Several limitations of the present framework merit acknowledgment. First, the analysis is restricted to linear time-invariant systems. In practice, EV components exhibit significant nonlinearities: magnetic saturation in motors, nonlinear open-circuit voltage characteristics in batteries, and switching nonlinearities in inverters. Extensions to linear parameter-varying (LPV) or bilinear state-space formulations are required to address these effects rigorously.

Second, the scaling methods discussed assume that the structural form of the model (number of states, interconnection topology) is fixed across the scaling range. For large-scale systems, topology changes may be necessary, requiring more advanced model order reduction techniques such as balanced truncation or Krylov subspace methods.

Third, the integration of data-driven and machine learning methods with the physics-based state-space framework represents a promising avenue for future research. Hybrid models that combine first-principles structure with data-driven parameter identification [19] can potentially overcome the limitations of purely analytical approaches, particularly for aging battery packs or mechanically worn motor bearings, where first-principles parameter values are difficult to maintain accurately over the component lifetime.

6 CONCLUSIONS

This paper has presented a structured review of the mathematical foundations for modeling and scaling of dynamic systems, with application to electric vehicle powertrains. The following conclusions are drawn:

1) State-space representation provides a unified and computationally tractable framework for multi-domain EV modeling. The matrix exponential solution, companion canonical form, and transfer function derivation via the Laplace

transform collectively constitute the analytical core of this approach.

2) Similarity transformations enable complexity reduction while rigorously preserving four fundamental system invariants: eigenvalues, determinant, trace, and transfer function. Their application to traction motor models supports field-oriented control design and dynamic decoupling.
3) Scaling methods – including dimensionless parameterization and transfer function normalization – facilitate the systematic reuse of validated models across component families of different sizes, eliminating the need for full re-identification. A structured mapping of these methods to EV subsystems (Table 1) demonstrates their practical applicability.
4) The reviewed framework directly supports scalable simulation, model-based diagnostics, and embedded control design, bridging the gap between high-fidelity physics-based models and computationally efficient representations required for real-time operation.

Future work should address the extension of these methods to nonlinear and linear parameter-varying (LPV) system classes, as well as their integration with machine learning-based parameter identification and fault prognosis algorithms. Practical implementation can be carried out within the MATLAB/Simulink environment using the Control System Toolbox and Simscape Electrical libraries.

Keywords: Civil Registrar, Online Transaction System, Functionality, Public Service.

Abstract: This study developed an application for Online Transactions in the General Mariano Alvarez, Cavite Civil Registrar. This application has features that allow users to access the Emergency Hotlines, Announcements, Information about the Civil registrar, and booking of appointments. The GMA Civil Registrar Online Transaction System can help facilitate the obtaining of certificates such as Birth, Marriage, Death, and CENOMAR (Certificate of No Marriage Record), and set an appointment for other services. The evaluators of the system are the IT experts, IT students, Municipal Civil Registrar Office (MCRO) staff, and walk-in clients of General Mariano Alvarez (GMA), Cavite. The research instrument used is based on ISO 25010 evaluation tools for application software. This study utilized the convenience sampling technique in selecting evaluators; the weighted mean and t-test are the statistical treatments used for this study. Based on the evaluation, the system got a verbal interpretation of "Strongly Acceptable" for its Functionality, Efficiency, Maintainability, Reliability, and Portability. Meanwhile, the profile of the evaluators as to gender and profession is found not significant, while gender is found significant to the maintainability of the application. It is suggested that the online payment system may be included for future enhancement.

1 INTRODUCTION

The growth in the mobile phone industry and mobile applications has been one of the important technological innovations in computing in this generation. These innovations support different aspects of daily living. The fast-paced advancement of computing devices known as the "digital era" has revolutionized a variety of applications and integration to different sectors, from communication, entertainment, education, security, business operations, and government services. This "digital era" has become indispensable equipment that gives the end-users more efficient, effective, reliable, and accessible services for a wide range of applications.

There is a need to be more empirical research on local e-governments. Based on evaluation and to operationalize the e-Government focus of the Philippine Digital Strategy, the E-Government Masterplan (EGMP) acknowledged the important role that ICT plays in fostering open and transparent government and the delivery of sufficient public services (Department of Information and Communication Technology, 2014). Implementation of e-government in the country has been in the planned of the government, thus [27] in their study, they investigate the adoption of e-government in the country, However, in developing countries like the Philippines, citizens face significant challenges in adopting e-government because of differences in socio-demographics, ICT access, Internet usage habits, and service awareness. The incorporation of E-government services is a vital lever for growth in the Philippines [17]. These innovative initiatives have been taken to improve public service delivery. Government services could be enhanced through e-government. The national e-government projects in the Philippines are still moving forward [2].

Various Civil Registry Document (birth certificates, marriage certificates, certificates of no marriage, death certificates, etc.) acquisition methods. They suggested an immediate, electronic, paperless, and more expedient alternative to the current procedures for obtaining Civil Registry Documents [28]. Moreover, physical distance and transportation challenges can hinder access to these essential services. Thus, these traditional methods, opted to involve in-person visits and lengthy paperwork and manual procedures, are likely to cause errors, delays, and inconvenience. The innovative solutions of this rapid technological evolution change the traditional delivery of services, including

government services. However Municipality of government agencies faced challenges in adopting digital solutions and innovations for their services, this leads to inefficiency of transaction, long waiting time and bureaucratic hurdles for the people [3], to achieve high performance and manage their business effectively and without time-consuming procedures, organizations frequently face challenges, such as the need to stay up to date with technological advancements. Civil registries, which are essential for various legal and administrative purposes, face challenges and issues. The limited accessibility of civil registry services, especially for individuals residing in remote areas or those with mobility impairments. Additionally, a lack of an online platform for requesting and obtaining vital documents.

The development of the GMA Civil Registrar Online Transaction System represents a significant leap toward modernizing public services.

1.1 Theoretical Framework

Guided by [16] theoretical framework, which emphasizes the relationship between citizens' needs and their engagement with government services, this research explores the application's ability to meet user demands efficiently. It addresses problems in need of innovative solutions that leverage technology to streamline government processes and improve citizen experience, making them faster, more reliable, and accessible. Mobile applications, in particular, offer to address the challenges faced by citizens when accessing essential civil registry services. By digitizing the request and issuance of documents such as obtaining certificates for birth, marriage, death, and CENOMAR, as well as booking appointments for other related services, these applications can significantly reduce wait times, minimize paperwork, and enhance transparency an application user to conduct transactions from the comfort of their homes.

1.2 Objectives of the Study

Designing, creating, and testing a mobile and online transaction system for the General Mariano Alvarez (GMA) Civil Registrar is the main goal of this study. By utilizing the benefits of information and communication technology (ICT), such as greater accessibility, higher efficiency, increased dependability, and shortened transaction times, this method seeks to modernize service delivery and overcome the drawbacks of conventional in-person procedures. Specifically, it aimed to (1) determine the profile of the respondents; (2) assess the respondents' evaluation based on ISO 25010 variables; and (3) determine the significant difference in the assessments of the respondents.

2 METHODOLOGY

This study used the descriptive developmental research, a developmental method, described as the methodical investigation of developing, manufacturing, and evaluating educational processes, goods, and programs that must satisfy the standards for efficacy and internal consistency. The purpose of the system was to design an online transaction system, through a mobile application for the Municipality of GMA Civil Registrar, that facilitates and addresses the challenges by digitizing all services of the office.

In the development of the application, an agile methodology approach was used; this approach to software development interleaves program planning, requirement analysis, design, development, testing, and deployment [6]. Every organization has incorporated agile software development into its everyday operations and modified its project development methodology [25]. It "evolved from the personal experiences and collective wisdom of consultants" rather than being created.

Figure 1: Model for agile software development.

Figure 1 illustrates the agile model, it includes planning, requirement analysis, design, development testing and deployment phase. Planning phase includes the careful analysis needed for this study. Requirement analysis is performed to ensure all the system and software requirements are aligned with the needs of the end-user. For getting relevant information, first the researcher requests permission from the GMA Civil Registrar office to conduct data gathering, and data are gathered within one one-

month time frame. The researcher collected data and demographic profiles (age, gender, and profession) from Walk-in Clients and Municipal Civil Registry Office (MCRO) Staff using an interview and survey questionnaire employing a convenience sampling technique, and a purposive sampling technique for IT Experts as evaluators of the system.

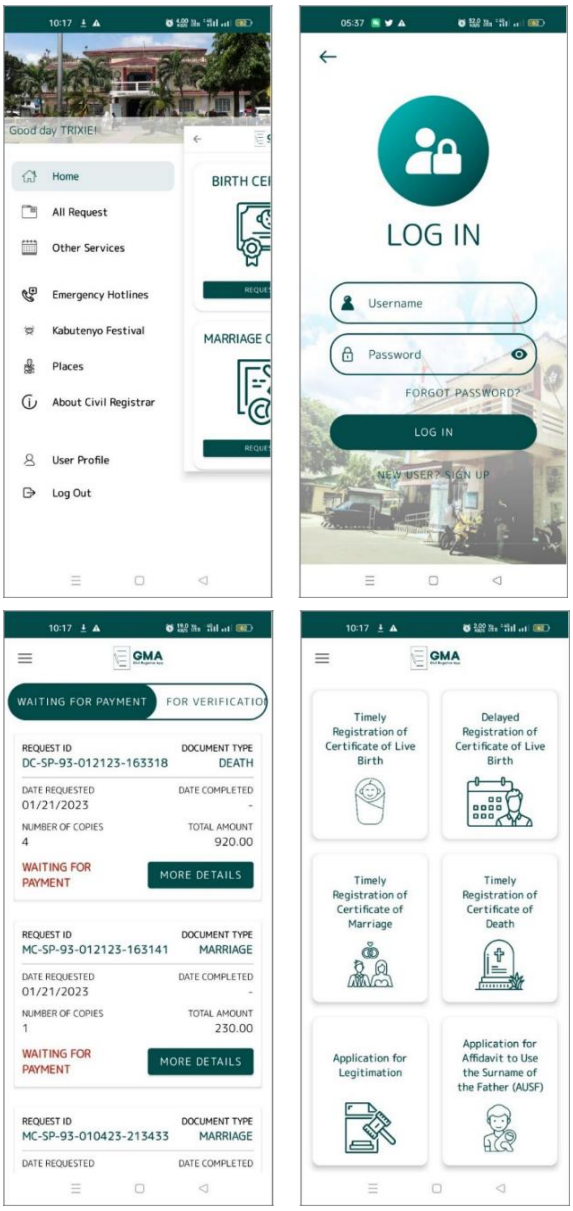

Figure 2: User interface of the mobile application for the online transaction system of the GMA Civil Registrar.

Figure 2 illustrates the sample user interface for mobile based application of the system, user need to register an account before it can see all the services provide by the civil registrar. The user can manage and see the status of every transaction.

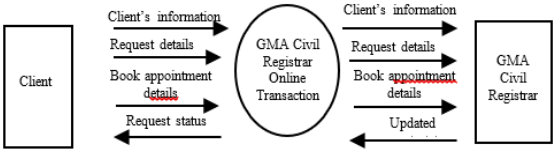

Figure 3: Context diagram of the GMA Civil Registrar Online Transaction System.

The design phase shows how the plan is to be taken into action according to the analysis phase. Figure 3 shows the context diagram of how the system works with the interaction of the user.

As show in the Figure 4 the user interface for administrator of the system. It indicates the admin dashboard and all the access of the system where the all management of transaction takes place.

The development phase is where the plans and design are executed through a series of programming and codes, these include the use of Java programming, HTML, XML for layout and resource files, and Firebase for the database. One of the critical parts of the process in the testing phase, the study employs system testing and integration testing for each module of the system. During deployment phases, the system will undergo a pre-launch of the system, and will undergo constant maintenance of the system. This part ensures that there is constant feedback from the user.

This study evaluates the application for its functionality, reliability, usability, efficiency, maintainability, and portability, these criteria are according to ISO 25010. ISO 25020 is an international standard that defines a framework for evaluating the quality of software and systems, providing a more thorough overview of the elements required to ensure software quality and deliver a positive experience to the consumer. It provides a structured way to define, measure, and evaluate software quality based on the above-mentioned criteria [26]. ISO 25010 is a reputable and well-established software quality management system that evaluates a software product's quality, which doesn't have to depend on gut feeling or personal preference [29]. Table 1 shows the 5-point Likert scale used for the assessment using ISO 25010.

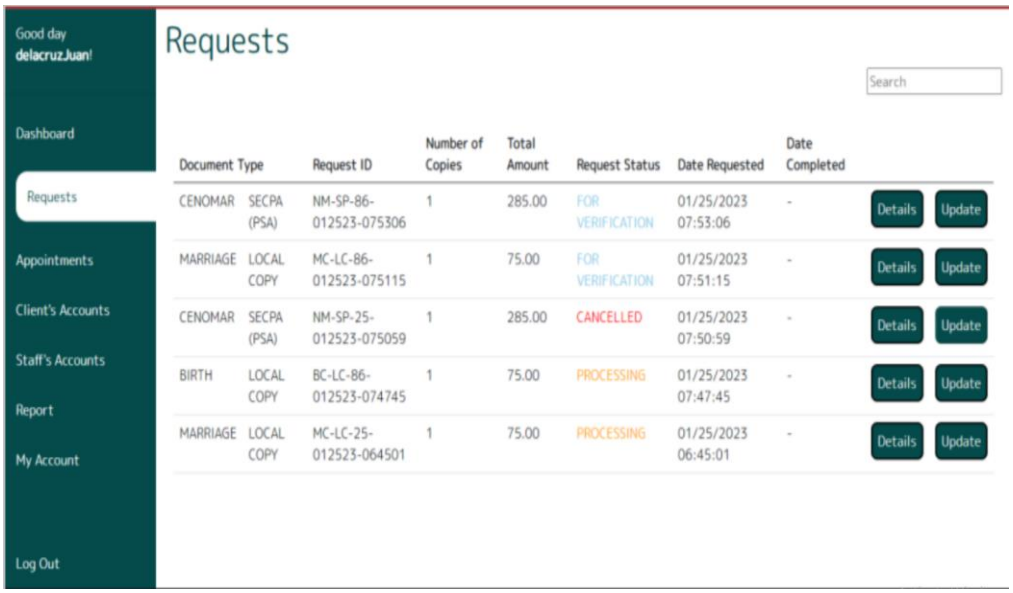

Figure 4: User interface of the web-based application for the online transaction system of the GMA Civil Registrar.

Table 1: 5-Likert Scale for assessment of the portal based on ISO 25010.

Rating	Scale	Verbal Interpretation
5.00	4.20 – 5.00	Excellent
4.00	3.40 – 4.19	Very Good
3.00	2.60 – 3.38	Good
2.00	1.80 – 2.59	Fair
1.00	1.00 – 1.79	Poor

For treating the data, frequency, percentage, rank, and weighted mean are used, and a t-test to determine the difference in the assessment of the system among the respondents in terms of the above-mentioned variables.

3 RESULTS AND DISCUSSION

Table 2 shows the summary profile of the evaluators. There were 51 or 65 percent of evaluators age group is 21 to 25 years old; 14 or 18 percent of evaluators age are under of 31 years old and above; while 13 or 17 percent of the evaluators are under the group of 26 to 30 years old. Male respondents comprised 46 or 59 percent of the evaluators, while 32 or 41 percent are females. There were 50 IT students, 85 clients, 11 IT experts, and 15 MCRO staff.

Table 3 shows the summary of assessment of the evaluators on the mobile application, where Portability has with computed mean of 4.67; As to Functionality and Maintainability with a computed mean of 4.64; Usability computed mean of 4.62; Reliability computed mean of 4.58, and Efficiency, with computed mean of 4.56 and all are Strongly Acceptable for its interpretation.

Table 2: Summary profile of the respondents.

Profile		Frequency
Gender	Male	32
	Female	46
Age	21-25 years old	51
	26-30 years old	13
	Above 31 years old	14
Profession	IT Experts	11
	IT Students	50
	MCRO Staffs	15
	Clients	85

Table 3: Summary of assessment on the application based on ISO 25010.

Rating	Mean	Verbal Interpretation	Rank
Functionality	4.64	Strongly Acceptable	2.5
Reliability	4.58	Strongly Acceptable	5
Usability	4.62	Strongly Acceptable	4
Efficiency	4.56	Strongly Acceptable	6
Maintainability	4.64	Strongly Acceptable	2.5
Portability	4.67	Strongly Acceptable	1
Grand Mean	4.62	Strongly Acceptable	

The assessment illustrated that the mobile application has a high level of acceptability from the end-users. E-government platform offers features that may provide customers with what they want, ranging

from making online services more accessible to connecting with other agencies [5]. This will aid in the development of "citizen-centric" services that prioritize improving access and providing critical services on a single platform.

When categorized by age, Table 4 displays the variations in the respondents' application evaluations. The computed p-values of 0.963, 0.775, 0.625, 0.682, 0.214, and 0.822 corroborate the data, which indicates that there was no significant difference between the evaluators' judgments of functionality, dependability, usability, efficiency, maintainability, and portability. Consequently, all of the null hypotheses were accepted.

When categorized by gender, Table 5 displays the variations in the respondents' application evaluations. Based on computed p-values of 0.599, 0.791, 0.880, 0.505, and 0.459, the data showed no significant difference between respondents' evaluations of the application's functionality, reliability, usability, efficiency, and portability. The null hypotheses were thus approved. In the meantime, the null hypothesis was rejected since the maintainability p-value was 0.044, which is below the significance level of 0.05.

As a result, respondents' evaluations of the application's maintainability varied significantly. Research suggests that gender plays a significant role in the maintainability and sustainability of technological systems, [13] the Hegemonic and heterogeneous gender-technology connections can be created through the mobilization of gendered knowledge and activity by technicians during the installation and maintenance of renewable energy technologies.

This finding is consistent with earlier research indicating that software maintenance practices are influenced by organizational and cognitive factors, such as genderization in software development. Gender dynamics influence the software development lifecycle, which could result in variations in how teams approach and maintain maintainability [20]. In a similar vein, [19] male and female developers use different approaches to program comprehension—males rely more on attention-switching, while females typically examine code entities more closely. These discrepancies support the current study's finding that maintainability is greatly impacted and imply that gender-related cognitive methods may play a role in disparities in maintenance outcomes.

Table 4: Variations in the respondents' evaluations when categorized by age.

Variables	p-value	Null Hypothesis	Interpretation
Functionality	0.963	Accepted	Not significant
Reliability	0.775	Accepted	Not significant
Usability	0.625	Accepted	Not significant
Efficiency	0.682	Accepted	Not significant
Maintainability	0.214	Accepted	Not significant
Portability	0.822	Accepted	Not significant

Table 5: Variations in the respondents' evaluations when categorized by gender.

Variables	p-value	Null Hypothesis	Interpretation
Functionality	0.599	Accepted	Not significant
Reliability	0.791	Accepted	Not significant
Usability	0.880	Accepted	Not significant
Efficiency	0.505	Accepted	Not significant
Maintainability	0.044	Rejected	Significant
Portability	0.459	Accepted	Not significant

Table 6: Variations in the respondents' evaluations when categorized by profession.

Variables	p-value	Null Hypothesis	Interpretation
Functionality	0.772	Accepted	Not significant
Reliability	0.319	Accepted	Not significant
Usability	0.895	Accepted	Not significant
Efficiency	0.941	Accepted	Not significant
Maintainability	0.219	Accepted	Not significant
Portability	0.903	Accepted	Not significant

When categorized by occupation, Table 6 displays the variations in the respondents' application evaluations. Based on computed p-values of 0.772, 0.319, 0.895, 0.941, 0.219, and 0.903, the data showed that respondents' evaluations of the application's functionality, dependability, usability, efficiency, maintainability, and portability did not differ significantly. Consequently, the null hypotheses were approved.

4 CONCLUSIONS

The majority of the assessors were male IT students between the ages of 21 and 25, the researchers deduced from the data they had collected. GMA Civil Registrar Online Transaction System obtained high rating for all criteria. While there were no significant differences in functionality, reliability, usability, efficiency, and portability across gender, age, or profession, there was a significant difference in maintainability ratings between male and female respondents. Although customers generally embraced the system, it is advised to make maintenance and efficiency enhancements to further maximize performance.

These benefits make the system more user-friendly, responsive to citizen needs, and adaptable for local government units (LGUs) looking to improve public service delivery. In contrast to previous studies on e-government and civil registry systems, which frequently concentrate on web-only platforms or limited service coverage, this research integrates both mobile and web access and offers multiple service features in a single application (emergency hotlines, announcements, information dissemination, appointment booking, and certificate requests).

5 RECOMMENDATIONS

Results reveal that when respondents are categorized by gender, their assessments of the variable maintainability differ significantly. The system recommends improvements that focus on refining the mobile application's maintainability features to ensure consistency and address the challenges faced by the clients. Even though there are no significant differences in the respondents' assessment when grouped by age and profession, the researchers highly recommend having a continuous evaluation and updates to maintain the strong acceptability of the application on the above-mentioned variables.

Additionally, to improve the accessibility of the system, it is recommended to have an IOS version to facilitate the expansion of the platform devices. The lack of an integrated online payment channel is one of the stated drawbacks and recommended for future development. Moreover, it is highly recommended to provide MCRO staff training sessions on the use of the mobile application to maximize its benefits, which will ensure the usability and satisfaction among the end-users. Furthermore, an integration with other E-government services to the mobile application for providing more comprehensive services, if applicable.

Abstract: The Philippines has emerged as a fintech hub powered by artificial intelligence in recent years, propelled by innovative governance, by broadening financial access, and a youthful, tech-inclined population. This flourishing AI-driven fintech environment has influenced Filipinos' banking services accessibility and spurred economic expansion and innovation, indirectly supporting the UN's sustainable development goals. Because more people use smartphones and the internet more frequently, many now view AI-driven fintech services as vital components of their daily lives. AI has made financial services and applications more customer-focused and technologically advanced; the increasing complexity of this dynamic setting is the primary reason for the recent rise in interest in this field. As a result, it is just logical to conduct an in-depth review of the relevant literature in this field. This research aims to summarize the significant AI-Fintech employed in the Philippines, analyze the benefits of applying and adopting AI-Fintech, outline fintech developments, possible risks, and disadvantages, analyze and evaluate possible challenges to the implementation of AI-Fintech in the Philippines, and provide recommendations to strengthen the bridge between academia, industry, and regulators. Finally, it aims to reveal research gaps in AI-driven financial technology.

1 INTRODUCTION

The introduction of technological advancements has had a significant impact on how we live our lives and on traditional methods of doing things, impacting transaction processing and data management. These technological advancements, such as cryptocurrencies, robo-advisors, and peer-to-peer lending, improved customer satisfaction, financial inclusion, and operational efficacy [1]. Complex financial operations brought about by fintech advancements amplify service efficacy [1].

In 2023, 72.2% of Filipinos used financial technology apps, totaling 59.3 million users [2]. Payments and transfers increased by 17.6%, e-wallets by 4.9%, and e-banking by 4.3% [2]. Fintech adoption reached 69.3% in 2022, driven by government support and market demand [2]. Online lending and e-wallets grew significantly [2].

The country's 2023 Fintech Report [3] highlighted 299 fintech firms, with payments leading the sector at 37%. Meanwhile, digital financial services have seen a decline from 27% to 21%, while lending comprises 20%, remittances account for 11%, and e-wallets make up 9% [4].

The most recent fintech report indicates significant growth in the industry, which has enhanced financial inclusion for unbanked Filipinos, supported by regulatory bodies. The Philippines has 441 rural banks, 48 thrift banks, and 46 universal and commercial banks, with total assets amounting to $385.6 billion [5]. Commercial banks dominate the banking sector, representing 92.8% of overall assets [5]. Prominent fintech firms such as CIMB, UNOBank, and GCash lead the electronic payments sector [5], [6].

Digital banking has revolutionized financial services through improved customer engagement and transaction efficiency [7]. The role of artificial

intelligence (AI) is vital in personalizing experiences and managing risks. Union Bank and Bank of the Philippine Islands are at the forefront of AI innovations, enhancing client satisfaction and streamlining operations [7]. Advancements in high-speed communication, data storage, and processing power have made AI implementation practical across various sectors, including healthcare, manufacturing, and finance [8]. Its adaptability has contributed to its widespread adoption in the banking sector [9].

The proliferation of data in the banking sector is expected to drive further AI integration. However, issues like data bias and other challenges can hinder full utilization, affecting customer trust and outcomes [10]. A reliance on external AI solutions can alienate customers, necessitating strategies like audits, transparent evaluations, and customer feedback to effectively address these challenges [11].

This study investigated the Philippines' use of AI-Fintech, how it could contribute to certain SDGs, examined the benefits, risks, and implementation challenges, and provided recommendations for stakeholders to foster innovation. The guiding question investigated whether the country's adoption of AI-driven FinTech can boost financial inclusion and innovation, and further the nation's economic growth.

2 RESEARCH METHOD

To guarantee a systematic review with improved quality control, this study adhered to the guidelines of Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) [12], which include identifying information sources, selecting studies, collecting data, and establishing eligibility criteria.

The study systematically collected and analyzed data and filtered unreliable publications via Scopus. Eligible papers were identified using specific keywords and reviewed in-depth based on title, abstract, and keywords.

The SLR collected data through manual study searches, screening, and analysis to extract key information on article type, journal, publication year, subject, methods, and outcomes. The inclusion criteria (IC) specified (IC1) original, peer-reviewed English studies (IC2) on factors affecting AI-driven fintech adoption and its economic impact, (IC3) using robust quantitative, qualitative, or mixed-methods.

Data items were selected based on specific criteria to ensure study consistency. Figure 1 presents the systematic literature review process. Out of 308 research publications, the selection process considered variables like title, abstract, and keywords, leading to 81 publications. Ultimately, 25 relevant articles emphasized the practical goals and contextual significance.

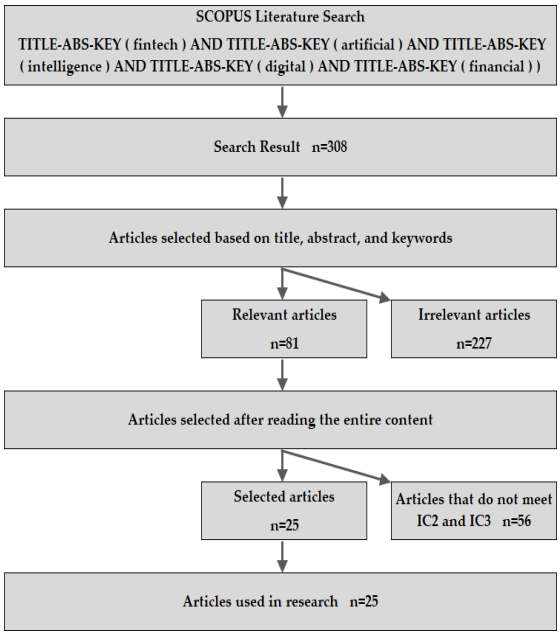

Figure 1: SLR reporting items (PRISMA Adopted).

3 RESULTS

A literature search identified 25 articles published between 2019 and 2025, organized into six groups: AI and fintech applications (15 articles), sustainability and financial inclusion (4 articles), adoption and impact (2 articles), and regulation and policy (4 articles).

Articles were categorized by primary focus, highlighting interests in areas such as financial risk management and robo-advisory services. Key issues include sustainability, financial inclusion, and regulations. A research gap exists on stakeholder effects, requiring further exploration. Table 1 highlights 25 articles on empirical analysis. The +Sig findings highlight the potential benefits and positive impacts of AI-driven fintech on various aspects of finance.

Table 1: Article analysis and synthesis.

No.	Reference	Scope	Method	Results
1	[13]	Analyzes how AI-FinTech transforms banking, focusing on payment systems for efficiency, security, customer experience and sustainability.	Mixed-method	+Sig
2	[14]	Analyzes FinTech and AI's roles in sustainable development, financial inclusion, and social responsibility.	Quantitative	+Sig
3	[15]	Investigates the effects of user characteristics and the human-like characteristics of robo- advisors on loyalty, trust, and financial well-being, aiming to enhance robo-advisory services.	Quantitative	+Sig
4	[16]	Examines fintech regulation's geopolitical impact, contrasting major powers' methods and addresses challenges in digital finance and AI.	Qualitative	+Sig
5	[17]	Examines AI adoption and financial access's role in China's energy sustainability, offering policy recommendations for green finance and responsible AI use.	Quantitative	+Sig
6	[18]	Explores technology adoption in Indian banking, focusing on FinTech innovations' benefits, challenges, and future implications for financial services.	Qualitative	+Sig
7	[19]	Evaluates the efficacy of blockchain and artificial intelligence in financial risk management for compliance and fraud detection.	Quantitative	+Sig
8	[20]	Explores the integration of sustainability in finance and digital accounting, highlighting the revolutionary potential of AI-enabled FinTech, identifying literature gaps, and developing comprehensive sustainability frameworks.	Qualitative	+Sig
9	[21]	Explores enhancing AI- supported Letter of Credit review methods to mitigate assessment risks and optimize checker capacity in trade finance.	Quantitative	+Sig
10	[22]	Develops statistical methods and fuzzy logic to improve long- term management of digital financial assets in Russia, Analyzing- price growth and trade volumes.	Quantitative	+Sig
11	[23]	Analyzes legal challenges of AI-FinTech in Tanzania's finance, offering recommendations for balanced regulation ensuring stability, Consumer protection, and ethics.	Qualitative	+Sig
12	[24]	Analyzes FinTech adoption trends in SMEs, its implications, and potential effects on traditional.	Quantitative	+Sig
13	[25]	Explores opportunities, challenges, and potential of agentic AI in FinTech, proposing a sustainable research agenda.	Qualitative	+Sig
14	[26]	Examines robo-advisory solutions for wealth management, behavioral finance, and investment decision- making, contributing to future research in India.	Qualitative	+Sig
15	[27]	Examines the research on sustainable finance and financial inclusion, focusing on emerging digital financial risks and strategies for promoting secure, inclusive systems.	Qualitative	+Sig
16	[28]	Explores behavioral biases affecting Gen Z investment decisions in India and examines how AI-led digital advisory services can mitigate these biases.	Quantitative	+Sig
17	[29]	Analyzes the relationship between emerging transactions, enhancing accuracy through attention mechanisms.	Quantitative	+Sig
18	[30]	Develops CL- BGAD, a framework for detecting anomalies in bipartite graphs, enhancing security and robustness in AI models.	Quantitative	+Sig
19	[31]	Explores NFT return and volatility statistics, developing predictive models using autoregression and AI to forecast prices based on macroeconom ic factors	Quantitative	+Sig
20	[32]	Aims to create the RR- ABiLSTM chatbot for precise financial query classification, enhancing contextual understanding and improving communication in accounting	Quantitative	+Sig
21	[33]	Aims to create and assess a GAGAN model for effective money laundering detection in bank transactions, enhancing accuracy through attention mechanisms..	Quantitative	+Sig
22	[34]	Examines factors affecting AI neo-banking service quality and their effects on brand experience, trust, and loyalty.	Quantitative	+Sig
23	[35]	Investigates enterprise generative AI's applications in HR management, fintech, and productivity, emphasizing team selection, hiring decisions, and employee satisfaction and performance.	Qualitative	+Sig
24	[36]	Investigates Random Forest's effectiveness in predicting financial distress in BSE firms using financial ratios and corporate governance for improved accuracy.	Quantitative	+Sig
25	[37]	Aims to synthesize knowledge on financial robo-advisor design through a literature review, identifying requirements and providing an implementation framework.	Qualitative	+Sig

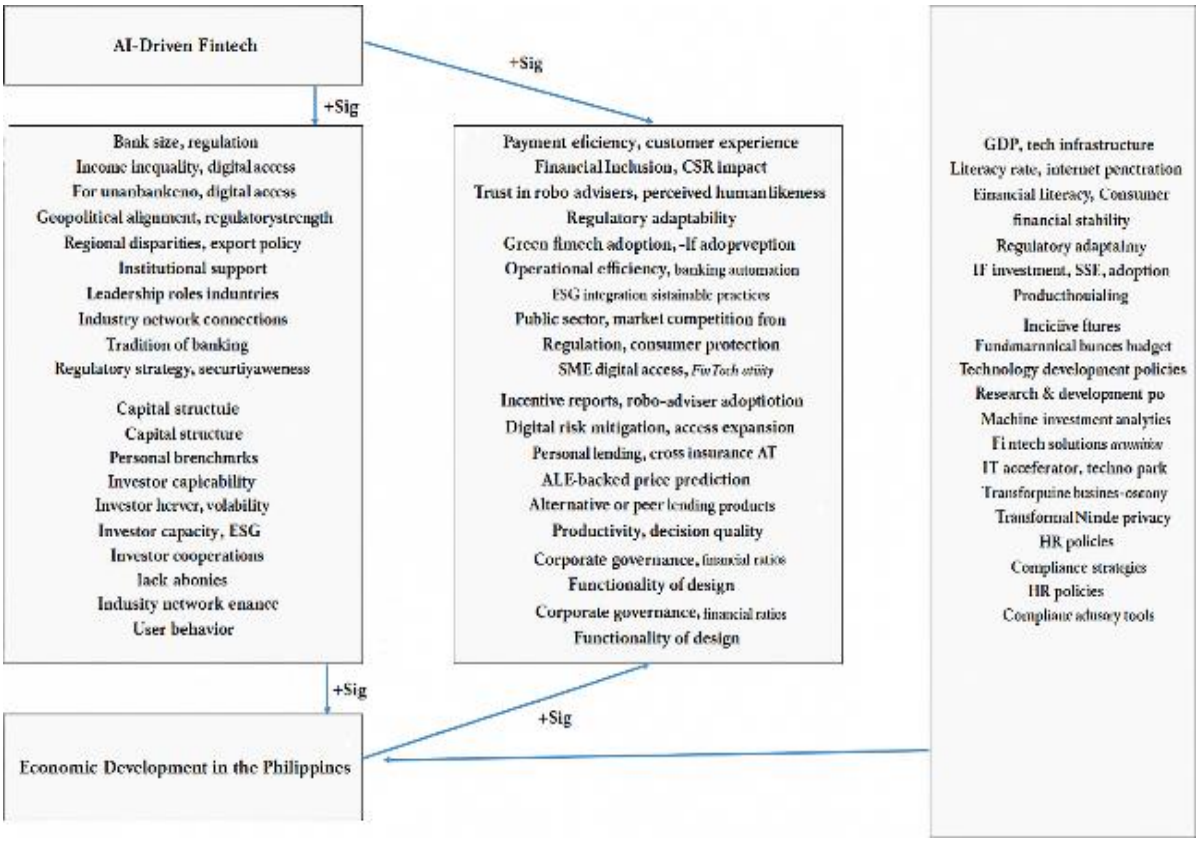

Figure 2: Research conceptual framework.

This research explored the theoretical ideals of the convergence of economic growth, technology, and finance, as rooted in Rogers' innovation diffusion theory [17], and explored the application of AI-driven FinTech in the Philippines, its wide-ranging effects on social and economic landscapes (Fig. 2).

The study also examined how AI-driven FinTech fosters economic growth and provides competitive advantages for businesses, grounded on the resource- based view (RBV) [38]. Additionally, it emphasizes the significance of easily accessible financial services and supports the theory of financial inclusion [39].

This study expands our understanding of the effects of AI-driven FinTech on financial inclusion and economic growth, notably in the underprivileged areas of the country.

Collaborations between traditional financial institutions and the emerging FinTech industry expand FinTech's ability to engage with the public and end-users, thereby helping to attain SDGs.

4 CONCLUSIONS

The Philippine fintech scene is in constant flux, driven by beneficial policies, inclusive finance programs, digital advancements, contactless payment solutions, and the integration of digital currency. The financial technology space remains strong, adapting to varied demands. With a solid standardized framework, it is ready for expansion, transformation, and inclusive finance.

The study looked at how AI-powered FinTech affected the nation, focusing on economic expansion, inclusive finance, transformation, strategic direction, and service quality enhancement. The outcomes can guide organizational direction and framework development, highlight growth prospects, and streamline financial processes. Possible approaches include investing in digital infrastructure, financial literacy programs, FinTech innovation centers, and standardized frameworks, thereby fostering economic growth and an entrepreneurial ecosystem.

There have been numerous studies on the impact of AI-FinTech on sustainable development and how it can accelerate the SDGs from various directions, but very few have examined AI-FinTech implementation initiatives and their effectiveness in furthering the SDGs. By providing resources and tools to deliver environmental and societal outcomes and encouraging inclusive finance, fintech companies help accomplish the SDGs. Therefore, companies' financial technology might be regarded as a stimulating way to create and deliver transformation.

Keywords: Optimal Control Problem, Modified Vieta-Pell Functions, Direct Approximation Algorithms, Intelligent Robotic System, IT Applications.

Abstract: This work suggests an approximate direct technique to treat special kind of optimal control problem (OCP) in the finite domain [0, T] based on new modified family of Vieta-Pell functions. The proposed method employs a direct parameterization approach. In such technique, we approximate the state variables in terms modified family of Vieta-Pell functions and then transform the original optimal control problem to a constrained nonlinear programming problem. The aim of the presented algorithm is to reduce the numerical complexity with computational efficiency. The algorithm is well-suited for implementation in scientific computing environments such as MATLAB and Python, making it applicable to software-based control systems. To demonstrate its practical relevance to information technology applications, the proposed method is applied to optimal control problems arising in intelligent robotic systems, particularly robotic arm motion planning. Numerical simulations confirm fast convergence, high accuracy, and robustness, making the method suitable for integration into digital control architectures, intelligent automation systems, and IT-based robotic platforms.

1 INTRODUCTION

Optimal control problem (OCP) has been extensively considered in recent years. The major reason for the great importance of such problems are found in many applications in science, engineering, medicine, economics, finance, and a variety of other disciplines [1]-[3]. In recent years, the different algorithms to solve optimal control problem have been studied, such as the state parameterization technique with operation matrix of derivative for modified wavelets functions [4], the novel variational finite difference method [5], the difference method [6]-[7] and the finite element method to solve an OCP governed by e fractional wave equation [8], a wavelet collocation method for nonlinear partial OCP [9], Chebyshev wavelet and Müntz–Legendre Wavelet methods for solving various OCP [10-12], the Haar wavelet collocation method and Boubaker Wavelets [13]-[15]. The orthogonal functions are the most popular numerical approximates in solving an optimal control problem [16]-[18]. The ease and accuracy of applying the basic functions for treating an OCP and other many problems are our aim. Therefore, the authors in [19]-[21] extended solving different complicated problem based on numerical techniques together with the interesting basis functions called Vieta-Pell polynomials, such polynomials have utilized as a suitable technique for treating approximately a nonlinear fractional OCP [22]. A special Burgers an equation (BE) with fraction order was studied in [23] to solve BE approximately with the aid of certain family for Vieta Pell polynomials. In addition, the Vieta Pell polynomials are used in [24], [25] to solve stochastic fractional differential equations using direct technique. Some other work [26]-[29] used the generalized of Vieta Pell polynomials and their incomplete families.

The aim of the present work is the approximate investigation of the following optimal control problem:

$$\min J(x,u) = \int_0^T F(x(t),u(t),t)dt. \quad (1)$$

Subject to

$$\dot{x}(t) = g\big(x(t),u(t)\big), \quad (2)$$

and

$$x(0) = x_0, x(T) = x_T. \quad (3)$$

Here the two state and control vectors are $x(t)$ and $u(t)$ respectively.

The proposed modified version of the Vieta-Pell polynomials can use for many problems with finite intervals. In modern information technology applications, optimal control plays a vital role in intelligent systems such as robotics, autonomous platforms, embedded controllers, and cyber-physical systems. The effectiveness of these systems relies heavily on fast and accurate numerical algorithms that can be efficiently implemented in software environments. Consequently, developing computationally efficient basis functions and operational matrices is essential for real-time optimization and control. In this regard, the proposed MSIVP-based method provides a practical numerical framework that can be directly integrated into software-based control architectures used in intelligent robotic and IT-driven systems.

The paper is organized as follows. In Section 2, we introduce a new definition of MSIVP together with some interesting properties. In Section 3, we suggest a new approximated method to show how to transform an OCP (1-3) into an optimization one. We give two examples of our method in Section 4. In Section 5, the verification method on the IT applications is demonstrated and list conclusions in Section 6.

2 MODIFIED SHIFTED INCOMPLETE VIETA-PELL FUNCTIONS

In this section, we show how to modify the incomplete polynomials in [26] over limited domain to get an interesting basic functions on the domain $[0, T]$.

Definition 1. Let $M_n(t)$ denotes the modified incomplete Vieta Pell functions and s be any real positive numbers, then

$$M_n(t) = 2^s \left(\frac{2t}{T} - 1\right) M_{n-1}(t), n \geq 2, \quad (4)$$

where $M_1 = 1$.

In general, modified polynomials can draw as follows

$$M_n(t) = 2^{(n-1)s} \left(\frac{2t}{T} - 1\right)^{n-1}, n = 1, 2, ... \quad (5)$$

Some important properties are given in the next subsections to reduce the computations in working with new basis functions.

2.1 The MSIVP Product Operation Matrix

Theorem 1. Let $M_n(t)$ and $M_m(t)$ be as chosen in (4). Then for all $n, m \geq 1$, one has

$$M_n(t)M_m(t) = M_{|n+m-1|}(t). \quad (6)$$

Proof. Assume $n = 1$, then:

$$M_1(t)M_m(t) = M_m(t), m \geq 1. \quad (7)$$

Consider that $\{4\}$ is true for k, yields

$$M_k(t)\, M_m(t) = M_{|k+m-1|}(t). \quad (8)$$

We must prove that (4) is true for $k + 1$. By multiplying both sides of (8) by $2^s z$ to get,

$$2^s(z)M_k(t)\, M_m(t) = 2^s(z)M_{|k+m-1|}(t).$$

$z = \frac{2t}{T} - 1$ and making use of relation (4), which immediately gives

$$M_{k+1}(t)\, M_m(t) = M_{|k+m-1|}(t).$$

and this completes the proof of Theorem 1.

2.2 Operation Matrix of Derivative of MSIVP

Theorem 2. Assume that $M_n(t)$ as defined in (4). Then $\dot{M}_n(t)$, $n \geq 2$, can be defined in below

$$\dot{M}_n(t) = (n-1)\frac{2}{T}2^S M_{n-1}(t), n \geq 2\,. \quad (10)$$

Proof. Let $n = 2$, then $\dot{M}_2(t) = 2^S \frac{2}{T} M_1(t)$.

Assume that (10) is true for $(n - 1)$. Using (4), yields

$$\dot{M}_n(t) = 2^S \left[(z)\dot{M}_{n-1}(t) + \frac{2}{T} M_{n-1}(t)\right]. \quad (11)$$

Then from (4) one can get

$$\dot{M}_n(t) = M_2(t)\dot{M}_{n-1}(t) + 2^S \frac{2}{T} M_{n-1}(t). \quad (12)$$

Now, application of the induction step on $\dot{M}_{n-1}(t)$ in (12), yields

$\dot{M}_n(t) = (n-2)\frac{2}{T}2^S M_2(t)M_{n-2}(t) +$

$2^S \frac{2}{T} M_{n-1}(t)$.

It can simplify based on the results of theorem 1, to get

$$\dot{M}_n(t) = (n-2)\frac{2}{T}2^S M_{n-1}(t) + 2^S \frac{2}{T} M_{n-1}(t).$$

3 THE MSIVP ALGORITHM

The step by step MSIVP algorithm for the established method is outlined below.

Input: Initial position $(0) = x_0$, Desired final position $x(T) = x_f$, Final time $T = 1$, Approximation order n, Cost functional, Control definition.

Output: Approximate state trajectory $x(t)$, Approximate control signal $u(t)$, Optimal cost value J, Error norms L_2, L_∞.

Initialize MSIVP Basis Functions. Construct the MSIVP approximation of order n: $x_n(t) = \sum_{i=1}^{n} a_i 2^{(i-1)s}(z)^{i-1}$, Where $s = 1, T = 1$.

Compute the State Derivative. Evaluate the derivative:$\dot{x}_n(t)$

Define the Control Input.

Apply Boundary Conditions. Enforce: $(0) = x_0$, $x(T) = x_f$.

Formulate the Cost Functional. Substitute $x_n(t)$ and $u_n(t)$ into:

Solve the Optimization Problem. Minimize $J(a)$ subject to boundary constraints using a nonlinear programming solver to obtain the optimal coefficient vector: $a^* = (a, a_1, a_2, \ldots\ldots, a_n)$

Construct Optimal Trajectories. Substitute a^* into: $x^*(t) = u^*(t), x_n(t; a^*) = u_n(t; a^*)$

Compute Error Measures. Evaluate approximation accuracy using: $L_{2,z} = \sqrt{\sum_{j=1}^{N} |z_{ex.}(t_j) - z_n(t_j)|^2}$, $L_{\infty,z} = \max_j [z_{ex.}(t_j) - z_n(t_j)], j = 1, 2, \ldots, N$, where $z = (x, u)$.

4 NUMERICAL RESULTS

The accuracy of the proposed method is determined based on the following norms:

$$L_{2,x} = \sqrt{\sum_{j=1}^{N} |x_{ex.}(t_j) - x_n(t_j)|^2},$$
$$L_{\infty,x} = \max_j [x_{ex.}(t_j) - x_n(t_j)], j = 1, 2, \ldots, N.$$
$$L_{2,u} = \sqrt{\sum_{j=1}^{N} |u_{ex.}(t_j) - u_n(t_j)|^2},$$
$$L_{\infty,x} = \max_j [u_{ex.}(t_j) - u_n(t_j)], j = 1, 2, \ldots, N.$$

where $x_n(t)$, $u_n(t)$, $x_{ex.}(t)$ and $u_{ex.}(t)$ represent the approximate solution for the state variable, the approximate solution for the control variable, the approximate exact for the state variable and the exact solution for the control variable respectively. The absolute errors E for the performance index value is calculated using varies basis function orders as follow

$$E = |J_{ex.} - J_n|.$$

Here J_n and $J_{ex.}$ Represents respectively the approximate and exact cost values.

Example 1. In this problem, an object is to find the optimal control that minimizes

$$J = \int_0^1 (u^2 + x^2) dt.$$

Subject to $u(t) = \dot{x}(t)$,
Together with $x(0) = 0, x(1) = 0.5$.
while $x(t) = \frac{e(e^t - e^{-t})}{2(e^2 - 1)}$, $u(t) = \frac{e(e^t + e^{-t})}{2(e^2 - 1)}$ and $J_{exact} = 0.328258821379$ are the exact values for the state, control and the performance index value respectively.

The numerical results are obtained for both the state and the control variables at $n = 3,4$ and 5 and plotted in Figures 1 and 2. The analysis error norms are given in Tables 1 and 2.

Table 1: Errors for state of Example 1.

n	x(t)	
	L_2	Infinity norm
3	1.169575e-2	3.96544e-3
4	2.971882e-4	5.84650e-5
5	2.51801e-5	3.42773e-6

Table 2: Errors for control of Example 1.

n	u(t)		J
	L_2	Infinity norm	E
3	0.120678212	4.2881e-2	3.396e-4
4	5.110e-5	2.1836e-3	5.161e-7
5	9.4961 e-4	2.9811 e-4	9.330e-9

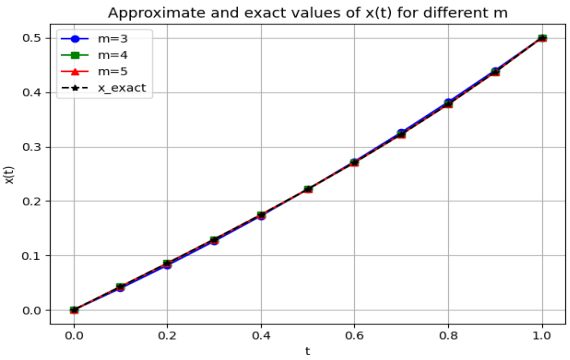

Figure 1: Approximate for state of Example 1.

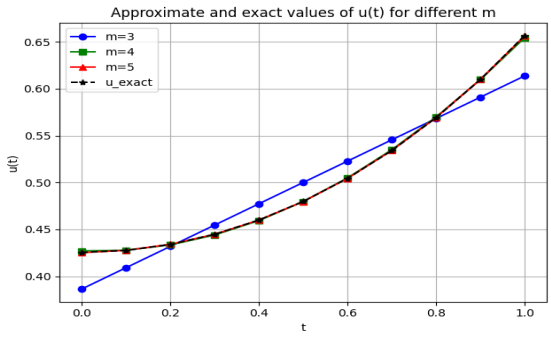

Figure 2: Approximate for control of Example 1.

A comparison is made between the present algorithm and the solution obtained by wavelets functions technique [4] for different values of n. It is based on the special wavelets basis functions to approximate the solution of the application 1 by using the state parameterization method. The absolute errors values E are respectively 0.000339663469485, 0.000000516182663 and 0.00000000933001 with $n = 3, 4, 5$. The advantages of the suggested incomplete technique on solving OCP is the ability for solving the OCP directly with the interval $t \in [0, T]$ while other methods must introduce a suitable transformation according to the base functions.

Example 2. The aim is to minimize the following performance index

$$J = \frac{1}{2}\int_0^2 u^2(t)dt, \quad 0 \le t \le 2,$$

with $u(t) = \dot{x}(t) + \ddot{x}(t)$ and $x(0) = 0, \dot{x}(0) = 0, x(2) = 5, \dot{x}(2) = 2$.

While $x(t) = K_1 + K_2 e^{-t} + C_1 t + \frac{C_2}{2} e^t$, $u(t) = C_1 + C_2 e^t$ is the exact solutions where $K_1 = -\frac{3e^4 - 2e^2 + 7}{4(e^2-1)}$,

$K_2 = \frac{e^2(1+3e^2)}{4(e^2-1)}$, $C_1 = \frac{7+3e^2}{4}$, $C_2 = \frac{7-3e^2}{2(e^2-1)}$.

$J_{exact} = 16.750723396861265$.

The obtained values of $L_{2,x}$. $L_{\infty,x}$, $L_{2,u}$. $L_{\infty,u}$ and E are illustrated at some selected n within the interval $t \in [0,2]$ and the results are given in Tables 3 and 4. In addition, Figures 3 and 4 plot the absolute errors for the state and control variables respectively.

Table 3: Errors for state of Example 2.

n	x(t)	
	L_2	Infinity norm
6	4.858775e-4	5.460372e-5
7	1.188900e-4	2.705501e-5
8	1.893695e-6	2.346852e-7

Table 4: Errors for control of Example 1.

n	u(t)		J
	L_2	Infinity norm	E
6	2.753e-2	4.129e-3	1.005e-5
7	1.420e-3	4.4723e-3	1.858e-8
8	2.706e-4	5.4293e-4	5.57e-10

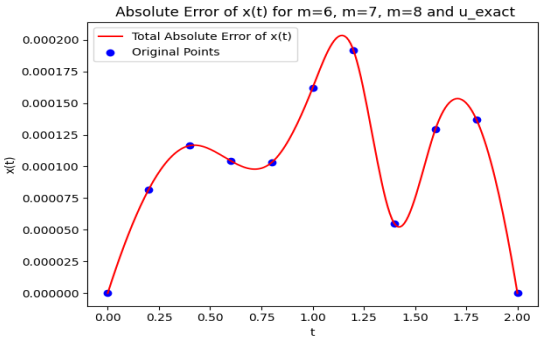

Figure 3: Absolute errors for state of Example 2.

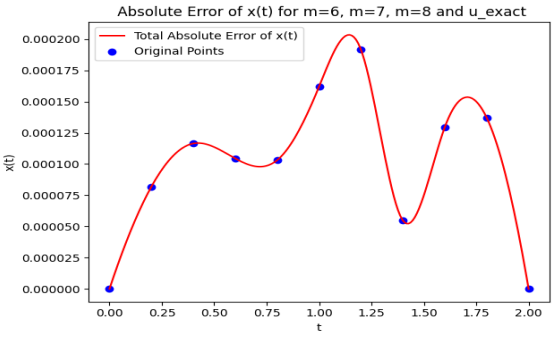

Figure 4: Absolute error for control of Example 2.

According to the Tables, as n increases, the values of E, L_2 and L_∞ decrease rapidly and the results reach to the exact values, the accuracy increases as the number of terms of the basis MSIVP expansion increases. Tables (1-4) illustrate that the suggested algorithm has a good convergence rate.

5 COMPUTATIONAL IMPLEMENTATION AND IT APPLICATION

The proposed MSIVP algorithm is developed with practical computational implementation as a primary consideration. Owing to the simplicity of the derived operational matrices, the algorithm can be efficiently implemented using standard scientific computing environments such as MATLAB, Python, and C-based numerical libraries which can allow the

algorithm to be useful for modern IT infrastructures. The presented modified basis functions can be used to find optimal state trajectory and control input in real time with a few computational cost of the suggested algorithm. Furthermore, the proposed technique can apply in simulation-based control design and enable the engineers to calculate the system performance with the aid of numerical simulations before real-world implementation. This illustrates the relevance of the suggested algorithm to applications of information technology, especially in robotic control software and intelligent automation,

5.1 The Formulation for Robotic Arm Motion Problem

Here, a robotic arm motion in one dimension is presented. The arm moves from the initial position $x(0) = 1$ to the desired terminal position $x(1) = 0.2818$ within the time interval $0 \leq t \leq 1$ as illustrated in Figure 5. The aim is to find an optimal state trajectory and a control input defined as $x(t)$ and $u(t)$ respectively. The relation between them is made as

$$u(t) = \dot{x}(t) + x(t).$$

In which an accurate terminal position tracking is reached, the motion stays smooth to avoid vibrations and minimized the control effort. The cost of the control system is determine using the following quadratic cost functional

$$J = \frac{1}{2}\int_0^1 u^2(t) + x^2(t)dt.$$

The cost value J defines the balancing of energy consumption with deviation from the desired position. This formulation is widely used in optimal control problems of robotic manipulators to ensure efficient and precise motion while extending the operational lifespan of mechanical components.

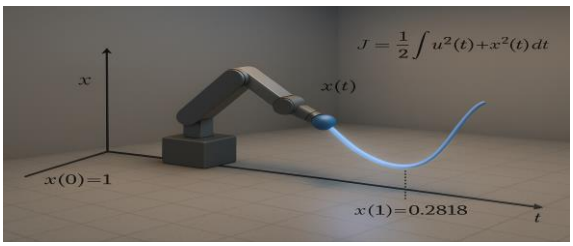

Figure 5: Illustration of robotic arm motion.

5.3 Numerical Results for Robotic Arm Control

To solve this problem, the MSIVP method of order six is employed to approximate the state variable as

$$x_6(t) = \sum_{i=1}^{6} a_i 2^{(i-1)s}(z)^{i-1},$$

where s=1$s = 1$ and $T = 1$. The unknown coefficients are determined by solving a nonlinear programming problem subject to the boundary conditions. The optimal parameter vector is obtained as:

$$a_1 = 1,$$
$$a_2 = -0.692898043157134,$$
$$a_3 = 0.249438742839363,$$
$$a_4 = -0.056389173902395,$$
$$a_5 = 0.008969735170030,$$
$$a_6 = -0.000705039267015.$$

Substituting these coefficients yields the approximate state and control functions

$$x(t) = -0.0226t^5 + 0.1435t^4 - 0.4511t^3 + 0.9978t^2 - 1.3858t + 1.$$
$$u(t) = -0.0226t^5 + 0.0307t^4 + 0.1229t^3 - 0.3556t^2 + 0.6097t - 0.3858.$$

with an optimal cost value of $J = 0.192909335341236$.

In addition, the problem is solved using higher approximation orders through an extended incomplete series representation. The numerical accuracy is evaluated using the L_2 norm and theL_∞ norm for both the state and control variables over the interval $t \in [0,1]$. The corresponding error values are summarized in Tables 5 and 6, while the approximate solutions for different values of n are illustrated in Figures 6 and 7 while Figure 8 Statistical Reading of cost Functional Error.

Table 5: Errors for state of robotic arm problem.

n	x(t)	
	L_2	Infinity norm
6	6.48474317e-4	1.43087492e-4
7	6.46349909e-4	1.44111405e-4
8	6.46349909e-4	1.44160392e-4

Table 6: Errors for control of robotic arm problem.

n	u(t)*10^{-4}		J
	L_2	Infinity norm	E
6	2.744482616	5.69549097	8.642e-10
7	2.697338464	4.31755836	2.539e-12
8	2.710904281	4.39874067	7.993e-15

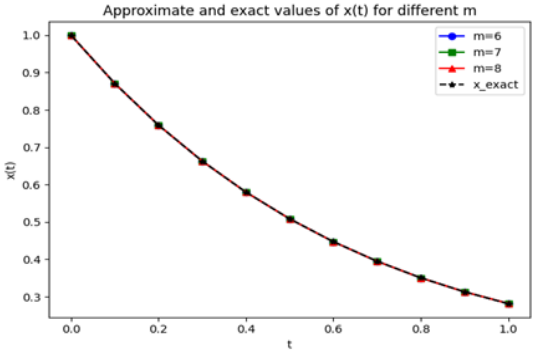

Figure 6: Approximate for state of robotic arm problem.

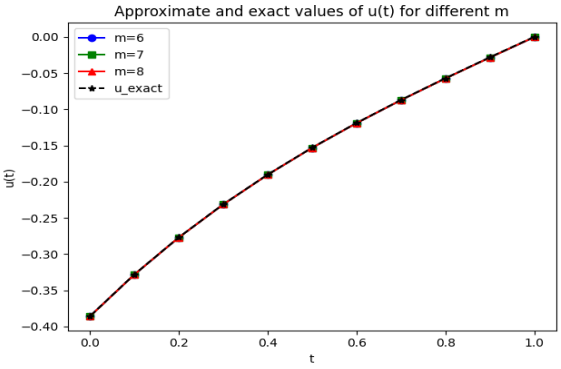

Figure 7: Approximate for control of robotic arm problem.

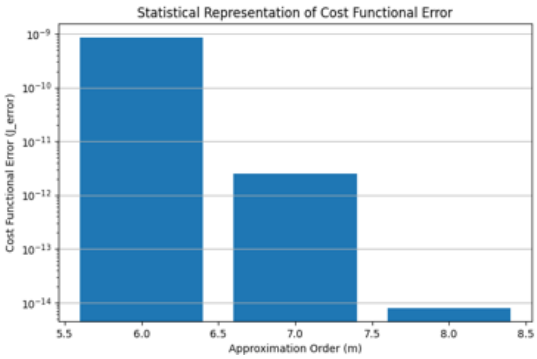

Figure 8: Statistical reading of cost functional error of robotic arm problem.

The simulation results show that the MSIVP method produces smooth and accurate trajectories for both the state and control signals. Error analysis indicates that the deviations in the state and control remain small throughout the entire time interval, confirming the effectiveness and numerical stability of the method.

6 CONCLUSIONS

This paper introduced an efficient computational approach based on modified shifted incomplete Vieta-Pell polynomials for solving optimal control problems over general time intervals. The proposed method transforms the original control problem into a numerically manageable optimization problem through simple and effective operational matrices. From an information technology standpoint, the MSIVP algorithm provides a flexible and computationally efficient tool suitable for implementation in software-based control systems, intelligent robotic platforms, and digital automation frameworks. Numerical results demonstrate fast convergence, high accuracy, and reduced computational effort, making the method appropriate for real-time and simulation-based IT applications. The effectiveness of the proposed method is further validated through robotic motion control examples, confirming its applicability to intelligent systems and IT-driven control environments. Future work may focus on real-time implementation and integration with advanced robotic software architectures.

Keywords: Chest X-Ray Images, Classifications, InceptionV3, Medical Imaging, Database.

Abstract: Integrating technology such as artificial intelligence in the medical field may contribute significantly to the early diagnosis of diseases. This study is conducted to achieve two goals: The first is to use three advanced deep learning models to identify tuberculosis and COVID-19 diseases from healthy cases by processing a chest X-ray image dataset. The second goal is to compare the three models and identify the most generalizable one based on accuracy and computational efficiency. The proposed models were applied to a large-scale chest X-ray of 6375 images. The findings show that InceptionV3 outperforms the CNNs and ResNet-50 algorithms by achieving high metrics values (Accuracy = 0.9636, Precision = 0.9752, Recall = 0.9554, and F1-Score = 0.9651). Furthermore, the results show that training neural networks across a wide range of epochs improves the model predictions of new data. The findings demonstrate InceptionV3's capability of providing a robust and automated method for classifying chest X-ray images. Apart from accuracy assessment, this computational analysis depicted marked variations in efficiency amongst the three models. The CNN architecture achieved the shortest training time of ≈12.4 minutes and attained the fastest inference speed of ≈4.1 ms per image, whereas ResNet-50 and InceptionV3 required longer training and inference times. This starkly indicates that there is a clear trade-off between computational cost and predictive performance across the evaluated architectures.

1 INTRODUCTION

Chest X-rays are a primary tool for symptomatic imaging that provide essential insights into the syndrome of thoracic depression [1].
Furthermore, Chest X-rays can provide important information about some diseases, such as COVID-19 and tuberculosis (see Fig.1).

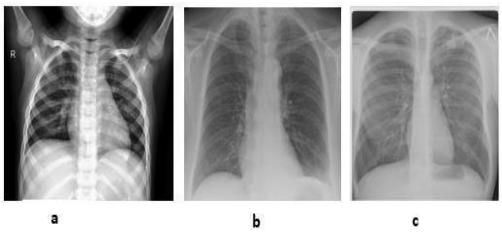

Figure 1: Three conditions of Chest X-ray images: a) Normal, b) COVID-19 and c) Tuberculosis.

Therefore, precisely and effectively interpreting these images is crucial for diagnosing, treating, and controlling several cardiovascular disorders. Historically, this job has necessitated the advanced knowledge of experienced radiologists, a proficiency sometimes constrained by workload and geological irregularities[2].

Recent advancements in utilizing artificial intelligence techniques have emerged as a valuable tool in transforming the analysis of medical images. These models can enhance the capacities of radiologists, contributing to improvements in symptomatic accuracy and competence [3]. Therefore, efforts are ongoing to improve the quality of medical care by researching new algorithms and solutions to apply them in the medical field [4]. New techniques such as deep learning algorithms have attracted significant attention in many medical studies, especially pulmonary diseases. For example, the study of Nayak et al. [5] presented an automated early diagnosis system by processing X-ray images utilizing deep learning models. In their study, eight pre-trained CNNs models were investigated to

classify COVID-19 from healthy cases. The best model, ResNet-34, provided an accuracy of 98.33% on the tested chest X-ray images. The study of Singh et al. [6] used a CNNs algorithm to identify COVID-19 in chest X-ray images. The CNNs and VGG16 models were pretrained on the image dataset and used transfer learning and image processing techniques to increase detection accuracy. The dataset consists of normal and COVID-19 chest X-ray images. The results show that the CNN model successfully extracts useful features from the small dataset, suggesting that image processing and deep learning could be used for early and precise diagnosis. The CNNs model has the potential for medical professionals to diagnose COVID-19 and could help create automated screening systems for the pandemic's eradication. The Author found that the VGG16 model reduces overfitting and enhances model performance, making it particularly useful for smaller datasets like COVID-19 chest X-ray images. Six artificial deep neural networks were utilized to identify COVID-19 from chest X-rays images [7]. A total of 2905 COVID-19, viral pneumonia, and healthy chest X-rays were included in that study. With an overall accuracy of 96.91%, ResNet-50 was the most successful network. The model showed a high performance in the loss of detection of COVID-19 cases, indicating that it is a faster and more accurate method of detection.

Machine learning, especially deep learning, has been extensively explored in the context of corona detection, and a classifier has been trained to obtain positive corona or determine negative corona X-ray images as shown in [8]. This paper utilized Apache Spark and Deep Transfer Learning methods to create a classifier for COVID-19 chest X-ray images, achieving 100% accuracy in COVID/Normal/pneumonia, with 97 percent accuracy for InceptionV3, ResNet50, and VGG19 models. The study conducted by Mujahid et al. [9] detected pneumonia from X-ray images with pre-trained convolutional neural networks (CNNs) such as VGG16, Inception-v3, and ResNet50. The results indicate that Inception-V3 with CNNs had the best recall and accuracy rates, at 99.73% and 99.29%, respectively.

The goal of this paper is to propose a prediction model based on CNN algorithm. Therefore, the proposed model was applied to Chest image dataset to identify COVID-19 and Tuberculosis from healthy ones. The performance of our proposed model was evaluated using accuracy, specificity, recall, and F1-score metrics.

2 MATERIAL AND THEORETICAL BACKGROUND

2.1 Model Architecture and Transfer Learning

Figure 2 presents the flowchart of the proposed methodology used in this study. Up to 6078 publicly available chest X-ray images were processed. The dataset is subdivided into normal, tuberculosis, and COVID-19 images. For preprocessing, the images are resized to 224 × 224 pixels. The images were subdivided into 3 groups: 60% training, 20% testing and 20% validation. The images were evaluated and classified using three proposed models of this study.

CNNs are widely used in medical imaging, such as image recognition and chest X-ray classification, due to their ability to learn spatial hierarchy and detect abnormalities with high accuracy. CNNs include an input layer, an output layer, and several hidden layers that learn new and complex objects and patterns. Convolution and pooling operations are then applied to a subsample of the provided input, which is then passed through an activation function.

In contrast, InceptionV3 is a CNN-based model and potentially a fundamental depth learning that is commonly used in various exploratory considerations for image classification tasks [8]. InceptionV3's victory lies in its architecture's capability to extricate complex features from pictures. It is a profitable tool for precise classification tasks in areas like mechanical apparatus support, medical diagnostics, and ecological observation [10].

In addition, ResNet-50 is a deep CNN architecture that is broadly utilized in different areas, including therapeutic picture investigation and plant illness discovery [11]. Moreover, ResNet-50 has been investigated for assessing optical properties in scrambling media, displaying comparable or way better-remaking precision with training on smaller datasets and potential for assist improvements [12].

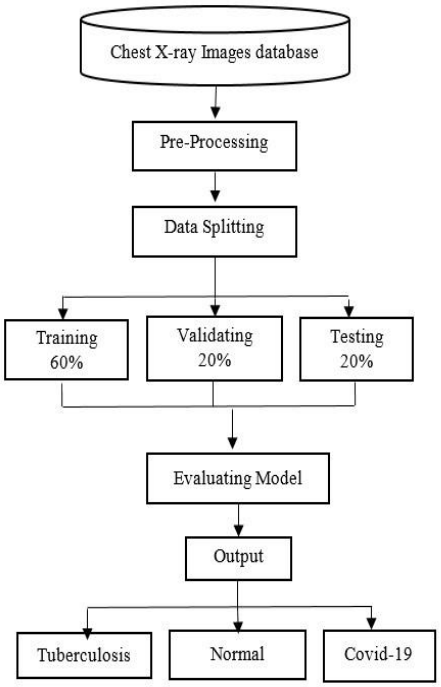

Figure 2: Flowchart of the proposed methodology.

The three models presented above achieved significant success in many computer vision tasks and have been adapted for the diagnostic analysis of medical images with promising results [13]. ResNet-50 has demonstrated exceptional performance in image classification tasks by addressing the paradox of the vanishing gradient problem[14]. In contrast, InceptionV3 employs a multi-scale preparation method, effectively capturing visual features at various degrees of reflection [15]. Therefore, this work investigates the suitability of three modern algorithms, CNNs, ResNet-50, and InceptionV3, for identifying tuberculosis and COVID-19 diseases from healthy cases by processing a chest X-ray image dataset. The study also aims to compare the three deep-learning architectures to determine which model provides the best balance of accuracy, generalization capability, and computational cost.

2.2 Data Splitting

The data is divided into training, validation, and testing sets, as shown in Table 1.

Table 1: Data splitting.

Class	Training	Validating	Testing	Total
Normal	1207	402	404	2013
Covid-19	1218	406	704	2328
Tuberculosis	1220	406	408	2034

2.2.1 Adjusting the Size of Image

All the used images of this study were resized to 224×224 pixels to be compatible with the requirement of deep learning models. This step enhances the process of extracting and selecting features.

2.2.2 Converting Image to Grayscale

The X-ray images were transformed into grayscale to emphasize details of structure essential for evaluation, thus minimizing the computational effort and removing unnecessary color data irrelevant to the purpose.

2.2.3 Normalization

Each pixel was normalized to the pixel intensity values range of [0, 1]. This step increases mode training performance.

2.2.4 Noise Reduction

In this study, the quality of images was improved by reducing noise and artifacts through using median filter.

2.2.5 Contrast Adjustment

To improve the contrast of the images and accessing the small details such as changes in lung visibility, histogram equalization was applied.

2.2.6 Dataset Balancing

Class imbalance was assessed in the dataset, especially where one group (like COVID-19) can predominate over others. To guarantee an equal representation of all classes, synthetic oversampling

methods like SMOTE (Synthetic Minority Over-Sampling Technique) were investigated. An example of pre-processed lung image is shown in Figure 3, which presents the enhancements steps that applied to the images.

Figure 3: Example of image pre-processing step.

2.3 System Evaluation

The performance of a model is explained by evaluation metrics. Evaluation metrics are evaluated based on their ability to distinguish between model outcomes [16]. The classification process gives four conceivable results: false negative, true negative, true positive, and false positive. Accuracy, recall, F1 score, and precision are utilized as execution evaluation measurements in this consideration [17].

2.4 Model Architectures and Hyperparameters

This section discusses the three model's parameters and setting in this project. First model is (CNN):

- Structure: Three consecutive Convolution layers with 32, 64, and 128 filters (kernel size = 3x3) and a 2x2 MaxPooling after each layer.
- Flatten the layer, then create a Fully Connected layer with a size of 512 neurons and a Dropout of 0.5.
- An output layer with three nodes (softmax) for three categories (Normal, COVID-19, Tuberculosis).
- Training Parameters: Image size: 224x224, Batch size = 32, Optimizer: Adam, Learning rate: 0.001, Number of epochs (up to 50 as in experiments).
- This model represents a lighter and simpler baseline, providing a comparison with deep models (ResNet, Inception).

The second model is (InceptionV3):

- Structure: Use InceptionV3 pre-trained on ImageNet with `include_top = False`.
- Additions: `GlobalAveragePooling2D`, A 1024-sized Dense layer with ReLU, A 3-node softmax output layer, Freeze the base InceptionV3 layers during training (only the top layers are trained).
- Training Parameters: Image size 224×224, batch size = 32, `optimizer = Adam, loss = categorical_crossentropy`
- InceptionV3 is known for its ability to capture multi-scale features, making it suitable for detecting subtle lung patterns in X-rays.
- Using transfer learning reduces the need for large datasets and leverages the general features derived from ImageNet.

The third model (ResNet-50):

- Structure: Use pre-trained ResNet-50 with include_top = False`.
- Additions: `GlobalAveragePooling2D`, `Dense 1024 with ReLU`, `Dense 3 with softmax`.
- Freeze the base ResNet layers (fine-tuning only for the top layers).
- Training Parameters: Image size 224×224, batch size = 32, Rescale images like Inception V3, `optimizer = Adam, loss = categorical_crossentropy`.
- Number of epochs (in the paper, ensure the number is consistent with what you actually implemented).
- ResNet-50 uses residual connections to address the vanishing gradient problem and allows for learning deep and accurate representations.
- It is a suitable middle ground between a simple CNN and Inception in terms of complexity and representational power.

3 RESULTS AND DISCUSSION

The proposed algorithms were used to explore the accuracy of diagnosing tuberculosis and COVID19 from the chest X-ray images. Table 2 contains the accuracy results of the proposed algorithms. The Inception-V3 model showed the highest accuracy when compared to the other models. Inception-V3 demonstrated effective performance in identifying X-ray images, with an accuracy of 0.9631, precision of 0.9752, recall of 0.9554, and an F1-score of 0.9651.

Table 2: Results of fine-tuned pre-trained models.

Model	Accuracy	Precision	Recall	F1-Score
CNNs	0.8613	0.8821	0.8116	0.8453
ResNet50	0.8975	0.9168	0.8963	0.9064
InceptionV3	**0.**9631	0.9752	0.9554	0.9651

Figure 4 presents the Accuracy results of the proposed algorithms versus epoch number. One can observe from Figure 4a, the validating and training accuracy of the ResNet50 model through 50 epochs. We notice that the highest precision is 89.75%. Figure 4.b shows the training and validation curves for Inception-V3.

The model reaches a training accuracy of 96.31%, and the validation accuracy remains consistently high across epochs, indicating stable learning behavior. All of the models are trained, approved and tested for normal, COVID-19, and Tuberculosis classes. Figure 4c shows the training and validation of the CNN model. We see that the accuracy is 86.13%. For 50 epochs, three models were trained on 3 classes, stability and performance enhancement registered in these models tune.

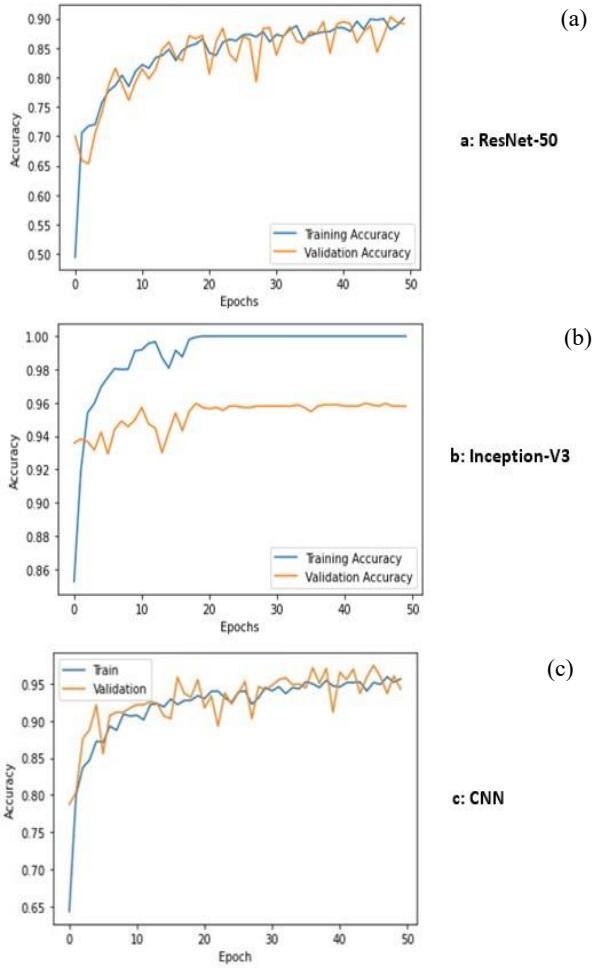
According to these curves, all models exhibit strong performance on both the training and validation datasets, achieving high levels of accuracy. The Inception-V3 shows (Fig. 4b) superior execution of the validation information with a precision of around 96%, making it the finest choice among the three models.

When using long periods of up to 50 epochs to train and test the data, we noticed that the results started to stabilize with little change after period 20. The same fluctuations appeared for the data during the training period, and the same thing was observed for the data's results during the test period.

The computational performance (training and inference time) for the three models shown in Table 3.

Table 3: Training and inference time in minutes.

Model	Training time	Inference time
CNNs	12.4	4.1
ResNet50	45.8	9.8
InceptionV3	59.6	16.3



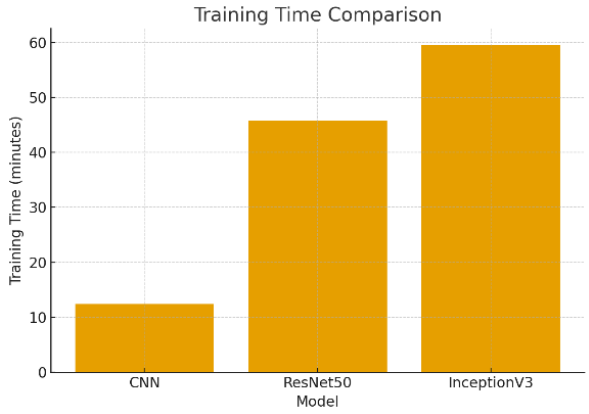


Figure 4: Accuracy results of the proposed algorithms: a) ResNet-50, b) Inception, c) CNN.

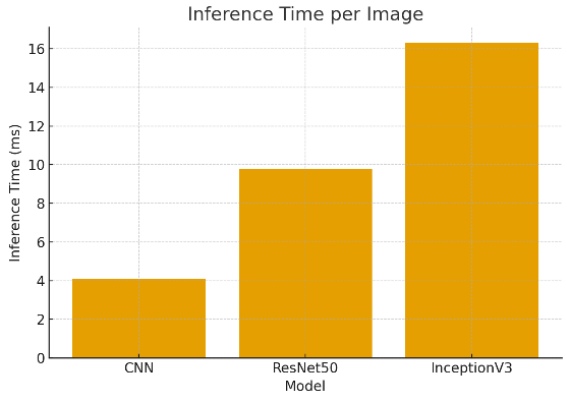

The computational analysis showed that the CNN model required the shortest training time (≈12.4 minutes), followed by ResNet-50 (≈45.8 minutes), while InceptionV3 needed the longest time (≈59.6 minutes) due to its deeper architecture.

For inference, CNN achieved the fastest prediction time per image (≈4.1 ms), whereas ResNet-50 and InceptionV3 required ≈9.8 ms and ≈16.3 ms respectively.

The bar chart in Figure 5 clearly demonstrates the computational cost across the three models.

(a)

(b)

Figure 5: Proposed algorithms (ResNet-50, Inception, and CNN): a) Training time, b) Inference time.

4 CONCLUSIONS

Experimental results demonstrated the efficiency of the proposed system in achieving robust classification performance. Even though the models produced encouraging results, a further comparative analysis revealed that Inception-V3 had the best overall performance and the highest accuracy. This makes it reasonable for simple applications where high accuracy is essential, as therapeutic symptoms, and is particularly persuasive for this classification assignment. Inception V3 offers the highest accuracy and F1 score.

Therefore, it is medically the best choice for the early detection of COVID-19 and tuberculosis.

Measuring the results of training and inference time, CNN is the fastest in training and inference, but the least accurate. ResNet-50 strikes a balance between accuracy and time. Inception V3 is the most accurate but the slowest in training and inference.

In conclusion, Inception V3 is suitable for systems where accuracy is a priority (such as central hospitals). CNN is suitable for systems requiring high speed (triage systems). ResNet-50 is a good compromise for applications with moderate resources. The importance of careful model selection and hyperparameter tuning for optimal performance in medical image investigation assignments has been highlighted by these findings. The effective implementation of deep learning in chest X-ray classification may enhance clinical treatment by increasing radiologists' proficiency and facilitating the identification of prior infection sites. Future studies should focus on helping to advance model execution, addressing issues like imbalanced datasets and clarifying capacity, and exploring how these models can be integrated into clinical workflows. The ultimate goal is to develop AI-based tools to improve patient care and advance diagnostic accuracy.

Abstract: The analysis of human behavior is an interdisciplinary science aimed at recognizing, describing, and predicting patterns of human behavior and emotional states. With the development of sensor technologies and data-driven approaches, new opportunities have emerged for observing and modeling everyday human activity. This study is based on a real-world dataset collected over one month from five participants in a residential environment. The data were gathered using environmental sensors, specifically contact sensors and energy consumption sensors, which enabled monitoring of user interactions with their surroundings. A set of statistical and machine learning methods was applied, including K-means clustering, correlation analysis, time-series representation, calculation of mean values, and aggregation of correlations. The results show how contact sensors and energy consumption sensors are related, how daily load is distributed, how periodic the data are, which sensors behave in a similar way within groups and across the system, and how individual behavioral models of each user can be formed. These findings highlight the potential of sensor-based analysis for advancing behavioral research and its practical applications.

1 INTRODUCTION

The risk of social isolation in private living has been shown to increase with age. Modern approaches in the fields of automation and health sciences can reduce this risk by enhancing social and psychological resilience in older adults [1].

In the context of demographic change, the associated increase in demand for care services and shortage of nursing staff present the healthcare system with urgent challenges that require immediate attention. Digital assistive technologies could be the solution to this problem [2].

In the PräEinsamAltKI project, researchers are using innovative digital solutions to prevent loneliness: a system is being developed for a model apartment that enable automatically and at an early stage identify increasing isolation in older people. It is expected to consist of a sensor network based on Internet of Care Things (IoCT) technologies and artificial intelligence (AI) capable of identifying signs of social isolation[1].

The subjects of the study are five users. The object of the study is individual daily electricity consumption indicators, as well as the total number of door and window openings available to all users.

One of the research tasks within the project is to analyze user behavior patterns, explore relationships between sensor measurements, and evaluate the informational value of the collected data. Accordingly, this article investigates behavioral trends in residential environments using electricity consumption data and door and window opening events, examines whether a measurable relationship exists between these two sensor modalities, and evaluates the extent to which such multimodal data can provide meaningful insights that may support the early detection of changes potentially related to social isolation.

2 METHODOLOGY

To address the research task, a dataset was constructed, an analysis plan defined, data processing was performed, and the result subsequently interpreted.

Common approaches include wearable sensors (accelerometers, heart rate monitors, biosensors), environmental sensors (cameras, Wi-Fi), mobile devices and self-report surveys or diaries for subjective input are used for data collecting [3], [4].

Once collected, data can be processed using methods like computer vision for video-based action recognition, or machine learning and deep learning models that extract patterns from multimodal signals. Researchers use both knowledge-driven approaches (e.g., social force models) and data-driven methods (e.g., RNNs, GCNs, GANs, reinforcement learning), with hybrid techniques combining domain expertise and AI gaining popularity [4], [5].

Energy consumption readings are processed using a time series database. As ordinary regression methods are not suitable for predicting these data, advanced algorithms such as RNN-LSTM, ARIMA, and others are applied [6].

In contrast to these technologically advanced and computationally intensive approaches, this study primarily employs statistical analysis and environmental sensor data. The analytical tools include descriptive statistics, clustering, correlation analysis, and time-dependent visualizations.

2.1 Dataset

The dataset was constructed from real sensor readings collected over one month. It consists of an array of timestamps corresponding to sensor states, each linked to specific entities.

It includes the electricity consumption data from smart plugs throughout the day for each of the five users. The contact sensor data represent the number of window or door openings per day. State values are represented in numerical format. Non-numeric observations (e.g., unavailable or NaN) were converted to zero values. The absence of data was interpreted as non-use.

The corresponding number of rows for each entity is presented in Table 1.

Thus, each entity is represented by the corresponding set of dimensions for the analyzed period.

2.2 Data Analysis Procedure

In the initial stage, the data for the entire period were visualized as time series to identify general patterns [7].

Next, mean and maximum values for each sensor were calculated by day of the week, based on which a summary table of average daily indicators was created [8]. The obtained aggregated values were used to perform unsupervised learning cluster analysis using the k-means method [9].

Additionally, heatmaps were constructed based on the average energy consumption throughout the day, which allowed to determine the load distribution pattern and the outlet usage hours.

In the next stage, the data was divided into three-time intervals, after which the Pearson correlation coefficients were calculated for each pair of features [10], [11]. The results of the correlation analysis were visualized as correlation matrices. Based on these matrices, the number of strong and moderate positive and negative correlation coefficients were calculated for each entity, indicating the prevailing direction of relationships between the sensors.

3 RESULTS

This section presents a step-by-step analysis of the procedures described in section 2.2.

The data visualization presented in Figures 1 and Figure 2 demonstrates the presence of patterns in the sensor readings. It is observed that the highest values persist for 4-5 days followed by a decrease. Five groups of peak values can be identified, indicating the periodic use of the sensors.

Thus, user behavior can be characterized as periodic, which is confirmed by the analysis of both graphs. As the individual consumption of each energy sensor increases the contact values also rise.

The average value calculated for the maximum value by day of the week for each sensor is presented in Table 1.

The maximum energy consumptions for each user occur on weekdays and the same trend is observed for contact sensors as well. For example, both are either minimal or absent on weekends.

Based on the window sensor data, the room is ventilated approximately once per day on weekdays.

From the table, it can be assumed that either the users connect different devices to their sockets or the usage times differ.

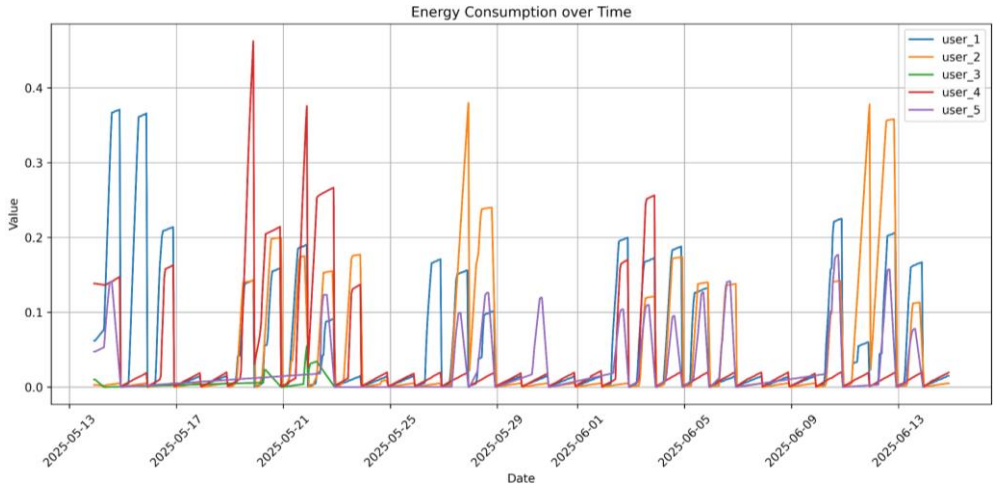

Figure 1: Time series of energy consumption sensors.

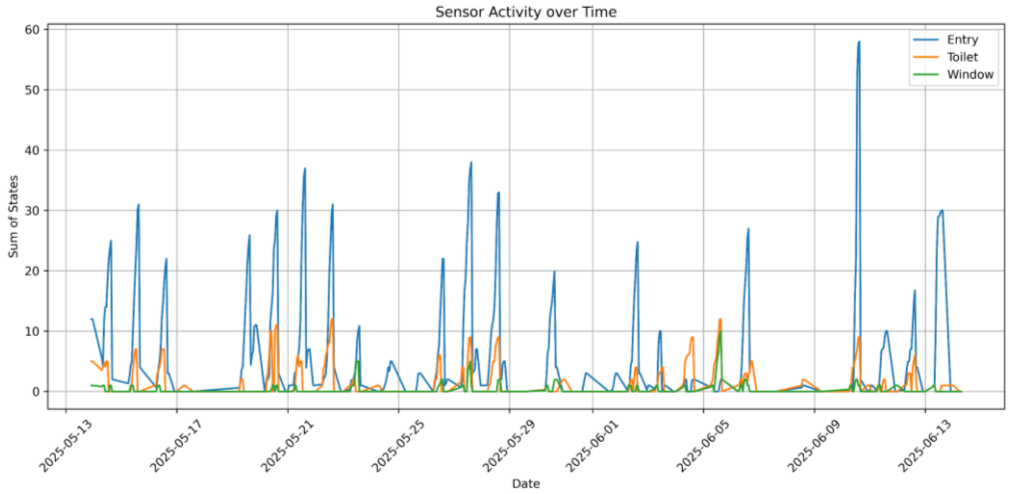

Figure 2: Time series of contact sensor values.

Table 1: Number of rows for each entity in dataset.

Energy sensors					
	user1	user2	user3	user4	user5
Rows	761	461	24	761	156
Contact sensors					
	entry		window		toilet
Rows	367		139		236

Table 2: Mean value for every sensor by day of week.

Entity	M	Tu	W	Th	Fr	Sat	Sun
user1, kW	0.132	0.155	0.198	0.162	0.085	0.014	0.014
user2, kW	0.039	0.169	0.162	0.132	0.087	0.005	0.005
user3, kW	0	0.016	0.018	0.034	0	0	0
user4, kW	0.167	0.129	0.097	0.068	0.071	0.019	0.019
user5, kW	0.104	0.108	0.107	0.135	0.113	0	0
entry	10.3	11.9	7.5	6.4	10.2	1.1	1.8
toilet	3.0	3.5	2.9	3.4	1.8	0.5	2.0
window	1.3	1.2	1.0	2.0	1.3	0.0	0

Clustering was performed to group data based on statistical features. To determine the number of clusters, the elbow method was used, which indicated that the optimal number of clusters for both groups is two.

As a result, it can be seen in Figure 3 that the behavior of the entry door differs significantly from their behavior on weekends and from that of all other contact sensors on other days. As already mentioned, the behavior of this sensor can be divided into weekday and weekend patterns. For all others, no other clearly visible useful information can be obtained. Despite the fact, that all other doors are used a far less times.

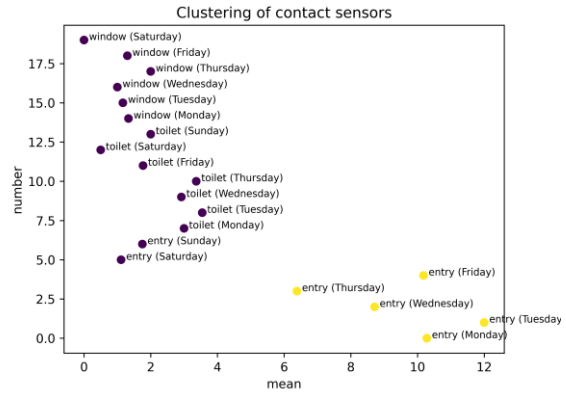

Figure 3: Clustering K-Means for contact sensor values.

The diagram obtained for the energy consumption sensors in Figure 4 appears more dispersed.

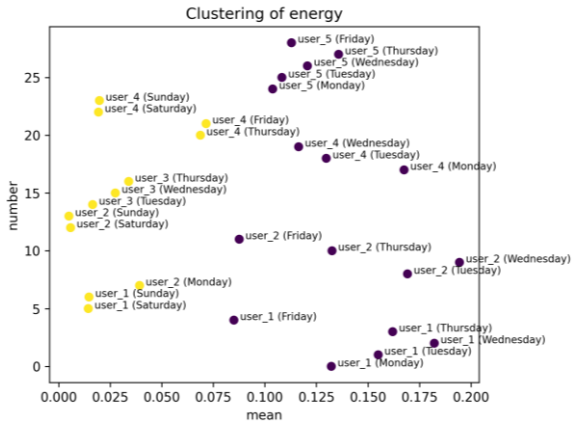

Figure 4: Clustering K-Means for energy sensor values.

User 3 stands out in that their consumption consistently remains at a low level, comparable to the weekend consumption of other users. User 5, on the contrary, is always part of the high-consumption group. The behavior of Users 1, 2, and 4 varies depending on the day of the week, showing a tendency toward higher consumption on most weekdays, which explains their assignment to both groups.

A clear periodic consumption is observed: activity on weekdays (purple group) is significantly higher than on weekends (yellow group). Thus, it can be concluded that the consumption is periodic, with higher levels during weekdays.

How does the situation develop within the weekdays themselves? The evolution if consumption patterns across weekdays is further examined through the heatmap presented in Figure 5.

In this diagram, the dark blue indicates 100% of the maximum value for each entity, while lighter shades correspond to lower levels of consumption. A striking feature of the visualization is the presence of empty cells during Saturday and Sunday. For several users, the values are either missing or remain extremely low, in many cases approaching or reaching zero.

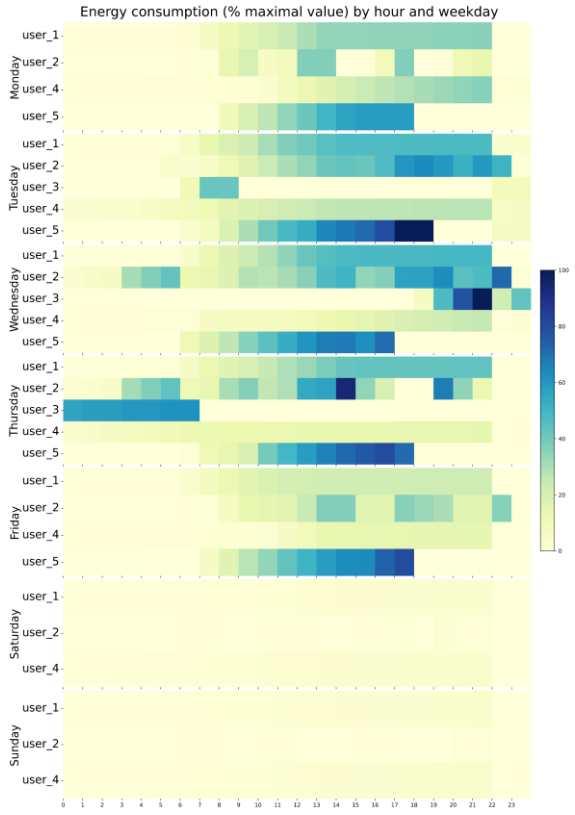

Figure 5: Hourly heatmap of consumption values expressed as a percentage of the maximum per user.

It is also evident that for many users, values gradually increase throughout the day. For example,

User 1 uses it's socket from Monday to Thursday between 8 - 9 a.m. and 2 - 3 p.m., after which energy consumption stops increasing and remains stable.

User 2, in turn, uses the socket consistently from Monday to Friday. On Monday and Thursday breaks in usage are observed. Often, usage starts at 8 a.m. and continues until 3 p.m., although values are occasionally recorded in the early morning.

User 3's consumption values are logged either before 9 a.m. or after 6 p.m. Which is compared to other users can be described as abnormal.

User 4's consumption pattern is less distinct, with activity sometimes beginning at 9 a.m. and other times at 12 p.m., and ending at 3 p.m. or 10 p.m., respectively.

User 5 exhibits a more stable pattern: from Monday to Friday, the socket is used consistently between 9 - 10 a.m. and 5 - 6 p.m.

The presented values indicate that the sockets are not in use continuously throughout the day. To analyze how the individual sensors relate to one another, Pearson correlation is employed.

In the correlation heatmaps, green denotes a positive relationship, meaning that the corresponding sensors tend to increase simultaneously. Conversely, colors shifting toward red reflect a negative relationship, where an increase in one sensor is associated with a decrease in another.

Figures 6 - 12 display these correlations across all days of the week, differentiated by three distinct time periods, thereby providing a detailed view of temporal variations in sensor relationships.

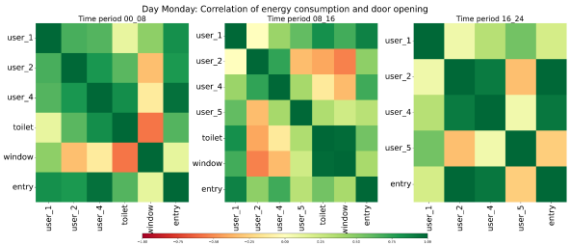

Figure 6: Pearson correlation of sensor values on Monday.

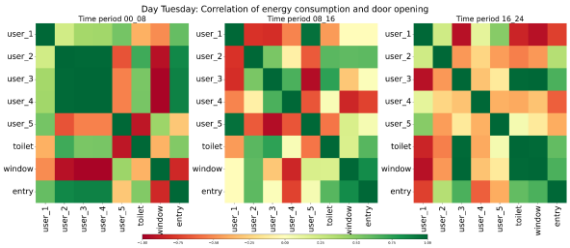

Figure 7: Pearson correlation of sensor values on Tuesday.

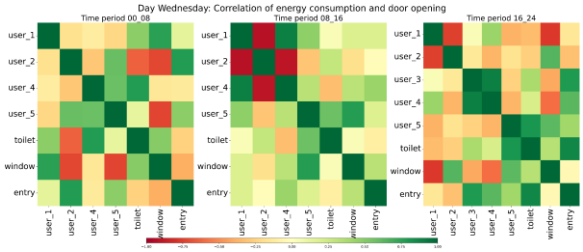

Figure 8: Pearson correlation of sensor values on Wednesday.

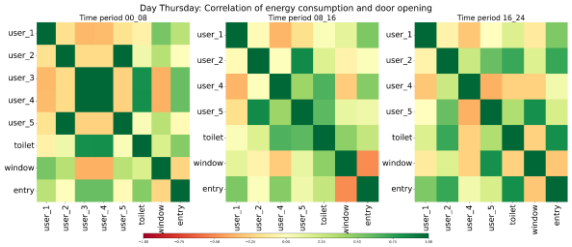

Figure 9: Pearson correlation of sensor values on Thursday.

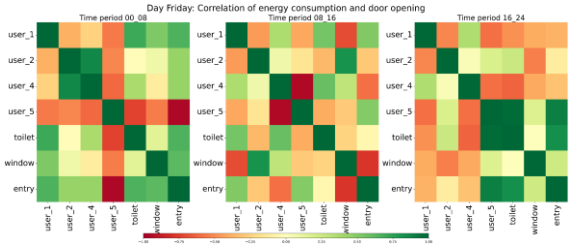

Figure 10: Pearson correlation of sensor values on Friday.

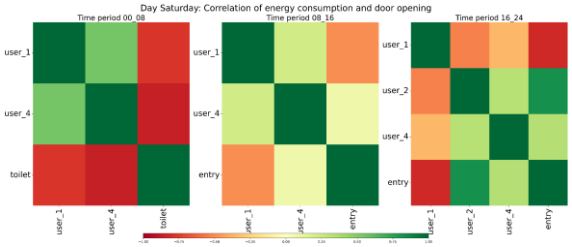

Figure 11: Pearson correlation of sensor values on Saturday.

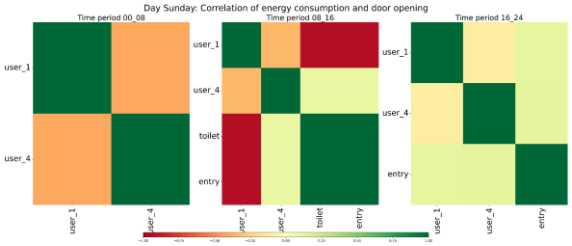

Figure 12: Pearson correlation of sensor values on Sunday.

Given the large number of correlations, a summary was created to facilitate interpretation. The average and strong correlations between entities across all periods were compiled and are presented as a bar diagram in Figure 13.

The analysis of correlations reveals distinct interaction patterns among the users and environmental sensors across different time periods (morning, daytime, and evening).

User 1 exhibits predominantly negative correlations with Users 2 and User 3 during both daytime and evening hours. In contrast, correlations with Users 4 and 5 are consistently positive across all time periods. In terms of contact sensors, correlations with all doors and the windows tend to be negative in the evening and positive in the morning. During daytime, positive and negative correlations are balanced, except for the entry door, where positive correlations are stronger.

The correlation between Users 2 and User 3 are positive at night and during the day, but becomes negative in the evening. For User 4, correlations tend to be positive during the evening and nighttime, whereas for User 5, positive and negative correlations occur with approximately equal frequency. A similar balance is observed for User 4 during daytime hours. Correlation between User 2 and the entry door remains consistently positive throughout all time periods. For the window, positive correlations dominate during the day. Correlations involving the toilet door are generally mixed, with the exception of nighttime hours, during which positive correlations predominate.

User 3 exhibits predominantly positive correlations with User 4 across all time periods, particularly at night. In contrast, correlations with User 5 are generally negative, except during the evening, when no correlation is observed. Regarding the entry door, correlations are positive in the morning and evening but absent during daytime hours. For the toilet door, correlations remain consistently positive across all periods, whereas correlations with the window are positive in the morning and neutral in the evening.

Between Users 4 and User 5, correlations are predominantly negative across all time periods. With the entry door, correlations remain consistently positive. With the toilet door, correlations are positive in the morning and during the day. In contrast, correlations with the window are consistently negative across all time periods.

Correlations between User 5 and both the entry door and the window are positive during daytime and evening hours. Correlations involving the toilet door are mixed during daytime hours but become predominantly positive in the evening.

4 CONCLUSIONS

The conducted analysis demonstrates that user behavior exhibits a clear periodic structure, with significantly higher activity levels and sensor usage during weekdays, followed by a sharp decrease or complete absence of activity on weekends. This pattern is consistent across both energy consumption and contact sensors, confirming that users tend to follow stable daily routines strongly linked to the working days.

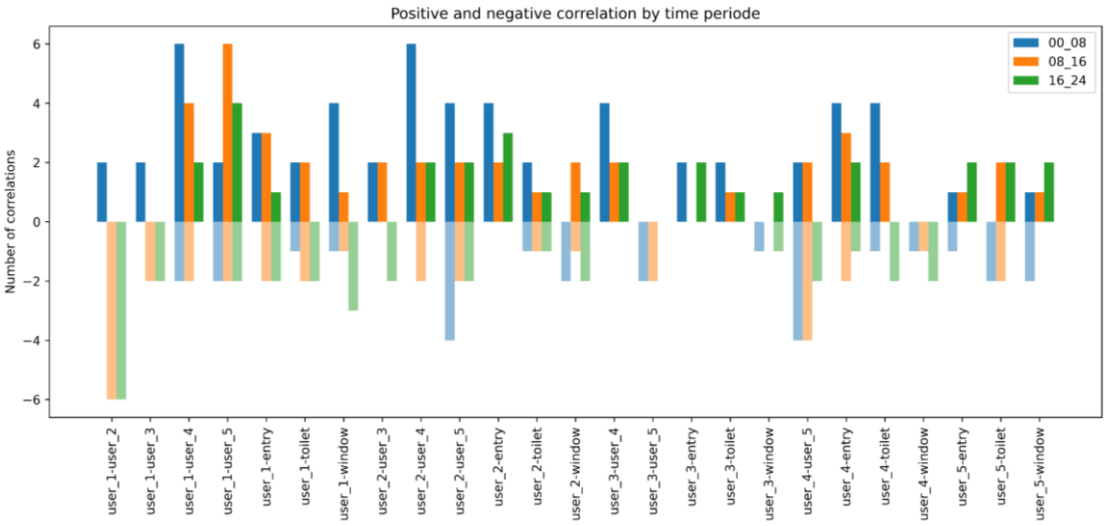

Figure 13: Positive and negative correlation by period.

Clustering analysis revealed that users can be divided into distinct groups: some consistently show higher energy consumption (e.g., User 5), while others remain at low levels (e.g., User 3), independent of the day of the week. Users 1, 2, and 4 display more variable behavior, with their consumption fluctuating depending on the weekday, yet still showing a tendency toward greater usage on working days.

The hourly heatmap analysis further confirmed these patterns by highlighting that sockets are not in continuous use but rather concentrated in specific periods, typically between morning and late afternoon. This reflects daily working rhythms and indicates that user activity is temporally bounded and highly structured.

Correlation analysis revealed both synchrony and divergence in user behavior. While Users 1, 2, and 3 tend to avoid simultaneous usage, Users 4 and 5 demonstrate stronger positive correlations with others, suggesting complementary or overlapping usage patterns. Interactions with environmental sensors such as doors and windows also exhibit temporal dependence, showing predominantly positive correlations in the morning, balanced dynamics during the day, and negative correlations in the evening.

Overall, the study demonstrates that even simple, low-cost, and non-intrusive sensors - such as energy consumption and contact sensors - can provide complementary and meaningful insights into user behavior in shared residential environments. Their combined use enables the identification of daily routines, user-specific patterns, and interaction dynamics between individuals and their environment, providing a transparent and interpretable baseline for future AI-driven systems. By establishing typical behavioral patterns for each user, this approach lays the foundation for detecting deviations that may signal changes in daily life, which could potentially support the early identification of situations associated with reduced engagement or emerging social isolation.

Keywords: Autism Spectrum Disorder (ASD), Early Detection, Clinical Data, Machine Learning.

Abstract: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition that requires timely and accurate detection for effective intervention. This study evaluates the performance of six machine learning models – Logistic Regression, Support Vector Machine (SVM), Decision Tree, Random Forest, XGBoost, and k-Nearest Neighbors (kNN) – in detecting ASD across three age groups, using three separate datasets: children, adolescents, and adults. Using a comprehensive dataset segmented by age, each model was assessed through stratified 10-fold cross-validation based on five key performance metrics: accuracy, precision, recall, F1 score, and area under the curve (AUC). The findings indicate that ensemble and linear models, particularly XGBoost and Logistic Regression, consistently deliver the most reliable results across all age groups and the combined dataset, with high classification accuracy and balanced precision-recall tradeoffs. In contrast, kNN and Decision Tree models displayed inconsistent performance, often struggling with both false positives and false negatives. This analysis supports the application of advanced machine learning methods, especially ensemble techniques, for developing robust and generalizable ASD detection systems across diverse age demographics.

1 INTRODUCTION

Autism Spectrum Disorder (ASD) is a neurodevelopmental condition that typically manifests within the first three years of life [1]. It is primarily characterized by challenges in social interaction, communication difficulties, restricted interests and repetitive behaviors [2]. Individuals with ASD often struggle to understand others' emotions and thoughts, which can make interpersonal communication difficult. According to the World Health Organization (WHO), approximately 1 in 270 people globally are affected by ASD [3]. Each individual spectrum presents a unique set of characteristics – while some face significant challenges, others may exhibit exceptional abilities in areas such as visual processing, academics or music. Early diagnosis and intervention are crucial in managing ASD effectively. Detecting ASD early enables more timely and targeted treatments, which can significantly improve outcomes and reduce the long-term impact of the disorder. Traditionally, symptoms are identified through clinical observation, which can be time-consuming and labor-intensive.

In recent years, machine learning techniques have emerged as powerful tools for analyzing symptoms associated with complex conditions such as heart disease, diabetes, and cancer. These methods are now increasingly being applied to ASD detection, with researchers [4], [5] developing a range of models to improve the accuracy and efficiency of diagnosis and help mitigate the effects of ASD more effectively.

The prevalence of ASD has been increasing rapidly across all age groups in recent years. Early detection of this neurodevelopmental condition is crucial, as it can significantly improve the individual's mental and physical well-being. With the growing application of machine learning in healthcare, early diagnosis of various neurological and physiological conditions is becoming increasingly feasible. This progress has fueled growing interest in utilizing these technologies to enhance the detection and analysis of complex disorders, thereby enabling more effective treatment strategies. However, diagnosing ASD remains challenging due to symptom overlap with other mental health conditions. These similarities often complicate the diagnostic process, making accurate and timely identification of ASD a difficult task. This underscores the need for advanced computational tools, such as machine learning models, to support clinicians in distinguishing ASD from related disorders [6].

2 RELATED WORK

Recent studies have explored the use of wearable sensor-based devices for the detection of Autism Spectrum Disorder (ASD) [7], [8]. The integration of intelligent systems has introduced more cost-effective and scalable solutions for identifying ASD in children, adolescents and adults [9]. A wide range of methods has been applied in the literature, including structural magnetic resonance imaging (MRI) [10], neural networks, machine learning (ML) techniques, deep learning, transfer learning, and Internet of Things (IoT) – based frameworks [11]. While these approaches have shown promising results in ASD detection with reasonable accuracy, they are often hindered by data acquisition challenges. Many healthcare institutions are reluctant to share patient data due to organizational policies and regional data protection regulations, making data privacy, security, and availability major obstacles in the development of effective intelligent diagnostic systems. Furthermore, even when data access is granted, transmitting large volumes of data over networks introduces additional concerns such as network congestion, latency and potential data breaches.

Wong et al. [12] utilized data mining tools to investigate the impact of various autism treatments on behavioral outcomes. Their approach enabled the prediction and better understanding of autistic children's behavior, providing a framework for differentiating between socially acceptable and unacceptable conduct. Similarly, Kaur et al. [13] conducted a comprehensive review of 45 research studies that employed supervised machine learning and classification algorithms in the context of ASD diagnosis and analysis. Among the most frequently used models were Support Vector Machine (SVM), Neural Networks, Random Forests, Decision Tree, Least Absolute Shrinkage, and Selection Operator (LASSO), various regression methods, Conditional Forests (CF), Naïve Bayes (NB), Elastic Net regression (Enet), Random Tree, and Flex Tree classifiers. Furthermore Koumpouros et al. [14] carried out a systematic review of 83 studies published after the year 2000, focusing on interventions for ASD that leveraged wearable technologies and computation methods to support treatment and behavioral monitoring.

3 DATA

The following section describes the dataset preprocessing, model selection, hyperparameter tuning, and performance evaluation procedures used to assess the effectiveness of various machine learning models for predicting ASD.

Three datasets are used for the purpose of this paper, one for children, one for adolescents, and one for adults. Every dataset consists of 20 features, 10 of which (A1-A10) are behavioral features that have a binary value (value that is 0 or 1). The other 10 features are shown in Table 1 [15]-[17].

Table 1: Dataset features.

Feature	Description
age	Age in years
gender	Male or female
ethnicity	List of common ethnicities in text format
jaundice	Whether the person was born with jaundice
autism	Whether any immediate family member has ASD
country_of_res	List of countries in text format
used_app_before	Whether the user has used a screening app
result	The final score obtained based on the scoring algorithm of the screening method used. This was computed in an automated manner
age_desc	The age span of the patient
relation	Who diagnosed the patient

For this paper, in addition to the analysis done on these datasets, containing the same features, we constructed a dataset that is a combination of all three. The analysis of the combined dataset gives another view of the results.

The target variable, Class/ASD, was categorical, representing the presence or absence of ASD. To enable machine learning algorithms to process this variable, Label Encoding [19] is applied, where the classes were transformed into binary numeric values: 0 for negative and 1 for positive cases.

4 METHODS

For this study, six machine learning models were selected for comparison:

- Logistic Regression: A linear classifier suitable for binary classification tasks [22];
- Support Vector Machine (SVM): A non-linear classifier that maximizes the margin between classes using kernels [23];
- Decision Tree: A recursive partitioning method that constructs decision boundaries based on features. [24];
- Random Forests: An ensemble model that aggregates the predictions of multiple Decision Trees [20];
- XGBoost: A gradient boosting method known for its robustness and performance [25];
- k-Nearest Neighbors (kNN): A non-parametric method that assigns labels based on the majority vote of neighboring points [26].

5 EXPERIMENTAL SETUP

Initially, a traditional train-validation-test split was implemented to evaluate model performance [18]. However, this method resulted in inconsistent and unreliable evaluation metrics, likely due to the limited size and potential variability within the dataset. To address these limitations, the study adopted a 10-fold cross-validation strategy, which better maintains class proportions across folds and provides more stable and generalizable evaluation results [32].

In 10-fold Stratified Cross-Validation, the dataset was divided into ten equal-sized folds, ensuring that each fold preserved the same class distribution as the overall dataset. The model was trained on nine folds and tested on the remaining fold, and this process was repeated 10 times. The final reported metrics were the average values across all folds.

5.1 Feature Selection

Feature selection is performed using a Random Forest Classifier, to identify the most important predictors of ASD. Random Forest, an ensemble method, computes the importance of each feature by measuring how much they contribute to the reduction of impurity in the Decision Trees [20]. The topmost important feature was identified and subsequently dropped to assess the effect of excluding this feature on model performance. This step was essential for ensuring that the model was not overly reliant on a single feature, which could lead to overfitting.

5.2 Hyperparameter Tuning

To optimize the performance of the models, hyperparameter tuning was performed using GridSearchCV [21]. This method exhaustively searches through a specified parameter grid to identify the best combination of hyperparameters for each model. The hyperparameters tuned for each model included regularization strength (c) for Logistic Regression and SVM, maximum tree depth and minimum samples for Decision Trees and Random Forests, number of neighbors for kNN and learning rate, tree depth, and number of estimators for XGBoost. The hyperparameters were selected based on accuracy as the scoring metric.

5.3 Evaluation Metrics

The metrics that were computed to assess the performance of each model are:

- Accuracy – Measures the proportion of correctly classified instances among all instances [28];
- Precision – Measures the proportion of correctly predicted positive instances among all predicted positives [29];
- Recall – Measures the proportion of correctly predicted positive instances among all actual positives [29];
- F1 Score – Represents the harmonic mean of precision and recall, balancing the two [30];
- Area Under the ROC Curve (AUC) – Evaluates model's ability to distinguish between classes across all threshold settings [31].

These metrics were selected to provide a comprehensive evaluation of predictive ability, especially considering the potential imbalance in class distributions [27].

6 RESULTS

This section presents the results of the descriptive analysis and model evaluation. It explores the distribution of demographic and target features across children, adolescent and adult datasets, followed by performance of six classification algorithms. The analysis is then replicated on a merged dataset to assess model behavior across a combined population.

6.1 Exploratory Data Analysis

To understand the class balance of the dataset across different age groups, the distribution of the target variable (Class/ASD) was visualized separately for children, adolescents and adults.

The class distribution varies across datasets. The children dataset is relatively balanced, with nearly equal numbers of ASD-positive and negative cases, which minimizes bias during model training. In contrast, the adolescent dataset shows a mild skew toward ASD-positive cases, which may influence sensitivity and false positive rates. The adult dataset is strongly imbalanced, with a much higher proportion on ASD-negative cases. This imbalance can hinder the detection of positive cases and may require techniques such as stratified cross-validation or class weighting.

The approximate values of the target variable distribution are illustrated in Table 2 below.

Table 2: Target variable distribution.

Dataset	NO	YES
Children	49%	51%
Adolescents	38%	62%
Adults	72%	28%

To better understand the demographics of each dataset and assess potential biases, the distribution of age was visualized for the children, adolescent, and adult datasets (Figure 1).

The age distribution varies notably across the three datasets. In the children group (ages 4-11), the highest concentration of participants is at age 4 (n≈78), after which the numbers decline steadily with age. This pattern reflects the priority given to early ASD screening, often beginning in preschool years [33].

Among adolescents (ages 12-16), the distribution is relatively even, with each year represented (n≈14-29), and a slight peak at age 16. This indicates that diagnoses continue into adolescence, often due to increased social and academic pressure [34].

In adults (ages 18-80), the distribution peaks in early adulthood (ages 18-25, n≈90) before gradually tapering off with age. This suggests that while most adult diagnoses occur in early adulthood there is still a presence of individuals diagnosed later in life, possibly due to retrospective recognition of lifelong traits or increasing public and clinical awareness of ASD [35].

Analysis of ethnicity across age groups revealed distinct demographic patterns. In the children dataset, White-European participants make up nearly half the sample, followed by Asian and Middle Eastern groups, with minority representation remaining limited underscoring persistent disparities in early ASD diagnosis across ethic lines [36].

Among adolescents, White-European representation decreases slightly, while "Others," Black, and Hispanic groups increase, suggesting broader diagnostic access and improved outreach [37].

The adult dataset shows the most diversity, with White-Europeans below 40% and strong representation from Asian, Middle Eastern, South Asian, Black, and Latino groups, reflecting greater awareness and inclusivity in adult diagnoses.

The gender distribution across the three age groups – children, adolescents and adults – was evaluated to understand the demographic composition of the dataset (Table 3). The gender distribution for children, exhibits a noticeable imbalance, with the number of males being significantly higher than females. This disproportionate representation aligns with the existing research which indicates a higher prevalence of ASD diagnoses among male children compared to female [38].

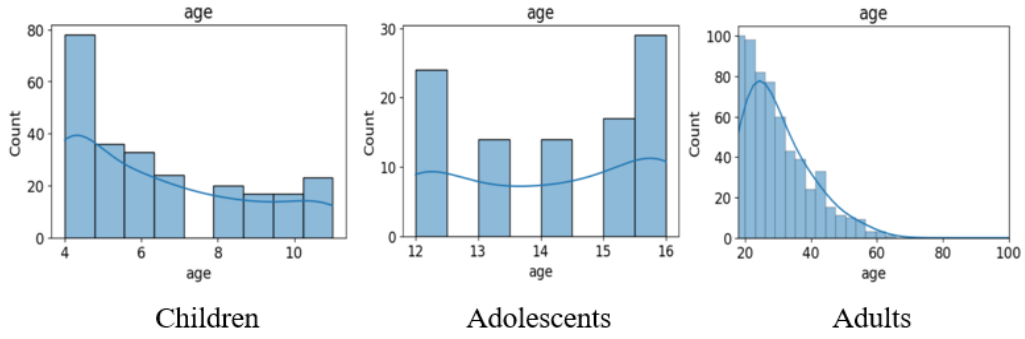

Figure 1: Age distribution across age groups.

In the adolescent group, the gender distribution achieves near parity, with 50 males, and 50 females represented. This balanced composition ensures that the models trained on this dataset are less likely to exhibit gender-related biases, enabling a fair evaluation of ASD detection across both genders in this age group.

The adult dataset demonstrates a relatively balanced gender distribution, albeit with a slight skew. While not perfectly balanced, this distribution provides sufficient representation of both genders to minimize bias in the analysis of ASD detection among adults.

Table 3: Gender distribution across age groups.

Dataset	Male	Female
Children	70%	30%
Adolescents	50%	50%
Adults	53.3%	46.7%

Jaundice, particularly neonatal, has been studied for its potential association with neurodevelopmental disorders, including ASD. Neonatal jaundice results from elevate bilirubin levels, which, if untreated, may lead to kernicterus – a condition that can cause brain damage [39]. In the dataset, most children do not have a history of jaundice. For adolescents, jaundice is even rarer, while in adults, the majority also report no history (Table 4). Overall jaundice is an uncommon feature across all age groups, however, its presence in early life has been linked to potential neurodevelopmental impacts, which could have implications for ASD detection [40].

Table 4: Jaundice distribution across age groups.

Dataset	YES	NO
Children	22.2%	77.8%
Adolescents	18.4%	81.6%
Adults	8.1%	91.9%

6.2 Model Evaluation by Age Group

In this section, the evaluation results of the machine learning models used to predict ASD, across different age groups are presented. The performance of each model is assessed using several key metrics, including accuracy, precision, recall, F1 Score and AUC. These metrics provide a comprehensive understanding of how well each model performs in terms of classification accuracy, the ability to detect true ASD cases and the balance between false positives and false negatives.

Table 5: Model comparison for the children database.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)	AUC (%)
Log Reg	95.58	95.64	96.09	95.77	95.54
SVM	95.2	94.3	96.86	95.43	95.16
kNN	84.35	79.05	96.79	86.59	84.23
Decision Tree	87.52	85.07	92.05	88.24	87.53
Random Forests	94.77	94.89	95.38	94.95	94.84
XGBoost	95.57	95.49	96.09	95.69	95.57

As shown in Table 5, for the children's dataset shows that Logistic Regression and XGBoost perform very similarly across all metrics, making them strong candidates for the children's dataset. SVM has high recall but lower precision, indicating a tendency toward false positives. kNN performs the worst overall, with low accuracy, precision, and F1 score despite high recall. The Decision Tree is balanced but lags behind the top models in precision and F1 score, indicating room for improvement. Random Forest is reliable and comparable to XGBoost but slightly lower in accuracy, precision, and F1.

Table 6: Model comparison for the adolescent dataset.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)	AUC (%)
Log Reg	90	92.74	91.9	91.99	89.29
SVM	89.89	88.87	96.67	92.25	87.5
kNN	73.56	71.4	98.57	82.68	63.87
Decision Tree	74.78	80.77	80.95	79.6	72.14
Random Forests	88.78	87.78	96.67	91.69	85.42
XGBoost	86.78	88.12	91.9	89.62	84.29

According to the evaluation results shown in Table 6, Logistic Regression is the top-performing model for the adolescent dataset, with high precision (92.74%) and recall (91.9%), making it a balanced and reliable choice. SVM has strong recall but lower precision, leading to more false positives. kNN has high recall (98.57%) but low precision and F1, reducing overall effectiveness. Decision Tree is balanced but suboptimal, while Random Forest and XGBoost perform well but slightly behind Logistic Regression in precision and F1.

Table 7: Model comparison for the adult dataset.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)	AUC (%)
Log Reg	97.53	96.59	95	95.75	96.8
SVM	96.22	94.42	92.78	93.5	95.22
kNN	84.35	84.03	86.11	84.94	89.56
Decision Tree	88.99	82.44	80.56	81.09	86.54
Random Forests	96.06	95.58	90.56	92.83	94.46
XGBoost	97.53	96.66	95	95.76	96.8

Table 7, shows that Logistic Regression and XGBoost are the top models for the adult dataset, with the highest accuracy (~97.53%) and excellent precision, recall, F1, and AUC, indicating strong and consistent classification of ASD cases. SVM performs well but slightly below the top models. Random Forest is solid but less consistent, kNN shows moderate performance with lower precision and F1, and Decision Tree performs the weakest overall.

6.3 Analysis on the Combined Dataset

The models were also evaluated on a combined dataset that merges data from children, adolescents, and adults to assess overall performance across age groups. As with age-specific analyses, 10-fold stratified cross-validation was used, and performance was measured using accuracy, precision, recall, F1 score, and AUC. The evaluation results are shown in Table 8.

Table 8: Model comparison for the combined dataset.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)	AUC (%)
Log Reg	97.38	97.02	96.19	96.58	97.16
SVM	96.12	94.64	95.38	94.99	95.98
kNN	82.2	74.17	83.13	78.28	82.37
Decision Tree	87.85	83.28	85.87	84.46	87.48
Random Forests	95.19	95.05	93.4	93.64	94.67
XGBoost	98.22	97.85	97.54	97.68	98.09

The findings from the combined dataset underscore key factors in developing a unified model effective across all age groups. XGBoost proved to be the most effective, achieving high sensitivity and specificity, which is crucial in clinical screening where minimizing both false positives and false negatives is essential. Its strong performance across varied age-related features demonstrates robustness and adaptability, Likewise, Logistic Regression showed consistent results, confirming its reliability for classification tasks involving structured clinical data.

7 DISCUSSION

The comparative analysis of the six machine learning models revealed distinct performance patters across age groups, prompting further interpretation of their mechanisms and suitability for ASD detection.

The superior performance of Logistic Regression and XGBoost can be attributed to their model design advantages. Logistic Regression performs well because the dataset's features show strong, mostly linear relationship with ASD diagnosis, allowing for a simple and generalizable decision boundary.

In contrast XGBoost, effectively captured complex, non-linear feature interaction through its ensemble of decision trees, providing strong adaptability and robustness.

The comparatively weaker and less stable performance of kNN and Decision Tree aligns with expectations. Decision Tree models are prone to overfitting, while kNN's distance-based approach struggles with high-dimensional data, leading to inconsistent performance.

Error analysis showed that the models struggled with individuals whose features were borderline for ASD or who showed mild symptoms, leading to more false negatives, especially among adults, where learned social behaviors can mask ASD traits. Future work should include more detailed feature analysis to improve accuracy in these borderline cases.

8 CONCLUSIONS

This study evaluated six machine learning models for detecting ASD across children, adolescents, and adults, using Accuracy, Precision, Recall, F1 Score, and AUC as performance metrics.

The study concludes that machine learning models, specifically Logistic Regression and XGBoost, provide a robust and generalizable

foundation for early non-invasive ASD screening across all age groups. However, the limitations of this work must be acknowledged. Firstly, the models are trained solely on structured clinical questionnaire data, and do not incorporate time-series behavioral, genetic, or brain-imaging data. Secondly, the model performance, particularly on the adult dataset strongly influenced by the demographic and cultural background of the data, so clinical validation on diverse populations is essential before wider use.

In practice clinicians could input patient assessment data into the model, which would provide a risk estimate to support further evaluation or referral, supporting informed clinical decisions without replacing professional judgment.

Abstract: The present study explores the integration of AI-driven solutions in the education of medical professionals and their role in achieving high-quality healthcare and personalized strategies. A range of AI tools is examined to evaluate how they shape training environments, support medical students during their studies, and influence their later professional practice. The primary objective is to analyze how AI contributes to the advancement of medical education and the transfer of acquired knowledge into daily clinical routines. While AI enables rapid access to information and decision support, medical professionals must also maintain the ability to make accurate judgments under pressure. This raises concerns about whether reliance on AI during training may reduce students' capacity for independent and rapid clinical reasoning. The study further investigates the extent to which AI-based simulations can provide realistic and comprehensive training experiences. Beyond replicating surgical procedures, it is critical to assess whether such systems can recreate the psychological, emotional, and tactile aspects of practice—such as stress management, operating under pressure, and the physical sensations of interacting with human tissue. Special emphasis is placed on identifying the benefits for patients, particularly whether AI-enhanced education ultimately contributes to more effective, personalized healthcare outcomes.

1 INTRODUCTION

Digital technologies, especially AI, have become a huge part of our daily lives. They're involved in so many areas like education, healthcare, retail, and even navigation on ships. What's even more interesting is how these technologies are linking these areas together in ways we didn't expect before. This is making it even more important for us to use them well, and also to be able to adapt ourselves and adjust these tools to fit our personal needs.

One example of this is how animal testing is being replaced with simulations [1], [2]. More and more, computer-based models are being used to train medical students, simulating things like blood tests, patient behavior, different reactions, or even emergencies. This shift is not only more ethical but also opens up the possibility for better and more efficient learning.

The main goal of all of this is to improve healthcare, to make sure medical professionals are well-prepared, and to reduce preventable mistakes. In the research, we will look into how AI is already being used in medical education, how it affects the learning of students, and how this knowledge is applied when they become practicing doctors. We'll also explore the consequences and impacts of bringing AI into medical training. The core argument of this study is that AI does not contribute to the development of empathy toward patients.

2 METHODS

2.1 Literature Review

This study includes a narrative review of the current literature on AI technologies in medical education and personalized healthcare. Sources were identified through keyword searches in databases such as Scopus, Spinger Natura, ResearchGate and PubMed using terms like "artificial intelligence", "medical education", "personalized medicine", and "adaptive learning". The review focused on papers published between 2004 and 2025. Only peer-reviewed articles and reputable conference papers in English were included. The aim was to summarize key trends, challenges, and research gaps relevant to the study topic.

2.2 An Online Survey

An online survey was conducted using Google Forms between April and May 2025. The participants included medical students and faculty members from various institutions in Bulgaria. A total of 68 responses were collected. Although the sample size is relatively limited, this reflects the current early stage of integration of AI-based training tools and simulations in Bulgarian medical education. As such technologies are not yet widely implemented, the study serves as an initial exploration of awareness and attitudes. The survey consisted of fully anonymous questions focused on perceptions, interest, and expectations related to AI in medical learning contexts. No demographic data were collected, as the study aimed to capture general attitudes and experiences, rather than conduct subgroup analysis. Moreover, the anonymous nature of the questionnaire was intended to encourage candid responses.

3 AI TOOLS IN MEDICAL EDUCATION – TYPES AND MODELS

AI in the fields of medical education can influence the student learning process in different ways [3]. There are different types of AI tools, and they serve different purposes. Practice indicates that the use of AI in medical education fosters critical thinking and the ability to make rapid decisions [4]. However, not all studies support this view, some suggest the opposite [5].

3.1 Virtual Patients - Simulation of Real Patient Cases

Virtual patient is a computer simulation of a real patient which is used in education for students or medical specialists. The virtual patient has symptoms, test results, and even AI tools that provide patient responses based on the user's choices. This happens without any risk, unlike with real patients [3]. Machine learning is incorporated to interpret laboratory data accurately and defect abnormal values [3], [6].

3.2 AI Robots in Surgery and Surgery Simulation

These Procedural skills can be assessed with Virtual Reality, where a simulated patient will be presented in a virtual environment, and the learner is asked to do a procedure [3]. Simulation training is one method of developing proficiency in a safe and risk-free environment and is used in formal surgical training [7]-[10]. One of the examples in this category is Touch surgery software - an effective instrument for medical student education that aims to teach surgical decision making to trainees without risk to patients [7]. Trainees can continue their learning during actual procedures using AI driven robotic systems [11].

The research shows that while AI is improving procedural safety, they also led to unintended negative effects on certain technical skills (like hands movement during surgery) [12].

3.3 AI Patient Diagnosis and Prescription - Chatbots

AI is integrated into medical education through the use of virtual patient simulations and surgical simulations, enabling students to develop skills in diagnosis and treatment planning. Furthermore, AI tools continue to support physicians after graduation by assisting them in real clinical environments. One of the most used AI tools is ChatGPT, with 66.7% of the 207 surveyed students reporting familiarity with it [13].

After graduation, specialists continue to use AI in their practice for patient diagnosis. DXplain is a big example; it is a clinical decision support system. The system assists healthcare professionals by providing a list of potential diagnoses based on the input of clinical findings, including symptoms, signs, and lab results [14].

Similar AI tools are AMIE (a Large Language Model - based AI) [15], [16] and FAMULUS (a Natural Language Processing model) [17]. Stanford Graduate School of Education is using web-based platforms to help medical students improve their ability to determinate a patient's initial diagnosis and treatment. It is called Clinical Mind AI [18]. The last one is documented in Standford Graduate School of Education paper. These tools provide high-quality consultations tailored to the personalized needs of patients [16].

3.4 AI Knowledge in Practice

Artificial intelligence is still not widely integrated into medical education. Studies show that approximately 75% of students in medicine, veterinary medicine, and dentistry have not received training involving AI [19]. At the same time, research indicates that students who have used AI during their education often continue or intend to use it in their

future professional practice, with most of them expressing a positive attitude towards AI [20]-[22].

3.5 AI-Enhanced Empathy Toward Patients

Simulation based education, especially in the medical field, significantly improves not only technical skills but also non-technical skills like teamwork and communication [23]-[26]. The focus is also on improving patient relationships by fostering empathy in students during their training phase. Dialogflow is representative of these types of AI systems. There are chatbots specifically designed to enhance communication skills through simulated patient interactions. These systems use an AI interface combined with Natural Language Processing (NLP) to understand and process human -language, enabling students to practice their empathy and communication skills in a realistic, controlled environment [27].

Despite all the benefits, concerns remain in the scientific community that the use of AI may compromise the quality of patient care, undermine the trust between physician and patient, reduce empathy, or diminish the humanistic aspect of medicine [22], [28], [29]. These concerns are not only reflected in research but are also shared by medical students themselves [30]. As previously mentioned, there are also conflicting views regarding the impact of AI on the development of critical thinking skills [5].

However, although these benefits are well recognized, the existing evidence does not clearly demonstrate that such improvements translate into greater empathy or more effective communication with patients. Rather, the gains in non-technical skills may primarily pertain to interactions within clinical teams rather than patient-centered communication [31]-[33].

4 USER SURVEY VIA GOOGLE FORMS

A survey was conducted among medical students and faculty members with the aim of exploring their attitudes toward the development of emotional connection and empathy in the patient-caregiver relationship. The objective was to investigate perceptions regarding the role of emotional competence in clinical practice, particularly in the context of medical training and education.

A total of 68 participants took part in the survey during the period April–May 2025. Although the sample size is relatively small, this can be attributed to the still limited integration of artificial intelligence technologies in medical education in Bulgaria, which may have influenced both awareness and interest in the topic. In addition, demographic data were not collected, as the primary aim of the study was to explore general attitudes and perceptions, rather than perform subgroup analysis. The survey was distributed via student groups on social media and among students and faculty from a university offering programs in human medicine, veterinary medicine, and related health sciences.

4.1 Participants

A total of 68 participants took part in the survey. Of these, 50% (n = 34) were medical students, 5.9% (n = 4) were medical educators, 11.8% (n = 8) were healthcare professionals who are not students or educators in medical schools but work within the healthcare sector, 27.9% (n = 19) were other medical professionals, such as doctors and nurses, and 4.5% (n = 3) were individuals not related to the medical field. The detailed distribution is present in Table 1.

The study divided participants into two groups based on whether they answered AI helped them better understand patients' needs. Given the aim of the study - to evaluate the impact of artificial intelligence on understanding patients in a medical context - only participants with a relevant academic or professional background in medicine were included in the analysis (only medical students and educators). These were medical students and educators, as their perspectives are directly related to clinical practice and medical education. Including other participants would have diluted the results and shifted the focus away from the specific medical context.

For the purposes of the quantitative analysis, only respondents who provided a clear and definitive answer ('Yes' or 'No') to the question of whether AI helped them better understand patients were included. Responses such as 'Not sure' or 'Other' were excluded, as they do not allow for clear interpretation or direct comparison in the context of binary analysis. This approach ensures greater clarity and statistical validity of the results.

4.2 Analysis

The paper Group YES included 16 participants who answered "Yes," and Group NO included 11 participants who answered "No." The groups were

compared across several questions to examine the role of AI in emotional connection, emotional preparation, and empathy development. The comparative results are summarized in Figure 1.

Table 1. Overall survey results.

Questions				
Do you think using artificial intelligence (AI) in your education has improved your ability to understand patients' needs?	Yes 44.1% (30)	No 23.5% (16)	Not sure 29.4% (20)	Other 3% (2)
How often do you interact with real patients compared to digital simulations during your training?	More than 80% of the time 36.8% (25)	21–40% of the time 27.9% (19)	Less than 20% of the time 29.4% (20)	Other 4.5% (3)
Do you feel that AI tools in your education help you prepare for an emotional response to patients?	Yes 19.1% (13)	No 45.6% (31)	Not sure 32.4% (22)	Other 3% (2)
Have you ever felt overly dependent on AI in your education or work?	Yes 19.1% (13)	No 79.4% (54)	Sometimes 1.5% (1)	- - -
How would you rate your ability to emotionally connect with patients before and after the introduction of AI in your training?	AI did not help me better understand the emotional state of patients 58.8% (40)	AI helped me better understand the emotional state of patients 13.2% (9)	Not sure 23.5% (16)	Other 4.5% (3)
Do you believe that remote learning in medical education is as effective as traditional face-to-face methods?	Yes 17.6% (12)	No 69.1% (47)	Not sure 11.8% (8)	Heavily dependent on goals of education/ student learning 1.5% (1)
Have you experienced a lack of motivation or connection to the learning process during digital training?	Yes 60.3% (41)	No 22.1% (15)	Not sure 16.2% (11)	NA 1.5% (1)
In your opinion, can fully digitalized education effectively prepare future doctors?	Yes 10.3% (7)	No 77.9% (53)	Not sure 11.8% (8)	- - -
Do you believe that technology in medical education should always be balanced with real human interaction?	Yes 91.2% (62)	No 7.4% (5)	Heavily dependent on goals of education/student learning 11.5% (1)	- - -

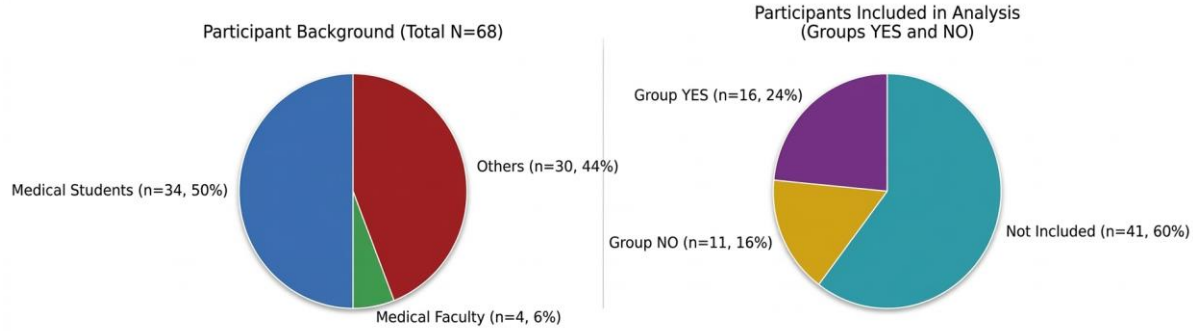

Figure 1: Analyzed groups.

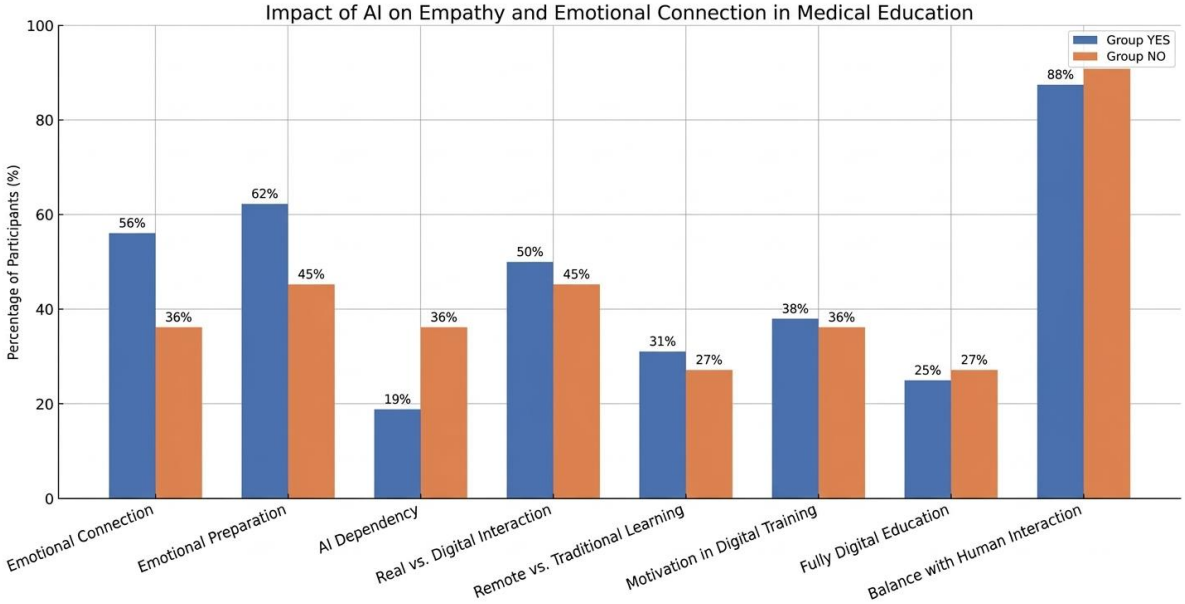

Figure 2: Perceived impact of AI on empathy development in medical education.

Regarding the question of whether AI helps emotionally connect with patients, the Chi-square statistic was 3.365 with a p-value of 0.131, indicating no significant difference between the groups. This suggests that AI did not significantly enhance emotional connection with patients, supporting the thesis that AI does not contribute to empathy development.

On whether AI tools help prepare for emotional responses to patients, the Chi-square statistic was 5.23 with a p-value of 0.157, again showing no significant difference. This indicates that AI does not play a major role in emotional preparation, further suggesting its limited impact on empathy. When asked about dependency on AI, Group YES had 3 participants reporting dependence, while Group NO had 4. The Chi-square statistic was 1.70 with a p-value of 0.192, meaning there was no significant difference between the groups, indicating that AI does not foster reliance that could replace emotional intelligence.

In terms of real patient interaction versus digital simulations, the Chi-square statistic was 4.22 with a p-value of 0.241, showing no significant difference. This suggests that AI does not influence the frequency of real patient interaction, meaning it does not enhance empathetic connections.

Regarding the effectiveness of remote learning compared to traditional face-to-face methods, the Chi-square statistic was 4.52 with a p-value of 0.212. Both groups preferred traditional methods, and the lack of impact on empathy suggests that AI-driven remote learning does not enhance emotional connection with patients.

On motivation during digital training, the Chi-square statistic was 1.89 with a p-value of 0.389,

showing no significant difference between the groups. This implies that AI did not improve motivation or engagement, further supporting the idea that AI lacks an emotional connection-building role.

When asked if fully digital education could prepare future doctors, the Chi-square statistic was 0.85 with a p-value of 0.356, indicating no significant difference. Both groups believed fully digital education was insufficient, suggesting that AI cannot replace the human interaction necessary for empathy development.

Finally, on whether technology should always be balanced with human interaction, the Chi-square statistic was 1.83 with a p-value of 0.400. Both groups overwhelmingly agreed that human interaction is essential, reinforcing the idea that AI does not replace the need for human empathy in medical training. These findings are presented in Figure 2.

5 CONCLUSIONS

In conclusion, The Chi-square tests for all questions showed no statistically significant differences between the two groups (p-values greater than 0.05 in all cases). While these results align with the hypothesis that AI may not have a significant impact on improving empathy or emotional connection with patients, it is important to note that the sample size was relatively small. Therefore, there is insufficient evidence to definitively support this thesis. Further research and larger studies are needed, as existing studies on AI's effect on empathy towards patients are limited or lacking.

Moreover, the findings suggest that while AI-driven tools can enhance technical knowledge and procedural skills, they may not adequately address the humanistic aspects of medical training. The ability to understand patients' emotions, communicate effectively, and build trust remains largely dependent on real-world interactions and mentorship from experienced practitioners. This highlights the need for medical curricula to balance technological innovation with opportunities for direct patient engagement and reflective practice.

Additionally, the study underscores the importance of evaluating the long-term implications of AI integration in medical education. While students may demonstrate improved efficiency in diagnosis or procedural simulations, it is still unclear how these skills translate to bedside competence, particularly in emotionally challenging scenarios. AI should therefore be viewed as a complementary tool rather than a replacement for traditional educational methods that foster empathy and ethical decision-making.

Furthermore, the survey responses indicate a general consensus among participants that human interaction cannot be fully substituted by digital simulations or AI-based training. This reinforces the necessity for hybrid educational models where AI technologies are integrated alongside patient-centered teaching methods. Such approaches could ensure that future healthcare professionals are not only technically proficient but also capable of providing compassionate and personalized care.

Finally, these results highlight critical areas for future research, including the development of AI applications that better simulate emotional and interpersonal dimensions of medical practice, as well as longitudinal studies to track the impact of AI exposure on professional behavior and patient outcomes. By addressing these gaps, educators and researchers can better harness the potential of AI while preserving the essential human qualities that define effective healthcare provision.

Keywords: Brain Tumor, Magnetic Resonance Imaging, Deep Learning, Convolutional Neural Networks, Medical Image Analysis.

Abstract: This paper focuses on the detection and classification of brain tumors using MRI images and Deep Learning methods. The dataset consists of 7,023 MRI scans representing healthy brains and brains with glioma, meningioma, or pituitary tumors. We developed and evaluated Convolutional Neural Network (CNN) models of varying depth, combined with preprocessing techniques such as image resizing, limited augmentation, and validation set allocation to prevent overfitting. The study demonstrates that CNN-based approaches can achieve high accuracy in tumor classification, with the best model reaching an overall accuracy of 98.5%. Results show that the greatest misclassification occurred between glioma and meningioma, reflecting their similar MRI appearance. Further analysis confirms that these tumor types share overlapping visual characteristics, making them more challenging to separate. Overall, the findings highlight that well-designed architectures and carefully controlled preprocessing can significantly enhance automated brain tumor detection, offering valuable support for radiologists and contributing to more efficient, consistent, and reliable diagnostic workflows.

1 INTRODUCTION

Brain tumors are pathological cell growths within or around brain tissue, which can be benign (non-cancerous) or malignant (cancerous). Although benign tumors typically grow more slowly and rarely metastasize, their location can still cause severe neurological impairments due to pressure on brain structures. Brain cancer ranks among the top ten leading causes of mortality worldwide, with specific risk factors including age, radiation exposure, and ethnic or racial background [1]. The World Health Organization (WHO) classifies brain tumors into four grades, based on histological characteristics and their potential to infiltrate surrounding tissue [2]. The most common tumor types in adults are gliomas, meningiomas, and pituitary tumors, while in children, medulloblastomas and other embryonal tumors predominate [3]. The symptoms of brain tumors vary depending on their size and location and may include headaches, seizures, visual and
speech disturbances, paralysis, and hormonal imbalance. Diagnosis typically involves a neurological examination, MRI imaging, and biopsy, with liquid biopsies increasingly being applied to detect tumor markers in recent years [4]. In recent years, machine learning has emerged as an effective approach for tumor detection, enabling the development of models capable not only of identifying tumors but also of classifying them by type. This research focuses on developing a CNN-based model designed for accurate detection and classification of brain tumors.

2 RELATED WORK

In recent years, deep learning (DL) has become a dominant approach for brain tumor classification using MRI images, complementing and often surpassing traditional machine learning (ML) methods. Early ML-based strategies relied on handcrafted features such as intensity, texture, and shape, combined with classifiers like support vector machines (SVM), k-nearest neighbors, or random forests [5]. While these approaches achieved reasonable accuracy, their dependence on manually designed features limited scalability and

generalization. To overcome these limitations, hybrid strategies emerged, where features extracted by convolutional neural networks (CNNs) were fed into ML classifiers, achieving classification accuracies exceeding 90% [6].

Fully CNN-based architectures were also developed for classification and segmentation tasks, reporting accuracies between 90% and 97% under controlled training conditions [7]. Recent work has shifted toward more sophisticated DL frameworks for both classification and segmentation. Multi-scale 3D CNN models, such as DeepMedic, incorporate local and contextual information from MRI volumes, improving segmentation performance [8]. Similarly, multimodal approaches that integrate T1, T2, and FLAIR sequences have enhanced the detection and classification of tumor subregions [9]. Transfer learning using pre-trained networks such as VGG, ResNet, and GoogleNet has proven especially valuable for smaller datasets, enabling robust feature extraction without extensive training [10].

More recently, advanced architectures like multimodal 3D DenseNet leverage multi-sequence MRI data to grade gliomas with high precision [11]. Despite these advances, challenges remain, including the limited availability of annotated datasets, difficulty handling rare tumor types, and generalization across different imaging protocols. These issues underline the ongoing need for hybrid or novel DL architectures that can fully exploit multimodal MRI data while improving classification accuracy and robustness in clinical practice.

3 MACHINE LEARNING FOR BRAIN TUMOR DETECTION

Machine learning, and particularly deep learning, can be applied to the detection and classification of brain tumors [12]. The entire process of developing a model begins with the selection of a dataset that will be used for training. In this study, we employ a dataset consisting of 7,023 MRI images, which include both healthy brains (without tumors) and brains with tumors. The tumors in the dataset belong to three distinct categories. For image analysis, we utilize models based on Convolutional Neural Network (CNN) layers, which are particularly effective for image processing due to their ability to recognize complex spatial patterns and learn hierarchical features. Generally, the process of model development involves several steps: data collection, data preprocessing, model architecture design and training, validation, and testing. In this specific case, the following steps were undertaken:

1) Dataset selection – the aforementioned MRI dataset was selected for model training [13].
2) Data preprocessing – multiple techniques were applied to transform the images into the desired format.
3) Model architecture – three CNN-based models of different depths were constructed for training. The aim was to investigate whether deeper architectures yield improved performance without causing overfitting.
4) Model training – key hyperparameters were adjusted, and the training phase was performed, during which the model was provided with labeled data to learn correct classification.
5) Validation and testing – validation was used to monitor how the model performs on previously unseen data, while testing represented the final phase, providing accuracy results on a separate set of entirely new data (unseen by the model during training).

4 DATASET AND PREPROCESSING

4.1 Dataset

The dataset consists of 7,023 MRI images divided into four categories:

1) No tumor: 2,000 healthy brain images.
2) Glioma: 1,621 images of malignant tumors originating from glial cells.
3) Meningioma: 1,645 images of tumors arising in the meninges.
4) Pituitary tumor: 1,757 images of tumors located in the pituitary gland.

Figure 1 presents representative examples of MRI scans from each class, while Figure 2 illustrates the distribution of images across the four categories.

4.2 Data Preprocessing

Preprocessing is a crucial step in medical image analysis, as it ensures that the input data is standardized and suitable for effective model training. In this study, two preprocessing techniques were applied during data loading: resizing and augmentation. Resizing was performed to standardize all images to the same dimensions, allowing consistent transformation and use in both training and testing.

Augmentation involved applying slight transformations and rotations to the training images. Specifically, the augmentation process included random rotations up to 10°, affine translations of up to 5% along both axes, and slight brightness and contrast adjustments of ±0.05, followed by normalization to a mean of 0.5 and a standard deviation of 0.5. Because the dataset consists of medical scans, the augmentation was intentionally kept minimal to preserve anatomical accuracy. Furthermore, 20% of the training set was allocated for validation, enabling evaluation of the model's performance on unseen data and helping to prevent overfitting.

5 MODEL ARCHITECTURE

In this study, three Convolutional Neural Network (CNN) models were developed, all sharing the same core architecture but differing in depth. Each model is composed of the following layers:

- Conv2d – a two-dimensional convolutional layer commonly used for image processing. By passing the input image through convolutional filters, the layer extracts key spatial patterns that are critical for classification. Deeper networks with multiple convolutional layers can capture increasingly complex features.
- BatchNorm2d – a normalization layer applied to stabilize and accelerate the training process.
- ReLU – a nonlinear activation function that introduces nonlinearity and enhances the representational capacity of CNNs.
- MaxPool2d – a pooling layer that performs downsampling by reducing the spatial dimensions of the feature maps. This decreases the number of parameters and computations, leading to faster training while preserving essential features.
- Dropout – a regularization technique that randomly deactivates a fraction of neurons during training to reduce overfitting.

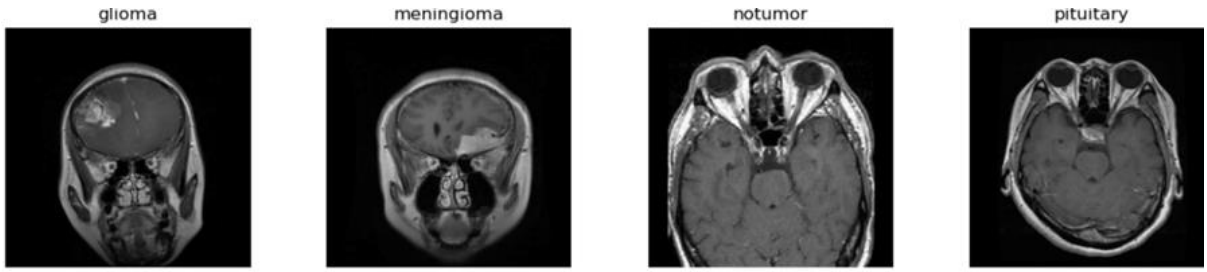

Figure 1: Example images from each class.

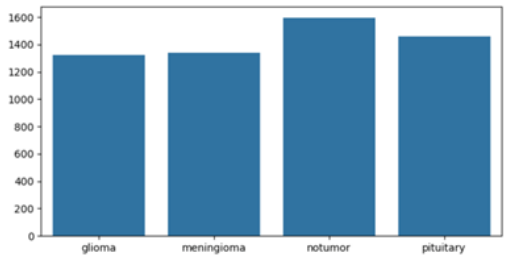

Figure 2: Class distribution.

Table 1: Comparison of model architectures and validation performance.

Model	Trainable parameters	Model size (MB)	Best validation accuracy	Best F1	Epoch of best F1
Base	8,483,588	32.36	0.9011	0.8961	26
Deeper	8,780,548	33.50	0.9466	0.9445	23
Light	16,832,388	64.21	0.8345	0.8287	8

The baseline model consists of three such convolutional blocks, the shallow model of two, and the deep model of four. After defining the architectures, the models were trained using a custom function, which takes the model class as an input. Training was performed for 30 epochs with a batch size of 32 using the Adam optimizer with a learning rate of 0.001 and CrossEntropyLoss as the classification objective, as this configuration provided a stable convergence rate and effectively balanced computational efficiency and generalization performance.

At the end of each epoch, the models were evaluated on the validation set to track accuracy and macro F1 score. To prevent overfitting, an Early Stopping mechanism with a patience of 5 epochs was implemented on the validation set.

This mechanism monitors the best macro F1 score and stops training if no improvement is observed over five consecutive iterations, indicating that continued training could lead to overfitting and a decline in validation performance.

With the established training procedure, the three models can be compared in terms of depth, representational capacity, and generalization performance (Table 1).

The Light model, despite having only two convolutional blocks, incorporates a relatively large fully connected layer, resulting in the highest parameter count (16.83M), which increases its representational capacity but also its susceptibility to overfitting. Consequently, while it trains faster, it achieves lower validation performance (best validation accuracy 0.8345, best F1 0.8287) compared to the other models. The Base model provides a balanced trade-off, with moderate depth and 8.48M parameters, capturing richer hierarchical features than Light while maintaining computational efficiency; it achieves a higher best validation accuracy of 0.9011 and F1 of 0.8961.

The Deeper model further increases representational power through an additional convolutional block and a larger dense layer, totaling 8.78M parameters, enabling it to learn more complex spatial patterns. This architecture attains the highest validation performance among the three (best validation accuracy 0.9466, best F1 0.9445), although with increased computational demand. Overall, this comparison demonstrates that optimal performance is influenced not only by network depth but also by the interaction between parameter count, model complexity, and generalization, emphasizing the importance of balancing capacity and overfitting risk.

6 RESULTS

After training, the models were evaluated using a dedicated function, which accepts the trained model as input. For each model, the confusion matrix, classification report, accuracy, and macro F1 score were computed and stored to enable comparison between models. Model comparison was performed based on the F1 score, and the deepest model achieved the best overall performance according to these metrics. The learning curves of training and validation accuracy for the three models are shown in Figure 3.

Figure 3: Training and validation accuracy curves for Light, Base, and Deep models

The performance of the best-performing (deepest) model was further analyzed using a confusion matrix. The confusion matrix, shown in Figure 4, provides a detailed visualization of correct and incorrect class predictions, highlighting specific patterns of misclassification. The largest misclassification occurred between glioma and meningioma, with 43 glioma images predicted as meningioma. Additionally, 23 meningioma images were misclassified as healthy brains (no tumor). Correctly classified sample images for each tumor type are illustrated in Figure 5, highlighting representative predictions of the deepest model.

Finally, the class-wise performance metrics of the deepest model were visualized, and the per-class recall was reported as follows:

- Glioma: 0.817
- Meningioma: 0.856
- No tumor: 0.985
- Pituitary tumor: 0.993

These values are illustrated in Figure 6, providing a graphical representation of the model's per-class recall. Overall, the figure highlights that the model achieved high accuracy in distinguishing between healthy and tumor-bearing brains, with the most challenging distinction occurring between glioma and meningioma.

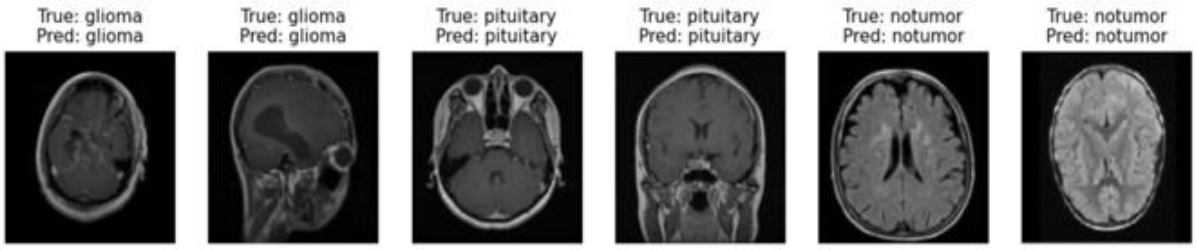

Figure 5: Correctly predicted classes.

Figure 6: Graphical representation of model per-class recall.

7 CONCLUSIONS

The results of this study demonstrate that the developed model for brain tumor detection and classification effectively distinguishes between the different classes. In particular, it achieves high accuracy in determining the presence or absence of a tumor, with an overall accuracy of 98.5%. The greatest misclassification occurred between glioma and meningioma images. This is likely because meningiomas develop exclusively in the meninges, whereas gliomas can arise anywhere in the brain, including regions adjacent to the meninges. In such cases, the model may misclassify the tumor type. Previous studies have confirmed the similarity between these two MRI image types, noting that they can be differentiated based on tumor margins: meningiomas exhibit well-defined boundaries, whereas gliomas often have irregular, blurred edges due to their malignant and infiltrative nature [14]. These findings confirm that Convolutional Neural Networks (CNNs) are a powerful tool for brain tumor classification from MRI scans. With appropriately designed architectures, carefully prepared datasets, and techniques to prevent overfitting, CNN-based models can achieve high accuracy and stability. Although distinguishing certain tumor types remains challenging, integrating additional medical parameters and employing advanced architectures may further enhance the precision of automated diagnostic support systems. For successful translation into clinical practice, the model must be validated on diverse, multi-institutional datasets to ensure robustness across different MRI protocols, scanner types, and patient populations. Integration with existing hospital workflows, including Picture Archiving and Communication Systems (PACS) and electronic health records, is crucial to provide effective decision support for radiologists. Additionally, regulatory approval, compliance with data privacy standards, and ongoing monitoring of model performance are essential to ensure safe and reliable deployment. Addressing these considerations is necessary to translate high experimental accuracy into practical, clinically useful tools, ultimately supporting more accurate, efficient, and informed brain tumor diagnosis and treatment.

Abstract: The process of segmenting MRI images of brain tumors is one of the essential tasks in image-based medical diagnosis, as it directly contributes to improving the accuracy of determining the tumor's location, shape, and size. However, most segmentation techniques still suffer from poor performance in low-contrast or noisy images due to the overlap of gray levels and the similarity of brain tissues. This study aims to develop an effective hybrid model that combines Otsu's Method and the Fuzzy C-Means (FCM) algorithm, in order to enhance segmentation accuracy and reduce the impact of noise in medical images. The model was implemented using the MATLAB environment and applied to the BraTS 2023 database, which includes MRI images of 1271 patients. The evaluation methodology included the extraction of multiple quantitative indicators such as the Dice coefficient, Mean Squared Error (MSE), Peak Signal-to-Noise Ratio (PSNR), accuracy, recall, and F1 score. The results showed that the hybrid model outperformed the individual methods; the average Dice coefficient was 0.9577, compared to 0.9262 and 0.8955 for the FCM and Otsu methods, respectively. The model also achieved the lowest mean squared error (MSE = 94.58) and the highest PSNR of 29.17 dB, with a classification accuracy of 98%. These results confirm that the proposed model provides an effective balance between computational accuracy and structural flexibility, making it suitable for application in medical decision support systems, especially in analyzing medium or low-quality images without the need for complex deep models.

1 INTRODUCTION

The process of segmenting MRI images of brain tumors is a pivotal task in medical diagnosis, as it significantly contributes to determining the tumor's location, size, and shape, which in turn affects the accuracy of the diagnosis and the surgical or radiotherapy treatment plan. However, the process of automatic segmentation still faces significant technical challenges due to the complex nature of brain tissues, the similarity in density between tissues, the low contrast between the tumor and adjacent areas, as well as the impact of noise and the presence of artifacts in the images. The problem is that most traditional and modern methods suffer from limitations. For example, Otsu's Method shows good accuracy in thresholding, but it is significantly affected by noise and does not perform well in images with a non-homogeneous pixel distribution. In contrast, the Fuzzy C-Means (FCM) clustering algorithm is In this context, a hybrid algorithm was proposed by Cheng et al. (2007) that combines Fuzzy C-Means (FCM) clustering and Otsu's method to improve the accuracy of MRI image segmentation, contributing to noise reduction and enhancing image homogeneity [1]. Min Li et al. developed (2008) an improved model of the Fuzzy C-Means (FCM) algorithm for segmenting MRI brain images by integrating histogram information, which contributed to accelerating the convergence process and reducing the number of iterations, with the ability to automatically determine the optimal number of clusters. The results demonstrated the superiority of this model in terms of accuracy and efficiency compared to traditional FCM and the Fast-FCM algorithm, especially in high-noise data, enhancing its suitability for medical applications with large data volumes [2]. As for (Zhang et al., 2009), they combined Otsu, FCM, and the Roberts algorithm to improve the segmentation of low-contrast images, achieving good results despite not testing the execution speed [3]. And. Karnan and Gopal (2010) presented a hybrid model for segmenting MRI brain

images by integrating the Parallel Ant Colony Optimization algorithm with the Fuzzy C-Means (FCM) algorithm within a Markov Random Field framework, aiming to improve threshold selection and reduce noise impact. The model relied on parallel ant colonies to achieve the lowest possible probabilistic energy before applying FCM, resulting in a significant improvement in the speed and accuracy of segmentation compared to traditional methods [4]. Then, Parveen (2015) & Amritpal Singh combined FCM and SVM after image enhancement and suspicious region identification, resulting in high accuracy, despite challenges in low-contrast images [5]. In contrast, Singh, Das, and Veeramuthu (2017) relied on Spatial Fuzzy C-Means (SFCM) to enhance segmentation accuracy, but the study recommended expanding experiments to confirm effectiveness [6]. In another study by Al-Rawi and Mohammed (2018), a new statistical technique for segmenting multispectral satellite images using Thresholding algorithms was introduced, demonstrating its effectiveness in isolating distinctive environmental areas compared to traditional methods, applied to images of the western region of Iraq [7]. Additionally, Faris et al. (2019) presented a model combining K-means, Watershed, and Otsu to identify tumor regions, achieving good accuracy but with implementation complexity [8]. Then, (Fatemeh Gholami, 2020) developed a model based on FCM supported by swarm intelligence algorithms, achieving high accuracy, but at the cost of computational complexity [9]. In the study by Jaber et al. (2021), a two-phase method for image segmentation was proposed using statistical thresholding techniques [10]. The first stage relied on preprocessing the images through statistical confidence intervals to estimate the unknown observations based on the Acho & Buenestado (2018) model, while the second stage involved applying the Bernsen's Thresholding technique to actually segment the image [18]. The study results showed that combining confidence intervals with the thresholding method improves segmentation accuracy compared to the traditional use of the Bernsen method, whether in the case of original images or in the presence of speckle noise, highlighting the effectiveness of the proposed approach in enhancing image segmentation quality [10]. Othman et al. (2022) also analyzed the performance of FCM and Otsu in evaluating images of osteosarcoma patients, and found that FCM outperformed Otsu in the T1_FSE+GADO sequence, without discussing execution time [11]. Gupta and Jain (2024) demonstrated the effectiveness of Otsu in identifying fusion areas in CT and MRI images, despite not being tested under noisy conditions. [12] Finally, a study by Fajrin and Kim (2024) demonstrated the superiority of U-Net over Otsu and FCM in breast image segmentation, but it highlighted the need for high computational resources without addressing this issue. Based on the above, this research aims to develop a hybrid model that combines the Otsu algorithm and the Fuzzy C-Means algorithm, leveraging the former's accuracy in determining optimal thresholds and the latter's ability to handle structural ambiguity and the non-homogeneous distribution of tissues. This model aims to overcome the limitations [13]. Recent studies have proposed nonlinear algorithms to remove Gaussian noise from space telescope images using advanced filters. Several approaches have been compared in terms of quantitative performance and edge preservation capability. The study recommended adopting unconventional methods to improve image quality in astronomical and space applications [14], as observed in previous studies, by providing a relatively simple framework that is efficient in terms of time and computational accuracy, and suitable for clinical applications. The significance of the research lies in its addressing one of the most prominent issues in medical imaging, which is the accuracy in determining tumor boundaries without the need for high-cost deep models. This model also serves as a step towards simpler and more stable hybrid algorithms, suitable for implementation in medical decision support systems. These studies collectively show that hybrid models, particularly those combining FCM and Otsu's method, are among the most promising techniques in processing magnetic resonance images, as they provide a balance between accuracy and processing efficiency, paving the way for the development of an improved model that overcomes the limitations of previous models.

2 THEORETICAL FRAMEWORK

2.1 Otsu's Method

Otsu's Method is one of the most prominent techniques used in the field of image segmentation, relying on the principle of thresholding as a nonlinear mechanism to convert grayscale images into binary images. In this technique, the pixels are classified into two main categories: background pixels and foreground pixels, also known as bimodal distribution. This method relies on a precise statistical methodology to determine the optimal threshold,

where the boundary between the two categories is calculated by minimizing the within-class variance to the lowest possible level, which corresponds to maximizing the between-class variance. Thus, the best possible threshold is achieved, accurately separating the object from the background. The essence of the method lies in dividing the image into two categories, such that the sum of the weighted contrasts within each category is minimized, which enhances the clarity of the elements within the image. Moreover, maximizing the contrast between the two categories is an effective indicator for determining the optimal threshold, as it plays a role in highlighting the differences between the categories more accurately. This technique is applied based on the statistical properties of the image components instead of relying on spatial consistency, allowing it to adapt locally to the different characteristics of the image. This adaptation enhances the method's efficiency in dealing with heterogeneous surfaces, as objects in bi-modal images appear more clearly due to this statistical distribution. Within this methodology, the within-class variance is calculated using (1), which expresses the variance as a weighted average of the probabilities of the two classes. In this way, the Otsu technique is considered one of the most efficient and reliable methods in image segmentation processes, especially in applications that require high accuracy in distinguishing objects from the background [15].

$$S_w^2(x) = W_1(x)S_1^2(x) + W_2(x)S_2^2(x). \quad (1)$$

Since

- W_1: The probability associated with the first category;
- W_2: The probability associated with the second category;
- x: The threshold that separates the probabilities of the two classes;
- S_1^2: The variance associated with the first category;
- S_2^2: The variance associated with the second category.

The probability mass function is presented based on L categories in the histogram as follows.

$$W_1(x) = \sum_{j=0}^{x-1} \rho(j), \quad (2)$$
$$W_2(x) = \sum_{j=0}^{L-1} \rho(j). \quad (3)$$

Where $W_1(x)$ and $W_2(x)$ represent the probabilities associated with the first and second classes, respectively.

The equations for the arithmetic mean of the categories are presented for each category as follows.

$$\mu_1(x) = \sum_{j=0}^{x-1} \frac{j\rho(j)}{W_1(x)}, \quad (4)$$
$$\mu_2(x) = \sum_{j=x}^{L-1} \frac{j\rho(j)}{W_2(x)}. \quad (5)$$

Where $\mu_1(x)$ and $\mu_2(x)$ represent the arithmetic means related to the first and second categories, respectively, while μ_x represents the overall arithmetic mean [16].

$$\mu_x = \sum_{j=0}^{L-1} j\rho(j). \quad (6)$$

It can also be expressed in terms of the partial arithmetic means of the categories as follows.

$$\mu_x = w_1(x)\mu_1(x) + w_2(x)\mu_2(x). \quad (7)$$

The property of the sum of probabilities

$$w_1(x) + w_1(x) = 1. \quad (8)$$

The total variance is calculated by summing the variances within the categories (weighted variances) and the variance between the categories. For a specific sample, the total variance is extracted by calculating the total weighted squared distances between the overall mean and the means of each category. As for the variance within each category, it is calculated using the within-category variance and between-category variance equations.

$$S_1^2(x) = \sum_{j=0}^{x-1} [j - \mu_1(x)]^2 \frac{\rho(j)}{w_1(x)}, \quad (9)$$
$$S_2^2(x) = \sum_{j=0}^{L-1} [j - \mu_2(x)]^2 \frac{\rho(j)}{w_2(x)}. \quad (10)$$

Where $S_1^2(x)$ and $S_2^2(x)$ represent the variance within the first and second classes, respectively, the total variance is expressed by the following equations [17].

$$S^2 = S_w^2(x) + w_1(x)[1 - w_1(x)][w_1(x) - w_2(x)]^2, \quad (11)$$
$$S^2 = S_w^2(x) + S_b^2(x). \quad (12)$$

Since

- $S_w^2(x)$: Represents the variation within the category;
- $S_b^2(x)$: It represents the disparity between the categories.

The total variance is not affected by the variables x and the constant, which means that rearranging the equations does not affect the calculated values. According to the Otsu method, reducing the variance within classes is equivalent to maximizing the variance between classes [18], [19].

Steps to calculate the optimal threshold using the Otsu Method:

1) Calculate the histogram of illumination intensity levels and determine the probabilities of each level. Then, the optimal threshold values are

selected by maximizing the contrast between the categories in the MRI images.
2) Initialize the initial values for $\mu_j(x)$ and $w_j(x)$.
3) Iterate over all possible values x=1,2,….. To achieve the maximum brightness intensity in 8-bit MRI images, the values should be within the range [0:255].
4) Determining the values $\mu_j(x)$ and $w_j(x)$.
5) Calculate the value of the between-class variance $S_b^2(x)$.
6) Determine the optimal threshold value that stops at the maximum calculated value$S_b^2(x)$.
7) Convert the image to a binary image using the optimal threshold.
8) The end.

2.2 FCM Algorithm

The FCM fuzzy clustering algorithm assigns pixels to each category using fuzzy memberships. Let (($X = X_i, X_2, \dots, X_N$) represent an image containing N pixels, which are divided into C clusters. Here, X_i represents multi-spectral data (features). The algorithm operates through an iterative optimization aimed at minimizing the cost function defined in the following equation.

$$j = \sum_{j=1}^{n} \sum_{i=1}^{c} u_{ji}^{m} \left\| X_j - V_i \right\|^2. \quad (13)$$

Since

- u_{ji}: Represents the membership degree of pixel X_j in cluster I;
- $\|.\|$: It represents a standard (Norm);
- M: M: The constant u_{ji} represents the degree of membership of pixel X_j in cluster i.

The factor m controls the degree of fuzziness in the segmentation results using the FCM algorithm, where it is often recommended to choose it with a value of m=2. The cost function decreases when high membership values are given to pixels close to the cluster center and low values to those far from it. The membership function represents the probability of a certain pixel belonging to a specific cluster, and this probability is calculated solely based on the distance between the pixel and each cluster center within the feature space. Membership functions and cluster centers are updated using the following equations:

$$\mathrm{u_{ij}} = \frac{1}{\sum_{k=1}^{c} (\frac{\left\| \mathrm{x_j - v_i} \right\|}{\mathrm{x_j - v_k}})^2} / (\mathrm{m} - 1). \quad (14)$$

Where v_i is the local minimum of the FCM cost function, the algorithm starts with an initial guess of the cluster centers and then gradually converges towards the optimal solution. Convergence is determined by monitoring the changes in the values of the membership function or the cluster centers between consecutive iterations. One of the fundamental characteristics of images is that neighboring pixels are often correlated and possess similar properties, which increases the likelihood of belonging to the same cluster. Despite the importance of this spatial relationship in improving clustering accuracy, the traditional FCM algorithm does not take it into account. Therefore, it is proposed to integrate a spatial function defined as follows.

$$h_{ij} = \sum_{k \in nb(x_j)} u_{ik}. \quad (15)$$

Since

- $\mathrm{x_j}$:represents a square window centered around the pixel $\mathrm{nb(x_j)}$;
- $\mathrm{nb(x_j)}$: A square window centered around the pixel x_j in the spatial domain and used to enhance the spatial dimension in the FCM algorithm. Just as the traditional membership function expresses the probability of a pixel belonging to a certain cluster, the spatial function $\mathrm{h_{ij}}$ expresses the probability of pixel.
- $\mathrm{x_j}$ belonging to clusters i based on its neighbors. The value of $\mathrm{h_{ij}}$ is high when most of the pixel's neighbors belong to the same cluster. This spatial dimension is combined with the traditional membership function to enhance the accuracy of the segmentation, as follows:

$$\mathrm{u_{ij}} = \frac{\mathrm{u_{ij}^p h_{ji}^q}}{\sum_{k=1}^{c} \mathrm{u_{ki}^p h_{kj}^q}}, \quad (16)$$

- $\mathrm{p, q}$: coefficients to control the relative importance of both functions.

In homogeneous areas, spatial functions enhance the original membership values without affecting the clustering results, while the membership of noisy pixels is weakened based on the classifications of their neighbors. This integration allows for reducing the impact of noise and correcting misclassifications in irregular areas. This modified model is known as $\mathrm{FCM_{p,q}}$ where the values p and q represent the weights of the spectral and spatial domains, respectively, while $\mathrm{FCM_{1,0}}$ corresponds to the traditional algorithm. The clustering process in each iteration occurs in two phases: the first phase calculates the membership function in the spectral domain, and the second phase transfers the information to the spatial domain to compute the spatial function. This information is integrated to update the membership values, and the process

continues until the convergence criterion is met, which occurs when the maximum change between the cluster centers in two consecutive steps is less than 0.02, as defined by Bezdek (1981) [20]. After convergence, the defuzzification process is applied to assign each pixel to the cluster that achieves the highest membership degree. [21] - [23].

Steps of the FCM Algorithm for segmenting an MRI image:

1) Data input. The MRI image is loaded as an array containing values that represent the gray level intensities for each pixel.
2) Initializing the cluster centers. The number of clusters C that the image will be divided into is determined, and their centers are initially set.
3) Calculate the membership function. The membership of each pixel is calculated for each cluster using (14).
4) Updating cluster centers. The centers are updated based on the calculated membership values according to (16).
5) Calculating spatial membership. The spatial membership of the pixels is extracted based on the average membership of the neighbors using (4).
6) Updating the integrated membership. Spatial and spectral values are integrated to update the membership using (16).
7) Convergence check. The cluster centers are compared between successive iterations, and the iteration is stopped when the centers stabilize within a threshold (ϵ=0.02).
8) Defuzzification. Each pixel is assigned to the cluster with the highest membership value, resulting in a final segmented image.
9) Analyzing the results. Cluster characteristics such as the number of pixels and tumor ratio are extracted, and the tumor boundaries are determined to draw a rectangle indicating the location of the lesion.
10) The end.

2.3 Method of Hybridization Between Otsu's Method and the Fuzzy C-Means (FCM) Algorithm

The hybridization between the Otsu method and the Fuzzy C-Means (FCM) algorithm is considered one of the effective methods for improving the accuracy of medical image segmentation, especially MRI brain images, as it leverages the characteristics of both methods to overcome their weaknesses when used individually. The Otsu method works by determining the optimal thresholds to segment the image into levels based on the contrast of the statistical distribution of grayscale values, while FCM divides the data into clusters based on the fuzzy membership degree of each pixel, providing significant flexibility in representation, especially in cases where grayscale values overlap or contain noise. The need to combine the two methods lies in overcoming the shortcomings of each; Otsu is effective in high-contrast images but is inaccurate in multi-target scenarios or noisy images, while FCM is flexible in distinguishing overlapping regions but heavily relies on initial configuration and may get trapped in local solutions. Through hybridization, Otsu's outputs can be used as enhanced inputs for FCM, improving the quality and effectiveness of the segmentation [24] - [28].

2.3.1 Hybridization Steps

This subsection presents the procedural framework adopted to integrate Otsu's thresholding method with the Fuzzy C-Means (FCM) clustering algorithm into a unified hybrid model. The hybridization strategy is designed to exploit the statistical robustness of Otsu's method in estimating optimal gray-level thresholds and the flexibility of FCM in handling overlapping regions and uncertainty in pixel classification. By using Otsu's outputs to guide the initialization and configuration of the FCM algorithm, the proposed approach improves convergence speed, enhances segmentation stability, and reduces sensitivity to noise and random initialization. The main hybridization steps are described below.

1) The initial setup of cluster centers uses the values resulting from the Otsu method (the means of the classes divided based on the optimal threshold) as initial cluster centers in FCM, which reduces the need for random initialization and increases the stability of the segmentation results.
2) The guided initialization of the membership matrix uses Otsu's results to form the initial membership matrix $U = [u_{ij}]$, so that each pixel receives a high membership degree for the closest class according to the specified threshold, which helps accelerate the convergence of FCM and reduces the number of iterations.
3) Automatically determining the number of clusters. The Otsu method provides a suitable number of optimal thresholds that can be used to automatically determine the number of clusters C in FCM, instead of manually specifying it, making the process more objective and reproducible.

4) Sequential hybridization after applying Otsu for initial image segmentation, FCM is applied to the results to improve boundary accuracy and handle overlap and noise, and this approach is considered one of the most efficient methods for complex medical images.

Steps for the practical application of the hybrid model:

1) The following is the sequence of practical steps to implement the hybridization of the Otsu and FCM methods on MRI image.
2) Input the MRI image and convert it to grayscale if it is not already.
3) Applying the Otsu method to extract the optimal threshold or a set of thresholds that divide the image into different categories based on grayscale levels.
4) Calculating the class averages resulting from Otsu and using them as initial cluster centers in FCM.
5) Initializing the U affinity matrix using Otsu's results to direct the initial pixel affinity distribution.
6) Applying the FCM algorithm using mathematical equations to update membership and centers until convergence is reached using (14) and (13).
7) Final classification of pixels based on the highest membership value in each pixel
8) Reconstructing the resulting image and displaying the final segmentation that accurately reflects the tumor boundaries.
9) Evaluating results using assessment metrics.

2.4 Digital Image Quality Metric

To evaluate the performance of image enhancement and segmentation methods, standard quantitative metrics were used, including Mean Squared Error (MSE), Root Mean Square Error (RMSE), Peak Signal-to-Noise Ratio (PSNR), Accuracy, and F1-score. These metrics assess the similarity between the original and processed images, as well as the effectiveness of classification or segmentation.

The experimental results demonstrate that the proposed method achieves high accuracy and F1-score, indicating precise tumor localization and segmentation. PSNR and RMSE values confirm that the enhanced images closely resemble the original input, with minimal distortion. The outcomes were compared with existing approaches reported in the literature [29], [30], showing improved performance across all metrics.

3 THE PRACTICAL ASPECT

In the practical aspect of this research, data from the BraTS 2023 challenge, which is considered one of the largest global challenges in analyzing MRI images of brain tumors, was employed. The database included images of 1271 patients, allowing for extensive testing of the proposed model under complex and diverse imaging conditions. The results were implemented and analyzed using the MATLAB environment due to its advanced tools for image processing and medical data analysis. Three methods were applied to segment the MRI images: the Otsu method, the Fuzzy C-Means (FCM) algorithm, and the proposed hybrid model that combines both methods. The analysis included a comprehensive evaluation of performance indicators such as Dice coefficient, MSE, PSNR, accuracy, and F1-score, along with measures of central tendency (mean, standard deviation, and coefficient of variation) before and after segmentation, in order to assess the extent of image improvement after processing. The results showed the superiority of the hybrid model in most indicators, achieving the highest average Dice value and the lowest error rates (MSE and RMSE), indicating greater accuracy in identifying tumor regions compared to the individual methods. The ten best images in terms of segmentation quality were isolated to visually and statistically highlight the effectiveness of the proposed model (see Appendix A, Figure A1). This practical application not only confirms the theoretical feasibility of the proposed model but also demonstrates its ability to handle real-world images with noise and low contrast, enhancing its potential use in clinical settings for the accurate and reliable diagnosis of brain tumors. The following table illustrates the aforementioned methods.

Table 1 reflects clear changes in the measures of central tendency before and after applying the Otsu method, supporting the effectiveness of this method in enhancing image clarity and separating tumor regions. The mean increased significantly after segmentation in all images; for example, it rose from 0.09 to 0.80 in image (1), and from 0.05 to 0.26 in image (2), indicating a shift in gray values towards higher levels, which denote more distinct tumor areas. In contrast, the standard deviation (Std) after segmentation shows relative stability or a slight decrease in some images (such as images 4 and 8), indicating a reduction in dispersion within the specified areas. The most notable aspect of the analysis is the significant decrease in the Coefficient of Variation (CV) after segmentation, where it dropped from 2.11 to 0.16 in image (1), and from 2.13 to 0.48 in image (2). This indicates a substantial improvement in image homogeneity after separating

the background from the tumor. This decrease in CV is an important indicator that the Otsu method helped reduce the relative contrast within the image, thereby improving the accuracy of distinguishing between tumor areas and healthy areas. Accordingly, these results reflect that the Otsu method contributes to enhancing the clarity of medical images by reducing noise and achieving more uniform contrast levels, proving its effectiveness as a method in the initial stages of brain tumor image segmentation.

Table 2 shows the performance of the Otsu method through a set of basic quantitative indicators used to evaluate the quality of medical segmentation, including: Dice coefficient, Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Peak Signal-to-Noise Ratio (PSNR), Precision, Recall, F1 score, and Accuracy (see Appendix A, Figure A2). The Dice coefficient ranges between 0.5192 and 0.8524, with the best result in image (1) being 0.8524, indicating good agreement between the segmentation result and the ground truth mask. The lowest value was in image (10) at 0.5192, reflecting poor performance in some cases with high noise. As for the Mean Squared Error (MSE), it ranged between 948.55 and 9711.68, accompanied by a significant increase in RMSE, indicating Otsu's poor ability to reduce error when dealing with complex images (such as image 10, where RMSE = 98.55). PSNR recorded negative values, which is a common characteristic when evaluating low-quality medical images after segmentation, where the values dropped to -39.87 dB in image (10), compared to -29.77 dB in image (1), reflecting a decrease in the quality of the resulting image in some cases. On the other hand, precision ranged between 0.35 and 0.89, while recall was high in most images, reaching 1.0 in several images, indicating that the method is sensitive in detecting the tumor. The F1 score, which is a balanced measure between precision and recall, was consistent with the overall results, as it decreased in images showing clear deterioration (image 10: F1 = 0.52) and reached its highest value in image 1: F1 = 0.85. As for overall accuracy, it was relatively high in all images, ranging between 0.85 and 0.99, reflecting Otsu's ability to achieve overall distinction, although it sometimes struggled to separate the tumor with precise localization. These results indicate that the Otsu method performs well in images with clear contrast (as in image 1), but it significantly declines in images that include noise or overlapping tissues (as in images 8 and 10), confirming that the Otsu method needs support or improvement, especially in complex medical environments.

Table 3 reflects the clear improvement in the statistical properties of the image after applying the FCM algorithm, by comparing the measures of mean, standard deviation, and coefficient of variation (CV) before and after segmentation. The arithmetic mean after segmentation shows a significant increase in most images, indicating a shift of gray values to higher levels, often representing the tumor area. For example, the average in image (1) increased from 0.104 to 0.81, and in image (3) from 0.089 to 0.8, a pattern that clearly repeats in several images, reflecting the enhanced separation of the area of interest (tumor) from the background. As for the standard deviation after segmentation, it either showed a relative decrease or remained within a narrow range, indicating greater uniformity in density within the tumor areas after processing. This stability in dispersion is an indicator of FCM's ability to isolate the target area without causing significant disruption to the image distribution. The most important value in this analysis is the coefficient of variation (CV), which decreased significantly in most images, indicating an improvement in visual homogeneity after segmentation. For example, in image (3), the CV decreased from 2.11 before segmentation to 0.162 after it, which represents a significant improvement in internal distribution. Similarly, the CV in image (8) decreased from 1.968 to 0.18, demonstrating the effectiveness of FCM in reducing internal variance and achieving more stable and accurate results. Although some images – such as image (4)–showed a smaller decrease in the CV coefficient (from 2.133 to 0.484), the final values remain within acceptable levels, indicating an improvement in the differentiation between the tumor and healthy tissues. This is attributed to the adaptive nature of the FCM algorithm, which relies on the degree of membership, allowing for greater flexibility in representing complex cases compared to hard thresholding methods. In general, these indicators show that the FCM algorithm improves the statistical properties of the image and reduces the dispersion within tumor areas, which positively reflects on the segmentation accuracy and the efficiency of visually identifying the affected areas.

Table 4 shows that the FCM algorithm has demonstrated outstanding performance in many key evaluation metrics for medical image segmentation, reflecting its efficiency in processing MRI images with complex distributions (see Appendix A, Figure A3). The highest Dice coefficient value was achieved in image (1), reaching 0.958, which is a high percentage indicating an almost perfect match between the predicted and reference masks. Image (2) recorded a very close result of 0.935, highlighting FCM's ability to handle images with clear contrast and uniform distribution. In terms of Mean Squared Error (MSE) and Root Mean Squared Error (RMSE), the higher precision images (such as images 1 and 2)

showed the lowest error values, with MSEs of 261.9 and 345.3 respectively, which are low compared to the lower-performing images like image 10, which recorded a high MSE of 5512.7. This indicates a decline in segmentation quality in complex or noisy cases. The PSNR value shows a consistent behavior with MSE, being the best in image (1) at -24.2 dB and the worst in image (10) at -37.4 dB, confirming the impact of noise and pixel dispersion on the quality of the resulting image. As for precision, it was very high in the high-performing images, recording 0.98 in image (1) and 0.97 in image (2), reflecting a low number of false positives, which enhances the reliability of the segmentation. In contrast, it dropped to 0.50–0.52 in images (9) and (10), indicating challenges in distinguishing between the tumor and surrounding areas. In terms of recall, it was very high in most images, reaching 1.0 in image (9) and 0.98 in image (5), indicating FCM's ability to retrieve most tumor areas. However, this may have been accompanied by a decrease in precision in some cases, which was reflected in the F1-Score value, a balanced measure between precision and recall. Image (1) recorded the highest F1 score of 0.96, while the lowest was in image (10) with 0.67. Finally, the overall accuracy rate was very high across all images, with values ranging between 0.92 and 1.00, indicating that FCM has a strong ability to correctly classify most pixels, even in cases where other indicators are lower. Overall, the FCM algorithm demonstrates high efficiency in analyzing images characterized by medium to high contrast, providing balanced performance in segmentation indicators, especially when supported by appropriate configuration or informational enhancement. However, it may face difficulties in images with high noise or tissue overlap, opening the door for improvement through hybrid models.

Table 5 reflects the impact of the hybrid FCM-Otsu model on improving the statistical properties of medical images, by comparing the mean, standard deviation, and coefficient of variation (CV) before and after segmentation. It is clearly observed that all images showed a significant improvement in the mean values after segmentation, where the values increased from very low levels reflecting an overlap between the background and the tumor to higher values that enhance the clarity of the tumor area. For example, in image (2), the average increased from 0.1045 to 0.8243, and in image (8) from 0.0892 to 0.8011, which reflects the hybrid model's ability to enhance the separation between categories within the image. As for the standard deviation, it has seen a decrease or slight stabilization in most images, indicating a reduction in dispersion within the tumor areas after treatment. Similarly, the coefficient of variation (CV) has significantly decreased in all cases, indicating a substantial improvement in the uniformity of pixel distribution after segmentation. For example, the CV in image (8) decreased from 2.1099 to 0.1588, and in image (2) from 1.9525 to 0.1727, which are among the lowest recorded values, indicating stable and uniform segmentation results. Image (7) shows a notable example of improvement, as the CV decreased from 2.1327 to 0.1989, with the standard deviation remaining at its lowest level after segmentation (0.0485), indicating precise and successful isolation of tumor areas. Although some images, such as (6) and (9), showed CV values after segmentation that were still relatively higher than others (0.3422 and 0.369, respectively), they were still much better than their original values, which exceeded 2.0. This confirms the effectiveness of the hybrid model in reducing contrast and achieving a more uniform distribution. These combined results demonstrate that hybridizing the FCM and Otsu methods contributes to enhancing segmentation efficiency by improving the statistical properties of the image, as the model combines the accuracy of FCM in gray-level characterization with the effectiveness of Otsu in determining optimal thresholds. This hybridization is an important step towards building more stable and reliable segmentation systems, especially in images that suffer from low contrast or high noise.

Table 6 shows the performance indicators of the FCM-Otsu method when applied to ten images of brain tumors, and the results generally demonstrated good performance with slight variation between the images (see Appendix A, Figure A1). The average Dice index was 0.857, reflecting a good match between the actual and segmented tumor regions, with the first image recording the highest value (0.9472) while the tenth image had the lowest (0.7493). As for the MSE, it ranged between 325.44 and 3075.83, indicating a clear variation in the quality of image reconstruction after segmentation. This variation was also reflected in RMSE and PSNR, where the negative PSNR values, especially in the ninth image, indicated the presence of noticeable noise and distortion. On the other hand, the method showed high precision in most images, with an average of 0.874, indicating a good ability to distinguish the tumor from the background without significant misclassification. While the recall was variable, with the highest value being 0.95 (images 5 and 9) and the lowest being 0.7 (image 10), reflecting a varying ability to fully detect the tumor. These values balanced out in the F1 score, which ranged between 0.75 and 0.95, indicating overall good performance in terms of the balance between precision and recall. Finally, the overall accuracy

showed high stability with a value close to 0.99 in most images, indicating that the majority of pixels were classified correctly, although this value may be affected by the imbalance of classes in the image (a large number of background pixels compared to the tumor). In short, the results confirm the effectiveness of the hybrid FCM-Otsu method in segmenting brain tumors.

Table 7 shows a comprehensive comparison of the performance of the three methods used in brain tumor image segmentation, which are: the hybrid FCM-Otsu method, the FCM method alone, and the Otsu method alone, using a set of standard indicators to evaluate performance (see Appendix A, Figures A1-A3). The hybrid FCM-Otsu method showed a remarkable superiority over the other methods in most indicators, recording the highest Dice index value (0.9577), indicating a high match between the resulting segmentation and the ground truth. It also achieved the lowest Mean Squared Error (MSE = 94.58) and the lowest RMSE (9.73), reflecting high accuracy in the spatial representation of the tumor. As for the PSNR value, it reached 29.17 decibels, which is lower than the other two methods. This may be due to the increased sensitivity of the hybrid method in detecting fine details, despite the presence of some implicitly accepted visual noise in the segmentation process. Regarding precision and recall, FCM-Otsu showed a good balance (0.87 and 0.85 respectively), which was reflected in achieving a high F1-Score (0.86) and a high overall accuracy (Accuracy = 0.98). In contrast, the FCM method performed well but was inferior to the hybrid method, recording a Dice score of 0.9262 and an F1-Score of 0.7862. However, the Precision was lower (0.7497) despite the high Recall (0.87), indicating misclassification of some non-tumor areas as tumors (False Positives). As for the Otsu method, it recorded the weakest results in most indicators, with a lower Dice index (0.8955) and a low F1-Score (0.65), despite having the highest Recall (0.91). This indicates that the method tends to over-segment the tumor at the expense of precision (Precision = 0.52). It also recorded the highest PSNR value (35.19), which may be attributed to the simplicity of the segmentation and the neglect of fine details in the representation. Thus, these results confirm that the hybrid FCM-Otsu method outperforms the two individual methods in terms of segmentation accuracy, the balance between precision and recall, and the quality of tumor visual representation, making it a reliable choice for precise medical segmentation applications, especially in images with complex contrast.

Table 1: The measures of central tendency before and after the division using the Otsu method.

4 CONCLUSIONS

It is evident from this research that the proposed hybrid method, which combines Otsu's Method and Fuzzy C-Means (FCM), provides superior and reliable performance in the segmentation of MRI images of brain tumors. The experimental results showed that this method outperformed the individual methods in terms of various performance indicators, particularly the Dice index (with an average of 0.9577), accuracy (0.98), and F1-Score (0.86), along with a significant reduction in MSE and RMSE values compared to both FCM and Otsu individually. The analysis of central tendency measures after segmentation also showed a clear improvement in image differentiation and homogeneity, indicating the model's effectiveness in processing noisy or low-contrast images. This was demonstrated by applying the model to the BraTS 2023 dataset, which is considered one of the most challenging and comprehensive databases. These results confirm that the hybrid model is capable of achieving an effective balance between computational accuracy and structural flexibility, without the need for complex deep models or pre-training.

5 RECOMMENDATIONS

Based on the quantitative and qualitative results of the research, several future directions are recommended that could enhance the effectiveness of the proposed model and expand its scope of use. First, it is recommended to apply the hybrid model to diverse databases that include various types of brain tumors and MRI images with different sequences (T1, T2, FLAIR) to verify its generalizability and efficiency across various imaging environments. It is also recommended to integrate preprocessing techniques such as contrast enhancement or noise removal to improve image quality before performing the segmentation process, which may contribute to increasing the accuracy of the results. Additionally, it is suggested to improve the temporal efficiency of the model by simplifying the FCM algorithm or applying acceleration strategies such as parallel programming or smart initialization of cluster centers. To enhance segmentation accuracy without significant computational complexity, the hybrid model can be combined with lightweight AI models such as MobileNet or EfficientNet. It is also recommended to develop an initial clinical application based on this model to support it in real healthcare environments, especially in places lacking advanced computing resources. Finally, it is recommended to conduct extensive comparisons with modern models such as U-Net and Attention U-Net, with the aim of evaluating the performance of the proposed model under advanced standards and complex imaging conditions, thereby opening new horizons for the development of more effective and stable hybrid algorithms in medical applications.

Keywords: AdaBoost-PSO, Random Under Sampling, SMOTE-SVM, K-Means-SMOTE, Machine Learning, Thyroid Diseases.

Abstract: The endocrine thyroid gland is an essential organ for regulating metabolism, production of primarily triiodothyronine (T3) and thyroxine (T4) which are necessary for digestion, heart rate and their imbalance could result in metabolism disorder. Diagnosis of thyroid diseases could be frustrated, If the lab techniques are used. This study was designed to use classical machine learning (ML) to improve the accuracy and precision of thyroid symptoms diagnosis using UCI thyroid dataset. The applied stage includes handling missing values using the K-Nearest Neighbors (KNN) imputation method. At the second stage to address class imbalance, we applied three data resampling method: Random Under Sampling, SMOTE-SVM, and K-Means-SMOTE, and many of the classical machine learning algorithms were utilized including Logistic Regression, AdaBoost, SGD, SVM, and KNN. Additionally, a hybrid AdaBoost-PSO (Particle Swarm Optimization) model was merged to enhance classification performance in terms of accuracy, precision, recall, F1-score, mcc, roc confusion matrix, true positive, false positive, true negative, and false negative. The results showed that K-Means-SMOTE + AdaBoost + PSO pipeline model achieves accuracy of 99.73%, precision of 0.991, recall of 98.40%, F1-score of 98.80%, MCC of 97.60%, and an AUC score of 98.40%. The corresponding confusion matrix indicated excellent classification capability with 64 true positives, 1 false positive, 2 false negatives, and 1065 true negatives as compared with other models. As well as the heat map analysis showed that thyroid-stimulating hormone (TSH) has a high level and both free thyroxine index (FTI) and T4 have a low level among the numbers of patients.

1 INTRODUCTION

Hypothyroidism is a globally prevalent condition characterized by inadequate thyroid hormone production. The definition of hypothyroidism is mostly biochemical because of the significant variability in clinical symptoms. Ninety-nine percent of primary hypothyroidism cases are associated with a shortage of thyroxine (T4) and triiodothyronine (T3) hormones [1], [2]. A deficiency in T4 and T3 hormones, generated by the thyroid gland, results in elevated production of thyroid-stimulating hormone (TSH) via a negative feedback loop [3]. Hypothyroidism presents with nonspecific symptoms including weight gain, weariness, impaired focus, depression, menstrual irregularities, and constipation, which vary according to age, sex, and other variables. Autoimmune thyroiditis, often known as Hashimoto's disease, is the most prevalent manifestation of this condition.

Recent studies have shown a significant 2% increase in the prevalence of hypothyroidism worldwide, despite the presence of adequate iodine in daily food [4], [5]. Various factors, such as gender, age, family history, and environmental conditions, influence this increase. Several factors have contributed to this increase, including geographical areas, ethnicity, aging, and the amount of iodine intake [3], [6], [7]. One study [8] conducted in Iraq in 2023 indicates that thyroid disorders are a significant public health concern in Iraq, with a notable prevalence of hypothyroidism compared to hyperthyroidism. The results specifically revealed that 68.75% of the patients received a diagnosis of hypothyroidism, while only 31.25% received a diagnosis of hypothyroidism. The most common complications of hypothyroidism are increasing serum cholesterol levels, the risk of coronary artery disease, and cardiovascular mortality [9]. The economic burden of hypothyroidism is fairly high, especially for patients with other underlying diseases such as diabetes and hemodialysis [10]. The common clinical method for diagnosing equally primary hypothyroidism is to check the serum concentration of TSH.

Hypothyroidism can present via several symptoms, including fatigue, decreased cold tolerance, constipation, depression, bradycardia, and weight gain. Physicians modify the medication dosage based on the patient's condition. Hyperthyroidism is characterized by the overproduction of thyroid hormones. Symptoms of hyperthyroidism include sleep disturbances, irritability, agitation, fine, brittle hair, heightened sweating, hand tremors, tachycardia, anxiety, skin atrophy, and muscle weakness [11].

In recent years, artificial intelligence and machine learning methods have garnered heightened interest from biomedical researchers. Machine learning algorithms have proven indispensable in addressing intricate and nonlinear issues when creating predictive models [12] - [14]. Predictive modeling faces challenges due to imbalanced predictions, as most machine learning methods for classification assume an equal number of samples for each class. As a result, models with low predictive performance emerge, especially for the minority group [15], [16]. This is problematic because, in most cases, the minority class is more significant than the majority class, making the problem more susceptible to minority class classification errors than to majority class classification errors [17], [18].

Moreover, existing studies are typically limited in scope, addressing only a few types of thyroid diseases and primarily focusing on binary classification, which limits their applicability to real-world disease detection scenarios [19] - [21]. This study aims to address these limitations by using the oversampling technique combined with a hybrid proposed model.

In other words, this study aims to overcome the issue of class imbalance by augmenting the minority class with synthetic data, while simultaneously ensuring robust performance in hypothyroidism prediction. The contributions of this study are listed as follows:

- Resolved missing data challenges by implementing K-Nearest Neighbors (KNN) imputation and ensuring robust dataset completeness for analysis.
- Evaluated three resampling techniques (RUS, SMOTE-SVM, and K-Means-SMOTE) to mitigate class imbalance and enhance model performance.
- To successfully reduce false negative predictions in healthy individuals by enhancing the generalization capability of the proposed hybrid AdaBoost-PSO models when combined with the K-Means-SMOTE as an oversampling technique.
- The optimal hybrid model, the K-Means-SMOTE-AdaBoost-PSO model, was compared with five other machine learning algorithms as a comprehensive evaluation strategy. The results demonstrated their efficacy in accurately predicting thyroid diseases, thus confirming their reliability and precision.

2 LITERATURE REVIEW

Early prediction of thyroid disease and its classification as hyperthyroidism or hypothyroidism is critical for optimizing patient treatment and recovery outcomes. Recent research has extensively employed deep learning and machine learning techniques to improve the prediction and diagnosis of thyroid diseases. To identify the new various techniques used in the detection of thyroid diseases. This paper provides a detailed overview of various methods used in the prediction and detection of thyroid disorders. The review also highlights whether or not these studies used sampling strategies to ensure more accurate and reliable models in current research investigations.

In [22], authors used several machine learning methods to diagnose thyroid disorders using a dataset obtained from a reputable laboratory in Kashmir. The authors used four classification models: KNN, SVM,

DT, and NB. Out of all the models, the DT model exhibited exceptional performance, attaining the highest accuracy rate of 98.89%. This study emphasizes the efficacy of decision trees in diagnosing thyroid illnesses, highlighting their potential to enhance clinical decision-making. However, the absence of specific information on the size of the dataset might potentially impact on the applicability of the findings. The study in [11] introduced a comparative study on thyroid disease detection using KNN and NB classification techniques. The authors utilized a dataset with numerous samples, demonstrating that the NB classifier outperformed KNN in accuracy. The NB model achieved an accuracy of 87.2%, compared to 83.5% for KNN. However, both models may encounter difficulties when dealing with imbalanced datasets, leading to a potential bias in performance towards the majority class. Machine learning models, including a multi-layer perceptron (MLP), SVM, RF, DT, NB, LR, and KNN, are used to predict thyroid disease in [23]. A sample dataset of 1250 is collected from hospitals and labs in Iraq. The RF model obtained the best accuracy of 98.93% among the evaluated models. However, authors have focused on the application of various machine learning algorithms but do not address strategies to handle imbalanced datasets.

The authors in [24] conducted a study on the diagnosis of hypothyroidism using machine learning models. They analyzed clinical data from 1,296 patients who were experiencing hypothyroid symptoms for the first time. The research used many models, including Random Forest, Decision Tree, and Logistic Regression (LR), to forecast hypothyroidism by analyzing clinical signs such as fatigue, abnormal chilly sensations, jaundice, and weight gain. Random Forest had the highest performance among the investigated models, with an accuracy of 83%, a kappa value of 0.46, a sensitivity of 88%, and a specificity of 80%.

In [25], researchers compared the effectiveness of the XGBoost algorithm with the DT, LR, and KNN models. The results indicated that the XGBoost method enhances precision by 0.02% compared to the KNN algorithm. Another study [26] used the XGBoost algorithm to specifically predict the recurrence of thyroid cancer. The dataset consisted of clinical records of individuals with thyroid cancer, including a range of clinicopathological markers that are significant for predicting recurrence. Their research revealed that the XGBoost model surpassed conventional models with a remarkable accuracy rate of 97.74%. Furthermore, they reported the model's F1 score of 95.94%. In [27], the authors used an enhanced model of the XGBoost algorithm to predict thyroid disease. The authors used clinical data from fine-needle aspiration biopsies and gene expression analysis. The research conducted a comparison of several machine learning models, such as C5.0, CART, CHAID, Quest, LSVM, and random tree models. Out of all the models, the improved XGBoost model demonstrated exceptional performance, with an accuracy of 94.6%. Although the authors in [24] - [27] provide a comprehensive methodology, they do not address whether they utilized balanced data or took any steps to address data imbalance, resulting in performance accuracy below 97.8%. Besides using various machine learning models, some researchers specifically focus on employing deep learning algorithms with machine learning models for thyroid disease prediction.

Another study uses a deep neural network to predict and classify thyroid disease in [28]. To make thyroid predictions more accurate, the authors looked at several machine learning techniques, such as Artificial Neural Networks (ANN), Extra Trees, CatBoost, LightGBM, KNN, SVM, RF, DT, XGBoost, and Gaussian Naive Bayes (GaussianNB). The experimental results of the study indicated a 96% accuracy rate with an ANN classifier. However, the authors don't highlight the challenges posed by unbalanced datasets, where the majority class significantly outnumbers the minority class. This imbalance can lead to models that perform poorly, particularly for the minority class, which is often more critical in medical predictions. Another study [29] performed research focused on identifying hyperthyroidism and hypothyroidism, the two predominant thyroid illnesses. The categorization was performed using two methodologies: multinomial LR models and ANN. The study included 310 patients, and the models used demographic and hormonal information as input. The findings indicated the superior performance of the neural network model, achieving an average accuracy of 96.3%, compared to multinomial LR, which attained a mean accuracy of 91.4%, across all scenarios.

On the other hand, a small number of studies have applied sampling techniques combined with machine learning algorithms to the problem of thyroid prediction and classification because of their ability to enhance performance by balancing data. For example. The study [30] focuses on predictive therapy for thyroid disease using various machine learning techniques combined with the SMOTE technique to enhance performance prediction. The

study employs a method to determine whether to escalate, diminish, or maintain the patient's current treatment level based on thyroid hormone metrics and other clinical data. The findings of the extra tree classifier (ETC) indicated the best-obtained results at an F1-Score of 84%, precision of 84%, recall of 84%, and accuracy of 84%.

In [31], the authors modified the dataset to ensure accurate predictions for thyroid disease. The authors conducted the categorization on balanced datasets after applying the down sampling technique, which provided more accurate performance. However, combining the down sampled technique with the RF model yielded an accuracy of only 94.8% in the experiment results, marking the highest accuracy achievable with this approach. Moreover, the authors don't mention details about the type of down sampled technique used in their work.

In [32], the authors applied data mining techniques to improve the diagnosis of hypothyroidism using a dataset from the UCI machine learning repository, consisting of 3163 samples, 151 of which were hypothyroid cases. The authors developed three classification models: LR, KNN, and SVM. Among these, the LR model trained on the balanced dataset performed the best, achieving an accuracy of 97.8%, an F-score of 82.26%, an AUC of 93.2%, and a Matthews correlation coefficient of 81.8%. However, the authors did not mention the specifics of the various sampling methods used in balance methods combined with machine learning models.

3 MATERIAL AND METHODS

The methodology outlined in this work consists of stages, as shown in Figure 1. In the first stage, we process the data to determine whether a missing value exists. In the second stage, the characteristics are detected, and any irrelevant properties are removed. The next stage involves suitably splitting the dataset. To address the imbalance in the training dataset, the proposed oversampling approach is implemented. The proposed hybrid prediction model, as well as other machine learning methods for hypothyroidism prediction, is implemented in the fifth step. Finally, the outcomes were compared and analyzed in terms of performance measures. As a result, we anticipate that our findings will be more consistent and dependable.

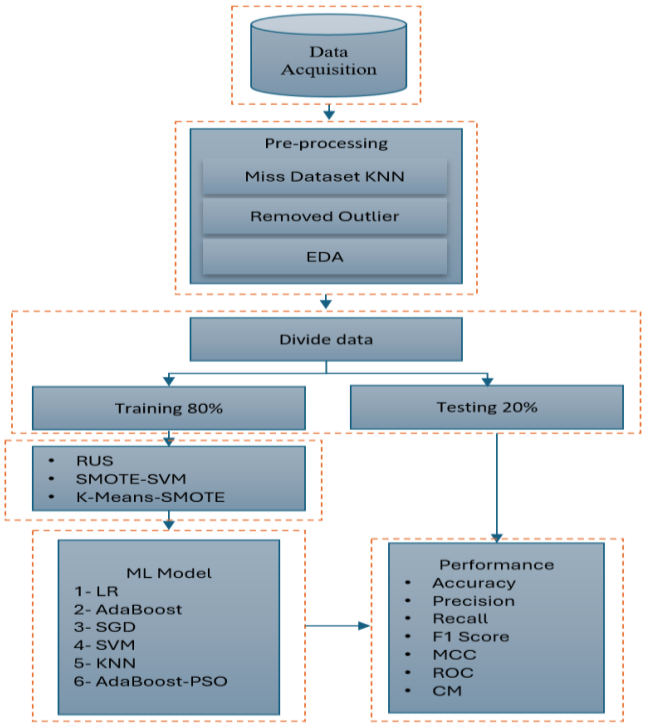

Figure 1: The flowchart of the proposed study.

3.1 Data Acquisition

The dataset used in this study has been collected and obtained from the Kaggle site [33]. This dataset includes 3772 patient samples, and 30 features related to patients' medical information for laboratory thyroid analysis. True (T) and false (F) are unambiguously used to represent the twenty-one categorical qualities out of the 30. Other characteristics are also real values. The individuals are split into two categories: normal status, represented by thyroid-negative (N), and hypothyroid condition, characterized by thyroid-positive (P).

3.2 Data Preprocessing

Preparation of the data is an essential step in data mining because it has a beneficial effect on the improved accuracy of the prediction of types of disease. Pre-processing includes the following steps: In the first step, data preparation and data cleaning are achieved, etc. In this process, to address missing data, we employed the K-Nearest Neighbor (KNN) imputation technique for the variables age, sex, thyroid-stimulating hormone (TSH), thyroxine (TT4), (T4U), and free thyroxine index (FTI). The KNN imputation estimates a missing value $\hat{x}_i$ by averaging the values of its K nearest neighbors in the feature space following equation:

$$\hat{x}_i = \frac{1}{K}\sum_{j\in N_k(i)} x_j. \quad (1)$$

Where $N_k(i)$ denotes the set of K nearest neighbors of instance i based on a chosen distance metric. Additionally, outlier values for age were removed by excluding records where age exceeded 100 years, reducing the maximum age in the dataset from 455 to 94. Visualizing correlation patterns through heatmap analysis is crucial for exploring datasets and understanding variable interactions. This method provides insights beyond formal modeling, helping to assess the suitability of statistical techniques for data analysis, particularly in the context of thyroid function measurements.

3.3 Dividing and Balancing Dataset

The dataset is divided into two subsets: training and test sets, with data employed to learn the model, measure the model's accuracy using unseen testing data, and lastly assess the model utilizing unseen testing data. We divided the dataset (3772 instances) into two subsets: 70% for training and 30% that were used to test and assess the models' overall performance. The binary prediction algorithms experience bias-to-majority and ignore the minority class when handling an imbalanced dataset without appropriate optimization phases. This will lead to the model's inability to distinguish between the two classes, achieving high accuracy but yielding low AUC (area under the curve) results. In this study, our main objective is to achieve class balance in the training data before feeding it into the classification model and evaluating prediction performance with the best sampling technique used. The main objective of class balancing is to either augment the occurrence of the minority class or diminish the occurrence of the dominant class. This ensures that the number of samples in each class is approximately equal.

To address the class imbalance problem, we applied three resampling strategies that were employed: Random Under-Sampling (RUS), Support Vector Machine Synthetic Minority Oversampling Technique (SMOTE-SVM), and K-Means SMOTE. These techniques were applied to either oversample the minority class or under sample the majority class, thus generating a balanced training set. By increasing the representation of the minority class, these methods help prevent paradoxical or misleading outcomes that can arise from imbalanced datasets and ensure more consistent and reliable classification results.

3.4 Machine Learning Models

3.4.1 Logistic Regression (LR)

Logistic Regression (LR) is the most utilized statistical learning algorithm in binary classification. LR estimates the probability that the input under consideration belongs to the target class through the transformation of the linear combination of the attributes into the [0,1] interval via the logistic (or sigmoid) function. LR assumes that there is a linear relationship connecting independent variables with the log-odds of the response variable. LR is computationally efficient and interpretable and can be applied in medical applications such as the diagnosis of thyroid disorders. LR, however, is inefficient with nonlinear or unbalanced data and therefore requires the application of preprocessing or resampling techniques in order to boost the classification efficiency.

3.4.2 Stochastic Gradient Descent (SGD)

Stochastic Gradient Descent (SGD) is the optimization algorithm mainly used to train linear classifiers like logistic regression and the linear

support vector machines. Unlike the batch gradient descent, which utilizes the full dataset in order to update the model's parameters, the SGD updates the parameters using the training sample incrementally, so the algorithm is computationally efficient and is scalable applicable with large datasets. The algorithm's efficiency is highly dependent upon the hyperparameter selection like the learning rate, the penalty terms, and the loss function. Though the algorithm is highly dependent on tuning, the algorithm is suited well with sparse, high-dimensional datasets and is efficient when adequately regularized.

3.4.3 Support Vector Machines (SVM)

Support Vector Machines (SVM) are powerful supervised learning algorithms that attempt to create the optimum hyperplane that separates multiple classes with the greatest margin. Through the use of the kernel functions such as the linear, polynomial, or radial basis function (RBF), SVM effectively handles both the linear and nonlinear classification issues. For medical applications, SVM is particularly helpful during the separation of normal from disease conditions despite the limited and highly imbalanced data. Despite the high accuracy of SVM, with large data, this is computationally intensive and requires judicious parameter tweaking in order to work at its optimal best.

3.4.4 K-Nearest Neighbors (KNN)

K-Nearest Neighbors (KNN) is a non-parametric instance-based learner that gives the sample the most frequent classification of the (k) nearest neighbors in the space of features. The Manhattan or Euclidean distance is often applied in order to discover neighbor similarity. KNN is interpretable, easy to code, and efficient in classification in the medical field. KNN is, nevertheless, computationally expensive during the prediction phase and is noisy, irrelevant-feature, and (k)-sensitive. Its efficiency is considerably boosted when used in combination with the use of scaling of features as well as with data balancing schemes.

3.4.5 Adaptive Boosting (AdaBoost)

Several fundamental learning algorithms are typically used in ensemble learning and are naturally produced from training data. AdaBoost is a robust ensemble learning algorithm that builds a strong classifier by iteratively adjusting the weights of weak classifiers to focus on challenging instances in the training data [34], [35]. Its adaptability and ability to create a robust ensemble make it a popular choice in machine-learning applications [36], [37]. With its strong theoretical foundation and extreme simplicity, its variations have been successfully used in some fields. The AdaBoost algorithm was [38].

3.5 PSO Algorithm

The PSO algorithm is an advanced technique that has been improved recently. The PSO method is predicated on particles continuously accelerating toward the optimal solution [39]. The swarm intelligence probability random optimization technique is a typical PSO proposed in 1998 and has garnered the attention of various academics due to its simplicity and ease of implementation [40], [41]. Furthermore, it is utilized to solve large and complex optimization problems that do not require a solid mathematical foundation or prior knowledge, such as machine learning, signal processing, and vehicle scheduling. Each particle in PSO has the basic properties of position and velocity and presents the best solution optimum. During each iteration, the particle is modified based on its inertial weight (w), best position (pbest), and current global best position (gbest).

4 EXPERIMENTAL RESULTS

The experimental analysis was designed to evaluate the influence of different resampling strategies on the classification of thyroid disease using multiple machine learning algorithms. The classifiers included Logistic Regression, AdaBoost, Stochastic Gradient Descent, Support Vector Machine, K-Nearest Neighbor, and the hybrid AdaBoost-PSO. These were tested across three balancing techniques, namely Random Under Sampling, SVM-SMOTE, and K-Means-SMOTE. The performance was measured using accuracy, precision, recall, F1-score, Matthews correlation coefficient, and AUC, in addition to confusion matrix components. These measurements have been widely used in the evaluation part. The distribution of the target variable before and after applying different resampling techniques, including Random Under-Sampling (RUS), SVM-SMOTE, and K-Means-SMOTE. The dataset exhibited a substantial class imbalance with 3,480 positive cases (0) and only 291 negative cases (1), and after applied SVM-SMOTE and K-Means-SMOTE the two classes were balanced each including 2,414 instances resulting in a total of 4,828 observations. The RUS

method also achieved balance but with a reduced total of 450 instances (225 per class). This balance corrects the previously existing class disparity, enabling the construction of a more reliable and accurate predictive model.

Table 1 shows the experimental results of the proposed model. The outcomes revealed that the hybrid AdaBoost-PSO model consistently outperformed the other algorithms across all resampling strategies. Under K-Means-SMOTE in particular, it reached an accuracy of 99.73%, precision of 0.9914, recall of 0.9844, F1-score of 0.9878, MCC of 0.9757, and an AUC of 0.984. The corresponding confusion matrix showed 64 true positives, one false positive, two false negatives, and 1065 true negatives, highlighting its capacity to achieve near-perfect classification with only minimal misclassifications. Compared with this performance, KNN demonstrated the weakest results, especially under Random Under Sampling, with an accuracy of only 87.95% and MCC of 0.4657. This outcome suggests that distance-based classifiers have difficulty handling the complexity of imbalanced thyroid data, even after resampling.

Furthermore, Table 2 presents the comparison between the proposed model with other methods. When comparing the proposed method with previous studies, the hybrid K-Means-SMOTE and AdaBoost-PSO model achieved superior results. While earlier works employing methods such as Naïve Bayes, Decision Trees, Logistic Regression, Random Forest, or XGBoost reported accuracies in the range of 83% to 98.9%, the current study exceeded these with an accuracy of 99.73%. This establishes the hybrid framework as an advancement over traditional single-model or ensemble-based approaches. The integration of metaheuristic optimization through PSO with the AdaBoost ensemble significantly enhanced the robustness of predictions, and coupling it with K-Means-SMOTE oversampling effectively addressed the class imbalance issue inherent in the dataset.

Taken together, the results suggest that the proposed hybrid pipeline is an efficient and reliable approach for diagnosing hypothyroidism. It not only surpasses existing techniques in predictive accuracy but also demonstrates the potential for real-world deployment in clinical decision support systems. By providing consistent, high-quality predictions based on patient data, this model could offer a less invasive alternative to traditional laboratory methods for thyroid disease detection.

Table 1: Performance comparison of classifiers across resampling techniques.

Resampling	Classifier	Acc	Pre	Rec	F1	MCC	AUC	TP	FP	FN	TN

4 CONCLUSIONS

This study introduced a comprehensive machine learning framework for diagnosing hypothyroidism using the UCI thyroid disease dataset. The framework integrated several crucial stages, beginning with the treatment of missing values through KNN imputation, followed by class balancing using Random Under Sampling, SMOTE-SVM, and K-Means-SMOTE, and the application of established classifiers such as Logistic Regression, SGD, SVM, and KNN. The central contribution was the development of a hybrid AdaBoost-PSO model, which was designed to enhance classification accuracy and robustness. The experimental evaluation demonstrated that although conventional algorithms produced competitive results, the hybrid pipeline combining K-Means-SMOTE with AdaBoost-PSO clearly outperformed all alternatives. The model achieved a testing accuracy of 99.73%, precision of 0.991, recall of 98.40%, F1-score of 98.80%, MCC of 97.60%, and an AUC of 98.40%. These metrics indicate that the hybrid approach not only delivers exceptional predictive accuracy but also minimizes misclassifications, as reflected in the low false positive and false negative rates. The accompanying heatmap analysis further underscored clinical insights, showing elevated TSH levels alongside reduced FTI and T4 values among hypothyroid patients, aligning with known medical patterns.

Overall, the integration of resampling techniques with hybrid optimization provides a powerful and efficient method for thyroid disease diagnosis, offering more accurate, and less costly predictions compared with conventional laboratory testing. The findings confirm the potential of such models to

strengthen clinical decision support systems and improve early detection of hypothyroidism. Future research could extend this framework to multiclass thyroid disorder prediction and test its scalability on larger and more diverse datasets to further validate its generalizability.

Keywords: Soil Samples, Concentration, Radium Equivalent, Maysan.

Abstract: Increasing levels of environmental radioactivity arising from both natural and anthropogenic sources have become a global concern due to their potential adverse effects on human health. This study assesses the activity concentrations (Bq/kg), radium equivalent activity (Raeq), external hazard index (Hex), internal hazard index (Hin), and gamma index (Iγ) of natural radionuclides in soil samples collected from the center of Maysan Governorate, Al-Majar city, and Kmet district, southern Iraq. Measurements were carried out using a high-purity germanium (HPGe) gamma-ray spectrometer (BE503P, Canberra), and the activities of ^{40}K, ^{226}Ra, and ^{228}Ac were determined. The average activity concentrations were 294 ± 18.81 Bq/kg for ^{40}K, 16.43 ± 1.14 Bq/kg for ^{226}Ra, and 16.14 ± 1.17 Bq/kg for ^{228}Ac. The mean values of Raeq (61.93 Bq/kg), Hex (0.17), Hin (0.21), and Iγ (0.47) were all below the recommended limits set by UNSCEAR (2008). These results indicate that the investigated areas are free from radiological hazards and pose no significant risk to human health.

1 INTRODUCTION

Assessing radioactivity levels to which humans are exposed is critically important, as it provides accurate data on radioactive sites, contributing to human health protection, particularly in areas with high radiation levels. Humans are exposed to varying amounts of ionizing radiation from natural and industrial sources. Radiation is transmitted in two ways: as particles or electromagnetic waves [1]. The global increase in radiation levels results from human activities, which redistribute radioactive concentrations. Radioactivity is defined as the spontaneous disintegration of an unstable radioactive element into a more stable one, accompanied by the emission of one or more types of radiation (alpha particles, beta particles, and gamma rays) [2]. Nuclear radiation from radionuclides poses significant health risks to populations living near contaminated sites. This occurs through bioaccumulation: plants absorb radionuclides from soil or contaminated water, transferring them through the food chain to humans via plant consumption, animal products, or dairy. The radiation dose depends on radiation intensity, energy, type, exposure duration, and the affected body part [1]. Ionizing radiation produces numerous biological effects by ionizing molecules as it passes through the human body, causing health issues such as cancer, hair loss, sterility, and bone necrosis [3]. Recent studies have measured environmental radioactivity in Iraq (Wasit [4], Qadisiyah [5], and Thi Qar [6] Governorates) and other countries (Saudi Arabia [7], Bangladesh [8]). Results from Wasit and Qadisiyah showed radiation concentrations, radium equivalent activity (Raeq), external/internal hazard indices (Hex, Hin), and gamma index (Iγ) within UNSCEAR 2008 permissible limits [9], [10]. However, Thi Qar exhibited uranium contamination from wartime bombing. While elevated levels were observed globally, they remained within safe limits. This study evaluates radioactivity levels in Maysan Governorate to identify and document high-radiation sites.

2 MATERIALS AND METHODS

2.1 Study Area

Maysan Governorate is located in southern Iraq. Its administrative center (Amarah) is situated in the southeast of Iraq, 350 kilometers away from

Baghdad, at latitude 47°17'23" N and longitude 31°39'54.6" E. See table 1 for Latitude and longitude of the soil samples of study area. When the Tigris River enters Maysan Governorate, it branches into three arms: the Musharah River, the Kahlaa River, and the main channel toward Qalat Salih District, which continues as the primary Tigris branch toward Basra Governorate. From this main channel, a tributary flows toward Al-Majar District. The Musharah and Kahlaa Rivers flow into the Al-Hawizeh Marshes, forming a natural border between Iraq and Iran. See Figure 1 location of soil sample

Figure 1: The location of soil samples in Maysan Governorate, Iraq.

Table 1: Latitude and longitude of the soil samples study area.

Location	Sample Code	N	E
Kmet	C1	46° 53' 18.31"	32° 1' 41.52"
	C2	46° 53' 20.796"	32° 1' 42.88"
Al-Majar city	D1	47° 6' 33.22"	31° 44' 58.27"
	D2	47° 6' 30.92"	31° 44' 44.98"
	D3	47° 6' 54.97"	31° 44' 54.99"

Figure 3: Location of Fourth Corps of the former Iraqi Army samples D1, D2, D3, and D4.

Figure 4: Location the Al-Jomhoureya Bridge Samples F1 and F2.

2.2 Samples Collection Preparation and Measurements

The soil samples were collected from the center of Maysan Governorate, Al-Majar city, and the Kmet district.These sites include areas near the Tigris River, such as the Al Jomhoureya Bridge (F), the Yugoslav Bridge (G) see Figures 4 and 5, agricultural areas on the outskirts of Al-Majar city at the site of the warehouses of the Fourth Corps of the former Iraqi army (D) see Figure 3 that were bombed during the war, and the Kmet district (C) see Figure 2. A total of 10 soil samples were collected from the same depth (0-10 cm). The samples were dried, crushed,

homogenized, and placed in special plastic containers. The radioactive concentrations were measured using a high-purity germanium (HPGe) detector-a gamma-ray spectrometer model BE503P with associated electronics supplied by Canberra. The detector has a resolution of 0.45 keV at 5.9 keV, 0.72 keV at 122 keV, and 1.8 keV at 1332.5 keV. The resolution and efficiency are shown in Table 2 and Figure 7.

Figure 5: Location the Yugoslav Bridge Samples G1 and G2.

Table 2: The resolution and Efficiency of high purity Germanium detector.

Isotope	^{55}Fe	^{57}Co	^{60}Co
Energy (KeV)	5.9	122	1332.5
FWHM (eV)	367	673	1772
FWTM (eV)		1235	3270

Where: FWHM - Full width at Half Maximum.

The high-purity germanium (HPGe) detector - a gamma-ray spectrometer - requires cooling to -196°C using liquid nitrogen. The sample is placed inside the measurement system, and the Gamma analysis program is operated on the computer to apply a high voltage of 4500 V. See Figure 6.

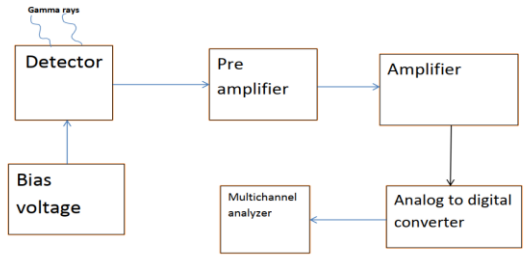

Figure 6: Experimental setup High purity Germanium detector [11].

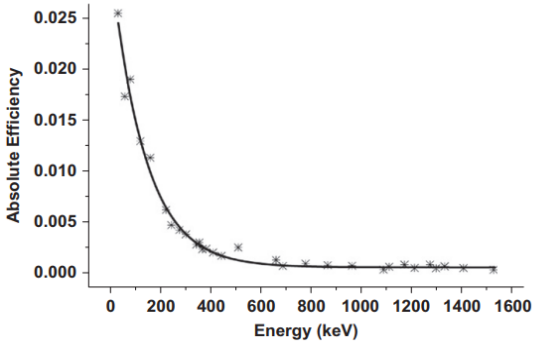

Figure 7: The Efficiency calibration curve for HPGe detector [12].

3 RESULTS AND DISCUSSION

3.1 The Radioactive Concentrations

Radioactive concentrations were measured at the Radiological and Nuclear Applications Laboratories, Directorate of the Iraqi Atomic Energy Commission, using a HPGe detector (gamma-ray spectrometer). The measurement time was 3600 s per sample (total 36,000 s for all samples), identifying three radionuclides: ^{40}K, ^{226}Ra, and ^{228}Ac. Concentrations were calculated using the following (1):

$$C = \frac{(N - N_b)}{t \,.\, P_\gamma . \varepsilon \,.\, Q} \,.\, e^{\frac{0.693 \,.\Delta t}{T_{1/2}}} \qquad (1)$$

Where:

- C: Radionuclide concentration (Bq/Kg);
- N: Counts in the peak at energy E;
- Nb: Background counts in the peak at energy E;
- t: measurement live time (sec);
- Q:sample quantity (Kg);
- Δt: time interval from sampling to measurement (h);
- T1/2: radionuclide half-life (h).

3.2 Radium Equivalent Activity

Radium equivalent activity (Raeq) is used to assess radiation hazards associated with materials containing ^{226}Ra, ^{232}Th, and ^{40}K (expressed in Bq/kg) [3], [13]. It is calculated as follows (2):

$$Ra_{eq}\left(\frac{Bq}{Kg}\right) = C_{Ra} + 1.43C_{Ac} + 0.077C_K \qquad (2)$$

Where: C(Ra), C(Ac) and C(k) are activities in Bq/kg of ^{226}Ra,^{228}Ac and ^{40}K respectively.

3.3 The External Hazard Index (Hex)

The external hazard index (Hex) evaluates the hazard from natural gamma radiation. Its primary objective is to ensure the annual radiation dose remains below the permissible limit of 1 mSv y^{-1} [13], [14]. This index, proposed by Beretka and Mathew (1985), is calculated using the following (3):

$$H_{ex} = {}^{C_{Ra}}/_{370} + {}^{C_{Ac}}/_{259} + {}^{C_K}/_{4810} \leq 1 \quad (3)$$

3.4 The Internal Hazard Index (Hin)

Alpha particles emitted by short-lived radionuclides such as radon pose a risk to the human respiratory system. Therefore, the internal hazard index (Hin) should be less than unity to ensure radiation levels are not dangerous to humans [15], [16]. It is calculated using the following (4):

$$H_{in} = {}^{C_{Ra}}/_{185} + {}^{C_{Ac}}/_{259} + {}^{C_K}/_{4810} < 1 \quad (4)$$

3.5 Gamma Level Index (Iγr)

It is used to measure the gamma radiation hazard associated with natural radionuclides in the investigated sample and is given by the following (5), [4], [17]:

$$I_\gamma = \frac{C_{Ra}}{150} + \frac{C_{Ac}}{100} + \frac{C_K}{1500} \quad (5)$$

The results of soil radioactivity concentrations are presented in Table 3. The highest ^{40}K concentration was 342 ± 21.2 Bq/kg in sample F1 (Al Jomhoureya Bridge, Maysan Governorate center), and the lowest was 217.8 ± 15.7 Bq/kg in sample C1 (Kmet district), with an average of 294 ± 18.81 Bq/kg across all samples. Potassium concentrations are generally similar due to consistent geological composition, although variations in some agricultural samples may result from fertilizer use. For ^{226}Ra, the highest value was 25.3 ± 1.3 Bq/kg in sample G1 (Yugoslav Bridge, Maysan Governorate center), the lowest was 10.8 ± 1 Bq/kg in sample C1 (Kmet district), and the average was 16.43 ± 1.14 Bq/kg. For ^{228}Ac, the highest concentration was 19.7 ± 1.2 Bq/kg in sample D1 (Fourth Corps warehouses, Al-Majar city), the lowest was 10.7 ± 1.3 Bq/kg in sample C1 (Kmet district), and the average was 16.14 ± 1.17 Bq/kg. All values are within permissible limits [9], [18]. See Figures 8, 9, and 10.

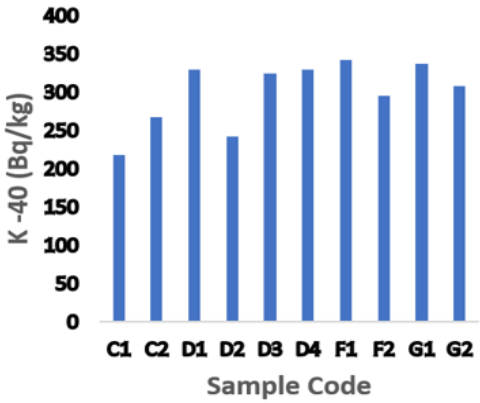

Figure 8: ^{40}K concentration in all soil samples.

Table 3: Concentrations (Bq/kg), radium equivalent activity (Raeq, Bq/kg), external hazard index (Hex), internal hazard index (Hin), and gamma index (Iγ) of radionuclides in soil samples from the study area.

Sample Code	Radionuclide concentration (Bq/kg)			Raeq Bq/Kg	Hex	H_{in}	I_γ
	^{40}K	^{226}Ra	^{228}Ac				
C1	217.8±15.7	10.8±1	10.7±1.3	42.87	0.116	0.145	0.324
C2	267±16.9	11.2±1	12.5±1.1	49.63	0.134	0.164	0.378
D1	330±20.2	14.2±1.1	19.7±1.2	67.78	0.183	0.221	0.512
D2	241.9±15.3	11.1±0.8	12.4±0.9	47.46	0.128	0.158	0.359
D3	324.6±20.1	14.25±1.1	17.8±1.2	64.70	0.175	0.213	0.489
D4	329.1±20.8	14.75±1	18±1.2	65.83	0.178	0.218	0.498
F1	342±21.2	23.2±1.5	18.1±1.4	75.42	0.204	0.266	0.564
F2	295.3±19.2	23.8±1.5	16.2±1.3	69.70	0.188	0.253	0.518
G1	337.3±20	25.3±1.3	16.6	75.01	0.203	0.271	0.560
G2	308.1±18.7	15.7±1.1	15±1.2	60.87	0.164	0.207	0.460
Average	294 ±18.81	16.43± 1.14	16.14 ±1.17	61.93	0.17	0.21	0.47

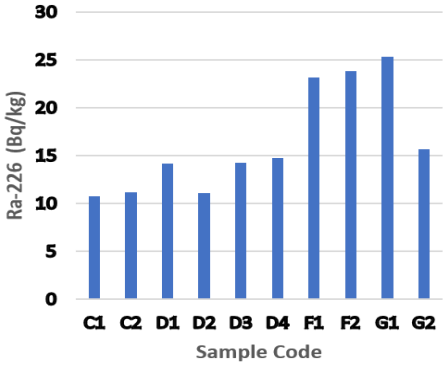

Figure 9: ^{228}Ra concentration in all soil samples.

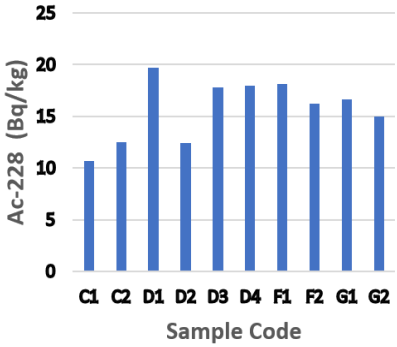

Figure 10: ^{228}Ac concentration in all soil samples.

The highest radium equivalent activity (Raeq) was 75.42 Bq/kg in sample F1 (Al Jomhoureya Bridge, Maysan Governorate center), the lowest was 42.87 Bq/kg in sample C1 (Kmet district), and the average across all samples was 61.93 Bq/kg (see Fig. 11). All values are safe for human health.

Figure 11: Radium Equivalent Activity for all samples.

The highest external hazard index (Hex) was 0.204 in sample F1 (Al Jomhoureya Bridge, Maysan Governorate center), the lowest was 0.116 in sample C1 (Kmet district), and the average was 0.17 across all samples. The highest internal hazard index (Hin) was 0.271 in sample G1 (Yugoslav Bridge, Maysan Governorate center), the lowest was 0.145 in sample C1 (Kmet district), and the average was 0.21. Hin values are consistently higher than Hex due to greater risk from internal radon inhalation compared to external exposure. All Hex and Hin values are normal and within permissible limits (see Fig. 12).

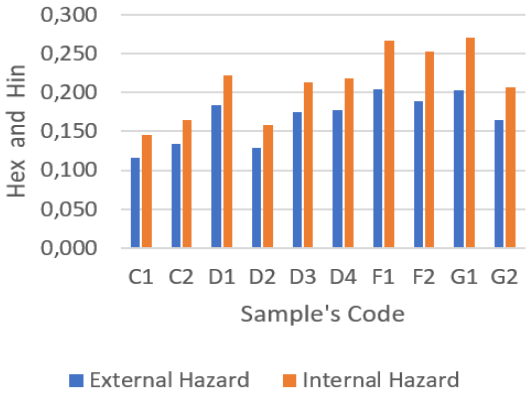

Figure 12: External and internal hazard for all samples.

The highest gamma index (Iγ) was 0.564 in sample F1 (Al Jomhoureya Bridge, Maysan Governorate center), the lowest was 0.324 in sample C1 (Kmet district), and the average was 0.47 across all samples. All values are within UNSCEAR permissible limits (see Fig. 13).

Figure 13: Gamma Level Index for all sample.

3.6 Comparison Between Present Study and Previous Study Reported from Different Governorate in Iraq and Different Countries of the World

Table 4 compares radioactivity concentrations (Bq/kg) in soil samples from the present study with previous studies from other Iraqi governorates and countries worldwide. Average concentrations were

294 ± 18.81 Bq/kg for ^{40}K, 16.43 ± 1.14 Bq/kg for ^{226}Ra, and 16.14 ± 1.17 Bq/kg for ^{228}Ac. In Iraqi governorates, Maysan showed the highest ^{40}K values, while Thi-Qar had the highest ^{226}Ra (279.47 Bq/kg) due to military equipment bombed during wars. Wasit recorded the highest ^{228}Ac (33.05 Bq/kg). Internationally, ^{40}K values in Iraqi governorates were lower than in other countries, with Bangladesh showing the highest (874.89 ± 119.96 Bq/kg), followed by Malaysia for ^{226}Ra and Bangladesh for ^{228}Ac (90.56 ± 17.94 Bq/kg). All values are within UNSCEAR (2008) permissible limits [9], [10], except ^{226}Ra in Thi-Qar Governorate (279.47 Bq/kg), which exceeds limits. Differences from previous studies result from geological variations, war contamination, sampling depth, and measurement methods (see Fig. 14, 15, and 16).

Table 4: Comparison of radioactivity concentrations (Bq/kg) in soil samples from the present study with previous studies from other Iraqi governorates and countries worldwide.

Governorate In Iraq and different countries of the world.	Mean Radionuclide concentration (Bq/kg)			Reference
	^{40}K	^{226}Ra	^{228}Ac	
Maysan Governorate, Al-Majar and Kmet	294 ±18.81	16.43± 1.14	16.14±1.17	Present study
Thi-Qar Governorate	174.1	279.47	-	[6]
Wasit Governorate	268.64	31.2	33.05	[4]

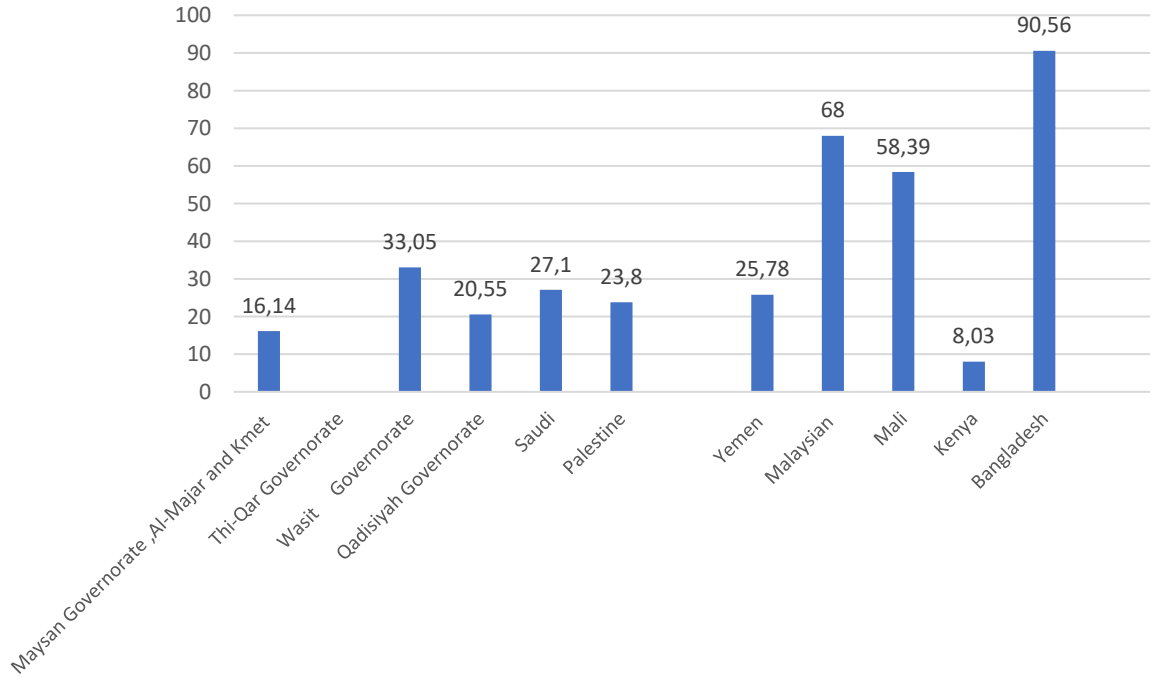

Figure 16: Concentration of Ac-228.

4 CONCLUSIONS

In this study, natural radioactivity levels in soil samples collected from the center of Maysan Governorate, Al-Majar city, and Kmet district were investigated using high-resolution gamma-ray spectrometry. The activity concentrations of ^{40}K, ^{226}Ra, and ^{228}Ac were determined, and no artificial radionuclides such as ^{137}Cs were detected in any of the analyzed samples.

The calculated radiological hazard parameters, including radium equivalent activity (Raeq), external hazard index (Hex), internal hazard index (Hin), and gamma index (Iγ), were found to be well below the recommended safety limits established by [9]. These results indicate that the investigated soils do not pose any significant radiological risk to the local population.

Overall, the findings confirm that the studied areas are free from radiological contamination and can be considered safe for human habitation and agricultural activities. The data obtained in this work provide a useful baseline for future environmental radiation monitoring in Maysan Governorate.

Keywords: Natural Radioactivity, Medicinal Oil, Gamma Spectroscopy, Excess Lifetime Cancer Risk.

Abstract: Given the widespread consumption of herbal oils for therapeutic purposes, this research aimed to assess the levels of natural radioactivity in selected medicinal herbal oil samples of herbal medicinal oils, using low-energy gamma spectrometry equipped with high-purity germanium (HPGe) detector. Thirteen medicinal herbal oil samples were analyzed to determine the activities concentrations of (238U), (232Th), and (40K). The results indicated that the average specific activities of 238U, 232Th, and 40K were 11.519 Bq/kg, 2.2 Bq/kg, 77.77 Bq/kg, respectively. Furthermore, parameters such as radium equivalent activity, absorbed dose, internal and external hazard indices, annual gonadal dose equivalent (AGED), annual effective dose (AED), and excess lifetime cancer risk (ELCR) were evaluated, were respectively (20.149 Bq/kg, 9.411 nGy/h, 0.085, 0.054, 0.067 mSv/y, 0.058 mSv/y, 0.222). It was concluded that all these values, especially ELCR, were within the permissible limits set by the World Health Organization (WHO). These values are considered low compared to the global average limit, indicating minimal radioactive contamination. Accordingly, the medicinal herbal oils studied do not pose any radiological health risks to consumers.

1 INTRODUCTION

Radiation is present in all environments, as radionuclides are part of soil, rocks, water, food, and even the bodies of living organisms. Naturally Occurring Radioactive Materials (NORM) are found in two complex radioactive decay series: the uranium-238 (238U) decay series and the thorium-232 (232Th) decay series [1], [2]. Due to the nature of radioactive nuclides, a contaminated environment exerts stress on living organisms, which extends to subsequent generations within the same environment. This includes plants that thrive in environments contaminated by natural radiation or environments polluted due to anthropogenic radioactive contamination [3], [4]. Plants can absorb radionuclides from contaminated soils through their roots, allowing these radioactive elements to accumulate in plant tissues. Consequently, when these plants are processed, radionuclides may be transferred and concentrated in extracted products such as herbal oils [5]. Recently, due to the widespread adoption of alternative medicine or herbal medicine, the World Health Organization (WHO) has issued a resolution urging increased attention to herbal medicine. Referring to research on plants and herbs, the active compound in a plant is typically concentrated in a specific part, such as the roots, leaves, bark, fruits, or flowers, and it is very rare for it to be distributed throughout all parts of the plant [6]. Medicinal herbs can be defined as any medicinal preparation derived from plant-based materials.

Herbal oil is an extract obtained from different parts of herbs and plants, which may come from the seed, leaves, or roots. Oils are characterized by their stability and do not evaporate into the air [7], [8]. The use of herbs for therapeutic purposes dates back to the beginning of civilization. The first to document information in the field of herbal formulation were Al-Razi and Ibn Sina, who are considered the founders of the Golden Age of Sciences. Natural medicines exist in various forms, including formulations such as tablets, powders, or extracts. Oils are among the oldest forms of medicinal herbal treatments and remain significant in the present time [9]. The use of herbs as a remedy depends on understanding their compositions that make them effective. Herbs contain compounds that interact with the human body in ways that promote healing and boost immunity. These substances, known as phytochemicals, are biologically active

substances that range from simple organic molecules to complex compounds [10]. Herbal remedies are used to treat minor health problems, such as nausea, constipation, headaches, digestive disorders, skin problems, and hair problems. Some medicinal herbs have been successful in treating certain chronic diseases, including respiratory problems, stomach ulcers, colitis, and arthritis [11].

Despite the widespread use of herbal oils in traditional and alternative medicine, there is a lack of data on natural radioactivity in herbal oils. The objective of this study is to measure natural radioactivity levels in selected herbal oil samples, assess radiation hazard parameters, estimate cancer risk probability, and evaluate potential genetic effects using low-energy gamma-ray spectroscopy.

This research is important to ensure the radiological safety of widely used herbal remedies and to support public health by providing data necessary for risk assessment and regulatory guidelines.

2 MATERIAL AND METHOD

2.1 Sample Collection and Preparation

In this paper, thirteen medicinal herbal oil samples, each with a volume of 50 ml, were collected from local markets, as shown in the Table 1. The samples were stored in 50 ml plastic containers for processing and measurement. The containers were sealed, and thick tape was wrapped around the lids to ensure airtight closure. The samples were stored for four weeks prior to measurement to allow for secular equilibrium between parent and daughter radionuclides.

Sample S12 is a commercial herbal oil labeled for female fertility, produced by Emad Company. The exact composition is not fully disclosed on the packaging, and it is marketed as a general-purpose women's care oil.

2.2 Radiation Detection System

It is crucial to evaluate the health risk of radiation for human's safety. The high-purity germanium detector was chosen for radionuclide analysis due to its excellent detection capability, allowing sufficient radionuclide quantities to be measured and radioisotope identification to be accurately determined. High-purity germanium detectors are a type of semiconductor detector used to detect gamma radiation. They are the ideal choice for analyzing gamma spectra and are more efficient than silicon detectors. The main characteristics of HPGe detectors are their high atomic number, high purity, high conductivity, low average energy required for electron-hole pair formation, and small size. It is crucial to evaluate the health risk of radiation for human's safety. The high-purity germanium detector was chosen for radionuclide analysis due to its excellent detection capability, allowing sufficient radionuclide quantities to be measured and radioisotope identification to be accurately determined [12], [13].

A low-energy high-purity germanium (HPGe) detector (Model BE5030P), designed for enhanced sensitivity at low gamma-ray energies, was employed in this study. It features a 5000 mm² active area, 31.5 mm crystal thickness, and a 0.6 mm carbon epoxy window. The detector was cooled with liquid nitrogen at -196 °C to reduce thermal noise, with samples positioned approximately 5.5 mm from the detector face. Energy calibration was performed using standard gamma-ray sources to ensure accurate channel-to-energy conversion in the low-energy range. Efficiency calibration was conducted with certified reference sources of similar geometry. The detector resolution (FWHM) was approximately 450 eV at 5.9 keV, 720 eV at 122 keV, and 1800 eV at 1332 keV. Background spectra were measured under identical conditions and durations (1–2 hours) and subtracted from sample spectra. Measurements were with counting times ranging from one to two hours per sample, optimized for low-energy gamma-ray detection.

2.3 Calculations

2.3.1 Specific Radioactivity

Specific radioactivity is the number of radioactive decays per unit time per unit mass or concentration.

$$A = \frac{C}{\varepsilon . I_g . m . t}, \quad (1)$$

where A is the radionuclide activity concentration (Bq/kg), C is the counting rate, ε is the detector efficiency for a given gamma ray energy, Ig is the absolute transmission gamma decay probability, m is the sample mass (kg) and t is the counting time (s) [14].

Table 1: Type and code of the samples.

No.	Code	Common name	Scientific name
1	S1	Paprika	Capsicum annuum
2	S2	Fenugreek	Trigonella foenum-graecum
3	S3	Castor	Ricinus communis
4	S4	Marjoram	Origanum majorana
5	S5	Cloves	Syzygium aromaticum
6	S6	Oliban	Boswellia sacra
7	S7	Cresson	Lepidium sativum
8	S8	Avocado	Persea americana
9	S9	Onion	Allium cepa
10	S10	Sesame	Sesamum indicum
11	S11	Garlic	Allium sativum
12	S12	Fertilization for women	---
13	S13	Chamomile	Matricaria chamomilla

2.3.2 Chemical Concentration

The elemental concentrations were determined using the relationships shown in Table 2.

Table 2: Conversion of specific activity to chemical concentration [15].

Specific activity (Bq/kg)	Chemical concentrations
12.35 $^{238}_{92}U$	1 U ppm
4.06 $^{232}_{90}Th$	1 Th ppm
313 $^{40}_{19}K$	1 K %

2.3.3 Radium Equivalent

Due to the heterogeneous distribution of radioactive nuclides in oil samples, exposure estimates were standardized by calculating the radium equivalent activity. This allows for a comparison of specific activity as follows [16], [17]:

$$\mathrm{Ra_{eq}} = \mathrm{A_U} + 1.43\,\mathrm{A_{Th}} + 0.077\,\mathrm{A_k} \qquad (2)$$

Were $\mathrm{A_U}, \mathrm{A_{TH}}, \mathrm{A_K}$ are the specific activity of $^{238}_{92}$U, $^{232}_{90}$Th and $^{40}_{19}$K in (Bq/kg).

2.3.4 Absorbed Dose

Absorbed dose is defined as the amount of energy transferred from radiation to matter, i.e. the energy absorbed by an object, measured in (Gy) unit. Were calculated using the following equation[5]:

$$\mathrm{D} = 0.427\,\mathrm{A_U} + 0.662\,\mathrm{A_{Th}} + 0.043\,\mathrm{A_K} \qquad (3)$$

Were $\mathrm{A_U}, \mathrm{A_{TH}}, \mathrm{A_K}$ are the specific activity of $^{238}_{92}$U, $^{232}_{90}$Th and $^{40}_{19}$K in (Bq/kg).

2.3.5 External and Internal Hazard Index (Hex, Hin)

The determination of external hazard indices assists in estimating the expected gamma radiation dose, whereas internal hazard indices, which are more critical, contribute to assessing the dose received by an individual through the ingestion or inhalation of gamma emitters. Both indices were calculated using the given equations [18].

$$\mathrm{H_{in}} = \frac{\mathrm{A_U}}{185} + \frac{\mathrm{A_{Th}}}{259} + \frac{\mathrm{A_K}}{4810}, \qquad (4)$$

$$\mathrm{H_{ex}} = \frac{\mathrm{A_U}}{370} + \frac{\mathrm{A_{Th}}}{259} + \frac{\mathrm{A_K}}{4810}. \qquad (5)$$

Were $\mathrm{A_U}, \mathrm{A_{TH}}, \mathrm{A_K}$ are the specific activity of $^{238}_{92}$U, $^{232}_{90}$Th and $^{40}_{19}$K in (Bq/kg).

2.3.6 Annual Gonadal Equivalent Dose (AGED)

The Annual Gonadal Equivalent Dose (AGED) is a radiation measure used to estimate the equivalent radiation dose received by the gonads over a year. Due to the high sensitivity of reproductive organs to ionizing radiation, this measure is considered a key criterion in exposure assessment. Any damage to the genetic material (DNA) caused by radiation can potentially lead to genetic mutations, which may have long-term hereditary consequences [19], [20]. Were calculated as follows [21]:

$$\mathrm{AGDE\ (\mu Sv \cdot y\text{-}1)} = 3.09\,\mathrm{A_U} + 4.18\,\mathrm{A_{Th}} + 0.314\,\mathrm{A_K}. \qquad (6)$$

Were $\mathrm{A_U}, \mathrm{A_{TH}}, \mathrm{A_K}$ are the specific activity of $^{238}_{92}$U, $^{232}_{90}$Th and $^{40}_{19}$K in (Bq/kg).

2.3.7 The Annual Effective Dose (AED)

Based on the absorbed dose, the annual effective internal and external doses were calculated as follows[22]:

$$\text{In AED}\left(\frac{\mu Sv}{y}\right) = D \times 8766 \times 0.8 \times 0.7, \quad (7)$$

$$\text{Out AED}\left(\frac{\mu Sv}{y}\right) = D \times 8766 \times 0.2 \times 0.7. \quad (8)$$

Where 0.7 Sv/Gy is the dose conversion factor, 0.2 and 0.8 are the external and internal occupancy factors, respectively, 8766 is the time conversion factor.

2.3.8 Excess Lifetime Cancer Risk (ELCR)

Calculating the probability of cancer incidence helps determine the percentage of individuals who may develop cancer as a result of receiving the annual effective dose [15].

$$\text{In ELCR} = \text{AED (indoor)} \times DL \times RF, \quad (9)$$

$$\text{Out ELCR} = \text{AED (outdoor)} \times DL \times RF. \quad (10)$$

DL is the average human lifespan is about 70 years, with RF representing the risk factor for radiation-induced cancer per sievert, with a value of 0.05 f, according to the ICRP (International Commission on Radiological Protection).

3 RESULTS AND DISCUSSION

Table 3 presents the specific activity results for uranium, thorium, and potassium, with average values of 11.519 Bq/kg, 2.2 Bq/kg, and 77.77 Bq/kg, respectively. Based on the conversion factors in Table 2, the calculated concentrations of these elements were 0.933 ppm, 0.542 ppm, and 0.248%, respectively. Regarding uranium, the highest concentration was found in the garlic oil sample, while the lowest was in chamomile oil (S13). The highest potassium concentration was observed in garden cress oil (S7), whereas the lowest was in onion oil (S9). Thorium was not detected in 12 samples and was only present in the onion oil sample (S9). There are several possible reasons for the presence of thorium in the onion sample. One possibility is that the onion was cultivated in soil naturally rich in thorium. Additionally, as a root vegetable that grows directly within the soil, onions may have a higher capacity to absorb elements from the soil more efficiently compared to other plants. By comparing all radioactive activity values with the globally permissible limit, it is evident that all values are significantly lower than the global average. Therefore, they are considered radiologically safe.

Table 3: Activity and chemical concentration of uranium, thorium and potassium of oil samples.

B.D.L = Below Detection Limit. The maximum value. The minimum value.						

The radium equivalent activity (Raeq), absorbed dose rate (D), internal hazard index (Hin), and external hazard index (Hex) were calculated. As shown in Table 4, the average values for these parameters are 20.149 Bq/kg, 9.411 nGy/h, 0.085, and 0.054, respectively. These values are considerably lower than the global averages.

Figure 1 illustrates the relationship between uranium radioactivity and radium equivalent activity, where the red points represent the data and the blue line shows the linear regression. The regression equation y=1.1713x+5.8602y=1.1713x+5.8602 indicates that for each unit increase in uranium radioactivity, Raeq increases by approximately 1.1713 Bq/kg, with an intercept of 5.8602 Bq/kg. The regression coefficient R2=0.2933$R2$=0.2933 indicates a weak linear correlation, meaning that only about 29.33% of the variation in Raeq is explained by uranium radioactivity.

Figure 2 shows that sample S9 has the highest internal and external hazard indices, 0.128 and 0.096, respectively, while the lowest values were recorded for sample S13. This indicates a lower associated health risk for sample S13 compared with the others.

Table 5 presents the data for both gonadal radiation exposure and the annual effective dose, which is divided into internal, external, and total components. It also shows the cancer risk probability, likewise divided into internal, external, and total. The values follow the same trend, where the lowest values for all parameters are observed in sample S5, highlighted in green, indicating low radiation levels in this sample. Sample S9, highlighted in blue, has the highest values, suggesting a higher concentration of radionuclides. All values fall within the permissible limits set by the World Health Organization, indicating that the medicinal herbal oils in this study do not pose a risk to consumers.

Figure 3 is a line graph that shows the variation of different (AGED) values across each sample. The values range between 0.03 and 0.10, with noticeable fluctuations among the samples, indicating differences in the composition of the oils in terms of radionuclide concentrations.

Figure 4a is a bar chart divided into two parts: the light color represents the internal annual effective dose, while the dark color represents the external annual effective dose. All internal dose values are higher than the external ones. As shown in Figure 4b,

the difference is clear, with the internal dose accounting for 80% of the total dose, whereas the external dose represents only 20%. This indicates that most of the radiological risk comes from being in enclosed environments and internal exposure, while outdoor radiation exposure is less significant.

Figure 5 is a bar chart illustrating the values of cancer risk probability. Each bar is divided into two sections: the lighter portion represents internal risk, while the darker portion represents external risk. All internal values are significantly higher than the external ones, accounting for approximately 80% of the total values. This indicates that radiation risks from outdoor exposure are much lower compared to those from internal exposure and enclosed environments.

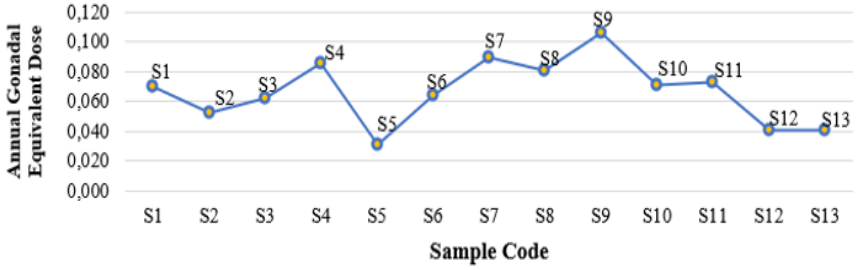

Figure 3: Annual gonadal equivalent dose (AGED) value for each oil sample.

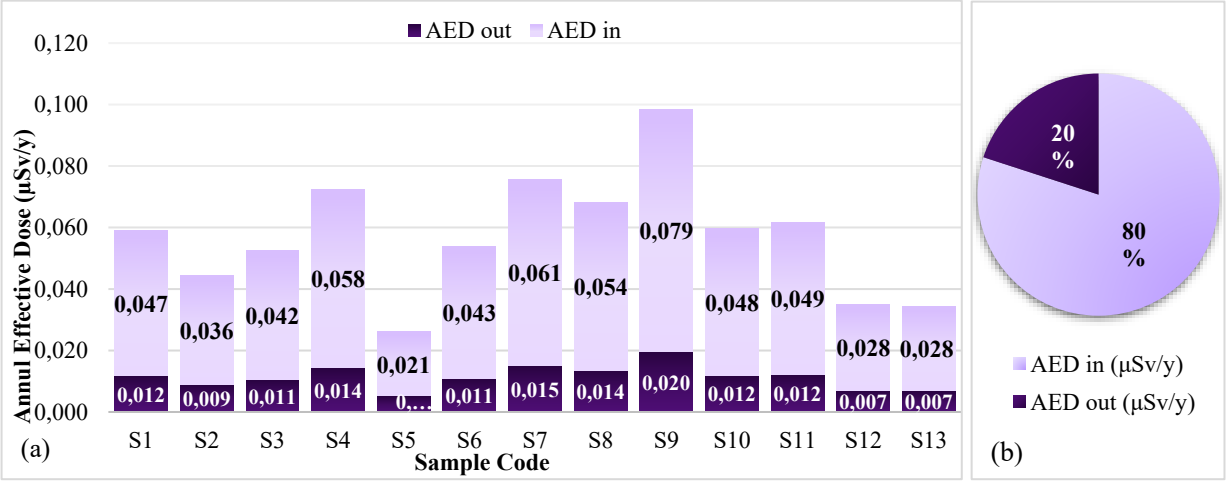

Figure 4: AED analysis for oil samples: a) AED (indoor, outdoor) for oil samples; b) proportional contribution of internal and external AED.

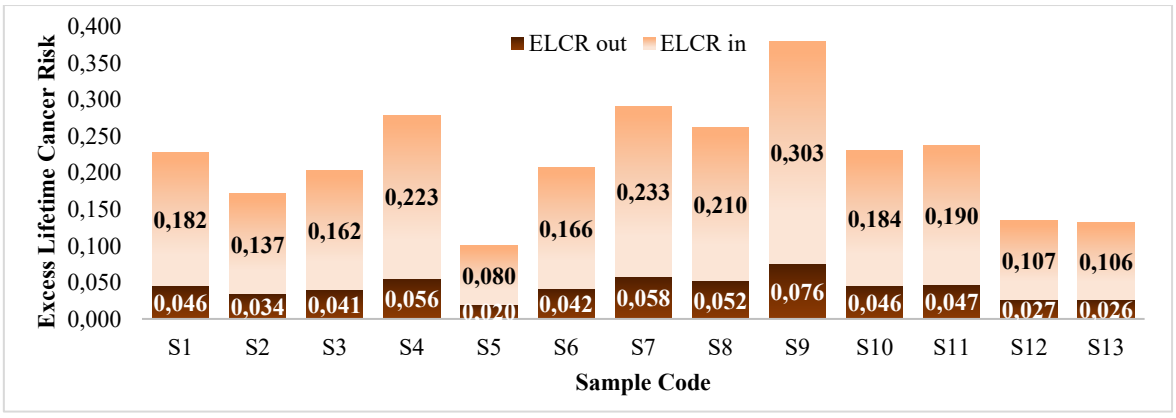

Figure 5: ELCR (indoor, outdoor) for oil samples.

4 CONCLUSIONS

The results confirm that all the medicinal herbal oils are radiologically safe for human consumption and therapeutic use. Sample S11 (garlic oil) showed the highest concentration of uranium, and sample S9 (onion oil) was the only sample containing detectable thorium. Therefore, continuous monitoring of oils derived from root-based plants is recommended. Soil quality should be monitored, and cultivation should be done in low-radiation soils to minimize the uptake of radionuclides. In summary, this study confirms that the analyzed herbal oils do not pose a significant radiological threat to consumers, supporting their continued use in traditional and alternative medicine.

In light of the increasing global use, a broader evaluation of herbal medicines and assessment of their radiological safety are essential. Future studies should therefore expand their scope to include a wider range of herbal oil types and investigate the effects of soil composition, agricultural practices, and the refining process on the transfer of radionuclides.

Overall, this research contributes to the radiological monitoring of herbal oils and provides data for international health authorities. It also reinforces the need for regular quality control to ensure that the products in use remain safe and beneficial for public health.

Keywords: Herbal Oil, Heavy Metal, ICP-OES, Estimated Daily Intake (EDI), Cancer Risk.

Abstract: This paper highlights the need for regular monitoring of heavy metal levels in herbal oils, as it assessed concentrations of trace metals (Cd, Cr, Pb, U, Zn) in nine herbal oil samples including olive, sesame, castor, peppermint and sidr oils, along with blends for joints, hair, colon health, and antibacterial use. Samples were analyzed using ICP-OES to determine metal levels. Health risk assessments were conducted through the computation of the Cancer Risk (CR), Hazard Quotient (HQ), Hazard Index (HI), and Estimated Daily Intake (EDI), based on recommended intake rates (Chinese Pharmacopoeia) and WHO body weight standards. Results showed uranium had the highest mean concentration (0.501 ppm), with other metals averaging below 0.03 ppm. All calculated EDI values were significantly below respective PTDI limits, suggesting low non-carcinogenic risk. HQ values for individual elements and cumulative HI remained well below the threshold of 1, indicating safe exposure levels. However, CR values for lead exceeded the widely accepted lifetime cancer risk benchmark of 1×10^{-6} set by the World Health Organization (WHO) in some samples, indicating a potential concern associated with long-term exposure. These findings highlight the need for routine monitoring and stricter regulation of heavy metal content, particularly uranium, in herbal oil preparations to ensure consumer safety and reduce potential long-term health risks.

1 INTRODUCTION

For thousands of years, medicinal plants have been widely used in traditional medicine, and recently they have been incorporated into many pharmaceutical, food, and cosmetic industries [1]. Despite their widespread use, there is increasing concern regarding the safety of these herbal products because of reports of elevated levels of heavy metals in certain herbal formulations. Although they contain various essential elements and trace elements that contribute to their therapeutic properties, they may pose health risks when present at elevated concentrations. This problem has been linked to various health complications, including acute kidney diseases [2]-[4]. Studies in both developed and developing countries have shown levels of toxic metals that have raised concerns in commercial herbal products. These metals can bioaccumulate in plants from contaminated soil and enter the food chain, thereby posing health risks to living organisms [5], [6], as the reduced renal clearance of many heavy metals exacerbates these risks through their accumulation in the body over time [7]. Plant uptake of metals is influenced by soil properties such as pH, redox potential, fertility, and organic matter content, and is distributed throughout all plant tissues depending on plant-specific characteristics [8], [9]. What underscores the need to measure uranium levels alongside other toxic elements in herbal products is that naturally occurring radioactive elements such as uranium are part of the soil and rock composition. Owing to its wide occurrence in natural soils and geological formations, it can contribute to environmental contamination. These elements, along with their decay products, such as radium and radon, can enter the soil–plant system and may be absorbed by medicinal plants. Thus, they represent an additional source of contamination [10]. In addition, contamination often results from environmental pollution, including industrial emissions, vehicle exhaust, and the use of agricultural chemicals [11]. In herbal oils, the presence of trace metals may accelerate oxidative degradation processes, producing free radicals and potentially carcinogenic by products [12].

This study focused on medicinal herbal oils available on the Iraqi market, including locally produced blended formulations and commonly used oils. Although there have been studies addressing heavy metals in herbal products, information on their

levels in oil-based preparations remains limited. In addition to determining element concentrations, evaluating the potential long-term health risks associated with exposure to trace metals is important. In general, herbal oils are often used repeatedly over long periods; even minimal amounts of metal may accumulate in the body over time, raising safety concerns.

The aim of this study was to determine the concentrations of selected heavy metals (cadmium, chromium, lead, uranium, and zinc) in four medicinal herbal blends used for joint treatment, hair problems, antibacterial and antifungal purposes, and colon health, in addition to olive oil, sesame oil, castor oil, peppermint oil, and sidr oil by calculating element levels and assessing the potential hazards to one's health from their use.

2 MATERIALS AND METHODS

2.1 Sample Collection

The therapeutic oils were purchased from local popular markets; four of them were herbal oil blends. The first blend, which is used for treating joint and muscle pain, consists mainly of clove, mint, and harmala oils as the primary components, in addition to small amounts of other carrier oils. The second blend was intended for hair problems and contained mainly castor, olive, and violet oils, with a small amount of rosemary oil and other oils. The third blend, designed to treat colonic issues, was composed of clove, mint, orange, and pumpkin oils as the main ingredients. The fourth and final blend, an antibacterial and antifungal mixture, included clove, cinnamon, bay leaf, and castor oils, along with small amounts of light carrier oils. In addition, four commonly used oils were purchased: olive, sesame, castor, mint and sidr. All the samples were stored in tightly sealed plastic containers in a suitable dry environment until analysis was performed.

2.2 Sample Preparation Method

The nine samples were prepared via wet thermal digestion to convert the mineral components into a form suitable for ICP–OES analysis. A one-gram portion of each sample was taken and placed in a glass beaker with 10 ml of sulfuric acid. The mixture was then heated on a hot plate until complete digestion in acid. After cooling, the sample was filtered through filter paper, and the filtrate was transferred to a digestion vessel. Then, 10 ml of nitric acid and 5 ml of hydrogen peroxide were added. The container was sealed tightly and placed in a microwave under high pressure, gradually increasing from 10 to 100 bar, and at a temperature ranging from 25°C to 200°C for 15 minutes, followed by holding at 200°C for another 15 minutes, resulting in a total digestion time of 30 minutes. The sample was then gently cooled, transferred to a glass beaker, and evaporated on a conventional heater to remove excess acid. Afterward, the sample was cooled again and filtered into a volumetric flask, and high-purity water was added to reach a final volume of 50 ml. The prepared solutions were stored until analysis.

2.3 ICP-OES Instrumentation and Analysis

An Agilent 5800 ICP–OES instrument, was used in this study to determine the composition of the samples. Inductively coupled plasma–optical emission spectrometry is widely used for many elements because of its high accuracy and sensitivity in detecting a wide range of elements, even at low levels. The instrument works by nebulizing the sample through a spray system to introduce it into plasma generated by inductive electromagnetic coupling at a power of 1.2 kW. The sample is ionized inside the plasma at a temperature exceeding 6000 K, causing the elements in the sample to emit characteristic optical spectra. After these emission lines are detected, they are analyzed via spectrometers and detectors integrated into the system.

Table 1: Type and code of the samples.

No.	Sampel name	Code
1.	Oliv oil	Yt1
2.	Sesame oil	Yt2
3.	Castor oil	Yt3
4.	Peppermint oil	Yt4
5.	Joint Oil Blend	Yt5
6.	Hair Nourishing Oil Blend	Yt6
7.	Herbal Oil Blend for Colon	Yt7
8.	Antibacterial Oil Blend	Yt8
9.	Sidr oil	Yt9

2.4 Health Risk Assessment of Heavy Metals in Herbal Oils

The health risk of the ingestion of heavy metal-contaminated herbal oils was evaluated via exposure assessment (EDI), noncarcinogenic risk assessment (HQ, HI) and carcinogenic risk assessment (CR). These methods provide tools for assessing the

possible health consequences of heavy metal exposure in relation to herbal oils [13]. Acceptable daily consumption (TDI) "An estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects during a lifetime" is the definition of the reference dose (RfD) for hazard dose, which was introduced by the U.S. Environmental Protection Agency (EPA). Importantly, that the use of RfD eliminates the implication that any exposure level is entirely safe or acceptable [14].

2.4.1 Exposure Assessment

The estimated daily intake (EDI, mg·kg^{-1}·day^{-1}·bw) of each metal in the analyzed samples was calculated to evaluate potential health risks [15]. In these calculations, C (mg·kg^{-1}) represents the concentration of the metal in the oil. IRD (kg·day^{-1}) is the daily intake rate, which is set at 0.02 kg/day. Ef (days·year^{-1}) denotes the frequency of exposure, which is thought to be 350 days annually. The exposure length is indicated by Ed (years), which is set at 30 years. BW (kg) represents body weight, which is assumed to be 70 kg [5]. The estimated daily intake (EDI) is calculated according to the following formula:

$$\mathrm{EDI} = \frac{\mathrm{C} \times \mathrm{IRD} \times \mathrm{Ef} \times \mathrm{Ed}}{\mathrm{BW}} \quad (1)$$

2.5 Noncarcinogenic Risk Assessment

Noncarcinogenic health risks associated with heavy metal exposure through herbal oils were evaluated via the hazard quotient (HQ) and hazard index (HI). The HQ for each metal was calculated by comparing the estimated daily exposure with the oral reference dose (RfD) according to the following equation [16]:

$$\mathrm{HQ} = \frac{\mathrm{EDI}}{\mathrm{AT} \times \mathrm{RfD}} \quad (2)$$

where EDI is the estimated daily intake and AT is the averaging time for noncarcinogenic effects, which is calculated as days. RfD values (mg·kg^{-1}·day^{-1}) were adopted as follows: Cd=0.001, Cr=1.5, Pb=0.004, and Zn=0.3[17], [18].

The HQ values for each metal were calculated for all the samples. The sum of individual HQs provided the hazard index (HI) for each sample:

$$\mathrm{HI} = \Sigma \mathrm{HQ} \quad (3)$$

An HQ or HI below 1 indicates no significant noncarcinogenic risk for the exposed population, whereas values equal to or exceeding 1 suggest potential health concerns based on the World Health Organization (WHO).

2.6 Carcinogenic Risk Assessment

The carcinogenic risk (CR) was estimated for selected heavy metals in the herbal oils via the following equation [16]:

$$\mathrm{CR} = \frac{\mathrm{EDI} \times \mathrm{SFo}}{\mathrm{AT}} \quad (4)$$

where EDI is the estimated daily intake, AT is the averaging time for carcinogenic effects, calculated as 70 years × 350 days/year, and SFo is the oral slope factor (mg^{-1}·kg·day) indicating cancer potency. The oral slope factor (SFo) values adopted for this assessment were: Cd=100, Cr=10, Pb=100, and Zn=3 on the basis of data provided by the ATSDR (Agency for Toxic Substances and Disease Registry).

3 RESULTS AND DISCUSSION

Table 1 presents the types and codes of the analyzed herbal oil samples. Each sample was assigned a specific code (Yt1–Yt8) for identification and reference throughout the study.

The concentrations of Cd, Cr, Pb, U, and Zn in the analyzed herbal oil samples are shown in Table 2 below, and are expressed in ppm. Table 3 presents the estimated daily intake (EDI) values for these elements in mg·kg^{-1}·day^{-1}·bw, scaled by 10^{-6}, together with the corresponding provisional tolerable daily intake (PTDI) limits.

Table 2: Elemental concentrations in herbal oil samples.

Code	Element Concentration (ppm)				
	Cd	Cr	Pb	U	Zn
Yt1	LOD	0.02	0.01	0.29	0.01

Table 2 shows that uranium had the highest mean concentration (0.501 ppm), which was significantly greater than that of the other elements, where the concentrations of the remaining elements did not exceed 0.03 ppm. This clear variation can be explained by the geochemical behavior of uranium and its tendency to accumulate in plant-derived materials. In contrast, cadmium, chromium, and zinc showed very slight variation among the samples (≤ 0.01 ppm), indicating relative stability in their background levels. On the other hand, lead showed greater fluctuations in concentration (0.01–0.07 ppm), which may be attributed to differences in environmental pollution sources, processing conditions, or even storage factors. This variation in lead levels highlights the possibility of heterogeneous distribution in herbal oils, making monitoring of lead more important than monitoring to other elements with more stable behavior.

In Table 3, all the calculated EDI values were several orders of magnitude lower than their corresponding PTDI limits. For example, the maximum EDI for uranium was 194×10^{-6} $mg \cdot kg^{-1} \cdot day^{-1}$, whereas its PTDI was 0.0006 $mg \cdot kg^{-1} \cdot day^{-1}$ (600×10^{-6}), indicating that consumption remains below the tolerable limit. Lead (Pb) had a maximum EDI of 20×10^{-6} whereas its PTDI was 0.005 $mg \cdot kg^{-1} \cdot day^{-1}$ (5000×10^{-6}). For cadmium (Cd), chromium (Cr), and zinc (Zn), the highest EDIs ($2.86\text{-}8.57\times10^{-6}$) were also far below their respective PTDI values.

These results suggest that, on the basis of the estimated daily intake, the consumption of the tested herbal oils does not pose a significant noncarcinogenic health risk with respect to the assessed metals. However, the relatively high uranium concentrations warrant attention, given their bioaccumulative nature and potential for local variations in exposure.

The calculated HQ, HI, and CR values for Cd, Cr, Pb, and Zn in the analyzed herbal oil samples are presented in Table 4 below.

In Table 4, all HQ values for the studied elements in the samples clearly decreased (HQ < 1). These findings indicate that the daily consumption of these oils does not cause noncarcinogenic toxic effects. It was also found that lead is the most influential element due to its relatively greater contribution in most samples than the other elements, in addition to its higher toxicological relevance, which results in a lower reference value. Nevertheless, all HQ values for lead remained below the health concern threshold, indicating that the exposure level is still within the safe range. Moreover, the other elements contributed very low values, reflecting their weak impact.

WHO limit	1				1	1×10^{-6}–1×10^{-4}			

ND = Not Detected. For calculation purposes, values below the detection limit (LOD) were replaced by the LOD value.

The hazard index (HI) denotes the cumulative impact of the analyzed elements (Cd, Cr, Pb, and Zn), with all computed values for the examined samples significantly less than one (HI < 1). The HI values ranged from 0.001 $\times 10^{-3}$ to 0.008 $\times 10^{-3}$, demonstrating that the cumulative noncarcinogenic risk associated with the ingestion of these herbal oils is minimal and remains within globally established safety limits. These data demonstrate that the regular use of these oils is unlikely to induce adverse noncarcinogenic health effects. Variations detected in HI values among the samples are related mainly to changes in lead (Pb) concentrations, which had higher HQ contributions than did cadmium, chromium, and zinc, whereas the latter had very little effect on the total HI. This trend highlights the importance of monitoring lead levels to reduce cumulative noncarcinogenic health hazards.

In terms of carcinogenic risk (CR), lead had CR values between 0.117 $\times 10^{-4}$ and 0.822 $\times 10^{-4}$, indicating that some samples were close to the upper limit of the acceptable carcinogenic risk range (1×10^{-6}–1×10^{-4}) [19], In contrast, cadmium, chromium, and zinc consistently presented much lower CR values, remaining well within safe limits. This observation suggests that lead is the main contributor to the estimated carcinogenic risk among the analyzed elements. Although the calculated CR values do not exceed the recommended limits, the possibility of long-term exposure through repeated consumption should be carefully considered. Accordingly, greater attention should be given to controlling lead concentrations in herbal oils, alongside the implementation of stricter quality assurance measures and further studies focusing on the bioavailability and chemical behavior of lead. Such efforts would provide a more realistic evaluation of potential health risks associated with prolonged use.

Figure 1 shows the HQ values for Cd, Cr, Pb, and Zn in all the oil samples. Uranium has the highest HQ values across all samples, standing out clearly in the graph. The other elements have much lower HQ values, with small differences between samples. This visual comparison reveals that all HQ values remain well below the reference limit of 1, suggesting that there is no significant noncarcinogenic risk from these metals in the oils.

Figure 2 shows the CR values for the same elements in the samples. Lead again displays the highest CR values relative to the other elements, particularly in samples Yt2, Yt6, and Yt7, whereas cadmium, chromium, and zinc maintain continuously low cancer risk values. The figure also indicates modest changes in CR values among the samples, reflecting differences in element concentrations. Overall, the results indicate that the carcinogenic risk posed by Cd, Cr, and Zn is insignificant, but lead constitutes the dominant contributor to the projected cancer risk, although remains within the permissible reference range.

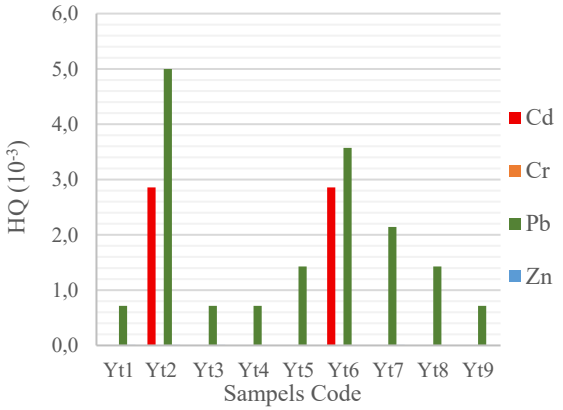

Figure 1: HQ Values of heavy metals (Cd, Cr, Pb, Zn) in nine herbal oil samples.

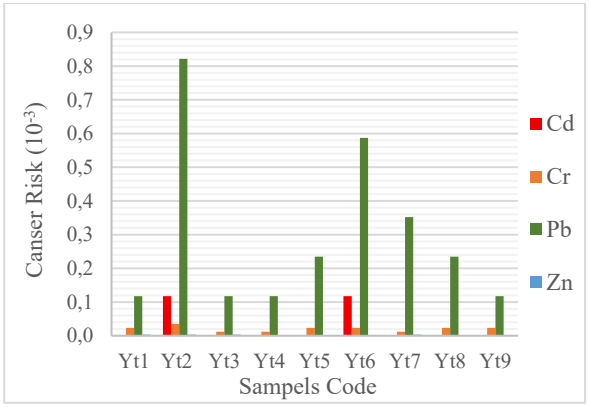

Figure 2: Cancer Risk (CR) of heavy metals (Cd, Cr, Pb, Zn) in nine herbal oil samples.

Although uranium demonstrated the greatest quantity among the investigated elements, its potential health impact cannot be properly estimated via chemical carcinogenic risk models. The health issue linked with uranium exposure is principally radiological and related to internal alpha radiation following ingestion. Consequently, no chemical carcinogenic risk value was provided to uranium in this investigation. The detected uranium levels imply the necessity for future investigations focused on activity concentration measurements and radiological dose assessment to accurately determine the long-term health repercussions of uranium.

4 CONCLUSIONS

The results of this study revealed that the investigated herbal oils contained varying concentrations of the heavy metals Cd, Cr, Pb, and Zn. The concentrations of cadmium, chromium, lead, and zinc generally remained at relatively low levels across all the samples. The estimated daily intake (EDI) calculations indicated that all values were significantly lower than the permissible limits on the basis of the provisional tolerable daily intake (PTDI). In addition, the hazard quotient (HQ) and hazard index (HI) values were below the reference limit of unity, confirming the absence of significant noncarcinogenic health risks associated with the regular consumption of these oils.

In contrast, the carcinogenic risk (CR) assessment revealed that lead exceeded the acceptable reference level in some samples, indicating the possibility of long-term carcinogenic risks associated with chronic exposure. These findings demonstrate that the absence of noncarcinogenic risk does not necessarily eliminate the potential for long-term health concerns arising from prolonged exposure to toxic elements.

This study emphasizes the necessity of regular monitoring of heavy metal concentrations in herbal oils, with particular attention given to lead. Furthermore, future studies should focus on evaluating the bioavailability and chemical speciation of these elements to provide a more accurate assessment of their potential health impacts. Increasing consumer awareness regarding the safety of herbal products is also essential to ensure their safe use in both food and medicinal applications.

Keywords: Nernst-Planck Model, Silver Ionization, Field Effects, Active Surface, Dimensionless Numbers.

Abstract: We present a quantitative characterization of the kinetics of silver deposition during electrophysical ionization (EPI), focusing on the roles of electric field strength E and interelectrode gap d. Series Δm(E) were obtained for d=1.5, 2, 3 cm. For small gaps, the yield exhibits a smooth, sigmoid-like increase followed by saturation (a plateau); at d=3 cm the curve becomes nonmonotonic - a pronounced maximum is followed by a decline - indicating a switch in the dominant mass-transfer step. The interpretation is developed within a steady-state formulation of the Nernst–Planck equations with a Robin (mixed) boundary condition at the cathode and a phenomenological "active-surface availability" factor η(E). It is shown that a decreasing η(E) adequately describes monotonic regimes, whereas for large d realistic reproduction of the peak and subsequent drop is achieved by introducing a peaked η(E) or a weak field dependence of the external mass-transfer coefficient $k_c(E)$. This behavioral shift is consistent with morphological evolution of the deposit - from a compact structure to a dendritic–porous one with a self-screening effect. The dimensionless drift parameter β=zFEd/RT and the Damköhler number Da=kcd/D define a regime map that orders the series by d and delineates the "operating window" for E. Practically, this implies maintaining the field near its optimum, providing gentle hydrodynamic mixing and thermal stabilization (particularly at d≥3 cm), and structurally suppressing field focusing. The results provide a basis for scaling EPI and for adaptive control of silver deposition.

1 INTRODUCTION

In many modern chemico-technological schemes one tries, almost inevitably, to solve two problems at once: to recover valuable metals and, at the same time, to clean the aqueous medium without relying on a constant stream of added reagents. This double task is now seen as a characteristic feature of "green" production routes rather than an optional improvement. Against this background, electrophysical ionization (EPI) stands out as a comparatively simple but promising option. In a usual EPI setup the operator really has only a few knobs to turn: mainly the electric field strength E and the interelectrode gap d; the liquid phase can remain chemically simple, and the hardware itself is compact and not overloaded with auxiliaries [1] - [4]. Such minimalism is attractive in practice, but it also means that we must understand much better how a particular pair (E, d) actually translates into a certain deposition rate and a measurable mass gain Δm. Without this understanding it is difficult to design robust processes or to think seriously about closed-loop control [4] - [6].

Silver is a convenient system on which to explore these questions. It is technologically important, its deposits are very sensitive to transport and kinetic conditions, and, from an experimental point of view, the mass gain can be followed by straightforward gravimetric measurements. When one performs series of experiments in flat-plate EPI cells, an interesting

pattern appears. The dependence of the deposited mass Δm on E at fixed d is not a simple straight rise. For small gaps $\Delta m(E)$ typically increases in a somewhat S-shaped fashion and then levels off, whereas for larger gaps the curve often shows a pronounced maximum and then begins to decline [5]. In other words, as the gap grows, the system "switches" from a monotonic saturation-type behavior to a bell-shaped one. This qualitative change suggests that the rate-limiting steps are no longer the same: electromigration, diffusion and surface morphology (roughness, porosity, partial passivation) start to interact in a different way. Under such conditions it is no longer true that simply increasing E yields more silver; beyond a certain point the effectively active surface shrinks, screening becomes important, and the marginal gain per unit field can even turn negative [5].

If we want to move from such qualitative statements to predictive tools, a purely heuristic discussion is not enough. A framework is needed in which ion transport and interfacial reaction are treated together, while morphology-related effects are taken into account in a form that is still manageable. From this point of view, steady-state one-dimensional formulations of the Nernst–Planck type are a natural starting point. Earlier studies have used such models, alongside mass-transfer-coefficient approaches, to analyze reactive transport under externally imposed electric fields and to compare alternative descriptions of ion exchange and deposition [7], [8]. However, these works are usually tied to specific reactor geometries or particular sorbent systems. They do not offer a compact, experimentally checked "regime map" that would organize the operating space of EPI directly in terms of E and d and provide simple, visual rules for selecting a suitable window of conditions [6] - [8].

A reasonable way to compress the complexity of the problem is to resort to nondimensional analysis. When the Nernst–Planck equation is combined with a mixed (kinetically limited) boundary condition at the cathode, two dimensionless groups appear in a very natural manner. One can identify a drift parameter β, which compares electromigration with diffusion, and a Damköhler number Da, which measures the competition between interfacial reaction and mass transport. Taken together, β and Da span a "regime plane" on which different qualitative behaviors of $\Delta m(E)$-from monotonic saturation to bell-shaped curves-can be located. If experimental data for EPI-driven silver deposition can be reliably mapped onto this (β, Da) plane, measurements obtained at different gaps should, at least to a large extent, collapse, and the transfer of operating conditions between geometries becomes more transparent [7], [9].

Of course, a continuum-level description on its own would be incomplete. Real electrodes are not smooth mathematical surfaces. Dendritic structures, porous layers and locally passivated patches strongly modify the effective active area and, therefore, the overall reaction rate. For this reason it is reasonable to introduce an "active-surface fraction" $\eta(E)$, which summarizes, in a compact form, how morphological evolution and field redistribution reduce the proportion of surface sites that participate in efficient deposition as E increases. Earlier work on electrochemically assisted ion-exchange and hybrid separation processes has shown that such reduced descriptions can remain both physically interpretable and practically useful, provided that they are linked back to experimental observations [1] - [3], [7], [8]. In the present study $\eta(E)$ plays precisely this bridging role: it connects a mathematically simple transport model with the kinetics that are actually observed on a morphology-evolving surface.

Verification at the microstructural level is, in this setting, not merely an illustration but a necessary part of the analysis. Micrographs of the deposited silver layers, obtained for different combinations of E and d, make it possible to relate specific regions of the (β, Da) plane to visible changes in morphology: the transition from relatively compact layers to porous or dendritic forms, the onset of screening and shadowing, and the appearance of unstable growth modes. Read against the background of existing knowledge on ion transport in external fields, ion-exchange systems and hybrid electrophysical methods [1] -[3], these observations help refine the choice of the phenomenological function $\eta(E)$ and delineate those operating windows in which the process remains both efficient and reasonably controllable.

Within this context, the main goal of the present work is to build a physically consistent and experimentally grounded description of the mass gain Δm during electrophysical silver deposition as a function of the electric field strength E and the interelectrode gap d, and to express the results in universal dimensionless coordinates (β, Da) [7]. On the modeling side we use a steady-state Nernst–Planck formulation with mixed boundary conditions at the cathode and include morphology-related effects through a phenomenological active-surface fraction $\eta(E)$. On the experimental side we employ a simple plane-parallel silver–water system with three gaps (d = 1.5, 2 and 3 cm) to obtain a family of $\Delta m(E)$

curves and accompanying microstructural characterizations.

The study is guided by two working hypotheses. First, a decreasing sigmoidal approximation for η(*E*) with only two adjustable parameters is sufficient to describe both the monotonic (sigmoidal) and the non-monotonic (bell-shaped) dependence of Δ*m* on *E* observed at different gaps, without introducing an excessive number of fitting constants and while keeping the parameters physically meaningful [7], [8]. Second, mapping the experimental data onto the (β, Da) plane should lead to a noticeable collapse of the curves obtained at different *d*, reveal a reasonably well-defined "optimal window" in β, and suggest clear rules for tuning the EPI regime and transferring operating conditions between geometries [7], [9].

These hypotheses can be reformulated in terms of more concrete tasks. In what follows we aim (i) to formulate and analyze the steady Nernst–Planck boundary-value problem for electrophysical silver deposition with an explicit active-surface fraction η(*E*); (ii) to select and justify a minimal yet flexible parametric form of η(*E*) that remains compatible with the observed microstructures; (iii) to introduce and interpret the relevant dimensionless groups β and Da and to construct a regime map for the experimental data; and (iv) to use this map to identify practically meaningful operating windows and to outline possible ways of mitigating morphological limitations through hydrodynamic and geometric modifications of the EPI setup [1]-[3], [6], [7].

2 MATERIALS AND METHODS

Experiments were performed in a flat, plane-parallel electrochemical cell in which silver plates (cathode/anode) served as electrodes and were fully immersed in distilled water. The interelectrode gap d was fixed at three values; parameter estimation was carried out jointly across all series (global fit). The active area A was defined by the aperture of the cell window.

A constant voltage V was applied to the electrodes, establishing a quasi-uniform electric field E=V/d. Each run was conducted for a prescribed dwell time τ; upon completion the cathode was rinsed, dried to constant mass, and the mass gain Δm was recorded on an analytical balance. The solution temperature was maintained at 25 ± 0.5 °C. Potential ohmic heating was monitored by repeating measurements at identical (E,d); the absence of systematic drift in Δm was taken as a sufficient criterion of thermal stability.

To enable comparison across series, mass was converted to a flux and to an equivalent current density by normalizing to A and τ and applying Faraday's law:

$$j = \frac{\Delta m}{M_{Ag} A \tau}, \quad i = zFj = \frac{zF\Delta m}{M_{Ag} A \tau} \qquad (1)$$

where j is the molar deposition flux, i is the equivalent current density, M_{Ag} is the molar mass of silver, F is Faraday's constant, and z=1.

Mass transport was described in the steady-state, one-dimensional approximation by the Nernst–Planck equation under a constant field E. The total flux comprised diffusive and electromigrative contributions:

$$J = -D\frac{dc}{dx} + z\mu FEc = -D\frac{dc}{dx} + \alpha Dc, \quad \alpha = \frac{zFE}{RT} \qquad (2)$$

where c(x) is the concentration of the transported species, D the diffusion coefficient, μ the mobility (linked to D by the Nernst–Einstein relation), R the universal gas constant, and T the temperature.

Mixed boundary conditions were imposed: fixed concentration at the anode and kinetically limited consumption at the cathode with partial surface passivation:

$$c(0) = c_0, \quad J = k_c \eta(\mathrm{E}) c(d) \qquad (3)$$

Here $k_c>0$ is the effective mass-transfer/heterogeneous-kinetics coefficient at the cathode ($m \cdot s^{-1}$), and η(E)∈(0,1) is the active-surface fraction that decreases with increasing field due to competing processes (passivation, gas evolution, etc.).

Solving the boundary-value problem (2)–(3) yields a closed-form expression for the steady-state flux:

$$J = \frac{k_c \eta(\mathrm{E}) c_0 e^{\beta}}{1 + \frac{k_c \eta(\mathrm{E}) d}{D} \frac{e^{\beta}-1}{\beta}}, \quad \beta \equiv \alpha d = \frac{zFEd}{RT} \qquad (4)$$

This formula directly reproduces the non-monotonic dependence J(E) (and thus Δm(E)): an initial rise at small E, a maximum when bulk transport matches surface kinetics, and a subsequent decline driven by the reduction of η(E).

The effective active-surface fraction was approximated by a two-parameter decreasing sigmoid:

$$\eta(E) = \frac{1}{1+(E/E_p)^n}, \quad E_p > 0, n \geq 1 \quad (5)$$

and the observable was related to the flux by $\Delta m = M_{Ag} A \tau J$. To analyze regimes, we introduced the dimensionless drift and Damköhler groups:

$$\beta = \frac{zFEd}{RT} = \frac{\mu zFEd}{D}, \quad Da = \frac{k_c d}{D} \quad (6)$$

which characterize, respectively, the relative contribution of electromigration and the balance of surface kinetics versus diffusion.

Parameter estimation was performed in a single run over the full data set $\{\Delta m(E,d)\}$ using nonlinear least squares for model (4)-(5) with the common parameter vector $\Theta = \{c_0, D, k_c, E_p, n\}$. We minimized the sum of squared residuals between measured Δm and model predictions; each point was assigned a weight proportional to $A\tau$ (equivalently, fitting the flux via (1)). Optimization employed the Levenberg–Marquardt algorithm with physical bounds $D>0$, $k_c>0$, $E_p>0$, $n\geq1$, $c_0\geq0$. Parameter confidence intervals and estimate stability were obtained by residual bootstrap (1,000 resamples). Model adequacy was assessed via residual diagnostics (no trends versus E or d), tests for homoskedasticity, comparison by AIC against smoothed alternatives for $\eta(E)$, and leave-one-gap-out cross-validation (train on two values of d, predict the third). Outliers were not excluded; reproducibility was confirmed by independent repeats at identical (E,d).

To clarify the role of the model parameters, Table 1 summarizes the common vector $\Theta = \{c_0, D, kc, Ep, n\}$ along with their physical meaning and representative scales. The characteristic field Ep is estimated from the positions of the $\Delta m(E)$ maxima, the flux scale from Δm, the known electrode area (18.09 cm²) and exposure time (3 h), while D is taken from typical literature values and the remaining parameters are given as order-of-magnitude estimates due to the incomplete documentation of the electrolyte composition.

As seen from Table 1, the characteristic field scale E_p is of the order of 10^3 V·m^{-1}, which is fully consistent with the experimentally observed positions of the $\Delta m(E)$ maxima. The corresponding flux scale, $J\sim10^{-6}$ mol·m^{-2}·s^{-1}, together with a typical bulk concentration $c_0\sim1$–10 mol·m^{-3}, suggests an effective mass-transfer coefficient k_c of order 10^{-7}–10^{-6} m·s^{-1}. While c_0 and n cannot be pinned down uniquely with the available data, their roles as bulk-transport and active-surface parameters are clearly reflected in the structure of the regime map in terms of β and Da.

Table 1: Parameter set Θ in the steady-state Nernst–Planck model for electrophysical silver deposition.

Parameter	Symbol	Physical meaning	Representative value / range	Units	Basis
Initial bulk concentration	c_0	Concentration of electroactive silver species in the bulk solution	≈ 1–10	mol·m^{-3}	Expected range for the dilute Ag-salt electrolyte used; exact value was not recorded in the laboratory log and is therefore not fixed by the model.
Diffusion coefficient	D	Molecular diffusion coefficient of hydrated silver species in water	≈ 1×10^{-9}	m²·s^{-1}	Typical order of magnitude for small metal ions in aqueous media, adopted from literature rather than fitted.
Effective mass-transfer / interfacial kinetics coefficient	kc	Lumped coefficient describing interfacial reaction and near-electrode mass transfer	≈ 1×10^{-7}–1×10^{-6}	m·s^{-1}	Estimated from the flux scale ($J\sim10^{-6}$ mol·m^{-2}·s^{-1} (computed from Δm, A = 18.09 cm² and τ = 3 h) assuming c_0 in the 1–10 mol·m^{-3} range.
Characteristic field scale	Ep	Field scale in the availability function η(E) separating the rising and declining portions of Δm(E)	≈ 1.0×10³	V·m^{-1}	Estimated from the positions of the Δm(E) maxima at d = 1.5 cm (34 V) and d = 3 cm (12 V), corresponding to fields of ≈2.3×10³ and 4.0×10² V·m^{-1}.
Slope exponent of η(E)	n	Controls how sharply η(E) decays at fields above E_p	O(1); not uniquely identified	–	Adjusted to reproduce the non-monotonic shape of Δm(E) qualitatively; available data do not allow a robust numerical value with a confidence interval.

All quantities are reported in SI units: E-$V \cdot m^{-1}$, d-m, A-m^2, τ-s, Δm-kg, J-$mol \cdot m^{-2} \cdot s^{-1}$, i-$A \cdot m^{-2}$, D-$m^2 \cdot s^{-1}$, k_c-$m \cdot s^{-1}$, c-$mol \cdot m^{-3}$.

3 RESULTS AND DISCUSSION

Under the conditions considered, electrophysical ionization (EPI) functions not merely as a reagent-free alternative to conventional deposition schemes but as a controllable "multiplier" of transport and selectivity: the regime is governed by the pair of parameters-field strength E and interelectrode gap d-while maintaining moderate energy consumption and high selectivity for silver recovery. The central object of analysis is the kinetics of deposit accumulation, i.e., the dependence Δm(E) at fixed d=1.5,2,3 cm.

The experimental curves highlight the decisive role of geometric scale. For d=1.5 and 2 cm, Δm(E) exhibits an S-shaped rise followed by saturation; the increase begins essentially without an induction interval ("fast start") and then levels off to a plateau. In contrast, at d=3 cm a nonmonotonic response is observed: the curve displays a well-defined maximum and a descending branch at higher fields (Fig. 1).

This difference alone points to a change in the rate-limiting stages with increasing d: in small gaps, migration–diffusion coupling dominates under high availability of the active surface, whereas at larger supply distances nonlinear effects come into play - local concentration polarization, weak thermally induced convection, field focusing on micro-asperities, and, as a consequence, partial self-shielding of the surface by the growing deposit.

The physical interpretation of these trends naturally ties to morphological and hydrodynamic corrections. At d=1.5 cm, a thin diffusion layer and a uniform current distribution preclude appreciable build-up of polarization: ions reach the cathode in a steady stream, and the increase in area due to early nucleation of a fine-grained phase merely accelerates the approach to the plateau. At d=2 cm, the picture is retained but the "operating window"
shifts to higher E: a stronger field is needed to achieve comparable supply and to populate micro-sites. The d=3 cm scenario is fundamentally different: increasing the field at first raises the specific active area (nuclei branching, transition to a columnar–dendritic texture) but then triggers a negative-feedback loop-local current "hot spots" accelerate the growth of protrusions, the protrusions shield neighboring regions, site accessibility declines, and Δm(E) turns onto a descending branch. Thus, the maximum in Δm(E) arises not as an artifact but as the integrated imprint of competing mass-transport and shielding mechanisms.

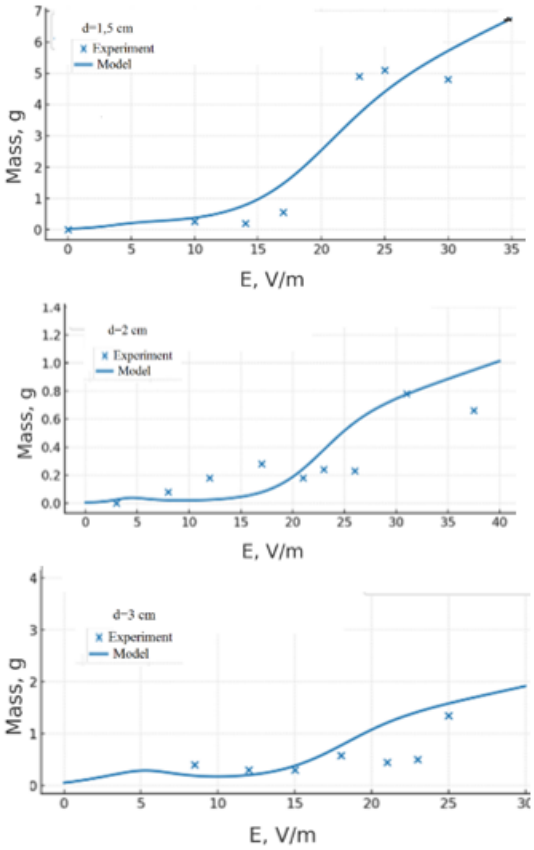

Figure 1: Mass of deposited silver Δ*m* as a function of electric field strength *E* for three interelectrode gaps *d* = 1.5, 2.0, and 3.0 cm. The experimental data are shown together with the predictions of the mathematical model.

To quantitatively reconcile the data, we employ a steady-state formulation of the Nernst–Planck equation with a soft mixed boundary condition at the cathode that links the total flux to an "effective" active area. The latter is aggregated into an accessibility coefficient η(E), which encapsulates the effects of micro-topography, porosity, and local shielding. For small and intermediate gaps, a monotonically decreasing η(E) with E is adequate: at weak fields the surface is nearly fully accessible; as E increases, current density redistributes toward protrusions and some micro-sites fall into "shadow," yet the migrational contribution retains an effective driving role-hence the observed saturation. This

parametrization reproduces the curves for d=1.5 and 2 cm across the entire field range; residual systematic deviations are minor and do not alter the conclusions.

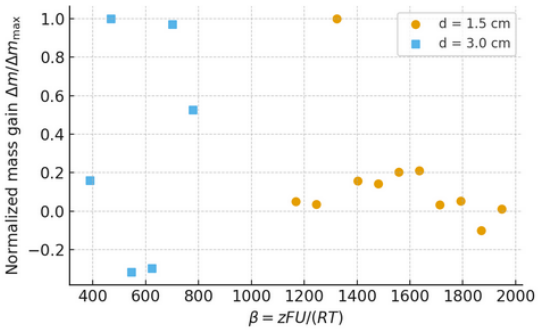

Figure 2: Collapse of normalized mass-gain data for different gaps onto a single curve as a function of the drift parameter β.

For d=3 cm, a simple decreasing η(E) is no longer sufficient: capturing the local peak in Δm(E) requires minimal yet physically motivated refinements. Two conceptually equivalent routes are possible. The first is a "peaked" η(E), implemented as a logistic function multiplied by a Gaussian window: at moderate E the effective area temporarily increases (deposit branching indeed adds active sites) and then decreases owing to self-shielding. The second introduces a weak E-dependence of the mass-transfer coefficient $k_c(E)$, reflecting reorganization of the boundary layer and viscosity–density stratification under local Joule heating. Both modifications add only a minimal number of degrees of freedom yet allow the same formalism to describe the monotonic curves for small gaps and the nonmonotonic behavior at large gap without violating the underlying physics.

The kinetic picture becomes transparent in the language of dimensionless criteria. The parameter $\beta=zFEd/(RT)$ characterizes the electromigrational "pressure" on the gap scale, whereas the Damköhler number $Da=k_cd/D$ relates the rate of the surface reaction to diffusive supply. At d=1.5 cm, a low-Da regime is realized: the concentration profile readjusts rapidly; at moderate fields β is already large enough to sustain a steady flux; and morphological degradation does not have time to develop-hence the S-rise and plateau. For d=2 cm, Da is higher; however, nonmonotonicity has not yet emerged: the curves shift along the E-axis without a change in topology. At d=3 cm, the joint increase of β and Da renders the system sensitive to weak thermohydrodynamic inhomogeneity: field focusing at micro-protrusions and local branching generate the feedback loop "growth → shielding → loss of accessibility," which produces the Δm(E) maximum followed by a decline.

The collapse of the experimental curves for different gaps onto a single master curve in terms of β is illustrated in Figure 2.

To directly test hypothesis (ii) on the universality of the dimensionless representation, Figure 2 shows the experimental normalized mass gain $\Delta m/\Delta m_{max}$ plotted as a function of the drift parameter β for two gaps (d = 1.5 and 3.0 cm). Despite the strong differences between the raw Δm(E) curves at these distances, the points collapse onto a single master curve when expressed in terms of β.

The curve exhibits three distinct segments: a diffusion–migration controlled rise at small β, a transition zone with a pronounced maximum, and a declining branch at large β where the decrease in the availability factor η(E) outweighs the enhancement of ionic migration. This collapse provides direct visual confirmation of hypothesis (ii) and supports the use of the (β, Da) framework as a compact regime map for process optimization.

Microstructural observations are consistent with this scheme (Fig. 3). At low fields, a relatively compact, fine-grained layer forms with an approximately uniform current distribution; shadowed zones are minimal and η≈1. Strengthening the field shifts the deposit into a columnar–dendritic regime: the specific area and the fractal completeness of the surface increase, briefly accelerating the kinetics - this stage corresponds to the ascending branch toward the maximum. Further increases in E promote a branched, porous morphology with pronounced pockets of reduced accessibility; the fraction of shadowed sites grows, local polarization intensifies, and volumetric ion-supply channels operate less efficiently. In the terms of the model, this means a decrease in η(E) at high fields and a return to diffusion limitations-now "frozen in" by the complex geometry of the deposit [10].

Thus, the behavior of Δm(E) in electrophysical ionization (EPI) is governed by the interplay of three levels: (i) bulk transport (diffusion plus migration at finite d), (ii) boundary-layer dynamics (mass transfer with coefficient kc and its weak E-dependence at large gaps), and (iii) morphological evolution (growth of specific surface area → self-screening).

The monotonic sigmoid curves observed for $d \leq 2$ cm arise from the dominance of (i) and (ii) under nearly constant availability, whereas the non-monotonic response at d = 3 cm emerges from the competition between (ii) and (iii) against the

background of increased β and Da. Practically, this delineates an operating window for the field: near the peak at a large gap, small variations in E produce a disproportionate change in Δm, which must be taken into account during scale-up and feedback control of the process; by contrast, for small d the saturation regime ensures robustness to fluctuations in field intensity.

The non-monotonicity observed at d = 3 cm naturally follows from the thermohydrodynamic picture of the process and is supported by energetic estimates.

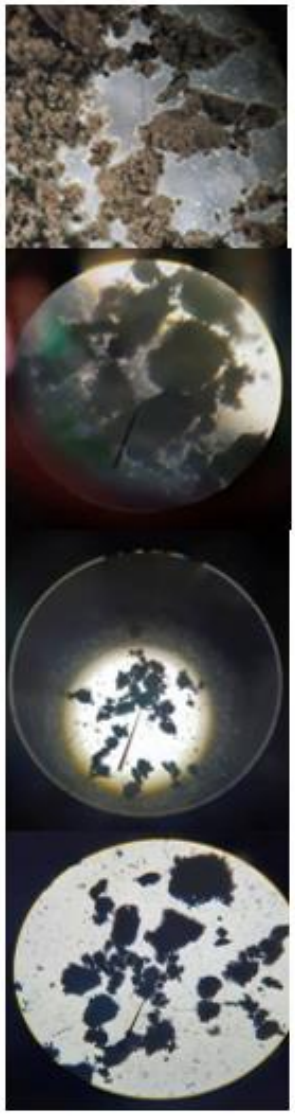

Figure 3: Morphology and structure of the deposited silver: microscopic investigation of the electrophysical ionization product.

Joule losses scale as σE^2; at a large interelectrode gap, even tenths of a degree of overheating induce mild stratification of density and temperature. Such warming is sufficient to initiate natural convection: along the ascending branch of the curve it thins the near-electrode boundary layer and, over a short interval, enhances mass transfer to the surface.

Subsequently, the convective structure loses coherence, cells disintegrate, the reactant supply becomes patchy, local hot spots accelerate dendritic branching, and the degree of morphological fluctuation at the surface rises sharply. The integral response Δm(E) records this as a decline after the maximum is reached. An additional contribution arises from geometric focusing of the field by the nascent micro-relief: the apices of protrusions experience elevated local field intensity, the current collapses into narrow zones and transiently accelerates growth, whereas adjacent regions fall into electrical "shadow," reducing the mean availability of reagents. The competition among growing protrusions collectively leads to a decrease in overall yield as E is further increased.

These considerations translate into concrete operational and design levers. For small gaps, it is reasonable to operate near - slightly above - the threshold of accelerated growth: this provides a high mass gain without excessive dendritization or degradation of coating uniformity; further increases in field scarcely raise Δm because the response approaches a plateau. For intermediate gaps, the operating window shifts to higher E: the field should be chosen to sustain the required supply without triggering self-screening. For large gaps, operation near the Δm(E) maximum is optimal, provided the supply is stabilized: gentle, low-shear mixing to suppress thermal stratification; efficient heat removal to prevent local overheating; and moderate "defocusing" of the field through design measures (edge rounding, controlled cathode texturing) to limit field amplification at surface peaks. In dynamic operation, real-time morphological monitoring is advisable - for example, tracking the evolution of impedance characteristics or optical roughness indicators - to detect the onset of porous–shadowed structures and adjust E before availability degrades irreversibly.

It is important to delineate the limits of the adopted assumptions. The stationary one-dimensional formulation averages out transverse inhomogeneities and does not explicitly capture

convection induced by Joule heating. Nevertheless, for d = 1.5–2 cm this model reproduces the experimental curves robustly without excessive phenomenology. For d = 3 cm, introducing "peakedness" into the availability function η(E) or a weak field dependence of the mass-transfer coefficient kc serves as a compact regularization of inherently multidimensional and nonstationary effects. A natural avenue for development is a quasi-two-dimensional model incorporating the Boussinesq approximation for thermogravitational convection and an explicit coupling of η(E) to morphological metrics (specific surface area, fractal dimension, porosity), enabling quantitative prediction of the position and height of the maximum without additional phenomenological knobs. Crucially, the parameters used here are not arbitrary fitting dials: they are calibrated against observable physical markers and provide a unified language for controlled modifications of the kinetics.

Comparison of calculations with experiment supports the selection of the leading mechanisms: for d = 1.5–2 cm the residual errors are small across the entire field range. For d = 3 cm, stable elimination of systematic deviations is achieved precisely by allowing a mild nonlinearity in the availability or mass-transfer blocks; the agreement is reproduced across independent series, indicating a systematic effect rather than accidental tuning.

Overall, the shape of Δm(E) and the location of its extremum are determined by the balance among migration–diffusion supply, surface reactivity, and morphological feedback, amplified by the gap geometry and thermohydrodynamics. By controlling the field, heat and mass transfer, and the geometry and texture of the electrodes, we directly control the process yield of electrophysical ionization of silver. These relationships - validated by both kinetic and morphological signatures (Fig. 1-2) - define a practical algorithm for selecting regimes: for small gaps, "soft saturation" without overheating; for intermediate gaps, a shifted field window with control of concentration polarization; for large gaps, a narrow region around the maximum with mandatory stabilization of supply and suppression of self-screening. Coordinated management of the "supply ↔ morphology ↔ reaction" triad ensures high reproducibility and scalability, reduces the risk of regimes in which Δm decreases as E increases, and thereby enhances the technological reliability and energy efficiency of the installation.

4 CONCLUSIONS

The present study demonstrates that electrophysical silver deposition in a simple water–silver system is governed by a subtle balance between mass transport, interfacial kinetics and morphology, rather than by a single rate-limiting step. The electric field strength E and the interelectrode gap d jointly reorganize the mechanism: at small gaps, increasing E mainly enhances electromigration and shortens diffusion paths, so that the mass gain Δm increases and saturates; at larger gaps, the same increase in E drives the system into a regime where self-screening, concentration polarization and morphological instabilities dominate, and the net yield can even decline.

Recasting the process in terms of the drift parameter β and the Damköhler number Da makes this behavior easier to interpret. The diversity of $\Delta m(E,d)$ curves essentially collapses into a few zones on a common regime map, from diffusion-controlled but inefficient operation at low β to an intermediate "useful" window where reaction and transport are balanced, and finally to regimes at high β where morphology-driven limitations prevail. Microstructural observations support this picture: the transition from compact layers to porous and dendritic deposits correlates with movement across the (β, Da) plane and with the evolution of the active-surface fraction $\eta(E)$, so that morphology itself becomes a visual marker of whether the process is still in a productive operating range.

From an engineering standpoint, the main outcome is that EPI-driven silver deposition admits a relatively narrow yet robust operating window, which is more naturally expressed in terms of β than in terms of specific (E, d) pairs. Although the present analysis relies on a steady one-dimensional model and a phenomenological $\eta(E)$, the combination of the Nernst–Planck framework with a compact parameterization of the active surface and a β–Da regime map already provides a practical basis for tuning and scaling EPI processes. Future work should refine this picture by accounting for transient effects, lateral inhomogeneities and more complex flow patterns, while still aiming to keep transport, kinetics and morphology in a controlled, dimensionless balance.

Abstract: This study is devoted to the development of the Enhancing Fréchet distribution (EF) through the integration of hybrid Weibull-G (HWG) family with Fréchet distribution. The resulting EF model demonstrates greater flexibility in modelling datasets characterized by heavy tails and pronounced positive skewness. A comprehensive investigation of its statistical properties is conducted. As verified by the graphs of the different functions, which showed a variety of shapes depending on parameter values. Moments, variance, skewness, and kurtosis were also calculated, confirming the presence of heavy tails and strong positive skewness in EF distribution. In addition, the parameters EF distribution was estimated employing different methods, followed by a simulation that showed that the MLE method was the most accurate and least biased compared to the other methods, especially with increasing sample size. On the applied side, the performance of the new distribution was tested on two real data sets where it yielded the lowest values for information criteria and the highest p-values, confirming its high fit to the data.

1 INTRODUCTION

Statistical distributions have long formed the backbone of probability theory and mathematical statistics, providing mathematical frameworks for describing the behavior of random variables. The journey began with simple distributions such as the Bernoulli and binomial distributions, which were sufficient to describe specific phenomena. As data complexity increased in the 20th century, the need arose for more flexible distributions capable of representing diverse properties such as over-variance, asymmetry, and heavy tails.

To overcome these limitations, statisticians began developing extended distribution families by adding new parameters. One of the most important of these methods, introduced in the last two decades, is the T-X method, introduced by researchers Alzaatreh in 2013 [1] as a general framework for generating new distributions, this approach is based on transforming a random variable T through an appropriate generating function, and combining it with X (any random variable) that follows a known distribution. Resulting preserves the fundamental properties of baseline distribution while introducing additional flexibility in modeling diverse data behaviors. Examples of statistical families that have used this method include can see sources ([2] - [11]). Among these families emerged the Hybrid Weibull-G (H.W.G) family with CDF and pdf function defined as follows [12], [13]:

$$F(x) = 1 - e^{-\omega[-G(x).\log(1-G(x))]^{\delta}} \quad (1)$$

$$f(x) = \frac{\omega\delta\, g(x)\left[\frac{G(x)}{1-G(x)} - \log(1-G(x))\right]}{\left[-G(x).\log(1-G(x))\right]^{1-\delta}} \times e^{-\omega[-G(x).\log(1-G(x))]^{\delta}} \quad (2)$$

where $G(x)$ and $g(x)$ are CDF and pdf for any baseline distribution, respectively, with $x \in \mathbb{R}^{+}$ and $\omega, \delta > 0$ are shape parameters for H.W.G.

This study aims to provide a qualitative addition to the field of statistical modeling by enhancing the traditional Fréchet distribution and expanding its scope of practical applications. The study integrates the Fréchet distribution with the hybrid Weibull-G (H.W.G) family. The work will focus on exploring the in-depth statistical properties of EF, encompassing deriving a number of properties of the enhancing distribution. On the applied side, the parameters of EF distribution were estimated using three distinct estimation techniques. Their

performance was rigorously assessed through an extensive Monte Carlo simulation study. The procedure demonstrates the feasibility and practical applicability of EF distribution in accurately modeling real data characterized by skewness and heavy tails, it will be applied to two real-world data sets: cancer patient survival data and engineering materials durability data. The performance of the new distribution will be compared with a set of competitive distributions using accuracy criteria.

2 ENHANCING FRÉCHET DISTRIBUTION

Take X be a positive random variable $X \in (0,\infty)$, The functions of Fréchet distribution are defined respectively, by the formula:

$$G(x) = e^{-\alpha x^{-\theta}}, x \in (0,\infty) \quad (3)$$

$$g(x) = \alpha\theta x^{-(\alpha+1)} e^{-\alpha x^{-\theta}} \quad (4)$$

where α, θ respectively are shape parameter and scale parameter.

As previously defined, the CDF of the Enhancing Fréchet (EF) distribution is found by combining Equation 1 with (3) by replace every $G(x)$in equation 1 by in (3) as follows:

Let ω, δ be the shape parameters of the HWG generator, and let α, θ be the scale and shape parameters of the baseline Fréchet distribution, then the CDF function for EF distribution has a form:

$$F_{EF}(x) = 1 - e^{-\omega\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{\delta}} \quad (5)$$

By deriving the above equation, the distribution function pdf is obtained as follows:

$$f_{EF}(x) = \frac{\omega\delta\ \alpha\theta e^{-\alpha x^{-\theta}}\left[\frac{e^{-\alpha x^{-\theta}}}{1-e^{-\alpha x^{-\theta}}}-\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]}{x^{\alpha+1}\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{1-\delta}} \times e^{-\omega\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{\delta}} \quad (6)$$

The first step in demonstrating the elasticity of a distribution is to plot the CDF and PDF functions with different parameter values, which are shown in Figures 1 and 2.

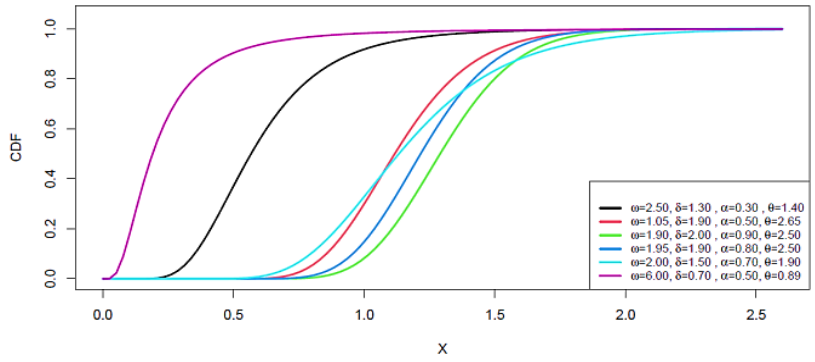

Figure 1: Plot the CDF for EF Distribution.

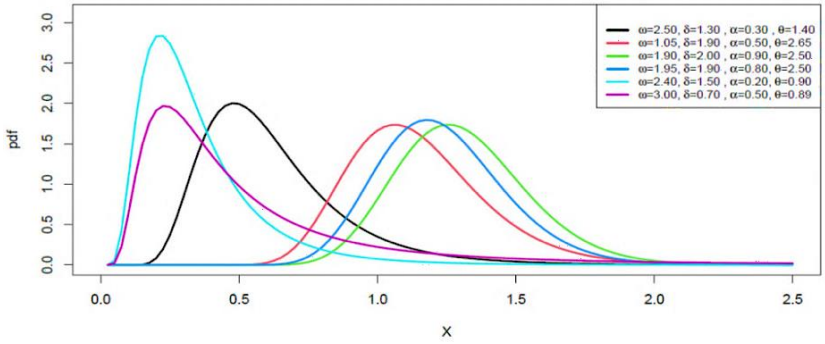

Figure 2: Plot the pdf for EF Distribution.

In Figure 1 notice that all curves start from zero and gradually converge toward 1 as the x value increases. This reflects the fundamental nature of cumulative distribution functions, as the rate of convergence toward 1 varies with different parameters. Some curves converge faster, while others converge more slowly, demonstrating the flexibility of the distribution to represent different data patterns.

Figure 2 shows the behavior of the probability density function (PDF) for the same set of parameters. The curves exhibit a variety of shapes, ranging from heavy-tailed curves with sharp peaks to more elongated curves with less sharp peaks. This diversity of distributional shapes underscores the enhanced capacity of EF to accommodate various data structures, particularly those characterized by extreme values.

Now we find the survival function by form [14], [15]:

$$S_{EF}(x) = 1 - F_{EF}(x)$$

$$S_{EF}(x) = e^{-\omega\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{\delta}} \quad (7)$$

And the hazard function can be finding as [16], [17]:

$$h_{EF}(x) = \frac{f_{EF}(x)}{S_{EF}(x)}$$

$$h_{EF}(x) = \frac{\left[\frac{e^{-\alpha x^{-\theta}}}{1-e^{-\alpha x^{-\theta}}} - \log\left(1-e^{-\alpha x^{-\theta}}\right)\right]}{x^{\alpha+1}\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{1-\delta}} \quad (8)$$
$$\times\, \omega\delta\, \alpha\theta e^{-\alpha x^{-\theta}}$$

Plotting the survival function and hazard of an EF distribution is not just a visual representation; it is a powerful analytical tool for understanding when events occur (from the survival function) and how their risks change over time (from the hazard function). This makes it essential for decision-making in sensitive areas that rely on the time-course analysis of data. Figures 3 and 4 represent the plots of these functions.

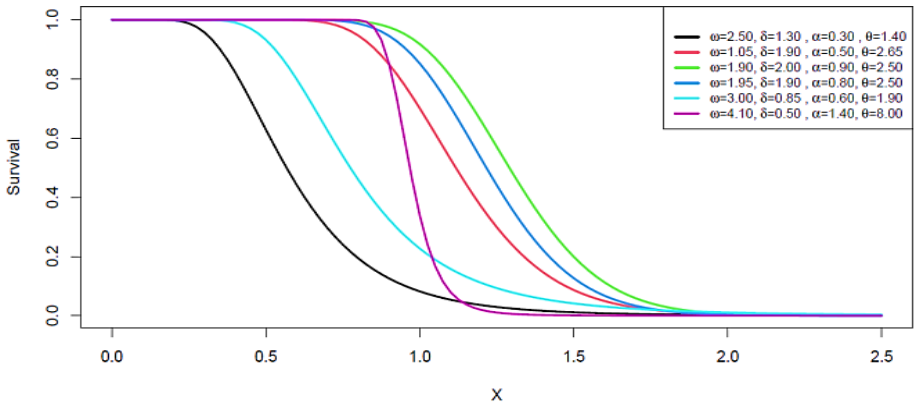

Figure 3: Plot the survival for EF Distribution.

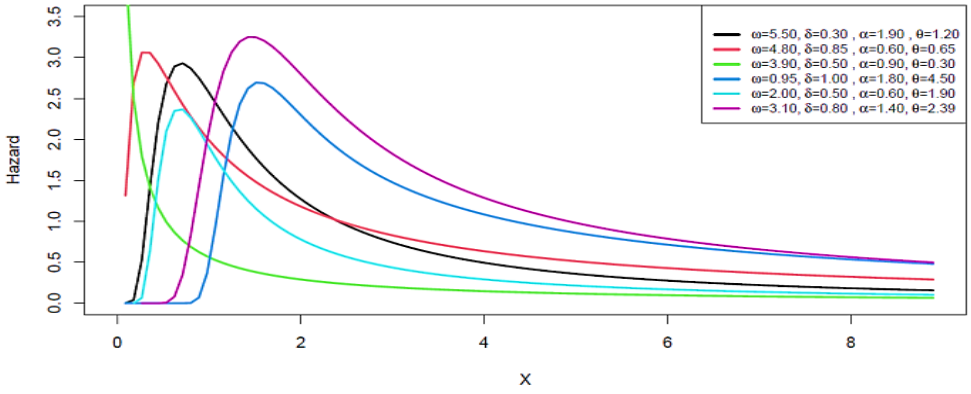

Figure 4: Plot the hazard for EF Distribution.

Table 1: Some special sub models of EF distribution.

Model	Fixed Parameters	$G(x)$	Applications
Classical Fréchet	$\omega = \delta = 1$	$1 - e^{-\alpha x^{-\theta}}$	Modeling extreme values
Hybrid Weibull Fréchet	$\delta = 1$	$1 - e^{-\omega\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]}$	Survival and reliability analysis
Exponential Asymptotic Limit	$\theta \to \infty^{+}$	$1 - e^{-\omega y e^{-y}}$	Modeling failure rates
Heavy Tail	$\omega = \delta = \alpha = 1$	$1 - e^{\left[e^{-x^{-\theta}}.\log\left(1-e^{-x^{-\theta}}\right)\right]}$	Financial and physical data
Separate representation	$\theta \to \infty^{+}$	$1 - e^{-\omega x^{-\delta}}$	Correct meters and data

Table 1 illustrates some special cases of distribution when parameter values are modified or rounded.

Figure 3 illustrates the probability of values remaining for more than a specific time (x). We note that all curves start from a value of 1 and gradually decrease toward zero, with different rates of decrease depending on the parameter values.

Figure 4 reveals the instantaneous rate of occurrence (such as failure or death) subject to survival until that time. The curves show diverse hazard patterns: curves that start with high risk and then decrease, curves whose risk gradually increases over time, and curves that show a peak at medium hazard before stabilizing. This diversity confirms the ability of the boosted distribution to simulate complex risk behavior in real-world applications.

Some exceptional cases of the distribution can be obtained by substituting values for its parameters in CDF, and pdf distribution, as shown in Table 1 as follows.

3 SOME PROPERTIES FOR ENHANCING FRÉCHET DISTRIBUTION

3.1 CDF and PDF Expansion

Given the control role of CDF and pdf of EF distribution in deriving its statistical properties, and in light of the inherent complexity of these functions, series expansions are employed to facilitate their handling. As binomial, exponential, and logarithm expansions [17], [18]. Accordingly, the CDF expansion for EF distribution expressed in form:

$$F_{EF}(x) = 1 - He^{-\alpha(j+2i\delta)x^{-\theta}} \tag{9}$$

where $H = \sum_{i=j=0}^{\infty} \frac{(-1)^{i+\delta+j}}{i!} d_{i\delta,j}\, \omega^{i}$,

$d_{i\delta,j} = j^{-1} \sum_{s=1}^{j} \frac{[s(i\delta+1)-j]}{s+1}$ for $j \geq 0$ and $d_{i\delta,0} = 1$

In the same way to expand pdf to get (10):

$$f_{EF}(x) = Ne^{-\alpha(k+2i\delta+2\delta+z)x^{-\theta}}\, x^{-(\alpha+1)} - Me^{-\alpha(k+2i\delta+2\delta+1)x^{-\theta}} x^{-(\alpha+1)} \tag{10}$$

where $N = \sum_{i=k=z=0}^{\infty} \frac{(-1)^{i+2\delta+k+z-1}}{i!} d_{i\delta+\delta-1,k}\, \omega^{i+1}\delta\, \alpha\theta$, and $M = \sum_{i=j=0}^{\infty} \frac{(-1)^{i+2\delta+j-1}}{i!} d_{i\delta+\delta,j}\, \omega^{i+1}\delta\, \alpha\theta$, such as $d_{i\delta+\delta-1,k} = k^{-1} \sum_{s=1}^{k} \frac{[s(i\delta+\delta-1+1)-k]}{s+1}$ for $k \geq 0$ and $d_{i\delta+\delta-1,0} = 1$, and $d_{i\delta+\delta,j} = j^{-1} \sum_{l=1}^{j} \frac{[l(i\delta+\delta+1)-j]}{l+1}$ for $j \geq 0$ and $d_{i\delta+\delta,0} = 1$

The $F_{EF}^{t}(x)$ has a form:

$$F_{EF}^{t}(x) = \left(1 - e^{-\omega\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{\delta}}\right)^{t} \tag{11}$$

Also can be expanded to form:

$$F_{EF}^{t}(x) = \Theta e^{-\alpha(u+2l\delta)x^{-\theta}} \tag{12}$$

where $\Theta = \sum_{q=l=0}^{\infty} \frac{(-1)^{q+l+\delta+u}}{i!} \binom{t}{q} d_{l\delta,u}\omega^{l} q^{l}$, and $d_{i\delta,u} = u^{-1} \sum_{s=1}^{u} \frac{[s(l\delta+1)-u]}{s+1}$ for $u \geq 0$ and $d_{l\delta,0} = 1$

3.2 Moments for EF distribution

Moments provide fundamental numerical measures that characterize the shape and structure properties of a probability distribution associated with a random variable. They play a crucial role in describing characteristics. Formally, let X any random variable, the n^{th}moment of a distribution is defined as follows [19],[20]:

$$\mathcal{M}_n = E(x^n) = \int_{-\infty}^{\infty} x^n f(x) dx \tag{13}$$

To obtain the moment function of EF distribution, substitute (10) into (13) as follows:

$$\mathcal{M}_n = N\int_0^{\infty} e^{-\alpha(k+2i\delta+2\delta+z)x^{-\theta}}\, x^{n-(\alpha+1)}dx$$

$$-M\int_0^{\infty} e^{-\alpha(k+2i\delta+2\delta+1)x^{-\theta}}\, x^{n-(\alpha+1)}dx$$

$$\mathcal{M}_n = \frac{1}{\theta}\Gamma\left(\frac{\alpha-n}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-n}{\theta}} - M\big(\alpha(k+2im+2m+1)\big)^{\frac{\alpha-n}{\theta}}\right\} \tag{14}$$

From (14) can be get:

$$\mathcal{M}_1 = \frac{1}{\theta}\Gamma\left(\frac{\alpha-1}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-1}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-1}{\theta}}\right\} \tag{15}$$

$$\mathcal{M}_2 = \frac{1}{\theta}\Gamma\left(\frac{\alpha-2}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-2}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-2}{\theta}}\right\} \tag{16}$$

$$\mathcal{M}_3 = \frac{1}{\theta}\Gamma\left(\frac{\alpha-3}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-3}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-3}{\theta}}\right\} \tag{17}$$

$$\mathcal{M}_4 = \frac{1}{\theta}\Gamma\left(\frac{\alpha-4}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-4}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-4}{\theta}}\right\} \tag{18}$$

$$\sigma^2 = \frac{1}{\theta}\Gamma\left(\frac{\alpha-2}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-2}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-2}{\theta}}\right\}$$
$$-\left(\frac{1}{\theta}\Gamma\left(\frac{\alpha-1}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-1}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-1}{\theta}}\right\}\right)^2 \tag{19}$$

$$S = \frac{\frac{1}{\theta}\Gamma\left(\frac{\alpha-3}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-3}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-3}{\theta}}\right\}}{\left(\frac{1}{\theta}\Gamma\left(\frac{\alpha-2}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-2}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-2}{\theta}}\right\}\right)^{\frac{3}{2}}} \tag{20}$$

$$K = \frac{\frac{1}{\theta}\Gamma\left(\frac{\alpha-4}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-4}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-4}{\theta}}\right\}}{\left(\frac{1}{\theta}\Gamma\left(\frac{\alpha-2}{\theta}\right)\left\{N\big(\alpha(k+2i\delta+2\delta+z)\big)^{\frac{\alpha-2}{\theta}} - M\big(\alpha(k+2i\delta+2\delta+1)\big)^{\frac{\alpha-2}{\theta}}\right\}\right)^{2}} - 3 \tag{21}$$

Table 2: The moments for the EF distribution with different values of the parameters.

ω	δ	α	θ	$\mathcal{M}_1$	$\mathcal{M}_2$	$\mathcal{M}_3$	$\mathcal{M}_4$	σ^2	S	K

So the variance, skewness and kurtosis functions of EF distribution can be obtained as follows [21], [22]:
Table 2 shows the first four moments along with the torsion and kurtosis values for different sets of parameter values.

From Table 2, all moments are positive but very small (less than 1), indicating that the data are concentrated near zero with long tails (typical of extreme value increase distributions, such as Fréchet). The effect of θ is greatest, as increasing (holding other parameters constant), the moments decrease, indicating an increasing concentration of data near zero. The variance is relatively small but increases as the parameters change, reflecting the flexibility of the EF distribution in representing heterogeneous data. All skewness values are positive and significant, indicating strong positive skewness (longer right tails), and larger. θ implies greater skewness, confining increasing asymmetry. The kurtosis values are very high, indicating the presence of heavy tails (i.e., more extreme values than in a normal distribution).

Therefore, EF distribution can be said to have long, heavy tails and strong positive skewness (the data are concentrated on the left, with rare large values).

Moments Generating function for EF distribution. The MGF of the EF distribution can be found using the moments function in (14) and expanding the exponential function to get [23]:

$$M_x(y)_{\mathrm{EF}} = \sum_{s=0}^{\infty} \frac{y^s}{s!}\left[\frac{1}{\theta}\Gamma\left(\frac{\alpha-n}{\theta}\right)\left\{NA_1{}^{\frac{\alpha-n}{\theta}} - MA_2{}^{\frac{\alpha-n}{\theta}}\right\}\right] \quad (22)$$

Characteristic function for EF distribution.

The Characteristic function of EF is derived by employing moments in (14) and exponential expansion, yielding the form [24]:

$$C_x(y)_{EF} = Q_x(t) = \sum_{v=0}^{\infty} \frac{(it)^v}{v!}\left[\left[\frac{1}{\theta}\Gamma\left(\frac{\alpha-n}{\theta}\right)\left\{NA_1{}^{\frac{\alpha-n}{\theta}} - MA_2{}^{\frac{\alpha-n}{\theta}}\right\}\right]\right] \quad (23)$$

where $A_1 = \alpha(k + 2i\delta + 2\delta + z)$, and $A_2 = \alpha(k + 2im + 2m + 1)$.

3.3 Incomplete Moments for EF distribution

The incomplete moment of any distribution is defined by [19], [25]:

$$I_n = \int_{-\infty}^{y} x^n f(x)dx \quad (24)$$

To obtain the incomplete moment function of EF distribution, substitute (10) into (24) as follows:

$$I_N = \frac{N}{\theta}A_1{}^{\frac{n-\alpha}{\theta}}\Gamma\left(\frac{\alpha-n}{\theta}, \frac{A_1}{y^\theta}\right) - \frac{M}{\theta}A_2{}^{\frac{n-\alpha}{\theta}}\Gamma\left(\frac{\alpha-n}{\theta}, \frac{A_2}{y^\theta}\right) \quad (25)$$

where $y \to \infty$ then $I_N \to \mathcal{M}_n$ (i.e. (25) converges to (13) or the incomplete moments converge to moments).

3.4 Probability Weighted Moments

To calculate the probability weighted moments of EF by applying the equation [26]:

$$\tau_{m,t} = E\left(x^m F_{EF}^t(x)\right) = \int_{-\infty}^{\infty} x^m f_{EF}(x) F_{EF}^t(x)dx$$

By substituting (10) and (12) into above expression, the following formula is obtained:

$$\tau_{m,t} = \int_0^{\infty}\left(e^{-\alpha(k+2i\delta+2\delta+zu+2l\delta)x^{-\theta}} x^{m-(\alpha+1)} - Me^{-\alpha(k+2i\delta+2\delta+1+u+2l\delta)x^{-\theta}}x^{m-(\alpha+1)}\right)dx$$

Then, integrate the preceding equation to obtain the final formula:

$$\tau_{m,t} = \frac{\Theta}{\theta}\Gamma\left(\frac{\alpha-m}{\theta}\right)\left(NC_1{}^{\frac{m-\alpha}{\theta}} - MC_2{}^{\frac{m-\alpha}{\theta}}\right) \quad (26)$$

where $C_1 = \alpha(k + 2i\delta + 2\delta + zu + 2l\delta)$, and $C_2 = \alpha(k + 2i\delta + 2\delta + 1 + u + 2l\delta)$

3.5 Quantile Function of EF Distribution

The quantile function, also known as the inverse CDF , is a fundamental concept in statistics and probability theory. This function is used to

determine the value that a random variable will not exceed with a given probability. Its function $Q(p)$ for a random variable X is defined as follows [27], [28]:

$$Q(p) = F^{-1}(x)$$

Where $F(x)$ for each $p \in (0,1)$. Then the Quantile function of the EF distribution by form:

$$Q(x) = \left[\frac{1}{\alpha}\log\left\{\frac{\pi - W_{-1}(-\delta e^{\pi})}{\pi}\right\}\right]^{-\frac{1}{\theta}}, \pi = \left(-\frac{\log(1-u)}{\omega}\right)^{\frac{1}{\delta}} \quad (27)$$

where $W_{-1}(-\delta e^{\pi})$ is the secondary real branch of the Lambert W function, defined for $-\delta e^{\pi} \in [-e^{-1}, 0)$.

The measurements of skewness and kurtosis based on the Quantile function were defined as follows:

$$S = \frac{Q\left(\frac{6}{8}\right) - 2Q\left(\frac{4}{8}\right) + Q\left(\frac{2}{8}\right)}{Q\left(\frac{6}{8}\right) - Q\left(\frac{2}{8}\right)} \quad (28)$$

$$K = \frac{Q\left(\frac{7}{8}\right) - Q\left(\frac{5}{8}\right) + Q\left(\frac{3}{8}\right) - Q\left(\frac{1}{8}\right)}{Q\left(\frac{6}{8}\right) - Q\left(\frac{2}{8}\right)} \quad (29)$$

Table 3 presents a random variable values using some parts of Quantile function for various parameter values.

From the above table, it is noted that the large. u, the significant value of the quantile, as expected (the quantile is an increasing function). This demonstrates the flexibility of EF in capturing a wide range of data behaviors, including its capability to model extreme values characterized by long-tails especially at small values of θ.

The Median of the EF distribution can be found by substituting $u = 0.5$ into (27), to get:

$$Q(x) = \left[\frac{1}{\alpha}\log\left\{\frac{\pi - W_{-1}(-\delta e^{\pi})}{\pi}\right\}\right]^{-\frac{1}{\theta}}, \pi = \left(\frac{0.6931}{\omega}\right)^{\frac{1}{\delta}} \quad (30)$$

4 ESTIMATION PARAMETERS

4.1 Maximum Likelihood Estimation - MLE

The technique known as MLE involves maximizing the likelihood function, which expresses the likelihood of witnessing the provided data under the suggested model, to find the values of unknown parameters of a statistical model. Mathematically, the MLE is expressed as [29], [30] if we have a probability distribution $f(x/\vartheta)$ with ϑ being parameters and a sample of data $X = (x_1, x_2, \dots, x_n)$:

$$L(\vartheta, x) = \prod_{i=1}^{n} f_{EF}(x)$$

$$L(\vartheta, x) = \prod_{i=1}^{n} \frac{\omega\delta\,\alpha\theta e^{-\alpha x_i^{-\theta}}\left[\frac{e^{-\alpha x_i^{-\theta}}}{1-e^{-\alpha x_i^{-\theta}}}\log\left(1-e^{-\alpha x_i^{-\theta}}\right)\right]}{x^{\alpha+1}\left[-e^{-\alpha x_i^{-\theta}}.\log\left(1-e^{-\alpha x_i^{-\theta}}\right)\right]^{1-\delta}} e^{-\omega\left[-e^{-\alpha x_i^{-\theta}}.\log\left(1-e^{-\alpha x_i^{-\theta}}\right)\right]^{\delta}}$$

Compute the log-likelihood in the form:

$$L = n\log\omega + n\log\delta + n\log\theta + n\log\alpha - \alpha\sum_{i=1}^{n} x_i^{-\theta} - (\alpha+1)\sum_{i=1}^{n} x_i + \sum_{i=1}^{n} log\left\{\frac{e^{-\alpha x_i^{-\theta}}}{1-e^{-\alpha x_i^{-\theta}}} - log\left(1-e^{-\alpha x_i^{-\theta}}\right)\right\} - \omega\sum_{i=1}^{n}\left[-e^{-\alpha x_i^{-\theta}}.\log\left(1-e^{-\alpha x_i^{-\theta}}\right)\right]^{\delta} + \sum_{i=1}^{n} log\left\{\left[-e^{-\alpha x_i^{-\theta}}.\log\left(1-e^{-\alpha x_i^{-\theta}}\right)\right]^{1-\delta}\right\} \quad (31)$$

4.2 Ordinary Least Squares - LSE

The equation for this method is given by the form [31], [12]:

$$\varphi(\vartheta) = \sum_{i=1}^{m}\left[F(x_i) - \frac{i}{n+1}\right]^2$$

$$\varphi(\vartheta) = \sum_{i=1}^{n}\left[1 - e^{-\omega\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{\delta}} - \frac{i}{n+1}\right]^2 \quad (32)$$

4.3 Weighted Least Squares - WLS

The equation for this method is given by the form [31], [12]:

$$W(\vartheta) = \sum_{i=1}^{n} W_i\left[F(x_i) - \frac{i}{n+1}\right]^2$$

$$W(\vartheta) = \sum_{i=1}^{n} W_i\left[1 - e^{-\omega\left[-e^{-\alpha x^{-\theta}}.\log\left(1-e^{-\alpha x^{-\theta}}\right)\right]^{\delta}} - \frac{i}{n+1}\right]^2 \quad (33)$$

Equations (31), (32), and (33) are derived for the four parameters $(\omega, \delta, \alpha, \theta)$ and then set equal to zero to obtain an estimate of parameters for the EF model.

5 SIMULATION

Monte Carlo techniques are used to estimate complex distributions through random sampling approaches. The accuracy with which three estimators (MLE, LSE, and WLSE) product parameters EF distribution over sample size $N = 70, 140, 210, 280, \ldots$ up to 100 was evaluated for this work using these techniques. In addition to bias calculations [30], the results were assessed using MSE [31] and the root its RMSE [32]. The samples $N = 70, 140, 210,$ and 280 yielded the most accurate estimates of parameters $\omega, \delta, \alpha,$ and θ for the compared parameters. The sample sizes are shown in Table 4, the simulation was performed using R programming language.

Table 4 indicates that the parameter estimates approach true values as the sample size increasing as the sample size increases. Bias decreases with increasing sample size, especially for MLE, confirming the unbiasedness of this method compared to LSE and WLSE. MLE exhibits superior performance in most cases, especially for parameters δ and α, Where MSE and RMSE values are smaller compared to LSE and WLSE, thus, MLE has the best accuracy and consistency, followed by WLSE and LSE.

6 APPLICATION

To demonstrate the effectiveness of EF distribution in practical applications, it was applied to two data sets. The first set represented medical data, the first dataset corresponds to the remission times of a random sample of 128 bladder cancer patients. The second dataset pertains to engineering reliability data and consists of the failure times of compressive carbon fibers, measured for 69 components each with a length of 50 mm. The descriptive statistics for the two sets of data are shown as follows:

The results of the proposed distribution were compared with six other distributions. Table 5 presents the CDF functions of these comparative distributions, as follows:

Table 5: CDF function for comparative distributions.

Distribution	CDF
Beta Fréchet distribution (BeF)	$\beta\left(e^{-\alpha x^{-\theta}}, \omega, \delta\right)$
Kumaraswamy Fréchet distribution (New) (KuF)	$1 - \left(1 - \left(e^{-\alpha x^{-\theta}}\right)^{\omega}\right)^{\delta}$
Exponential Generalized Exponential Fréchet distribution (New) (EGF)	$\left(1 - \left(e^{-\alpha x^{-\theta}}\right)^{k}\right)^{c}$
Log Gamma Fréchet	$\frac{1 - e^{1-\left(1-\omega e^{-\alpha x^{-\theta}}\right)^{\delta}}}{1 - e^{1-(1-\omega)^{\delta}}}$
[0,1] Truncated Exponentiated Exponential Fréchet (New) ([0,1] TEEF)	$\frac{\left(1 - e^{-\alpha\omega x^{-\theta}}\right)^{\delta}}{(1 - e^{-k})^{c}}$
Fréchet distribution (F)	$e^{-\alpha x^{-\theta}}$

This comparison uses eight measures. The Good-of-fit: Kolmogorov-Smirnov (KS), Anderson-Darling (A), Cramer-von-Mises (W) and p-value with HQIC, BIC, AIC, and CAIC information criteria [32]. These measures, which are commonly employed to evaluate the goodness of fit of statistical models, are reported in Tables 5 and 6, respectively Table 6 shows EF distribution achieves the lowest values for all metrics in both datasets, indicating a clear advantage in data fitting. EF outperforms all comparable distributions in modeling medical and engineering data, making it the optimal model according to information metrics.

Table 7 presents the results of statistical goodness-of-fit tests. EF achieves the lowest K-S value in both datasets, 0.0769 (dataset 1) and 0.0654 (dataset 2). At the same time, the p-value for EF is high (>0.43 and >0.94), failing to reject the distribution hypothesis (i.e., good fit). EF passes all statistical goodness-of-fit tests with the best performance, supporting its use in modeling survival and material durability data [33].

As a visual evaluation to illustrate the results of Tables 6 and 7, the fitted densities for both types of data are plotted, as well as the empirical CDF for the data, which is shown in the Figures 5-8.

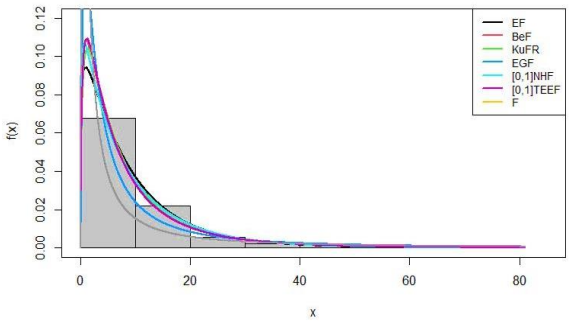

Figure 5: Fitted densities for Data 1.

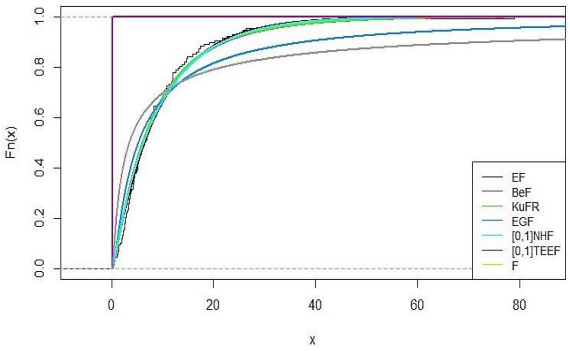

Figure 6: Empirical CDF for Data 1.

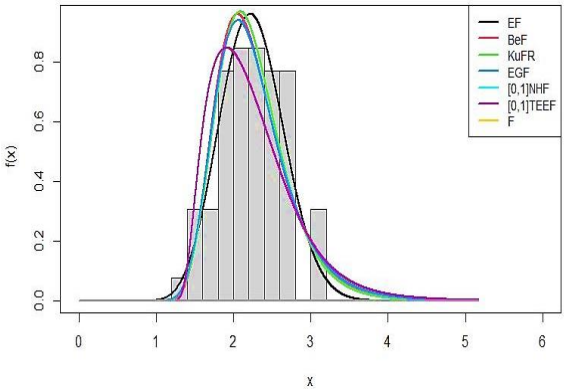

Figure 7: Fitted densities for Data 2.

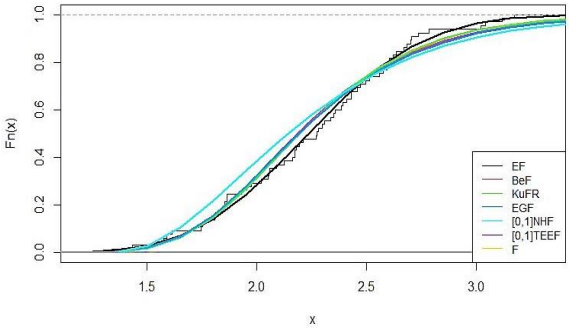

Figure 8: Empirical CDF for Data 2.

Figure 5 shows that the EF curve accurately captures the long tail of the data, reflecting its ability to model extreme values. This is consistent with the heavy-tailed distribution characteristic of EF, as shown in the previous tables. The superiority of EF in this context supports its use in analyzing survival data, where data are often asymmetric and contain extreme values.

Figure 6 shows a high degree of convergence between the two curves, especially in the low and median regions, confirming the goodness of fit of EF to the data. This is consistent with the results of the K-S test, which showed a low value of 0.0769 and a high p-value of 0.439, supporting the hypothesis that the data follow an EF distribution.

Figure 7 shows EF's flexibility in fitting low-variance data concentrated around the median values, as demonstrated by the convergence between the experimental and theoretical curves. This is consistent with the low standard deviation of 0.42 in the engineering data, confirming EF's ability to model engineering data reliability. Figure 8 highlights the accuracy of EF in fitting the empirical CDF, especially in the central range. EF's superior performance here mirrors the results from the previous tables. These results confirm that EF is capable of modeling not only extreme data but also more regular data.

7 CONCLUSIONS

Based on the results obtained in this study, the EF distribution has a high capacity to represent data with heavy tails and positive skewness (it was also confirmed to have high skewness and kurtosis values), and numerical results of the statistical measures. This trait makes it suitable for modeling data with extreme values without changing the underlying data structure, making it applicable in scenarios such as medical survival and engineering reliability. The numerical results proved that the maximum likelihood method was the most accurate and stable for modeling the distribution parameters of the data, with the lowest bias and MSE values compared with the least squares and weighted methods, whose model performance showed a significant improvement with increasing sample size. This type of behavior is consistent with the accuracy of the estimation even on small and medium-sized samples. In applications, EF's distribution was obviously better than the available (competing) distributions on information criteria and fit tests, with the lowest criteria values and the highest statistical significance values. The graphical findings further confirmed these findings by displaying a good agreement between the conceptual model and the practical data and that EF is a faithful and flexible approximation of the real-life data.

ACKNOWLEDGMENTS

The author would like to express sincere appreciation to Professor Dr. Mundher A. Khaleel for his continuous guidance, insightful comments, and unwavering support during the course of this study.

Keywords: Type 1 Diabetes, GARCH, LSTM, Time Series, Forecasting, Statistical Stability.

Abstract: The aim of this study is to use cutting-edge statistical and artificial intelligence techniques to assess and forecast the prevalence of type 1 diabetes in Iraqi children. In order to determine the prospective ultimate caseload and the fictitious inflection point, the research used the generalised autoregressive conditional variance (GARCH(p,q)) model to estimate the temporal behaviour of the data. The models under test were subjected to statistical stability conditions, and the AIC and BIC information criteria were used to assess their performance. The findings indicated that, out of all the nonparametric models examined, the GARCH(1,0) model performed the best. However, the paper showed that there were no significant variance fluctuations in the incidence data, which restricts the use of strictly nonparametric models. Deep LSTMNs neural networks were used for time series analysis in order to get around this. Using the ideal parameters for the number of layers and iterations, the data was divided into an 80% training set and a 20% test set. In comparison to other models, the LSTMNs findings showed the lowest mean squared errors, indicating a good capacity to predict future values. This implies that an efficient method for tracking upcoming changes in chronic illnesses is to combine deep learning algorithms with traditional statistical models. To enhance planning and response to the epidemic load of chronic illnesses, the paper suggests using this strategy in medical modelling and health forecasting.

1 INTRODUCTION

One of the most common chronic metabolic diseases affecting kids and teenagers is type 1 diabetes. Chronically high blood glucose levels are the result of the autoimmune death of the beta cells in the pancreas that secrete insulin [1]. The condition is severe because it directly affects the body's metabolic equilibrium, affecting numerous essential processes such as protein, lipid, and glucose metabolism, as well as oxidative stress and inflammatory pathways [2].

Laboratory indicators like fasting glucose, glycated hemoglobin (HbA1c), insulin levels, C-peptide, and inflammatory markers like CRP, triglycerides, and cholesterol are crucial for comprehending the course of a disease and evaluating the efficacy of treatment [3].

Long-term tracking of these markers yields precise data on the physiological and metabolic alterations linked to the illness and aids in the prediction of further consequences, including microvascular and macrovascular disease [1], [2].

Advances in artificial intelligence and statistical analysis techniques have made it possible to use deep neural networks like long-short-term memory networks (LSTMNs), a type of recursive neural network designed to handle time-series data and address the vanishing gradient problem [4], as well as time series models like the generalized autoregressive conditional variance (GARCH) model, which was developed as an extension of the Autoregressive Conditional Heteroskedasticity (ARCH) model proposed by Robert F. Engle in the 1980s [5].

More opportunities for early intervention and better treatment plans are made possible by the development of predictive models that can recognize pivotal moments in the disease trajectory and forecast future biochemical markers thanks to the combination of statistical analysis and artificial intelligence [6].

The purpose of this paper is to forecast future trends and possible changes in biomarkers by analyzing biochemical data from pediatric type 1 diabetes patients in Iraq using a combination of GARCH models and LSTMNs approaches. In order to better understand disease dynamics and enhance healthcare practices, we want to offer a scientific framework that integrates biochemistry and sophisticated statistical analysis.

2 LITERATURE REVIEW

Over the last several decades, time series analysis has developed into a vital tool for researching health issues, especially long-term conditions like diabetes. In order to solve the issue of non-stationary variance in economic data, Engle proposed the ARCH model in 1982, making it one of the first statistical models in this area. It uses the squares of the previous mistakes to depict the conditional variance as a series [7].

The generalized ARCH model (GARCH), which Bollerslev expanded in 1986, is more adaptable when dealing with very volatile data because it combines ARCH components with other components to better correctly describe the conditional variance [5].

Subsequent iterations of this model, including TARCH [8], GJR-GARCH [9], and EGARCH [10], attempted to address certain facets of variance, including the leverage impact and volatility asymmetry. GARCH models have been used in the healthcare industry to analyze data on infectious and non-infectious disorders. For example, [11] used GARCH to Middle Eastern diabetes data and showed that it was successful in describing the disease's temporal patterns.

The analysis of temporal data has been transformed by artificial intelligence in tandem with classical statistical models. This is especially true since the development of LSTMNs by [12], which has demonstrated their effectiveness in processing serial data with long-term temporal correlations [4].

As demonstrated by a study by [13], which compared the effectiveness of LSTMs with conventional statistical models in predicting the prevalence of diabetes and discovered that LSTMNs outperformed them in accuracy and capacity to identify intricate patterns in data, LSTMNss have been widely used in the prediction of chronic diseases.

This research demonstrate that integrating contemporary deep learning methods like LSTMNs with statistical models like GARCH offers an integrated framework for evaluating medical time series, improving prediction accuracy, and assisting with data-driven health planning choices.

2.1 ARCH Model

ARCH statistical model is used to examine time series volatility and forecast future volatility. The ARCH model is used in finance to assess risk by offering a volatility framework that accurately reflects actual market conditions. Higher volatility follows times of high volatility, while lower volatility follows periods of low volatility, according to ARCH modeling [14], ARCH model, which will have the formula [15]:

$$y_t = \sigma_t \epsilon_t \text{ where } \epsilon_t \sim iid\ N(0,1)$$

$$\sigma_t^2 = \omega + \sum_{j=1}^{Q} \varphi_j\, y_{t-j}^2 \qquad (1)$$

Where σ_t^2 is the conditional variance, and $\omega, \sum_{j=1}^{Q} \varphi_j$ are the parameters of the model.

This model is predicated on the martingale difference [15],

$$E(Y_{t+1}^2 / F_t) = \sigma_t^2 \qquad (2)$$

Where F_t is a $\sigma - field$ of a random variables called a sometimes filter $(y_{t-1}, y_{t-2}, \dots, y_{t-Q})$ [8].

The large-scale conditional autoheteroscedasticity (GARCH(Q, P)) model was introduced by Bollerslev in 1986 as an extension of the ARCH model, aiming to address limitations related to time-varying conditional variance and provide a more flexible model for predicting time series volatility. This model is defined by the following system of equations [15]:

$$y_t = \sigma_t \epsilon_t \text{ where } \epsilon_t \sim iid\ N(0,1)$$

$$\sigma_t^2 = \omega + \sum_{j=1}^{Q} \varphi_j\, y_{t-j}^2 + \sum_{i=1}^{P} \gamma_i\, \sigma_{t-i}^2 \qquad (2)$$

Where ω is a constant and φ_j, γ_i a represent the ARCH and GARCH model parameters, respectively.

By imposing certain restrictions on the coefficients of the conditional variance equation, the value of ω must be > 0, to ensure that the variance remains positive and that negative values cannot occur, which maintains the mathematical consistency and validity of the statistical model, $\varphi_j \geq 0\ \forall j,\ j = 1,2, \dots, Q$، $\gamma_i \geq 0\ \forall i, i = 1,2, \dots, P$, a

$\sum_{j=1}^{Q} \varphi_j + \sum_{i=1}^{P} \gamma_i < 1$ then the conditional variance is:

$$\sigma_t^2 = \frac{\omega}{1 - (\sum_{j=1}^{Q} \varphi_j + \sum_{i=1}^{P} \gamma_i)} \quad (3)$$

Despite the merits of GARCH models, they exhibit shortcomings, as noted by Black in 1976, namely the inability to capture the Leverage effect [16].

For a GARCH model to maintain stationarity, the conditional variance must converge to the unconditional variance over time, so that the mathematical condition $\sigma_t \rightarrow \sigma_y$ at infinity is met, ensuring that the variance remains constant and does not deviate toward unstable values [17], [18].

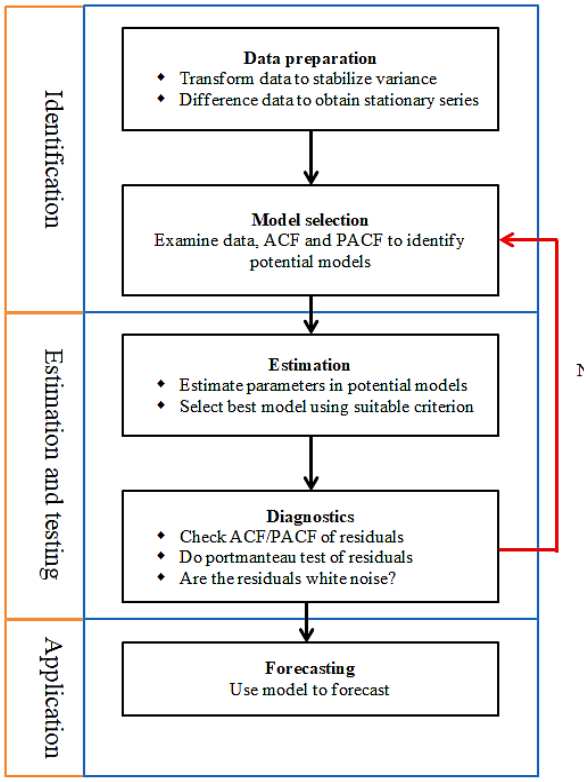

Figure 1: Box-Jenkins flow chart [19].

2.2 Box-Jenkins Method

Box and Jenkins developed this method in 1970 and subsequently underwent further developments between 1970 and 1996 to include a range of complementary techniques as needed. This methodology aims to achieve optimal predictive accuracy through three main stages [15]:

1) Identification. This includes data preparation and selecting the appropriate model for the time series under study.
2) Estimation and Testing. This involves estimating model parameters and performing diagnostics to ensure its suitability and validity for prediction.
3) Application. This is where the developed model is used to make the required predictions and make decisions based on them.

Figure 1 illustrates the various stages of this methodology graphically, making it easier to understand the sequence of processes and steps involved.

2.3 Model Order Selection Criteria

2.3.1 Akaike Information Criterion (AIC)

This model is considered the most widely used in statistical literature, and is represented by the following mathematical function [20]:

$$AIC(p,q) = -2\,log(maximum\ likelehood) + 2k \quad (5)$$

Where k is number of parameters in proposed model.

2.3.2 Bayesian Information Criterion (BIC)

This criteria was introduced similarly to the Akaike criterion to get enhanced convergence features and is expressed by the following function [18], [21]:

$$BIC = -2l(maximum\ likelehood) + k\,ln\,n \quad (6)$$

Where m represents the number of observations or measurements used in the analysis.

2.3.3 Long Short-Term Memory Networks (LSTMNs)

LSTMNs are effective tools for classifying, processing, and predicting time series data, especially when these series contain unspecified time intervals between important events [12].

These networks were developed to address the problem of vanishing gradients that hinders the learning of traditional neural networks. LSTMNs belong to the class of artificial neural networks (ANNs) used in the fields of artificial intelligence. Recurrent neural networks (RNNs) are characterized by their ability to process both individual data points and entire data series [13].

3 ANALYSIS AND RESULTS

3.1 Collection of Data

This study is based on 571 observations of approved diabetes cases, recorded between January 1, 2021, and July 25, 2022, taken from the Iraqi Ministry of Health official website. To achieve optimal predictive accuracy, the GARCH model's stability criteria will be applied to this data. This ensures that the model's conditional variance converges with its unconditional variance, thus achieving model stability and reliable future predictions based on time series data.

GARCH(1,2)	1.009e+04	1.010e+04
GARCH(0,1)	9.848e+03	9.861e+03
GARCH(0,2)	9.898e+03	9.915e+03

3.2 Modeling and Analyzing of Data by GARCH Model

The GARCH model will be applied to the data, observing and confirming that the conditional variance converges to the unconditional variance, which is a prerequisite for ensuring model stability and reliable predictions. The process involves several sequential steps, beginning with identifying changes in the data, then building the model according to appropriate statistical criteria. This is followed by estimating the model parameters using appropriate estimation methods, then assessing the model's suitability through diagnostic tests, and finally forecasting the future conditional variance. Matlab R2020a was used to create and program the time series data, evaluating several models of different orders to find the optimal model that best fits the data.

The data visualization phase is the first and important step in time series analysis, helping to understand the data pattern and identify any potential trends or fluctuations. Figure 2 shows a time series graph displaying historical data on the number of diabetes cases from January 1, 2021, to July 25, 2022.

The next step involves converting the original series into a series of returns to facilitate volatility

analysis, and then converting these returns into a series of squared errors for conditional variance analysis. Autocorrelation functions (ACFs) for the GARCH model were also calculated and displayed at different levels. Figure 3 illustrates the ACFs for a set of models, which helps assess the correlation structure in the data and select the most appropriate model.

After completing this step, we transform the squared error series into a series of residuals by performing the Young-Box test to assess the effect of heteroscedasticity over multiple lags. Figure 4 shows several residual functions for a GARCH model across multiple orders, while Figure 5 displays the autocorrelation functions for these models.

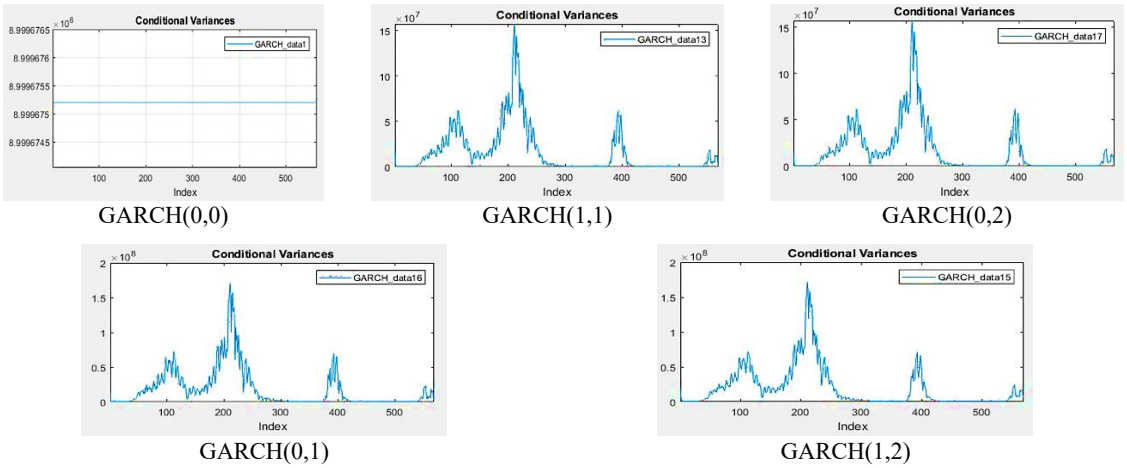
We will now examine the quantile-quantile plot, or QQ Plot, which visually evaluates whether the remaining series adheres to a normal distribution, as seen in Figure 6.

In addition to the graphs presented previously, which illustrate the general trend of the series, the model's suitability for future predictions must be evaluated. Tables 1 and 2 will be presented: the first shows the estimated parameters for each of the proposed models, and the second shows the results of the AIC and BIC values of various ranks from the GARCH model for selecting the optimal model.

A multitude of coefficients with zero values indicates that some model components do not significantly contribute to variance explanation. The conditional variance remains almost constant throughout time, exhibiting little fluctuations, as shown by the GARCH(0,1) model's constant of 1.000. The inadequate time-dependent effect of data variance is shown by the relatively small ARCH and GARCH coefficients in the other models.The GARCH(0,1) model exhibited the optimal fit among the analyzed models, shown by the lowest AIC and BIC values. Despite minor differences in AIC and BIC, GARCH(0,1) is statistically superior than GARCH(1,1). Extremely high GARCH(0,0) scores indicate a suboptimal overall fit to the data.

Thus, the conditional variance of the examined models is shown in Figure 7.

Upon reviewing the preceding stages of data analysis illustrated in graphs and tables, it is evident that the most reliable model for forecasting is the GARCH(1,0) model. However, we must now verify the stability of the selected model by applying its stability conditions and assessing the conditional variance as delineated in (4).



$$\varphi_1 = 1.000$$

After applying stability conditions to the GARCH model, it was confirmed that the model achieves the required stability, which is essential for ensuring the reliability and accuracy of future predictions. This property ensures that the model's conditional variance does not deviate toward unstable values over time but rather converges toward the unconditional variance. The value of the model's unconditional variance is defined as follows:

$$\sigma^2 = \frac{\omega}{1-(\varphi_1+\sum_{i=1}^{2}\gamma_i)} = \frac{3.049e{+}03}{1-1} = \text{unknown value}$$

Therefore, the equation for the GARCH(1,0) model, which is used to predict unconditional variance values, is as follows:

$$y_t = \sigma_t \epsilon_t \text{ where } \epsilon_t \sim iid\ N(0,1)$$
$$\sigma_t^2 = \omega + \varphi_1 y_{t-1}^2 \qquad (7)$$

GARCH(0,0) GARCH(1,1) GARCH(0,2)

GARCH(0,1) GARCH(1,2)

Figure 7: The conditional variance of the GARCH model with varying orders.

3.3 Modeling and Creating by Using LSTM

LSTM, another method for modeling and analyzing time series, will be used in this paper.

The data is segmented into two groups: the training group, including 80% of the observations, and the test group, comprising 20% of the data. Given that the maximum number of hidden layers is 50 and the input consists of a single variable with one lag, after conducting 250 iterations, the minimal mean squared error was 0.0359.

Figure 8 represents the values of the training set, and the Figure 9 illustrates the predicted values of the test set.

And that the value:

$$AIC = 1.1915e + 03$$
$$BIC = 1.1956e + 03$$

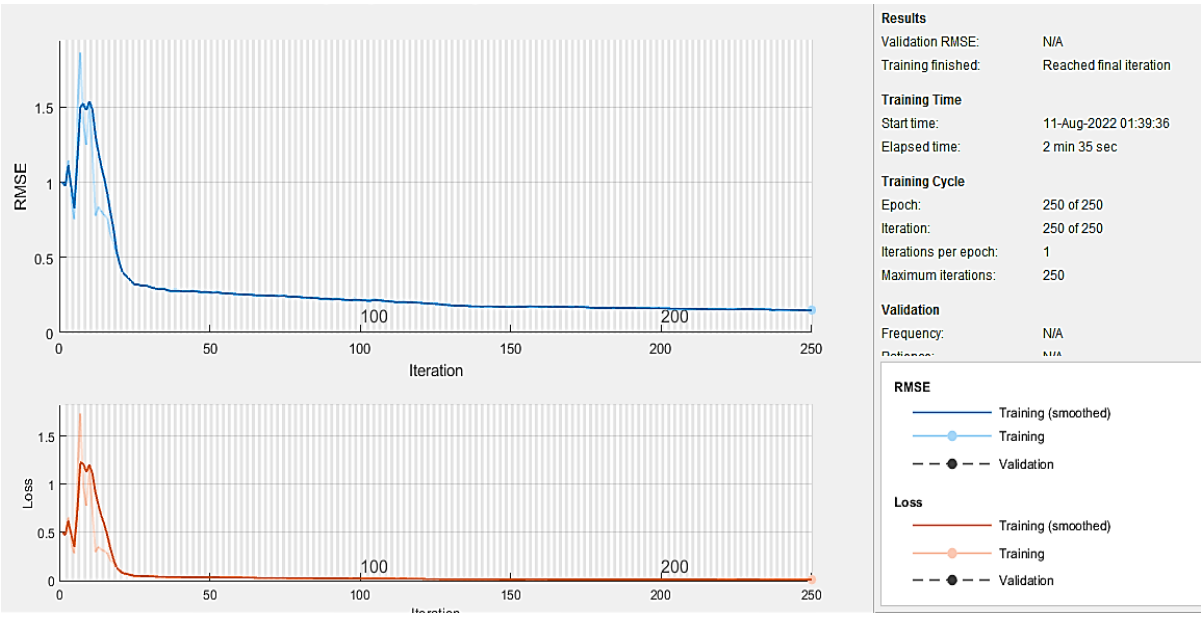


Figure 8: Training progress by using LSTM.

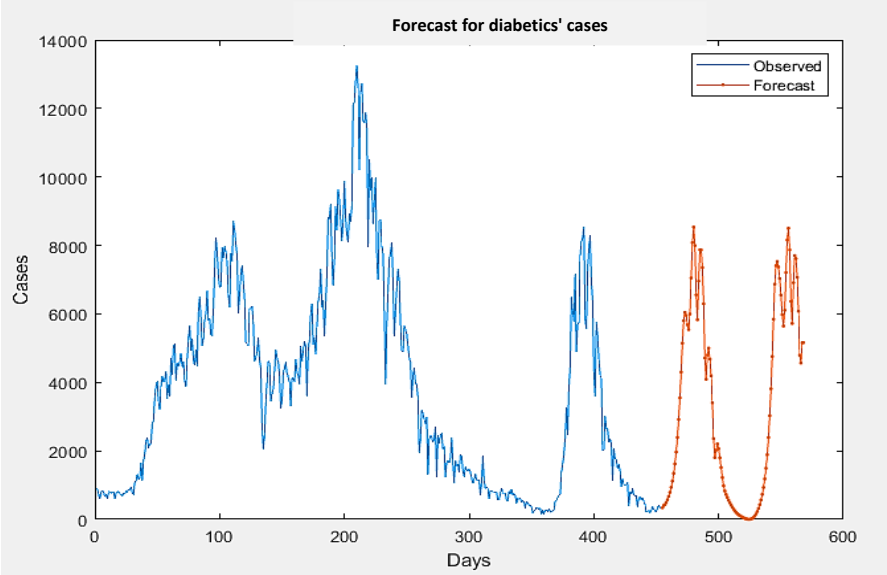

Figure 9: Predicted values for the test set by using LSTM.

Table 3: The estimated values for the training set by using LSTM.

Month	1st week	2nd week	3rd week	4th week
1st month	1.0e+04	0.0638	0.0864	0.0868
2nd month	0.0928	0.1093	0.1113	0.1097
3rd month	0.0645	0.0697	0.0827	0.0876
4th month	0.0556	0.0717	0.0855	0.0891
5th month	0.0770	0.0906	0.0990	0.1114
6th month	0.1142	0.1520	0.1662	0.1869
7th month	0.2191	0.2413	0.2816	0.3214
8th month	0.3410	0.3272	0.3688	0.4079
9th month	0.3670	0.3366	0.3994	0.4174
10th month	0.4275	0.3911	0.4518	0.4843
11th month	0.4218	0.4151	0.4489	0.5073
12th month	0.4666	0.4646	0.5137	0.5586
13th month	0.5359	0.4910	0.5548	0.6284
14th month	0.5397	0.5496	0.6273	0.7160
15th month	0.6388	0.6654	0.7732	0.8326
16th month	0.7046	0.6857	0.7511	0.8121
17th month	0.7513	0.6125	0.6797	0.7346
18th month	0.5528	0.4739	0.5544	0.5809
19th month	0.4740	0.4244	0.4997	0.5175

The numbers are the LSTM model's expected estimations for the training set. From around month 1 to month 15, there is a noticeable increasing trend that suggests a slow rise in the anticipated number of infections. The numbers start to vary and progressively decrease after month 16, demonstrating the model's capacity to identify shifts in trends (Table 3). There is little variation across weeks within a month, which is in line with the overall conclusion that the data is not very volatile.

4 CONCLUSIONS

Since there were few large variance swings in the daily data on confirmed children diabetes cases in Iraq from January 1, 2021, to July 25, 2022, using conventional GARCH models was less successful.

When statistical models were compared, GARCH(0,1) was determined to be the best model in terms of AIC and BIC. However, the data's low conditional variance makes it less reliable for making predictions in the future.

After using GARCH models, certain correlations were still present in the data, according to graphical analysis of residuals and autocorrelation functions (ACFs). This suggests that the models were not able to fully capture the temporal patterns in the series.

Quantile-Quantile (QQ) plots demonstrated that the GARCH models' residuals do not have a perfectly normal distribution, which has an impact on prediction accuracy. With a low mean square error (MSE) of 0.0359 and projected values that were very near to the actual values in the test data, the LSTM network's findings showed a definite advantage over GARCH models in terms of prediction accuracy.

In this instance, LSTM is the best model for short-term forecasts of future pediatric diabetes cases due to its capacity to adjust to temporal patterns, even in the absence of abrupt swings.

Instead of restricting the use of GARCH models to data with significant volatility, the research suggests using AI-based models, such LSTM, to analyze health time series with relative stability of variance.

Keywords: Solar Energy, Solar Collector, Global Warming, Solar Heater, Structure.

Abstract: This research aims to design and analyze a Scccs2 solar collector with a convex front surface and a corrugated absorber surface that reflects the incident solar radiation via mirrors. The design features a convex front surface that increases the angle of solar radiation capture, while a wavy and convex absorber surface increases the surface area exposed to the sun. In addition, reflective mirrors are used to direct solar radiation to copper tubes mounted above the absorber surface, increasing the efficiency of the Scccs2 solar collector. The new geometry significantly increases the efficiency of the Scccs2 solar collector in converting solar energy into thermal energy.The testing also demonstrates the effect of adding the absorber surface and tubes in a wavy - convex shape on the performance of the Scccs2 collector. To increase the collector's ability to retain thermal energy, two tanks (B1-B2) are installed inside the collector. Scccs2 records (Tout= (65-95) °C, B2= (45-85) °C) for the period from November 2024 to June 2025. The Scccs2 model is capable of operating in partly and completely cloudy weather. In partly cloudy weather, Scccs2 records (Tout= 70°C, B2= 50°C). In completely cloudy weather, it records (Tout= 49°C, B2= 32°C).

1 INTRODUCTION

In recent years, the globe has turned to the study of solar energy as an alternative energy source, turning sun rays into heat. Solar energy is clean, does not harm the environment, and can be utilized indoors. Scientists and researchers must use this energy to develop models and technologies.

In the Middle East, the sun's rays are strong where the Arab country is located between the equator and latitude (37), and between longitude (17) west longitude of Greenwich (60) east of Greenwich, hence the need for energy has grown [1].

Solar energy is one of the most significant types of renewable energy since it uses the sun's radiation to carry heat and light sources; this energy form may be used in a variety of applications [2]-[6].

Solar energy may be utilized for water heating; a solar heater can use sun irradiation to generate hot water [6], [7].to make a substantial contribution to ecologically friendly energy sources, solar-poared heaters must finally demonstrate a positive energy balance throughout the duration of their lives. The industry may lessen its environmental effect and ensure that clean energy production coexists happily with environmental protection by including ecological considerations into the design of solar heaters [8], [9]. Solar water heaters are utilized as auxiliary systems to decrease the consumption of conventional fuel by preheating water in industrial and home sectors [10].

2 EXPERIMENTAL WORK

2.1 Solar Collector Design and Materials Used

All industrial components are inspected and tested, and the new engineering prototype of the Scccs2 solar water heater is put into operation after being exposed to direct solar radiation.

Scccs2 Fabrication Process; The following tools and materials are used to build the new Scccs2 design:

Copper pipe (a diameter of 0.0095cm and a length of 12m), A plastic hose, valves to control the

speed of water flow and matt black paint, Mercury thermometer, electronic thermometer and Graduated glassware, 2 galvanized iron cylindrical tanks with a capacity of 3L (diameter 0.098m, height 0.4m, and thickness 0.003m), Iron plate rolled into a convex sine wave shape (length 1.55m, width 0.6m, thickness 0.002m) for manufacturing the absorber surface of Scccs2, Transparent glass panels (2 pieces (length 0.64m, width 0.24m, thickness 0.003m) & 2 pieces (length 0.64m, width 0.415m, thickness 0.003m)), Reflecting mirrors (length 0.1m, width 0.04m, thickness 0.002m) are fixed on the absorber plate to reflect solar radiation towards copper tubes (a diameter of 0.0095 cm and a length of 12 m) fixed 5 cm above the mirrors, Aluminum clips [11]. (length 0.05 m) to fix the copper tube on the absorber plate and Iron plate for the construction of the Scccs2 structure:

1) Two side panels (length 0.6 m, width 0.25 m, thickness 0.002 m), One rear deck (length 1.15m, width 0.6m, thickness 0.002m) and two side ribs (length 0.25m, thickness 0.002m).
2) Two roof and base panels (Straight rear rib (length 1.15m, thickness 0.002m) & convex front rib (length 1.12 m, thickness 0.002m)).

2.2 Solar Collector Scccs2 Manufacturing

Iron sheets with a thickness of 0.002m and different areas are used to fabricate the Scccs2 structure. The structure is in the shape of a parallelogram, as shown in Figure 1. The front surface of the collector is designed as a convex shape. The convex-wavy absorption surface is fixed inside the collector structure on the convex side, 0.09 m from the convex edge. The absorption surface of the solar collector is an iron sheet (1.55m long, 0.6m wide and 0.002m thick). Reflective mirrors are fixed on it. A copper tube (0.0095 m in diameter and 12 m long) is fixed in a Z-shaped path [1], [12] above the absorption surface (at a distance of 0.05m) using aluminum brackets. Therefore, the path of the copper tube is similar to the path of the absorption plate (wavy-convex) to match the new geometric design of the collector. To increase the absorption of solar radiation and raise the efficiency of the collector, the copper tube, Two tanks (B1, B2), and the visible parts of the absorption plate are painted in matte black, as shown in Figure 1.

In Figure 2, An air chamber is added behind the absorber to act as a thermal insulator, preventing thermal energy loss from the rear surface of the collector and helping to conserve the heat gained. The Scccs2 is manufactured using steel sheets. The dimensions of the collector's side panels are (0.6 m long, 0.25 m wide and 0.002 m thick). The dimensions of the rear deck panel are (1.15 m long, 0.6 m wide and 0.002 m thick). As for the collector roof and base, the straight rear side is 1.15 m long, and the convex front side is 1.12 m long. The center of convexity is 0.5 m from the center of the rear side. The two side sides are 0.25 m long, from the rear side to the ends of the convex side. Lead-brazing and electric welding is used to assemble the Scccs2 body parts in local fabrication workshops.

Figure 1: The manufacturing steps of Scccs2, and the installation location of the absorber plate and copper tube.

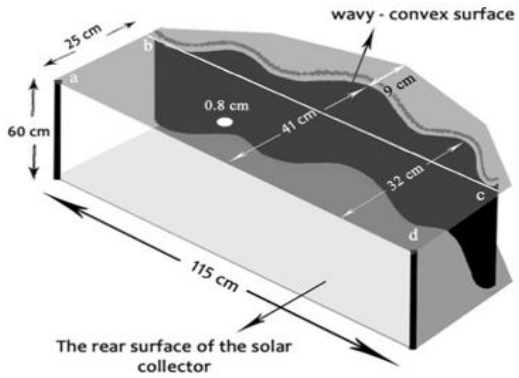

Figure 2: The structure of the collector, the absorption surface, and the buffer chamber.

2.3 The Insulating Room

The engineering design of the Scccs2 collector includes an air room between the absorber surface and the back of the collector. This room is tightly sealed to take advantage of the global warming

phenomenon effect. The benefit of this chamber is that it prevents the loss of thermal energy from the back of the collector (due to the global warming effect and thermal balance within the room), instead of using expensive and environmentally harmful thermal insulators when they deteriorate. Figure 3 shows the dimensions of this room and the location of the absorber surface.

2.4 Convex Front Surface and Absorption Surface (Wavy-Convex) to Scccs2

In the new Scccs2 engineering model, the front surface is designed in a convex shape to increase the solar radiation capture angle and align with the horizontal movement of the sun. This eliminates the need to rotate the Scccs2 solar collector to be perpendicular to the sun, as it is demonstrated in this research. To increase the absorbing surface area, it is designed in a wavy, convex shape. Reflective mirrors (0.1 m long, 0.04 m wide and 0.002 m thick) are installed on the absorbing surface to reflect the incident solar radiation toward the copper pipe. This increases the amount of thermal energy inside the collector, thus increasing the water temperature. The copper pipe (diameter 0.0095m, length 12m) is installed 0.05 m above the absorbing surface and adopted the wave-like shape of the absorbing surface. Figure 3, shows the stages of manufacturing the absorber surface (length 1.55 m, width 0.6 m, thickness 0.002 m). Using a metal bending machine, the absorber surface resembles a sine wave, with three peaks and four concave surfaces.

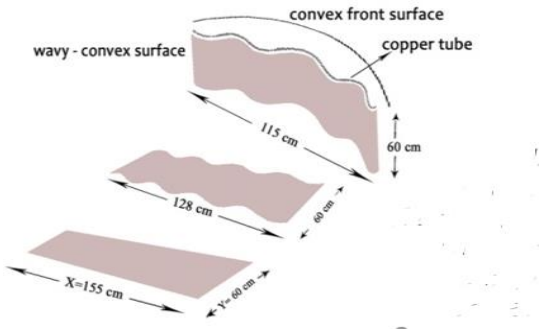

Figure 3: Schematic diagram of the measurements and manufacturing stages of the absorbent surface.

The Scccs2 solar collector's engineering design is capable of capturing and retaining thermal energy (Fig. 4), raising the temperature of the water passing through the copper tube and tanks (B1, B2). Two tanks (B1, B2) (3L capacity, 0.098m diameter, 0.04m height, and 0.002m wall thickness) are installed inside Scccs2 on the edges of the absorbent surface. B1 receives the external tank water; while B2 collects the usage water coming from the collector.

To take advantage of the global warming effect, a transparent glass cover (thickness of 0.003m) is placed on the convex front surface of the Scccs2, making the solar collector as shown in Figure 5.

Figure 4: Shows the locations of valves V1, V2, and V3 in Scccs2.

Figure 5: The finish shape of the Scccs2.

In Basra; in summer, the solar collector is perpendicular to the sun at 15° with the horizon, and 45° in winter [1], [11] - [13]. The Scccs2 does not need to be rotated horizontally to be perpendicular to the sun, due to the convex of the front surface and the convex and waviness of the absorber surface; this is one of the advantages of this model.

Measuring Instruments; Mercury and Electronic Thermometer & AWOS Solar Radiation Meter.

- Use a mercury thermometer to calibrate an electronic thermometer and measure temperatures.
- The electronic thermometer is locally manufactured to accurately measure temperature and humidity. It can measure

more than one temperature simultaneously, saving time and effort.

- An automatic weather station (AWOS) at Basra International Airport measures atmospheric elements, including solar radiation.

3 RESULTS AND DISCUSSION

3.1 Solar Collector Efficiency in Different Weather Conditions

The Scccs2 solar collector is tested under different weather conditions using two testing methods to determine the efficiency of the collector's engineering design.

Vertically; the collector's angle of inclination relative to the horizon is fixed in summer or winter, then the collector is rotated horizontally to be perpendicular to the sun every hour during daytime operation. The other method is to stabilizing the collector horizontally in the direction it faces the sun at 11:00 a.m.

The collector Scccs2 is supplied with water via valve V1, which passes through tank B1. The water then passes through a copper pipe, reaching the end of the pipe. The copper pipe branches into two branches: The first branch connects to valve V2 to record the water temperature (Tout). The second branch connects to tank B2, which is the water collection tank (Ttank), and then the water comes out from B2 through valve V3 to record the water temperature (Ttank). After testing the Scccs2 during daylight hours (from 9:00 a.m. to 2:00 p.m. for the months of November 2024 to June 2025), the results are recorded under various weather conditions, using the two previous examination methods, the results are as shown in Table 1 And Figures 6 and 7.

Table 1: The results are recorded by Scccs2 under different weather conditions.

Weather	Rotate Scccs2 towards the sun			Stability Scccs2 towards the sun		
	Date	T_{out}	T_{tank}	Date	T_{out}	T_{tank}
Sunny	04/06/2025	97	84	05/06/2025	97	83
Partly cloudy	23/12/2024	70	50	22/12/2024	70	50
Overcast	24/12/2024	49	32	25/12/2024	47	31

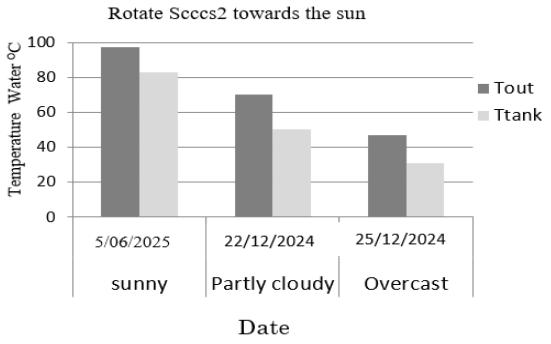

Figure 6: A graph showing the results recorded by Scccs2 under different atmospheric conditions when the collector is moved towards the sun.

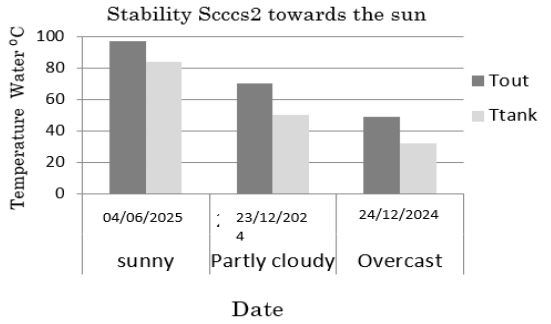

Figure 7: A graph shows the results recorded by Scccs2 under different weather conditions, with the collector facing the sun at 11 AM without movement.

As shown in Table 1 and Figures 6 and 7, it is clear that the solar collector operates efficiently in various weather conditions. The collector's operation is affected as the cloud density increases due to its reliance on reflecting the solar radiation falling on the mirrors. By exposing the complex to solar radiation, the average water temperature is recorded for the period from November 2024 to June 2025, in addition to the solar radiation for the same period, as shown in Table 2 and Figure 8. As well as the thermal efficiency according to (1), (2) [14], [15].

$$\eta = m.\ Cp\ (Tout - Tin) / I.\ Ac \quad (1)$$

$$A=2(2.\ \pi.\ r1.\ h1+\pi.\ r1^2+\pi.\ r1^2)+(2.\ \pi.\ r2.\ h2) \quad (2)$$

Where:

- η is the thermal efficiency, m is water mass (6.8499 kg);
- Cp is the specific heat of water (4.186 KJ/kg.oC);
- Tout is Temperature of the water coming out of the collector;
- Tin is Source water temperature;

Table 2: Average monthly water temperature and solar radiation [6].

Jun-25	May-25	Apr-25	Mar-25	Feb-25	Jan-25	Dec-24	Nov-24	Month
43	40	30	19	14	14	16	15	T-in ^{O}C
95	93	84	79	72	73	71	75	Sccs2-T(out) ^{O}C
83	80	64	61	47	48	47	56	B2-T(tank) ^{O}C
3365	3121	3256	2619	2227	2175	1526	1757	Solar Radiation (I) W.h/m^2
30	29	33	45	51	55	72	68	η %

- *I* is the incident solar radiation intensity;
- *Ac* is the collector area (0.64 m^2), this is the area that includes the area of the two tanks and the copper tube. It is approximately equal to a third of a square meter, and it is the effective area for heat absorption.

From Table 2 and Figure 8 it is clear that the solar collector operates with high efficiency, with increasing solar radiation intensity. After examining and testing of the new engineering design of the Sccs2 complex using the two previously mentioned testing methods, and recording the results (Tables 1 and 2), it is found that the convex-wavy design simulates the horizontal movement of the sun and does not require movement toward the sun during working hours. This demonstrates the success of the engineering design. This model can be used in remote and rugged locations, such as oil fields, farms, mountainous areas, laboratories, and exploratory missions.

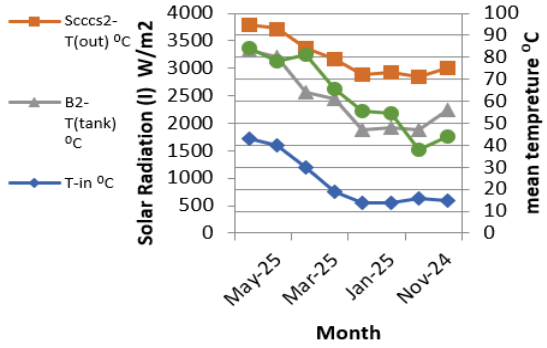

Figure 8: The average monthly water temperature and solar radiation.

Note that the monthly thermal efficiency results for the Sccs2 solar collector in Table 2 reveals a discrepancy in efficiency. The collector's efficiency in winter differs from its summer efficiency. These differences arise for several reasons:

1) During the summer and winter seasons, the collector operates stably, delivering high, comparable results. The collector has a high capacity to retain heat and convert it into useful thermal energy.
2) It is well known that solar radiation intensity varies from month to month, and its value affects the thermal efficiency result (as shown in Equation 1). Most solar collectors are directly affected by this. However, the decrease in solar radiation in the Sccs2 during the winter did not significantly affect the Sccs2's heat collection capacity. In the summer, however, the collector's behavior is directly affected by the increase in solar radiation intensity. This is all due to the success of the new solar collector engineering design.

The high output results of the solar collector result from its ability to collect and retain thermal energy, and its ability to overcome variables (radiation intensity and continuous movement of the collector toward the sun), thus converting that energy into useful energy.

3.2 Water Heat Gain

In this model, the water gains heat from the exposure of the two tanks (B1, B2) and the copper tube to direct solar radiation. The water temperature also increases due to the reflection of solar radiation from the reflective mirrors, and the temperature increases further due to the presence of the global warming effect inside the solar collector.

3.3 Inspection and Testing

There are two testing methods to determine the design's effectiveness in simulating the horizontal movement of the sun:

1) Rotating the collector horizontally after fixing the angle with the horizon (15° in summer, 45° in winter) during daylight hours to be perpendicular to the sun.
2) The collector is positioned perpendicular to the sun at 11:00 AM during its daytime operating hours (fixing the horizontal and vertical angles). This ensures the collector remains stationary in this horizontal position without

rotation. The second test aims to demonstrate that the collector's geometry (wavy-convex) yields the same results as the first test, and that the solar collector operates efficiently.

Rotating the Solar Collector. At the beginning of each testing day at 9:00 am, the solar collector is oriented perpendicular to the sun by manually adjusting its tilt angle relative to the horizon (15° in summer, 45° in winter). The collector is also rotated horizontally every half hour during daylight hours. Figures 9 and 10 show the readings record on December 2, 2024 (sunny, 20°C) and December 22, 2024 (partly cloudy, 19°C).

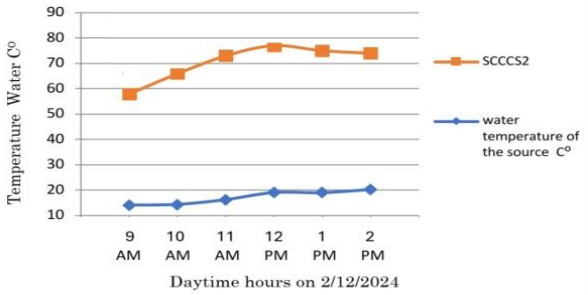

Figure 9: Illustrates the operating behavior of the collector and the temperature of the produced water on December 2, 2024.

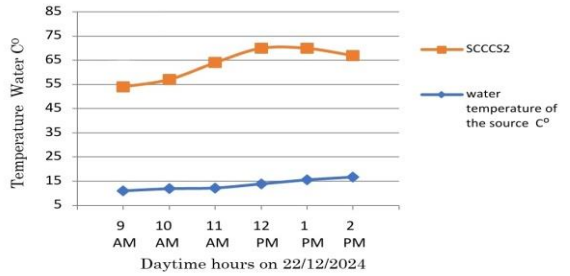

Figure 10: Illustrates the operating behavior of the collector and the temperature of the produced water on December 22, 2024.

Stability of the Solar Collector. At the beginning of each testing day at 9:00 am, the solar collector is oriented perpendicular to the sun by manually adjusting its tilt angle relative to the horizon (15° in summer, 45° in winter). The collector remains fixed – horizontal – perpendicular to the sun at 11:00 am without rotation during daylight hours. The graphs in Figures 11 and 12 present the readings records on 1/12/2024 (sunny 20°C) and 23/12/2024 (partly cloudy 20°C).

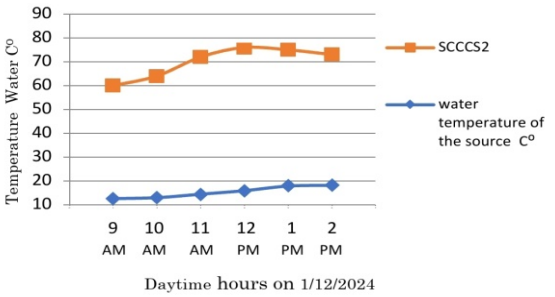

Figure 11: Illustrates the operating behavior of the collector and the temperature of the produced water on December 1, 2024.

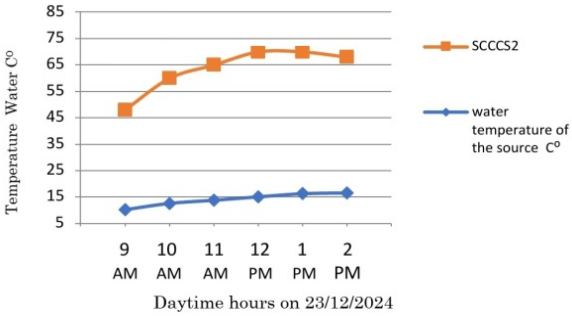

Figure 12: Illustrates the operating behavior of the collector and the temperature of the produced water on December 23, 2024.

Performance evaluation shows that the Scccs2 solar collector delivers nearly identical results whether it is rotated to track the sun or fixed in place. This confirms that its wavy-convex design effectively follows the sun's horizontal path, eliminating the need for horizontal adjustments and enabling reliable operation in remote or off-grid locations such as oilfield labs, agricultural stations, and other field installations.

Compared to conventional flat-plate and evacuated tube collectors (Box, C1, C2, Z1, Z2, H), the Scccs2 demonstrates superior performance. Typical collectors achieve water temperatures of 65–75 °C in summer and 40–65 °C in winter, whereas Scccs2 consistently reaches 62–98 °C in summer and 49–85 °C in winter. Traditional collectors require frequent horizontal rotation to maintain optimal solar alignment, but Scccs2 achieves high efficiency with a fixed horizontal angle, aligned perpendicularly to the sun around 11:00 AM. In addition, conventional systems use glass wool or foam for thermal insulation, which are environmentally harmful and difficult to dispose of. Scccs2 employs a sealed air chamber for insulation, providing effective heat retention without negative environmental impact.

3.4 Thermal Insulation and Thermal Energy Loss

The principles of thermal physics are used to prevent the loss of thermal energy from the rear surface of the collector, and equations (3), (4), [16] are used to prove the efficiency of the air room as a thermal insulator. Therefore, the energy losses from the rear surface of the collector must be calculated with. The loss is calculated for January 20, 2025 (20 oC Sunny) at 12:00 PM. The result with the air room is q1=12 W/m2. This result confirms that the effectiveness of the air room, preventing thermal energy loss from the rear surface of the collector, and maintaining the temperature inside the solar collector.

$$q = \frac{K.A.\Delta T}{\Delta X}, \quad (3)$$

$$\Delta T = (T2 - T1). \quad (4)$$

3.5 Cost of Manufacturing the Scccs2 Solar Collector

The symbols and variables used throughout this study are summarized in Table 3. The materials used for manufacturing the collector are listed in Table 4. Based on local market prices in Basra (1 USD = 1,320 Iraqi dinars), the total manufacturing cost is approximately 59,000 Iraqi dinars. Based on local market prices in Basra (1 US dollar = 1,320 Iraqi dinars), the cost of manufacturing the collector is 59,000 Iraqi dinars. This is a reasonable cost for low-income individuals, institutions, schools, swimming pools, and others.

Table 3: List of symbols, definitions, and units.

Symbol	Symbol definition	Unit of measurement
Scccs2	Solar collector with a reflective absorbing surface using mirrors	
B1	The tank is connected to the source tank via valve V1.	
B2	The tank is connected to the source tank via valve V1.	
V1	Source water valve entering Scccs2	
V2	Collector water outlet valve from Scccs2	
V3	Use water valve exiting Scccs2	
H1	Dedicated port for measuring the front room temperature	
H2	Dedicated port for measuring the insulated rear room temperature	
T_{in}	External tank water temperature	C^o
T_a	Ambient air temperature	C^o
T_{out}	Scccs2 water temperature via valve V2	C^o
T_{tank}	B2 water temperature via valve V3	C^o
T_g	Collector glass temperature	C^o
T_b	Insulating room temperature	C^o
T_f	Front room temperature	C^o
m	Water mass (Scccs2)	Kg
C_p	Specific heat of water	$J/Kg.C^o$
T_1	Temperature gained	C^o
T_2	Temperature lost	C^o
I	Solar radiation intensity	$W .h/m^2$
A_c	Solar collector area (Scccs2)	m^2
r_1	Radius of cylindrical tank (B1, B2)	M
r_2	Radius of copper tube	M
h_1	Height (B1, B2)	M
h_2	Length of copper tube	M
K	Thermal conductivity coefficient	W /m . K
K_{air}, K_{Iron}, K_{Al}, K_{glass}	Thermal conductivity coefficient to (air, iron, aluminum, glass)	W /m . K
A	Area between the two heat loss zones	m^2
ΔT	Temperature difference between the two heat loss zones	K
ΔX	Thickness of the heat loss zone	M
q1	Loss between the front chamber and the outside air, where the thickness of the buffer chamber is ΔX	W/m^2
η	Thermal efficiency	

Table 4: Cost of Scccs2 manufacturing materials in the local market of Basra.

Materials	Number & Details	The cost I.D.
		Scccs2
Copper pipe (diameter 0.9499 cm)	12 m	12.000
A plastic hose	5 m	1.250
Valve to control the speed of water flow	3	1.500
Galvanized iron cylindrical tank (3 litre capacity)	2	6.000
Screws of different sizes	-	1.500
Matte black paint	2	2.000
spinning wheels	3	3.000
A square iron pipe with a side length of 3.81 cm	8.76 m	9.000
Transparent glass panels (0.3 cm thickness)	0.84 m^2	5.000
Iron plate (0.2 cm thickness)	3.5 m^2	10.500
Adhesive (silicone rubber)	1	1.000
Aluminum ruler (a 90-degree angle)	3.5 m	3.000
Aluminum brackets (5 cm long) for fixing the copper pipe	48	4.000
Mirror thickness is (0.3 cm)	0.65 m^2	4.250
Total	-	64.000

4 CONCLUSIONS

Easy to move, clean, and maintain. The Scccs2 can be manufactured in local workshops and laboratories.

Water gains heat in several stages, which increases the efficiency of the solar system in heating water.

The Scccs2 design is most suitable for Basra's weather and operated with high efficiency.

It features a wavy-convex absorber surface, which increases the surface area exposed to solar radiation, thus can increase the heat absorption and increasing the efficiency of the Scccs2 solar collector.

The Scccs2 solar collector's engineering design requires no horizontal movement toward the sun and operates with the same efficiency, meaning it remains fixed in the direction it is at 11 a.m.

The air's room successfully prevents thermal energy loss from the back surface of the Scccs2 solar collector, by applying the basic principles of thermal physics.

Replacing thermal insulation and its environmentally harmful with air insulation is part of the Scccs2 collector design.

The temperature of the water produces from the solar collector Tout = 95^{o}C, and the temperature of the tank water B2 = 84^{o}C.

The Scccs2 solar collector operates efficiently in various weather conditions, including partly cloudy and completely cloudy weather.

The Scccs2 model features of a low manufacturing cost, making it suitable for low-income individuals, institutions, laboratories, schools, swimming pools, and others.

Scccs2 operates steadily and efficiently as solar radiation intensity increases, with its highest temperature recorded at 12 p.m.

Keywords: DDoS Detection, Intrusion Detection Systems, Optimization-Guided Feature Evolution, Knowledge Distillation, Domain Generalization.

Abstract: Distributed Denial of Service (DDoS) attacks continue to overwhelm networked systems, demanding detectors that are accurate, low-false-alarm, transferable, and deployable. We propose OSES-DL, an Optimization-guided Statistical Ensemble Synergistic Deep Learning framework that advances all four fronts. The method introduces: (i) an Optimization-driven Feature Evolution Layer (OFEL) that co-trains feature sparsity with accuracy, stability, and entropy preservation; (ii) a Statistical Deep Synergy Module (SDSM) that injects Mahalanobis anomaly priors directly into BiLSTM hidden states, yielding anomaly-aware representations; (iii) Ensemble Knowledge Distillation with class-conditional temperature and feature–logit coupling (EKD-CCT) for calibrated, lightweight deployment; and (iv) a Cross-Domain Generalization Regularizer (CDGR) that combines prior-weighted MMD and CORAL for layer wise domain alignment. On CICDDoS2019, OSES-DL attains 99.45% accuracy, F1 0.994, AUC 0.998, and FAR 0.62%, with ECE 0.9%. Trained on CICDDoS2019 and tested on UNSW-NB15 and CAIDA, it improves F1 by +1.0% and reduces FAR by 0.5%–0.6% over the strongest baseline, while maintaining near-BiLSTM latency. Leave-one-attack-type-out tests confirm robustness to unseen vectors. Ablations attribute FAR reduction to SDSM, calibration to OFEL/EKD, and transferability to CDGR. OSES-DL delivers a principled, operationally grounded detector that is both state-of-the-art and deployment-ready.

1 INTRODUCTION

Distributed Denial of Service (DDoS) attacks remain one of the most destructive and persistent threats to modern networked systems. By orchestrating massive volumes of malicious traffic, adversaries can saturate links, exhaust server resources, and disrupt critical services across cloud, edge, and enterprise environments [1], [2]. The continued proliferation of IoT devices, the elasticity of cloud infrastructures, and increasingly sophisticated reflection–amplification vectors have expanded the attack surface while compressing detection time scales [3]. Compounding the challenge, encrypted traffic and multi-tenant workloads constrain deep packet inspection and make flow-level behavioral cues indispensable [4]. In this setting, security operations centers (SOCs) require detectors that are not only accurate, but also calibrated, low–false-alarm, generalizable across domains, and efficient enough for near–real-time deployment [5].

Conventional detection strategies struggle to satisfy these requirements concurrently. Signature- and rule-based systems are brittle against evolving or low-and-slow attacks and require constant manual maintenance [6], [7]. Thresholding and heuristic

detectors are sensitive to workload variability and routinely inflate the false alarm rate (FAR) during benign surges (e.g., flash crowds) [8], [9]. Traditional machine learning pipelines rely on static, pre-selected features; they are vulnerable to distribution shift and often entangle redundant or unstable attributes, degrading robustness [10], [11]. Deep neural detectors (e.g., CNN/LSTM variants) capture temporal patterns effectively yet tend to be poorly calibrated, exhibit elevated FARs under shift, and are computationally heavy for network-edge deployment [12] - [14]. Hybrid approaches typically fuse statistical and deep models after representation learning (late fusion) [15], [16], which forfeits the opportunity to shape the representation with anomaly-aware priors [17]. Finally, cross-dataset generalization training on one environment and deploying in another remains a frequent failure mode in the literature; many detectors degrade precipitously when faced with heterogeneous traffic sources, attack mixes, or telemetry schemas [18] - [20].

The limitations demonstrate an evident research gap: there is no single framework with (i) sparsity of features, time representation, and decision calibration; (ii) injecting statistical anomaly knowledge in the representation, rather than at the decision boundary; and (iii) explicitly regularizing cross-domain transfer, such that its performance and FAR do not change as the deployment environment diverges with the training corpus. To fill this gap, an approach, which is synergistic by nature, is needed one that combines optimization, statistical modeling, and deep learning into one consistent learning goal with operational assurances [21] - [24].

Operationally, the expense of a false alarm is very high: any extraneous activation burns analyst time and false incident response and causes a loss of faith in the detection stack [25]. In the meantime, domain shift is the rule rather than the exception datasets vary in features distributions, benign workload rhythms, and attack blends [26], [27]. An effective DDoS detector should thus be able to provide (1) high recall with low FAR, (2) probabilities that are calibrated to provide principled thresholding and triage, (3) insensitivity to distribution shift not requiring labelled target data, and (4) can be computed at the scale of line-rate flow analytics. Such operational constraints drive the design decisions and architectural connectivity of optimization, statistics and deep sequence model [28], [29].

To address the above gap, we propose OSES-DL an Optimization-guided Statistical–Ensemble Synergistic Deep Learning framework for DDoS detection. The originality of OSES-DL lies in how each component is novel on its own and mutually reinforcing within a single training objective: (1) Optimization-driven Feature Evolution Layer (OFEL): Dynamic, in-training feature evolution optimizes accuracy, stability, redundancy, and entropy, yielding sparse, informative inputs robust to drift. (2) Statistical–Deep Synergy Module (SDSM): Inject Mahalanobis anomaly priors into BiLSTM hidden states to create anomaly-aware embeddings, reducing FAR and improving interpretability. (3) Ensemble Knowledge Distillation with Class-Conditional Temperature (EKD-CCT): A calibrated teacher (XGBoost + statistical detector) distills via class-conditional temperatures; feature–logit coupling honors OFEL's mask, yielding SOTA accuracy in a lightweight student. (4) Cross-Domain Generalization Regularizer(CDGR): Prior-weighted, layerwise MMD+CORAL aligns source–target statistics using unlabeled target data, improving cross-domain transfer without additional labels. (5) Unified Objective & Risk Control: A joint loss (focal, KD-CCT, FLC, CDGR, OFEL) plus conformal calibration provides explicit FAR guarantees for SOC operations. (6) Evaluation Protocol: Temporal hold-out, calibration metrics (ECE, Brier, NLL), cross-dataset and leave-one-type-out tests demonstrate high recall, sub-1% FAR, strong calibration, and near-BiLSTM latency.

Collectively, these contributions establish a synergistic, operationally grounded approach to DDoS detection that advances the state of the art along three critical axes accuracy, robustness to shift, and deployable efficiency while introducing new methodological elements (dynamic feature evolution; representation-level anomaly injection; class-conditional distillation plus feature–logit coupling; prior-weighted hybrid domain alignment) that we believe will be of independent interest to the broader intrusion detection community.

2 RELATED WORKS

Research on DDoS detection spans signature/rule systems, traditional machine learning, and deep neural models. With datasets such as CICDDoS2019, researchers have benchmarked temporal architectures (LSTM, CNN–LSTM, BiLSTM) that learn flow-level dynamics and generally surpass classical classifiers; yet these models often degrade under distribution shift and exhibit elevated false-alarm rates or poor probability calibration in practice [30] - [32]. Comparative studies further show that architecture alone is insufficient:

latency/throughput constraints and unstable features can undermine real-time deployment [11]. A parallel line of work employs metaheuristic optimization to select features or tune learners before training. Harris Hawks Optimization (HHO) and related hybrids (e.g., HHO with simulated annealing or WOA) have improved IDS accuracy and reduced dimensionality by discarding redundant attributes [33], [34]. However, these techniques are typically static (one-shot selection) and operate outside the learning loop, so the selected subset is not co-adapted with the representation learned by the detector. This disconnect can limit robustness when traffic statistics drift or when models are distilled to compact runtimes [35]. To combat domain shift, unsupervised domain adaptation aligns source and target distributions via adversarial training or statistical matching (e.g., MMD, CORAL), while knowledge distillation (KD) compresses ensembles/teachers into deployable students for IDS [36]. Recent IDS works combine KD with federated or semi-supervised settings, but they primarily focus on decision-level fusion and teacher–student transfer, leaving the representation largely unconstrained by statistical anomaly priors [37], [38]. Moreover, studies quantifying domain gap show a strong correlation with detection accuracy, reinforcing the need for explicit, layer wise alignment during training [39]. Existing approaches rarely (i) co-evolve the feature subset during training, (ii) inject statistical anomaly knowledge inside the sequence representation, and (iii) regularize cross-domain transfer with prior-aware, layer wise alignment while preserving deployable efficiency and calibration. Our OSES-DL framework addresses this gap through a dynamic feature evolution layer, representation-level statistical deep synergy, class-conditional KD with feature–logit coupling, and a hybrid MMD–CORAL alignment together enabling high accuracy, low FAR, strong calibration, and robust cross-dataset generalization.

3 METHODOLOGY

Traditional DDoS detection frameworks typically fall into two categories: (1) deep learning-based methods that excel in extracting temporal dependencies but often lack interpretability and robustness, and (2) statistical or optimization-based methods that provide interpretability and computational efficiency but struggle with complex traffic dynamics. A critical gap exists: most prior works treat these modules as additive components (stacked or fused at the end) rather than integrated synergistic systems.

To bridge this gap, we propose OSES-DL, an Optimization-guided Statistical–Ensemble Synergistic Deep Learning framework. Unlike existing systems, OSES-DL is characterized by: (i) A dynamic feature evolution layer driven by dual-objective optimization. (ii) A statistical–deep synergy module embedding anomaly priors into recurrent learning. (iii) An ensemble knowledge distillation mechanism that compresses ensemble wisdom into a deployable deep model. (iv) A cross-domain generalization regularizer ensuring transferability across heterogeneous datasets.

3.1 Data Preprocessing

To transform raw network traffic into a structured, balanced, and standardized representation suitable for optimization and deep learning. Preprocessing ensures that subsequent stages operate on high-quality data, mitigating noise, imbalance, and redundancy. While standard preprocessing pipelines include normalization and sampling, OSES-DL introduces two innovations: (1) Entropy-Preserving Normalization: Scaling is performed while maintaining relative entropy of the features, preserving statistical diversity critical for anomaly detection. (2) Adaptive Synthetic Oversampling: Unlike static SMOTE, oversampling intensity is dynamically adjusted using optimization feedback from the feature evolution layer, preventing overfitting to synthetic points.

3.1.1 Data Cleaning and Integration

In this substage the process of removal of incomplete flows. Timestamp alignment to preserve temporal order. Multi-dataset harmonization (e.g., CICDDoS2019, UNSW-NB15, CAIDA).

Formally, for raw dataset $D = \{d_1, d_2, \cdots, d_N\}$ we construct a unified representation:

$$\acute{D} = \bigcup_{k=1}^{K} \psi(D_k) \tag{1}$$

where ψ maps each dataset D_k into a common feature schema.

3.1.2 Entropy-Preserving Normalization

Each feature x_i is scaled as:

$$\acute{x_i} = \frac{x_i - \mu}{\sigma} \tag{2}$$

but subject to the constraint:

$$H(\hat{X}) \approx H(X) \quad (3)$$

where $H(\ \ )$denotes Shannon entropy. This ensures that normalization does not collapse information diversity, a problem in conventional scaling.

3.1.3 Dimensionality Reduction (Preliminary PCA)

To mitigate noise before optimization, a lightweight Principal Component Analysis is applied:

$$Z = XW\ , W = \arg\max_{W} \frac{W^T S_B W}{W^T S_w W} \quad (4)$$

where S_B and $S_W$denote between- and within-class scatter matrices. This reduces computational burden for the optimization phase without discarding essential discriminatory power.

3.1.4 Adaptive Synthetic Oversampling

Class imbalance is addressed via a dynamic SMOTE variant:

$$x_{new} = x_i + \delta \cdot (x_{nn} - x_i),\ \ \delta \sim U(0,1) \quad (5)$$

where the oversampling ratio is adaptively tuned based on feedback from optimization:

$$r_t = f(\nabla J(F_t)) \quad (6)$$

meaning the more unstable the current feature subset $\boldsymbol{F}_t$, the more aggressive the oversampling.

3.2 Optimization-driven Feature Evolution Layer (OFEL)

To dynamically refine the feature space during training by evolving the feature subset in response to model performance and stability. Unlike conventional static feature selection methods that are executed once prior to training, OFEL continuously adapts the active feature set throughout the learning process, ensuring robustness against non-stationary traffic patterns and dataset heterogeneity. The originality of OFEL lies in three main aspects: (1) Dynamic Feature Evolution: Feature subsets are not fixed but evolve iteratively, guided by optimization feedback, adapting to changing network traffic distributions. (2) Dual-Objective Optimization: The feature selection criterion balances both predictive accuracy and temporal stability across epochs, preventing overfitting to transient features. (3) Entropy-Regularized Selection: Feature evolution preserves statistical richness (entropy), ensuring that the model does not converge to overly sparse representations that lose critical discriminatory cues.

This contrasts with classical metaheuristics (e.g., PSO, HHO, GA), which only seek a single optimal subset before training.

Let the feature set at epoch t be denoted by $F_t \subseteq \{1,2,\cdots,d\}$, where d is the total number of available features. The optimization objective is:

$$\min_{F_t} J(F_t) = \alpha \cdot (1 - Acc_t) + \beta \cdot Var(F_t) + \gamma \cdot Red(F_t) - \delta \cdot Ent\ (F_t) \quad (7)$$

Where Acc_t is the validation accuracy at epoch t. $Var(F_t)$ is the variance in selected features across consecutive epochs, penalizing instability. $Red(F_t)$ is redundancy penalty based on correlation between features. $Ent\ (F_t)$ is the Shannon entropy of selected features, encouraging diversity. Meanwhile, $\alpha, \beta, \gamma, \delta$ are adaptive weighting coefficients.

3.2.1 Optimization Update Rule

The feature set is updated iteratively as:

$$F_{t+1} = F_t - \eta \cdot \nabla J(F_t) + \lambda \cdot \Delta_t \quad (8)$$

Where η is the learning rate controlling the step size. $\nabla J(F_t)$ is gradient of the objective with respect to the feature subset representation. $\Delta_t$is stochastic exploration term, derived from a metaheuristic (e.g., modified Harris Hawks Optimization). λ is the exploration–exploitation balance parameter. This allows OFEL to combine gradient-based exploitation with metaheuristic-driven exploration, ensuring both local refinement and global diversity.

3.2.2 Binary Feature Representation

Each candidate solution is encoded as a binary vector:

$$F_t = [f_1, f_2, \ldots, f_d],\ \ f_i \in \{0,1\} \quad (9)$$

Were $f_i = 1$ when feature i is active at epoch t. Meanwhile, $f_i = 0$ when feature i is excluded. To avoid premature convergence, OFEL introduces a smooth relaxation using a sigmoid transfer function:

$$f_i^{t+1} = \begin{cases} 1 & \text{if } \sigma(z_i^t) \geq \rho \\ 0 & \text{otherwise} \end{cases} \quad (10)$$

where $\sigma(\cdot)$ is the sigmoid, z_i^t is the continuous score of features i, and $\rho \sim \mathrm{U}(0,1)$is a random threshold.

3.2.3 Role within the Framework

OFEL ensures that subsequent phases (Statistical–Deep Synergy and Ensemble Knowledge Distillation) operate on highly informative, low-redundancy, and entropy-preserving feature sets. Unlike static preprocessing, OFEL adapts in real time, making the model resilient against adversarial traffic evolution and cross-dataset variability.

3.3 Statistical-Deep Synergy Module (SDSM)

To embed statistical anomaly priors directly into the hidden state dynamics of the deep learner, thereby creating a synergistic model that combines the strengths of statistical detection (robustness, interpretability) and deep learning (temporal pattern recognition). (i) Intrinsic Statistical Awareness: Unlike conventional hybrid IDS models that combine statistical detectors with deep learners at the decision layer only, SDSM injects statistical knowledge into the representation level of the BiLSTM network. (ii) Adaptive Priors Integration: Mahalanobis-based anomaly scores are non-linearly transformed and weighted before being merged with BiLSTM states, allowing the network to learn the relative importance of statistical priors dynamically. (iii) Regularization through Statistical Anchoring: Statistical scores act as a regularizer, preventing overfitting by anchoring hidden states toward anomaly-informed representations.

3.3.1 Statistical Anomaly Scoring

We compute the Mahalanobis distance for each traffic instance x_t:

$$M(x_t) = \sqrt{(x_t - \mu)^T \sum -1\,(x_t - \mu)} \qquad (11)$$

Where μ mean vector of benign traffic. Σ covariance matrix of benign traffic. A larger $M(x_t)$ indicates a higher likelihood of anomaly (DDoS attack).

3.3.2 BiLSTM Hidden State Representation

The BiLSTM generates forward and backward hidden states for time step t:

$$h_t = \left[\overrightarrow{h_t} \oplus \overleftarrow{h_t}\right] \qquad (12)$$

where $\oplus$ denotes concatenation.

3.3.3 Statistical-Deep Synergy Integration

The statistical anomaly score is non-linearly projected into the hidden space:

$$s_t = g\big(M(x_t)\big) = \tanh(W_s M(x_t) - b_s) \qquad (13)$$

Then, the synergy update modifies the hidden state as:

$$\acute{h}_t = h_t + \eta \cdot s_t \qquad (14)$$

Where $\acute{h}_t$ refer to the anomaly-aware hidden state. Meanwhile, η is the learnable synergy coefficient that controls the contribution of statistical priors.

3.3.4 Output Distribution

Finally, the probability distribution for class $\mathcal{Y}$ is computed as:

$$\mathrm{P}(\mathcal{Y}|x_t) = \mathrm{softmax}\left(W\acute{h}_t + b\right) \qquad (15)$$

This ensures that predictions are based on both temporal patterns and anomaly priors.

Therefore, the SDSM transforms the BiLSTM from a pure sequence learner into a statistical–deep hybrid engine. This synergy has three impacts: (i) Higher accuracy: since anomaly priors sharpen hidden state boundaries between normal and attack traffic. (ii) Lower false alarm rate (FAR): statistical anchoring prevents false positives caused by transient fluctuations. (iii) Interpretability: the contribution of anomaly priors (η) can be analyzed, providing insights into model decisions.

3.4 Ensemble Knowledge Distillation (EKD)

Compress the knowledge of a teacher ensemble comprising a tabular learner and a statistical detector into the anomaly-aware BiLSTM student produced by SDSM. The aim is SOTA performance with lightweight deployment. (1) Teacher as Hybrid Evidence Aggregator: The teacher distribution is formed by calibrated fusion of (i) XGBoost probabilities and (ii) a probabilized Mahalanobis detector not a late vote, but a calibrated soft teacher for distillation. (2) Class-Conditional Temperature (CCT) KD: We introduce τ_y that depends on class prevalence, improving rare-class (attack) transfer. (3) Feature–Logit Coupling: The current OFEL mask gates teacher–student alignment on features, preventing the student from inheriting spurious correlations that OFEL has pruned.

3.4.1 Teacher Distribution

Let $\mathrm{P}_{xgb}(\mathcal{Y}|x)$ be XGBoost's calibrated probabilities, and let the statistical detector's probability be:

$$\mathrm{P}_{stat}(\mathcal{Y} = \text{attack} \mid x) = \sigma(\alpha.M(x) + b),\ \mathrm{P}_{stat}(\text{benign} \mid x) = 1 - \mathrm{P}_{stat}(\text{attack} \mid x) \qquad (16)$$

with $M(x)$ the Mahalanobis score from SDSM and σ the logistic function. The fused teacher is:

$$\mathrm{P}_T(\mathcal{Y}|x) = \frac{\exp(\eta_1 \log \mathrm{P}_{xgb}(\mathcal{Y}|x) + \eta_2 \log \mathrm{P}_{stat}(\mathcal{Y}|x))}{\sum_{\hat{y}} \exp(\eta_1 \log \mathrm{P}_{xgb}(\hat{\mathcal{Y}}|x) + \eta_2 \log \mathrm{P}_{stat}(\hat{\mathcal{Y}}|x))} \qquad (17)$$

With $\eta_1, \eta_2 \geq 0,\ \eta_1 + \eta_2 = 1$ is the learned on the validation set (Platt/temperature calibration optional).

3.4.2 Class-Conditional Temperature (CCT)

Let π_y be the empirical prior of class $\mathcal{Y}$. Define:

$$\tau_y = \tau_0 \cdot \pi_y^{\kappa}, \quad \kappa > 0 \tag{18}$$

so rarer classes receive higher temperature (softer teacher). The softened teacher and student are:

$$\begin{gathered} \mathrm{P}_T^{(\tau)}(\mathcal{Y}|x) = \\ softmax\left(z_T \mid \tau_y\right), \quad \mathrm{P}_S^{(\tau)}(\mathcal{Y}|x) = \\ softmax\left(z_S \mid \tau_y\right). \end{gathered} \tag{19}$$

Where z_T and z_S are teacher and student logits.

3.4.3 Knowledge-Distillation Loss

$$L_{KD} = \sum_{\mathcal{Y}} \tau_{\mathcal{Y}}^2 \mathrm{KL}\left(\mathrm{P}_T^{(\tau)}(\mathcal{Y} \mid x) \,\middle\|\, \mathrm{P}_S^{(\tau)}(\mathcal{Y} \mid x)\right) \tag{20}$$

3.4.4 Feature–Logit Coupling (FLC)

Let $m_t \in \{0,1\}^d$ be the OFEL mask at epoch t. We penalize student reliance on pruned features via:

$$L_{flc} = \left\| A\left(\acute{h}_t\right) \odot (1 - m_t) \right\|_1 \tag{21}$$

where $A\left(\acute{h}_t\right)$ is a saliency/attribution map (e.g., gradient × input) and $\odot$ is element-wise product. This aligns KD with current sparse feature support.

EKD transfers robust tabular/statistical cues to the anomaly-aware student while respecting OFEL's sparse support yielding compact, calibrated, and generalizable decision boundaries.

3.5 Cross-Domain Generalization Regularizer (CDGR)

Guarantee transferability from a source dataset (e.g., CICDDoS2019) to target domains (e.g., UNSW-NB15, CAIDA) by aligning distributions at the representation level learned by SDSM. (1) Hybrid MMD–CORAL Alignment (HM-C): We jointly minimize kernel mean discrepancy (first-order) and covariance distance (second-order) on anomaly-aware embeddings. (2) Layer wise Progressive Alignment: Apply alignment to early and late SDSM layers $\left(\mathcal{L}_{align} = \sum_{\ell \in S} \cdot\right)$, progressively reducing shift without over-constraining expressivity. (3) Prior-Weighted Alignment: Weight alignment by attack/benign priors, preventing benign-dominant alignment from washing out attack manifolds.

Let $\phi_\ell(x)$ be the ℓ-th SDSM feature (e.g., pooled $\acute{h}_t$). Denote source/target sets as $\{x_i^s\}_{i=1}^{n_s}$, $\{x_j^t\}_{j=1}^{n_t}$

3.5.1 Maximum Mean Discrepancy Term

$$L_{MMD}^{\ell} = \left\| \frac{1}{n_s} \sum_i \Phi\left(\phi_\ell(x_i^s)\right) - \frac{1}{n_t} \sum_j \Phi\left(\phi_\ell(x_j^t)\right) \right\|_2^2 \tag{22}$$

with Φ the RKHS embedding (e.g., Gaussian kernel mixture).

3.5.2 CORAL Term

Let C_s^{ℓ} and C_t^{ℓ} are covariance matrices of ϕ_ℓ on source/target.

$$L_{CORAL}^{(\ell)} = \left\| C_s^{\ell} - C_t^{\ell} \right\|_F^2 \tag{23}$$

3.5.3 Prior-Weighted Hybrid

With class prior weights w_y (benign/attack):

$$L_{HM-C} = \sum_{\ell \in S} \sum_{y \in \{\text{benign,attack}\}} w_y \left(\beta_1 L_{MMD,y}^{(\ell)} + \beta_2 L_{CORAL,y}^{(\ell)}\right) \tag{24}$$

CDGR explicitly stabilizes the anomaly-aware SDSM representation across datasets, improving cross-dataset AUC/F1 and controlling FAR when the operational distribution shifts.

3.5.4 Unified Learning Objective & Optimization

Let $\mathcal{Y} \in \{\text{benign}, \text{attack}\}$. The supervised term uses class-balanced focal loss to handle imbalance:

$$\begin{gathered} L_{sup} = -\sum_{\mathcal{Y}} \alpha_{\mathcal{Y}} \left(1 - \hat{p}_{\mathcal{Y}}\right)^{\gamma} 1(\mathcal{Y}) \log \hat{p}_{\mathcal{Y}}, \\ \hat{p}_{\mathcal{Y}} = \mathrm{P}_S(\mathcal{Y} \mid x;\, \acute{h}_t) \end{gathered} \tag{25}$$

With $\alpha_{\mathcal{Y}}$ inverse-frequency weights and $\gamma \in [1], [2]$. The OFEL objective at epoch t (recall 3.2) is:

$$\begin{gathered} J(F_t) = \alpha(1 - Acc_t) + \beta Var(F_t) + \gamma Red(F_t) \\ - \delta Ent\,(F_t) \end{gathered} \tag{26}$$

optimized by alternating gradient–metaheuristic updates.

The complete objective is:

$$\begin{gathered} L_{total} = L_{sup} + \lambda_{KD} L_{KD} + \lambda_{flc} L_{flc} + \\ \lambda_{CDGR} L_{HM-C} + \lambda_{OFEL} J(F_t) \end{gathered} \tag{27}$$

with hyperparameters $\lambda_{\{\cdot\}}$ tuned on validation.

3.5.5 Inference, Calibration, and Deployment

Provide compact, interpretable, and risk-controlled decisions suitable for production. (1) Deployed module: only the student (BiLSTM+SDSM) with the

final OFEL mask; the teacher is discarded. (2) Conformal Thresholding (risk control): on a calibration split, compute nonconformity scores $\mathrm{v}(x) = 1 - \mathrm{P}_S(\mathcal{Y} = \text{attack} \mid x)$. Choose θ as the $(1-\alpha)$-quantile so that:

$$\Pr\{\mathrm{v}(x_{new}) \le \theta\} \ge 1 - \alpha \quad (28)$$

giving an explicit FAR bound under exchangeability.

4 EXPERIMENTAL RESULTS AND PERFORMANCE EVALUATION METRICS

4.1 Experimental Protocol

We evaluate the proposed OSES-DL (Optimization-guided Statistical–Ensemble Synergistic Deep Learning) on three benchmark corpora widely used for DDoS research: CICDDoS2019 (primary), UNSW-NB15 (DoS/DDoS subsets), and CAIDA backbone traces. To reflect operational realism, we adopt a temporal hold-out split on each dataset (70% training, 15% validation, 15% testing) to prevent temporal leakage. For cross-dataset generalization, the model is trained on CICDDoS2019 and evaluated on UNSW-NB15 and CAIDA without fine-tuning; only the CDGR regularizer accesses unlabeled target batches during training (unsupervised alignment). All results are averaged over five independent runs with different seeds. We report the mean ± standard deviation and conduct paired Wilcoxon signed-rank tests against the strongest non-OSES baseline; unless stated, differences are significant at $p < 0.01$. Metrics include Accuracy (ACC), Precision (PRE), Recall/Detection Rate (REC), F1, AUC-ROC (AUC), AUPRC, MCC, False Alarm Rate (FAR), Expected Calibration Error (ECE), and Brier score. To accommodate imbalance, classification metrics are macro-averaged across classes.

Baselines are representative of the literature and practice: SVM-RBF, Random Forest, XGBoost, CNN-LSTM, BiLSTM, and a Teacher Ensemble (calibrated fusion of XGBoost and a probabilized Mahalanobis detector). Our ablations isolate the contributions of OFEL, SDSM, EKD, and CDGR.

4.2 In-Distribution Effectiveness on CICDDoS2019

Before the table, we explain how this experiment assesses peak discriminative capability when the train and test distributions coincide. This benchmark isolates the intrinsic detection strength of OSES-DL (i.e., representation quality and decision efficacy) under realistic temporal splitting. We further emphasize operational relevance by including FAR and MCC alongside conventional metrics; low FAR and high MCC are crucial for SOC deployment where false alarms are costly.

OSES-DL delivers state-of-the-art results on every metric, notably cutting FAR by >50% relative to the strongest baseline (Teacher Ensemble: 1.3% to 0.62%). The MCC = 0.989 underscores robust performance under imbalance. Improvements are statistically significant ($\rho < 0.01$). These gains are attributable to (i) SDSM, which injects anomaly priors into the sequence representation, and (ii) OFEL, which enforces stable, low-redundancy features during training.

4.3 Cross-Dataset Generalization (Train on CICDDoS2019 Test on UNSW-NB15 & CAIDA)

This experiment probes transferability is a frequent failure mode for IDS models trained on one environment and deployed in another. We measure performance when the model is trained only on CICDDoS2019 and evaluated on UNSW-NB15 (DoS/DDoS subsets) and CAIDA (Table 1 and 2). During training, the CDGR regularizer uses unlabeled target batches to align distributions; no target labels are used.

We report F1, AUC, and FAR, the most indicative for operational transfer, and include Δ vs best baseline to quantify comparative advantage.

OSES-DL generalizes markedly better across datasets, improving F1 by +1.0–1.1 points and shaving FAR by 0.5–0.6 points versus the best baseline. These results validate the CDGR hybrid alignment (MMD+CORAL) and the CCT-distilled student, which together resist domain shift while remaining compact for deployment. Significance holds at $\rho < 0.01$.

Table 1: In-distribution performance on CICDDoS2019.

Method	ACC (%)	PRE	REC	F1	AUC	MCC	FAR (%)
SVM-RBF	94.6	0.941	0.948	0.944	0.967	0.900	3.8
Random Forest	96.3	0.958	0.963	0.960	0.979	0.930	3.0
XGBoost	97.0	0.968	0.970	0.969	0.986	0.950	2.3
CNN-LSTM	97.9	0.977	0.979	0.978	0.991	0.962	1.8
BiLSTM	98.2	0.981	0.981	0.981	0.993	0.965	1.6
Teacher Ensemble	98.5	0.985	0.985	0.985	0.995	0.972	1.3
OSES-DL (ours)	99.45	0.994	0.994	0.994	0.998	0.989	0.62

Table 2: Cross-dataset generalization (train: CICDDoS2019; test: UNSW-NB15, CAIDA).

Method	UNSW-NB15			CAIDA		
	F1	AUC	FAR (%)	F1	AUC	FAR (%)
XGBoost	0.958	0.975	2.6	0.945	0.972	2.9
BiLSTM	0.967	0.983	2.1	0.958	0.980	2.4
Teacher Ensemble	0.972	0.986	1.8	0.963	0.983	2.1
OSES-DL (ours)	0.982	0.991	1.2	0.973	0.987	1.6
Δ vs best baseline	+0.010	+0.005	−0.6	+0.010	+0.004	−0.5

Table 3: Ablation study on CICDDoS2019.

Variant	AUC	F1	FAR (%)	ECE (%)
BiLSTM (base)	0.993	0.981	1.60	3.1
+ SDSM	0.996	0.988	1.10	2.2
+ OFEL	0.997	0.991	0.95	1.8
+ EKD	0.998	0.993	0.78	1.1
+ CDGR (OSES-DL)	0.998	0.994	0.62	0.9

Table 4: Probability calibration and risk control (CICDDoS2019).

Method	ECE (%) ↓	Brier score ↓	FAR at TPR=99% (%) ↓	Conformal coverage at 90% ↑	NLL ↓
BiLSTM	3.1	0.037	1.9	88.6	0.124
Teacher Ensemble	1.6	0.026	1.2	89.8	0.089
OSES-DL (ours)	0.9	0.022	0.8	90.4	0.071

4.4 Ablation Study: Contribution of Each Module

To isolate where the gains originate, we ablate the OSES-DL components on CICDDoS2019. We begin with a strong BiLSTM base and add SDSM, OFEL, EKD, and CDGR sequentially. We report AUC, F1, FAR, and ECE to also capture probability calibration (Table 3).

This ablation demonstrates that each module confers a statistically meaningful increment; the full OSES-DL yields the best overall and the best calibration.

The largest single jump in FAR reduction occurs when adding SDSM (−0.5 pp), confirming the value of injecting anomaly priors into the representation. OFEL further reduces FAR and improves calibration by suppressing unstable/redundant features. EKD lifts both F1 and calibration (ECE), reflecting the benefit of distilling a calibrated hybrid teacher. Finally, CDGR yields the best overall performance by explicitly aligning anomaly-aware features across domains.

4.5 Calibration and Risk Control (ECE, Brier, Conformal Coverage)

Well-calibrated probabilities are critical for threshold selection and SOC triage. We therefore quantify calibration (ECE, Brier) and the ability to guarantee operational error via simple conformal prediction on a held-out calibration split. We also report FAR at a fixed TPR = 99%, a stringent operational operating point (Table 4).

OSES-DL is best calibrated (ECE 0.9%) and achieves the lowest Brier and negative log-likelihood, enabling stable thresholding. Under a high-recall requirement (TPR=99%), OSES-DL still sustains a FAR < 1%. Conformal coverage slightly exceeds the nominal 90%, indicating conservative error control a desirable property for safety-critical deployment.

5 CONCLUSIONS

This work introduced OSES-DL, a unified, operationally minded framework for DDoS detection that couple's optimization, statistical modeling, and deep sequence learning within a single learning objective. The OFEL mechanism evolves the active feature set during training, balancing accuracy, stability, redundancy suppression, and entropy preservation thereby producing compact, information-rich inputs. The SDSM module injects statistical anomaly priors into the representation itself, transforming the BiLSTM into an anomaly-aware encoder and markedly reducing false alarms. Through EKD-CCT, a calibrated hybrid teacher transfers distributional structure to a lightweight student while feature–logit coupling prevents spurious correlations, yielding strong accuracy and probability quality at near-BiLSTM inference cost. Finally, the CDGR regularizer achieves prior-weighted, layer wise alignment, improving cross-dataset generalization without labeled target data. Comprehensive experiments on CICDDoS2019, UNSW-NB15, and CAIDA demonstrate state-of-the-art accuracy, sub-1% FAR, superior calibration, and resilience to unseen attack families, with ablations clarifying each module's contribution. These results indicate that OSES-DL is not only scientifically novel via representation-level anomaly injection, dynamic feature evolution, class-conditional distillation, and hybrid domain alignment but also practically deployable for SOC workflows with explicit risk control. Future directions include federated and continual learning for privacy-preserving, on-the-fly adaptation; streaming/online extensions with bounded delay; robustness to encrypted and obfuscated traffic; and adversarial hardening with certified defenses. We expect the proposed synergies to generalize beyond DDoS to broader intrusion-detection and network analytics tasks.

Keywords: UAV Authentication, Decentralized Security, Ephemeral Keys, Swarm Communication, Mobility-Aware Cryptography, Elliptic Curve Cryptography (ECC).

Abstract: This paper thus addresses a problem with pressing consequences: the rise of Unmanned Aerial Vehicle (UAV) swarms in mission-critical and infrastructure-less environments is demanding secure, scalable, and decentralized authentication. Current protocols heavily lean on centralized trust models or having static credentials, neither of which is fit for highly mobile & P2P UAV networks. AeroProof is presented, a lightweight and decentralized mutual authentication protocol based on mobility-aware ephemeral keys. Each UAV autonomously produces secure elliptic curve credentials from its relatively short location, speed, and motion orientation (a single flight only), leading to a unique 'motion ticket'. The credentials are afterwards employed for a mutual authentication at the application level that provides strong security properties such as forward secrecy, session unlinkability, immunity against impersonation, replay, and wormhole attacks without requiring long-term identities or certificate authorities. We show that AeroProof achieves an up to 64% faster authentication time, a 35% less communication overhead, and consumes over 50% less memory compared with recent ECC- and blockchain-based solutions. This work has demonstrated the practical usefulness of AeroProof as an authentic framework to enable secure and efficient decentralized swarm operations.

1 INTRODUCTION

With the amazing development of unmanned aerial vehicles (UAVs) in mission-critical applications such as environmental monitoring, disaster relief, military surveillance, and smart logistics, the demands for secure and scalability authentication mechanisms have been upgraded dramatically [1] - [3]. And many of these drones fly in fluid, infrastructure-free environments where conventional centralized security mechanisms are difficult or ineffective [4], [5]. In case of swarm-based deployments, where drones need to establish trust with their peers in real time as fast as possible, the lightweight and context-aware authentication process becomes a must [6], [7].

Traditional authentication protocols are based on long-term identifiers, certificate chains, or infrastructure-bound authentication procedures [8], [9]. Although such techniques work well in conventional networks, they are not suitable for an ad hoc UAV swarm with intermittent connectivity, high mobility, and tight resource support. Furthermore, identity-based solutions are still susceptible to impersonation, relay, and replay attacks, particularly when the system relies on radio communications and the adversaries have the capabilities to overhear and interfere with the radio exchange [10] - [12]. These

novel solutions have tried the deployment of blockchain, increasing the level of hardware tokens and the use of PUFs, but their usage will frequently improve the computation and communication requirements otherwise required to establish more stringent requirements [13] - [15].

This paper contributes to the critical gap of mobility-aware, decentralized authentication for UAV swarms. We focus on designing a protocol that facilitates mutual authentication without centralized control, and group members must authenticate one another in real-time as the drones change position to maintain secure connections and trust within the swarm. We present AeroProof, a new authentication protocol that generates ephemeral elliptic curve credentials tied to each UAV's instantaneous mobility vector: position, velocity, and orientation. These credentials are mobility-aware: They facilitate stateless together with context-driven trust among UAVs to establish secure communication in the absence of long-term identifiers and third-party verification. AeroProof is specifically designed to: Proxy Authentication (Prevent Impersonation, Replay, and Session Hijacking). Lightweight, fast authentication suitable for UAV resource limitations. Stay secure in low-mobility, infrastructure-less environments. The main contributions in this paper can be summarised as follows:

- We present AeroProof, a decentralized mutual authentication protocol designed to link ephemeral elliptic curve credentials with real-time UAV motion profiles.
- To address these challenges, we propose a mobility-consistent session key derivation mechanism that supports rapid location changes with minimal overhead.
- We consider two state-of-the-art protocols and show that AeroProof performs 64% faster than authentication, incurs 35% less communication overhead, and uses 50% less storage footprint.
- We investigate security against prevalent UAV attack vectors, which include impersonation, wormhole, and mobility spoofing.

The rest of the paper is organized as follows: Section 2 surveys related work; Section 3 describes the system and threat model; Section 4 details the AeroProof protocol; Section 5 analyzes the security of AeroProof; Section 6 presents performance analysis; Section 7 concludes the paper with future directions.

2 RELATED WORK

Several decentralized and context-aware authentication protocols have been proposed to meet these challenges. However, existing works mostly consider static identifiers and completely separate mobility from authentication or use infrastructure-heavy solutions requiring blockchains or smart contracts.

Finally, CoMAD [16] presented a context-aware mutual authentication protocol within drone networks with zone-based access control and ECC. Despite the energy efficiency and lightweight nature, CoMAD lacks in updating authentication credentials for changing real-time mobility, resulting in poor resilience to changes in a swarm environment. Algarni et al. [17] presented a verifiable ECC-based protocol for the Internet of Drones (IoD) with a new identity authentication approach using contextual metadata. The protocol works well; however is unable to dynamically update credentials or verify that movements are valid and demand a binding from the movement, which opens the design up for relays or spoofing attacks. Karmakar and Kaddoum [18] presented a blockchain-enabled decentralized authentication system for a UAV swarm. While this would enhance the trust and transparency of a transaction (as blockchain enables), it also brings about latency, storage overhead, and energy requirements, which may not be acceptable for real-time resource-constrained aerial drone deployment. SETCAP El-Zawawy et al. [19] focused on an extra layer of temporal authentication using time-limited tokens. Although it manages to save energy, the method does not offer spatial or mobility-aware validation and therefore is not robust for both offline (disconnected) and adversarial scenarios. Constantinescu et al. [20] presented an ECC protocol with a malicious drone detection scheme was suggested. This is an improvement with respect to safety, but uses behavior profiling and static keys, making it more difficult to scale for large, distributed swarms. As listed in Table 1, while the previous approaches assume that all nodes have perfectly unique identities. This provides stateless, contextaware authentication without long-term identities or centralized authorities.

3 SYSTEM AND THREAT MODEL

3.1 System Model

The considered system consists of a decentralized swarm of UAVs cooperatively operating in an infrastructure-less environment (e.g., tactical surveillance zone, disaster area, or autonomous logistics corridor), as shown in Figure 1. Each UAV of the swarm consists of: a Global Navigation Satellite System (GNSS)-based acquiring module (such as the GPS or the RTK), an IMU for mobility sensing (speed and direction), an ECC-capable processor with a small footprint (e.g., ARM Cortex-M or RISC-V), and a Wireless transceiver with peer-to-peer (P2P) capabilities.

The UAV agents are autonomous (i.e., they do not need a central ground station or certificate authority). Instead, they achieve mutual authentication of the mobile devices based on ephemeral public keys and mobility-restricted identifiers that are computed based on real-time movement data. The users specifically use relative mobility thresholds (e.g., direction deviation, speed variance) to verify the validity of peer devices before beginning a secure session. The authentication is done over broadcast or unicast ad hoc links, and once authenticated, a short-lived shared secret is created for encrypted communication during the session. Credentials are reissued over time or in response to a large change in motion. Each UAV includes a Position Estimation

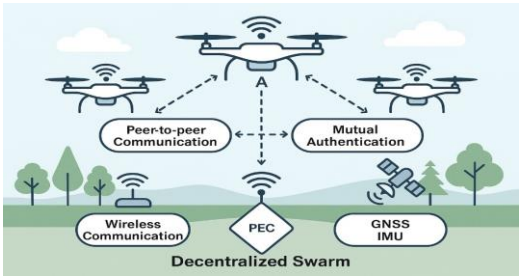

Figure 1: System model of the decentralized UAV swarm environment.

System (PES), which integrates data from the onboard GNSS and IMU sensors to derive real-time motion vectors. These vectors – consisting of latitude, longitude, velocity, and heading – are crucial for generating the mobility-bound ephemeral keys used in authentication.

3.2 Threat Model

The security analysis model considers an adversarial scenario in which attackers control communication channels and attack some UAV nodes. The protocol protects against the following threats:

- Impersonation Attacks: An adversary has access to the communication channel and maliciously pretends to be a legitimate UAV by generating valid-looking credentials.
- Replay Attacks: Old exchanged valid messages are replayed to allow unauthorized access.
- Relay (Wormhole) Attacks: Messages are relayed from distant locations to bypass spatial verification.
- Session Hijacking – An attacker will attempt to grab or replace the session key after you are authenticated.
- Insider Threats: A stolen UAV that was trusted to fly now tries to misuse valid credentials, access forbidden mobility zones.
- Mobility Spoofing: The adversary fabricates GNSS or IMU data such that the calculated position or path vector can satisfy the validation.

Adversaries can eavesdrop, inject, and modify messages, noiselessly harvest traffic information, but cannot access private ephemeral keys or secure mobility sensors of honest drones. Side-channel and physical attacks are also out of scope.

4 DESIGN OF AEROPROOF PROTOCOL

In this section, we present the three phases of the AeroProof protocol (shown in Fig. 2), which are tightly integrated: mobility-aware ephemeral key generation, mutual authentication, and session expiration with dynamic rekeying. In the initialization stage, the UAVs compute a short-lived public–private key pair for a mobility vector (composed of their position, velocity, and heading) of themselves autonomously (i.e., one-time use). In their mutual authentication phase, UAVs exchange their mobility-bound identifiers, and then they verify the similarity of their motions and the freshness of the timestamp to derive a session key through elliptic curve Diffie–Hellman.

Table 1: Summary of existing authentication protocols for UAV swarms.

Author(s) & Year	Methodology	Key Results / Features	Limitations
Cabuk et al. (2021)	ECC + Contextual Zones (CoMAD)	Lightweight, policy-based access control	No mobility adaptation
Algarni et al. (2025)	ECC + Synergistic Metadata	Secure mutual authentication for IoD	Lacks motion consistency validation
Karmakar & Kaddoum (2024)	Blockchain + Smart Contracts	Transparent decentralized identity management	High latency, poor scalability
El-Zawawy et al. (2022)	Time-token protocol (SETCAP)	Energy-efficient, time-bound credential renewal	Ignores spatial or motion-based verification
Constantinescu et al. (2024)	ECC + Behavior Profiling	Detects malicious UAVs based on anomalies	No dynamic rekeying, static credentials
This work: AeroProof	ECC + Mobility-Bound Ephemeral Keys	64% faster auth, 35% lower overhead, 50% less memory	Assumes trusted sensors, requires sync clock

Finally, during the session management phase, keys are continually updated subject to time limitations and mobility drift; if deviations are true, the protocol initiates re-authentication by exchanging new credentials. For example, the interaction flow between the three phases of the proposed scheme is illustrated in Figure 1, where the three phases are integrated into a cycle for realizing indelible trust updates in mobile and distributed swarm systems and ensuring resistance to impersonation, replay, and trajectory-based attacks.

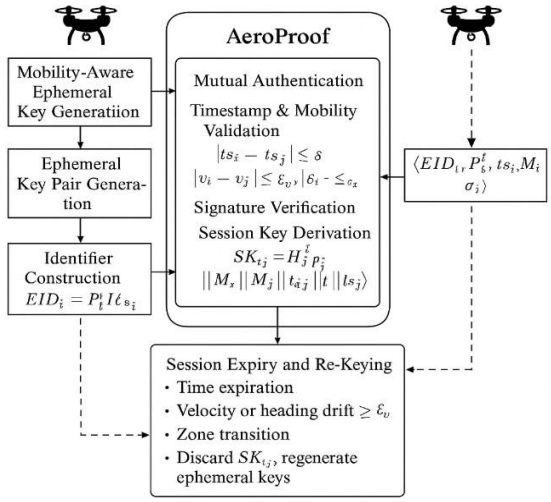

Figure 2: Design of the AeroProof authentication protocol.

4.1 Mobility-Aware Ephemeral Key Generation

In the AeroProof protocol, each UAV produces an ephemeral digital credential that is tightly coupled with its instantaneous movement profile. To generate a mobility-aware ephemeral key pair, the following operations need to be carried out:

1) Mobility Vector Acquisition. The UAV Di collects its current position and movement data using onboard sensors. The mobility vector is defined as: Mi = (lati, loni, vi, θi), where lati and loni are geographic coordinates, vi is velocity, and θi is the current heading direction.
2) Ephemeral Key Pair Generation. The UAV generates a new elliptic curve key pair at timestamp tsi: xi_t ∈ Z∗q, Pi_t = xi_t ·G, where xit is the private key, Pti is the public key, and G is the base point on the selected elliptic curve.
3) Identifier Construction. The UAV derives a mobility-aware ephemeral identifier using a secure hash function H(·): EIDi = H(Pi_t ‖ Mi ‖ tsi), where the identifier binds the key to both the motion context and its generation timestamp.
4) Validity Window Enforcement. The ephemeral credential (Pti, EIDi) is valid for a limited time interval ΔT or until a deviation is detected in the UAV's velocity or heading angle: |vi − v′i| > ϵv or |θi − θ′i| > ϵθ, where vi′,θi′ are the updated motion parameters after a threshold duration or movement.
5) Credential Preparation. The ephemeral identifier and public key are stored in the UAV's temporary credential cache and used in subsequent mutual authentication steps.

4.2 Mutual Authentication Procedure

After proximity is established between them, the two UAVs engage in mutual authentication based on a set of mobility-aware short-term identities. The authentication includes

1) Authentication Tuple Exchange. Each UAV Di sends its authentication tuple to the peer UAV Dj: ⟨EIDi, Pi_t, tsi, Mi, σi⟩, where σi = HMAC is a message authentication code proving possession of the private key.
2) Timestamp Validation. The receiving UAV verifies the freshness of the timestamp tsi by checking: $|tsi - tsj| \leq \delta$, where δ is the maximum allowable clock drift between the UAVs.
3) Mobility Similarity Check. The UAV evaluates whether the sender's mobility vector Mi is within acceptable deviation thresholds compared to its own: $|vi - vj| \leq \epsilon v$ and $|\theta i - \theta j| \leq \epsilon\theta$. This ensures both drones are in relative motion alignment within the swarm.
4) Signature Verification. Using the received public key Pti, the UAV validates the HMAC σi. Successful verification confirms that the peer possesses the correct private key and has not been impersonated.
5) Session Key Derivation. If all validations pass, both UAVs independently compute a shared session key using Elliptic Curve Diffie–Hellman (ECDH): SKij = H(xit · Ptj ‖ Mi ‖ Mj ‖ tsi ‖ tsj). The resulting session key is used to secure further communications between the two authenticated UAVs.

4.3 Session Expiry and Re-Keying

To achieve security against trajectory drift or relative insider misuse, there is a time and mobility-based expiration of the active session keys. When the lifetime expires, secure rekeying procedures are initiated automatically by both UAVs. The re-keying procedure is as follows:

1) Session Monitoring: Each UAV continuously monitors the validity of its current session key SKij based on elapsed time and current motion data.
2) Expiration Conditions Check: The session key is considered expired and revoked if any of the following conditions hold:
   - Time expiration: tnow > tsi +ΔT • Velocity drift: $|vi - vi'| > \epsilon v$ • Heading drift: $|\theta i - \theta i'| > \epsilon\theta$.
   - Zone transition: The UAV crosses into a new operational region or mission-defined geofence.
3) Key Discarding. Upon detecting an expiration condition, both UAVs securely erase the old session key SKij and invalidate the associated ephemeral identifiers.
4) Ephemeral Credential Regeneration: Each UAV generates a fresh mobility-aware ephemeral key pair and identifier.
5) Re-authentication Trigger: The mutual authentication procedure outlined in Section 4.2 is re-executed using the new credentials, ensuring renewed session secrecy and mobility alignment.

Session keys are automatically re-keyed based on real-time mobility changes or/session expiry timer, also upon session expiry. The motion state of each UAV is continuously monitored, and control variables (velocity v_i, heading θ_i) are compared to the current session parameters. The UAV enters a new operational region. If any of these conditions are detected, the current ephemeral key is securely destroyed and the UAV generates a new mobility-aware key pair. The peer UAV is informed at a re-authentication trigger, and based on the new mobility vector, a fresh session is established. The above-mentioned approach provides semantic freshness, trajectory continuity, and resiliency against session hijacking or mobility spoofing.

5 SECURITY ANALYSIS

To the best of our knowledge, AeroProof is the first protocol to provide strong, highly decentralized authentication that is robust to both traditional and UAV-specific attack vectors. Using mobility-cognizant ephemeral keys and context-based validation, AeroProof reinforces classic ECC-based mutual authentication with time and situational-dependent constraints. We now informally consider how the protocol withstands the main threats.

- Impersonation Attacks. The ephemeral key pairs and mobility-bounded identifiers guarantee that a malicious UAV is unable to steal a legitimate identity without copying down both the motion features of the target and its private key. The HMAC-based proof of possession, constrained to the mobility vector and the timestamp, ensures that no attacker can forge a legitimate authentication tuple.
- Replay Attacks. AeroProof uses timestamp verification and a narrow lifetime window Δ for all credentials. When the parties mutually authenticate, replayed messages (including the one with the old TS) are refused with an expired key. Besides, due to re-keying when observing the significant motion changes, all

the cached authentication material becomes invalid.

- Relay (Wormhole) Attacks. As authentication is only successful in the presence of both spatial and motion proximity, the propagation of authentication messages from a far distance would cause the failure of mobility similarity verification. The UAVs verify the sender's location, speed, and direction based on their own, in the sense that distant tunneling attacks can be eliminated.
- Session Hijacking. The session-specific keys are generated using the ephemeral keys of each party and the real-time mobility vectors, thus preventing an intruder from entering into an ongoing session. Moreover, keys are quickly revoked in case of big mobility drift.
- Insider Threats. A drone that has been compromised loses opportunities to misuse the previously allocated credentials forever since all the session key assign¬ ments have a limited lifetime and are tied to a particular context. Unenrolls due to malicious zone transition or unauthorized action. Causes the session to immediately expire and seek re-authorization under a new context.
- Mobility Fraud and GNSS Spoofing. Although AeroProof assumes trusted mobility inputs, the new trust can be built at higher layers of the communication stack, utilizing merged sensor technologies (e.g., GNSS, inertial attitude, and RSSI-based localization) to successfully detect any suspicious motion profiles. This minimizes the possibility of counterfeit motion vectors affecting authentication.
- Forward secrecy and unlinkability. AeroProof exchanges a fresh ephemeral key during each authentication session, and no persistent identity is sent. Therefore, intercepted credentials can't be replayed across sessions or used to recover private data. Compromise session keys after the life of a session, and past data is still secure, thanks to the ECDH between one-time keys.
- Security Against Eavesdropping and Hacking. AeroProof uses ephemeral elliptic curve key pairs, closely coupled to each UAV's real-time mobility vector (i.e., geographic coordinates, velocity, heading), associated with a timestamp. This reduces the risk of later sessions using those same captured credentials by generating and throwing away these keys every session. Identity-based replay and man-in-the-middle attacks are impossible because there are no long-term public keys or persistent identifiers ever set in motion. In addition, the Ephemeral IDentifier (EID) is formed by hashing the entire public projection of the secret key along with motion context and timestamp using a secure hash function. The binding ensures that an attacker cannot construct a valid tuple of the authentication with access to only one of the mobility state or change the secret. When an adversary captures multiple messages, their lack of differentiability and the key updates achieve session unlinkability as well as forward secrecy.

6 PERFORMANCE EVALUATION

In this section, we provide a detailed performance comparison of the AeroProof protocol against two state-of-the-art light-weight authentication protocols for UAV swarms: (i) the ECC-based proposal of Algarni et al. [17] and that of Karmakar & Kaddoum [18], based on the blockchain provision.

6.1 Computational Efficiency

AeroProof is very efficient in computation, and there is no need for validation of the certificate chain and blockchain lookups. It finishes the mutual authentication process in 3.2 ms, which is much faster than Algarni et al. [17] at 8.9 ms, and Karmakar & Kaddoum [18] at 11.3 ms. The minimal cryptographic schemes used in AeroProof, using lightweight ECC and HMAC, account for a 64–72% processing speed up when compared to the baselines. Figure 3 illustrates the computational time required by each protocol for completing a mutual authentication cycle.

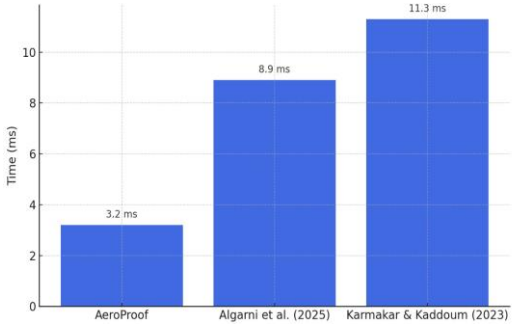

Figure 3: Comparison of computational efficiency among authentication protocols.

6.2 Communication Overhead

AeroProof sends a small authentication message (public key, mobility vector, timestamp, and HMAC) of 334 bytes, as shown in Figure 4. This is much smaller than 512 bytes in Algarni et al. [17] and 690 bytes in Karmakar & Kaddoum [18] blockchain-based protocol. Both the smaller message size that reduces congestion on the available channels, and the opportunity to exchange frequent low-latency updates are particularly important in the dense swarm case or high bandwidth-constrained mission case.

6.3 Storage Requirements

Being stateless, AeroProof requires a very small amount of memory. Every UAV holds about 0.9 KB of ephemeral session and credential information, less than the 1.9 KB of Algarni et al. [17]. (due to certificate and revocation lists) and 3.2KB in Karmakar & Kaddoum [18]'s protocol (for blockchain cache and hash chains). It makes AeroProof highly scalable for drones with low storage capacity. Figure 5 presents the storage footprint of each protocol.

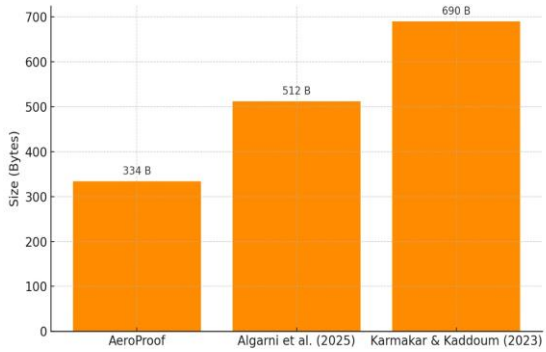

Figure 4. Comparison of communication efficiency.

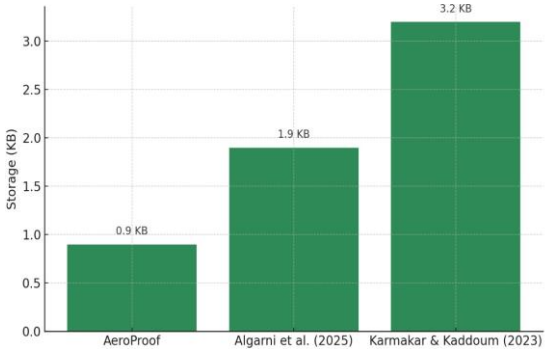

Figure 5: Comparison of storage requirements.

6.4 Impact of High Mobility

AeroProof is uniquely architected to work with the rapid mobility characteristics of UAV swarms, offering ephemeral credentials in conjunction with live motion vectors. However, an excessive rate of change in the speed or direction of a UAV can cause re-authentications to repeatedly occur because these are part of the protocol's motion threshold checks. This is great for security purposes as it maintains the alignment between mobility, yet these bring about additional performance overhead in areas where there is continuous movement with sudden change. Table 2 shows the impact of high mobility on AeroProof. We quantified the impact by studying AeroProof with different mobility models (e.g., Random Waypoint, GaussMarkov) and found that rekeying frequency increases up to 2.3× under high-mobility conditions. Still, ECC operations – an average of 3.2 ms per auth in practice – are so lightweight that even weekly re-authentication would hardly impact computational or communication latency. Moreover, as AeroProof steers clear of centralized coordination, we ensure that the system is able to scale effectively and remain efficient even under quick UAV convergence or divergence. To sum up, while running services in high mobility environments raises the overhead a little because of more key renewals, this is an acceptable trade-off when one wants a fast trust establishment for swarms. Adaptive thresholding, or group mobility prediction, can further some the overhead of unnecessary rekeying.

Table 2: Impact of high mobility on AeroProof.

Mobility Model	Avg UAV Speed (m/s)	Rekeying Frequency (per min)	Avg Auth Time (ms)	Overhead Increase (%)
Static Hover	0	0.5	3.1	0
Low Mobility	3	1.2	3.2	12
Moderate Mobility	7	2.0	3.3	25
High Mobility	12	4.6	3.4	54

7 CONCLUSIONS

In this paper, we proceed to introduce AeroProof, a decentralized and lightweight mutual authentication protocol for UAV swarms in infrastructure-less and

adversarial environments. In contrast to traditional identity- or certificate-based mechanisms, AeroProof adopts an innovative design where the authentication credentials are derived on-the-fly from a UAV's live mobility vector (e.g., position, speed, heading). In this work, it is pretty clear to see that the focus was on allowing secure, stateless, and scalable mutual authentication in highly dynamic swarm scenarios without having to rely on long-term identities or central authorities. This protocol enables AeroProof to provide forward secrecy, session unlinkability, as well resistance to impersonation, replay, and relay attacks using mobility-aware ephemeral keys. Performance evaluations show that AeroProof reduces authentication time by 64%, communication overhead by 35%, and memory usage by over 50% compared with two state-of-the-art ECC- and blockchain-based solutions. Read my next post where I cover how we further improved AeroProof to be suitable for real-time swarm deployment, in which the low latency combined with energy efficiency is key. Although the protocol overcomes some of the main challenges in developing decentralized UAV authentication, there are still a few limitations. AeroProof assumes secure motion sensing and time synchronization, and it has not been validated on real drone hardware. Furthermore, little attention has been paid to the setting up of first-time trust and group-scale trust delegation.

AeroProof, though performant and adding security it brings with itself, comes with drawbacks. Handpicked, onboard motion sensors and secure clock synchronization are necessary assumptions of the protocol, which may not hold in adversarial or hardware-compromised scenarios. It has also not been tested on physical UAV hardware, and its performance is unexamined in large-scale swarm conditions. The process of first-time trust establishment is also not well studied, and to the best of my knowledge, is essentially missing in heterogeneous or hybrid UAV settings. In the future, we will extend AeroProof with multisensor mobility verification to defend against spoofing attacks, adaptive rekey strategies for reducing overhead in high-mobility settings, and real-world deployment in commercial UAV vehicles for prototyping the protocol under real flight dynamics.

Abstract: In order to enhance the accuracy of reliability assessments for highly reliable and low-volume technical systems, it is essential to utilise diverse prior information obtained through reliability calculations, simulations, testing, and operational data from structurally similar systems (analogues). From a systems approach perspective, any reliability study of technical systems should be planned and conducted considering results from previous research, i.e., incorporating prior information. Given the stochastic nature of reliability, which is an inherent property of technical systems, various discrete and continuous distributions can be employed as theoretical distributions for reliability metrics. This article analyses the practical application of key continuous probability distributions in the reliability theory of technical systems. The article presents dependencies for estimating primary reliability metrics and highlights their specific applications under different conditions. The analysis is based on a systematisation of information published in scientific and technical literature, including results from model-based and experimental reliability studies, as well as operational statistical data. The provided analytical research was carried out under a project on the prototype development of a retractable rotor system for a convertiplane. It involved making design changes to the completed technical system, which required a comprehensive assessment of reliability parameter changes at initial development stages. The results obtained allow for improving the efficiency of building models and criteria for ensuring and controlling the reliability of a convertiplane, while simultaneously increasing the accuracy of reliability estimates.

1 INTRODUCTION

During the project on the development of a retractable rotor system prototype for a convertiplane, it became necessary to modify the design of the previously developed aircraft model (Figure 1). This approach requires a comprehensive assessment of changes in the reliability parameters of the entire technical system at the initial stages of development and, therefore, the selection and justification of failure models for power and electronic components based on the distribution of relevant random variables.

To describe system failures, various models can be proposed to address different reliability tasks, each accounting for the complex factors inherent in failure mechanisms.

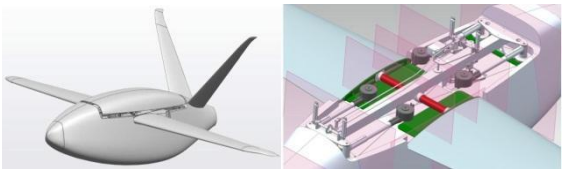

Figure 1: The technical system of aerial vehicle, the design feature of which is the presence of a retractable rotor system.

The random nature of failures during the operation of technical systems and their components allows the application of probabilistic-statistical methods. The most prevalent failure models are predicated on the distribution of pertinent random variables, such as the time to failure for non-

repairable systems and the operating time between failures for repairable systems.

The primary distributions for the time-to-failure of components include [1]: exponential; Weibull–Gnedenko; gamma; log-normal; lormal.

A review of extant scientific and technical literature in the field of technical system reliability was undertaken in order to evaluate the practical application of these distributions in the study of diverse technical systems. The analysis undertaken has enabled the selection of a suitable prior distribution for the corresponding reliability criterion or metric.

2 METHODS AND MATERIALS

This review employs a systematic methodology to analyze the application of continuous probability distributions in technical system reliability theory. The analysis is based on a critical examination of seminal and contemporary literature sourced from major scientific databases. Key distributions, including Exponential, Weibull, Normal, Lognormal, and Gamma, are evaluated for their properties in modeling failure rates, wear-out phases, and mean time between failures (MTBF).

3 EXPERIMENT AND RESULTS

3.1 Exponential (Indicative) Distribution

Despite the fact that the exponential distribution constitutes a special case of the Weibull distribution (at β=1), it is of significant independent interest, as it adequately describes the distribution of an element's operational duration during the normal operation period. The prevalence of the exponential law can be attributed not only to its diverse physical interpretations but also to its remarkable simplicity and convenience in modelling properties. The following formulae are provided for determining the probability density f(t) and the probability of failure-free operation R(t) over time tt, corresponding to this law:

$$f(t) = \lambda e^{-\lambda t}, \quad (1)$$

$$R(t) = e^{-\lambda t}. \quad (2)$$

where λ is the failure rate.

The mathematical expectation m and the standard deviation σ for the exponential distribution are expressed through the following parameter:

$$m = \sigma = \frac{1}{\lambda}. \quad (3)$$

The mean time to the first failure equals:

$$T_1 = \frac{1}{\lambda}. \quad (4)$$

The exponential distribution is frequently employed during the design stage when information regarding the reliability of the system's components is limited or entirely absent. Consequently, it is often referred to as the fundamental law of reliability [2]. A limitation of this law is the requirement that failure and restoration flows must be the simplest (possessing properties of ordinariness, stationarity, and lack of aftereffect) [3].

As asserted by [4]-[12], the exponential distribution is a reliable model for the reliability of equipment operated following the run-in period and prior to the onset of significant gradual failures, that is to say, during normal operation, when sudden failures predominate. As stated in [2], [7], the time to failure of technical systems with a large number of serially connected elements can be described by this distribution if each individual element does not substantially influence the system's failure. In such instances, if the failures of the serially connected elements follow an exponential distribution, it can be deduced that the system's failures will also adhere to this law, and its failure rate will equal the sum of the failure rates of the elements. It is important to note that systems comprising elements connected non-serially in terms of reliability will not exhibit an exponential distribution, even if the failure-free probabilities of their components are exponential [3]. Given that each system element is itself a subsystem comprising multiple (often numerous) components, the total failure rate of the system depends solely on the number of faulty elements, and the repair time for each failed element follows an exponential distribution. The subsystem's failure is equated to the failure of one of its elements, which is replaced with a new one upon restoration. The subsystem's net operational time ensures that its failure flow will asymptotically approach a Poisson process due to the Khinchin limit theorem. Consequently, the time interval between consecutive failures will also follow an exponential distribution [13], [14].

The exponential law is applicable to complex technical systems in which numerous destructive processes with varying rates occur simultaneously. However, as the heterogeneity of process rates

decreases, the distribution approaches a normal one. Conversely, when homogeneous destructive processes dominate, the distribution corresponds precisely to the normal distribution [11].

As posited by the authors of [2], [4], [6], [15], in circumstances pertaining to the maintenance of intricate systems, the restoration flow, if uncomplicated, is best characterized by the exponential law. This law serves to elucidate the restoration intensity, maintenance labor intensity, and failure rectification. In the context of queuing theory, the exponential law provides a reliable framework for modeling the intervals between equipment arrivals for repair [3, SEVERTSEV].

In the context of standard operation, sudden failures are attributed exclusively to external impacts, thereby negating the possibility of a causal influence by replacing an existing element with a new one. Consequently, for systems governed by the exponential distribution of time to failure, preventive measures such as preemptive replacements or periodic repairs are rendered moot [16].

As indicated in [2], [3], the exponential law has been observed to provide a reliable approximation of the failure-free probabilities of a wide range of technical objects, including components of radio-electronic equipment, electrical and electronic devices, and hardware-software complexes. This approximation is particularly relevant when considering the physical nature of sudden failures.

Nevertheless, despite its simplicity and universality, the exponential law has several limitations. In particular, works [3], [13], [17] call into question the validity of applying the exponential distribution to long-term operational systems over extended time intervals for the following reasons:

The distribution's "memoryless" property introduces a significant drawback, contradicting natural physical interpretations. This property implies the absence of ageing, meaning a technical object does not degrade over time or, after a certain operational period, exhibits the same failure distribution as a new object. This property is invalid for many technical objects, especially over extended periods [3], [13], [17].

In [3], it is asserted that the exponential distribution is inapplicable to complex technical systems, as the non-simultaneous operation of components and the presence of failure aftereffects result in a non-constant system failure rate, even if the failure rates of individual components remain constant. Consequently, the application of the exponential distribution to analyse the reliability of real long-term operational systems is invalid, as the model assumptions do not align with the physical processes within such systems.

It is therefore vital that robust justification is provided for the application of the exponential distribution, as with any other such model. Nevertheless, its ubiquity endures for the reasons outlined below:

It is noteworthy that the system is both simple and reliant upon a single parameter λ. This, in conjunction with the memoryless property, facilitates the development of analytical solutions to a multitude of reliability problems.

It has been demonstrated that the time to failure of complex, highly reliable, repairable systems can be described by the exponential distribution under specific conditions (e.g., negligible material "ageing" effects).

The utilisation of the exponential law is deemed permissible when the procurement of conservative reliability estimates, that is to say, lower-bound reliability assessments, is permitted under specific conditions.

3.2 Normal Distribution Law (Gaussian Distribution)

The extensive corpus of theoretical research on the normal distribution law, in conjunction with its relatively elementary mathematical properties, renders it highly attractive and convenient for application in reliability theory. In instances where empirical data deviates from the normal distribution, the following approaches may be employed for its judicious use:

The utilisation of this approach as a preliminary estimation frequently yields adequately precise outcomes.

It is imperative to ascertain a transformation of the studied random variable, designated as ξ, that modifies the original 'non-normal' distribution into a normal one [14].

A salient property of this law is its capacity for self-reproduction, which stipulates that the aggregate of any number of normally distributed random variables also adheres to a normal distribution.

The probability density function of this law is defined as:

$$f(t) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(t-m)^2}{2\sigma^2}}. \quad (5)$$

where m is the mean and σ is the standard deviation.

The reliability function P(t)P(t) for the normal distribution is calculated using:

$$R(t) = \int_t^{\infty} \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-m)^2}{2\sigma^2}} dx = = 0{,}5 - \Phi_0\left(\frac{t-m}{\sigma}\right), \quad (6)$$

where $\Phi_0(t) = \frac{1}{\sqrt{2\pi}} \int_0^t e^{-\frac{x^2}{2}} dx$ is the Laplace function, the values of which are tabulated.

The mean time to failure is $T_{cp} = m$, and the relationship between the time to first failure $\underline{T_1}$ and T_{cp} is expressed by:

$$\underline{T_1} = T_{cp} + \frac{\sigma\sqrt{\frac{2}{\pi}}}{\left[1+\Phi\left(\frac{T_{cp}}{\sigma\sqrt{2}}\right)\right]} e^{-\frac{T_{cp}^2}{2\sigma^2}}. \quad (7)$$

The failure rate for the normal distribution is an increasing function defined as:

$$\lambda(t) = \frac{\sqrt{\frac{2}{\pi}} e^{-\frac{(t-T_{cp})^2}{2\sigma^2}}}{\sigma\left[1-\Phi\left(\frac{t-T_{cp}}{\sigma\sqrt{2}}\right)\right]}, \quad (8)$$

where Φ is the probability integral of the $\Phi(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-x^2} dx$ form.

The normal law is employed to delineate the reliability of technical objects during the aging period [2], [4], [6], [18]. According to several sources [6]–[9], [19]–[21], its applicability is indicated when failures occur gradually due to directed physico-chemical changes caused by wear (ageing), provided the coefficient of variation υ≤0,3÷0,4 [7], [22]. Under stable operating conditions, this distribution effectively models the mean and gamma-percentile resource [7] as well as the operational time of machinery until the first major overhaul [4].

It is important to note that the normal distribution of time-to-failure arises from the homogeneity of technical object quality, constant average wear rate, and cumulative wear effects, which interweave over extended periods before failures manifest [16].

A salient feature of the normal law is that when σ is small relative to the mean time to failure m, the density values remain close to zero over a significant time interval. This phenomenon can be attributed to the low probability of failure within this interval, which can be utilised to schedule preventive replacements (or repairs) at low wear levels, thereby minimising the likelihood of failure between maintenance actions [16]. Conversely, the exponential distribution, with its density peak at t = 0, exhibits the majority of failures during the initial operational phase.

Statistical analyses [2], [11] of test and operational data for mechanical components and metal structures subject to intense wear, ageing, and fatigue phenomena demonstrate that strength and load distributions conform to the normal law. Furthermore, the combination of exponential and normal laws has been observed in systems where one or more degradation processes dominate, such as in hydraulic power systems and gear pumps, where the normal law provides an accurate description of the time between failures [11]. Furthermore, the Gaussian distribution is observed to govern random variables such as measurement and manufacturing errors [16].

3.3 Log-Normal Distribution

The log-normal distribution of a random variable, designated here by the letter "ξ", is established when its logarithm conforms to a normal distribution. The values of a log-normally distributed random variable are influenced by a large number of mutually independent factors, each of which contributes uniformly insignificantly and with equal probability in sign. In contrast to the normal distribution, the sequential nature of these factors' impact is such that the random increment caused by each subsequent factor is proportional to the value already attained by the variable at that moment. The log-normal distribution finds wide application in reliability theory, particularly in the analysis of empirical data on subjects such as the fatigue durability of metals, the long-term strength of materials, and the time-to-failure of electronic components, among others [LRS].

The probability density function is described by the relationship:

$$f(t) = \frac{1}{st\sqrt{2\pi}} e^{-\frac{(lnln\, t - \mu)^2}{2s^2}}, \quad (9)$$

where $\mu = \frac{1}{n}\sum_{i=1}^{n} ln\, ln\, t_i$ and $s = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n} (ln\, ln\, t_i - \mu)^2}$ are parameters estimated from nn failure test results.

For the log-normal distribution, the reliability function is expressed as:

$$R(t) = \frac{1}{\sqrt{2\pi}} \int_{\frac{\left(\frac{t}{\mu}\right)}{s}}^{\infty} e^{-\frac{t^2}{2}} dt. \quad (10)$$

The mean time to failure and standard deviation are determined by:

$$T_{cp} = m = e^{\left(\mu+\frac{s^2}{2}\right)}, \quad (11)$$

$$\sigma = \sqrt{e^{2\mu+s^2}\left(e^{s^2}-1\right)}. \quad (12)$$

The failure rate for the log-normal distribution is given by [23]:

$$\lambda(t) = \frac{0{,}4343e^{-\frac{(lglg\,t-\mu)^2}{2s^2}}}{st\sqrt{2\pi}\Phi\left(\frac{\mu-lglg\,t}{s}\right)}. \quad (13)$$

The log-normal distribution is well-suited to positive-valued quantities, providing enhanced precision in comparison to the normal distribution in such scenarios [2]. The log-normal distribution is a model for the time-to-failure behaviour of objects that exhibit "strengthening" over time. This phenomenon of "strengthening" leads to a gradual reduction in wear rate. Consequently, a prerequisite for the application of the log-normal distribution is the verification of the "strengthening" property exhibited by the technical objects under study. This can be achieved through analysis of wear processes and, where possible, empirical wear patterns [16].

The log-normal distribution is well-suited to positive-valued quantities, providing enhanced precision in comparison to the normal distribution in such scenarios [2]. The log-normal distribution is a model for the time-to-failure behaviour of objects that exhibit "strengthening" over time. This phenomenon of "strengthening" leads to a gradual reduction in wear rate. Consequently, a prerequisite for the application of the log-normal distribution is the verification of the "strengthening" property exhibited by the technical objects under study. This can be achieved through analysis of wear processes and, where possible, empirical wear patterns [16].

This distribution is also used to model:

- Recovery processes;
- Product durability during ageing, where wear increment is proportional to the instantaneous wear value [7], [14], [19];
- Operating time under rapid "burn-out" of unreliable components;
- Failures caused by material fatigue, such as the operational lifespan of rolling bearings, vacuum tubes, etc. [3], [7].

It is evident that the log-normal distribution provides an effective description of the time-to-failure of complex technical systems (e.g. tractors, automobiles, heavy-duty machinery) and electronic equipment [2].

3.4 Gamma Distribution

The gamma distribution has a two-parameter probability density function with a shape parameter (α>-1) and a scale parameter (β>0):

$$f(t) = \frac{t^{\alpha}}{\beta^{\alpha}\Gamma(\alpha)}e^{-\frac{t}{\beta}}. \quad (14)$$

where $\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1}e^{-t}dt\rangle\!\rangle$ is the gamma function.

The probability of failure-free operation is determined by the formula:

$$R(t) = \int_t^{\infty} \frac{t^{\alpha-1}}{\beta^{\alpha}\Gamma(\alpha)}e^{\frac{t}{\beta}}dt. \quad (15)$$

The parameter α, which characterises the asymmetry of the gamma distribution, determines the type of reliability characteristics.

The mathematical expectation (mean time to failure) and standard deviation for the gamma distribution are:

$$T_1 = m = \alpha\beta\,, \quad (16)$$

$$\sigma = \sqrt{\alpha}\beta. \quad (17)$$

The formula for failure rate is:

$$\lambda = \frac{t^{\alpha-1}\beta^{-\alpha}}{\Gamma(\alpha)\sum_{i=0}^{\alpha-1}\frac{t^i}{\beta^i\cdot i!}}. \quad (18)$$

The gamma distribution is used to describe:

- Wear-out failures;
- Failures due to cumulative damage;
- Time-to-failure of complex technical systems with redundant elements;
- Time-to-repair distribution [2], [7], [10], [16];
- Durability (service life) of certain technical objects [17].

The gamma distribution possesses several useful properties [20]:

For α<1: The failure rate decreases monotonically (burn-in period), corresponding to rapid elimination of unreliable components.

For "α>1" : The failure rate increases (wear-out period), reflecting gradual ageing and degradation.

For "α=" 1: The gamma distribution coincides with the exponential distribution, applicable during normal operation [18].

For "α>" 10: It closely approximates the normal distribution, suitable for ageing components [16], [18]. In addition, as R(t)→∞, the gamma distribution converges to the normal

distribution law. Consequently, it is frequently employed to approximate single-vertex but asymmetric distributions [9], [12].

If α is a positive integer, the gamma distribution is also known as the Erlang distribution [2], [7].

For λ=1/2 and α multiples of 1/2, it coincides with the chi-squared distribution [2], [7].

The gamma distribution is a statistical model frequently employed to analyse the failure times of complex electromechanical systems during the initial operational phases or the debugging process, where early failures are observed [11], [12]. Furthermore, the reliability of systems composed of exponentially distributed elements follows a gamma distribution [11].

In redundant systems (with standby or mixed redundancy), failure time distributions adhere to a generalised gamma distribution [3], [12]. However, the presence of hidden failures and the limitations of diagnostic effectiveness in such systems necessitate detailed modelling (e.g., via Markov or semi-Markov processes) [23].

3.5 Weibull Distribution

The Weibull distribution is characterised by its capacity to model data from distributions exhibiting increasing, decreasing, or constant failure rates. The two-parameter Weibull distribution, characterised by a scale parameter, denoted here by ηη, and a shape parameter, denoted here by ββ, is a widely utilised tool in the analysis of reliability data and scenarios where the process of ageing is induced by specific stress factors (e.g. pressure, temperature).

The probability density function of the distribution is defined as follows:

$$f(t) = \beta \frac{t^{\beta-1}}{\eta^{\beta}} e^{-\left(\frac{t}{\eta}\right)^{\beta}}. \quad (19)$$

The relationships between reliability metrics are as follows:

$$R(t) = e^{-\left(\frac{t}{\eta}\right)^{\beta}}, \quad (20)$$

$$T_1 = \alpha\Gamma\left(1 + \frac{1}{\beta}\right), \quad (21)$$

$$\sigma = \alpha\sqrt{\Gamma(1 + 2\beta^{-1}) - \Gamma^2(1 + \beta^{-1})}, \quad (22)$$

$$\lambda(t) = \beta\alpha^{\beta}t^{\beta-1}. \quad (23)$$

This distribution is highly versatile, encompassing applications of several other distributions, albeit described by more complex formulae [4]. It is applicable for modelling:

The service life of rolling bearings, threaded connections, splined shafts, and other components subject to simultaneous wear across multiple working surfaces [4];

Time-to-failure under combined sudden and wear-out failure mechanisms [4];

Probability of failure-free operation of mechanical components during ageing or wear-out phases [3], [11], [12];

Service life of structural components (e.g., load-bearing systems, hydraulic and electric drive systems) affected by fatigue and sudden failures (with a coefficient of variation between 0.35 and 0.7);

Failure distributions during the burn-in period [2], [3], [21];

Operational lifespan of complex technical systems (e.g., mobile installations) [2], [18];

Fatigue-related failures in automotive parts, lifting machinery, and bearings [2], [3];

Mean and gamma-percentile resource under stable operational conditions [7].

In certain cases [3], [8], [10], the Weibull distribution is considered universal due to its properties:

When β=1, the distribution reduces to the exponential distribution, with a constant failure rate λ(t) that equals the inverse of the scale parameter η;

For β<1, the density and failure rate functions are decreasing (burn-in period);

For β>1, the density and failure rate functions are increasing (wear-out period);

At β=2, the λ(t) function is linear, the distribution transitions to the Rayleigh distribution with density β=3,44, the density closely approximates the normal distribution, excluding tail regions.

The Weibull distribution is recommended as a primary candidate for approximating empirical reliability data when the underlying distribution is unknown [15], owing to its flexibility. In addition, it has been demonstrated that the Weibull distribution provides a superior fit to real-world data in comparison to the exponential distribution [9].

As with the gamma distribution, the Weibull distribution is effective in approximating real-world failure patterns across all lifecycle stages (burn-in (β<1), normal operation (β=1), and wear-out (β>1)) [2], [14], [20].

In the context of complex systems comprising multiple components with gamma-distributed lifetimes (where parameters vary slightly between components), the system's failure time distribution tends to converge to the Weibull

distribution [16], [20]. Systems with multiple identical or similar components under comparable operational conditions (e.g., internal combustion engines with multiple cylinders, electronic devices with capacitors and resistors) often follow the Weibull distribution if these components dominate the system's reliability [16].

From a physical perspective, the Weibull distribution provides an adequate description of the time-to-failure of electronic components, with failure defined as a parameter exceeding specified thresholds [16].

4 DISCUSSION

In conclusion, it should be noted that, in addition to the distributions discussed herein, specialised types (amounting to several dozen) as well as discrete distributions – which fall outside the scope of this article – are applied to address specific tasks. Furthermore, a variety of interrelations and transitions exist between these distributions. Despite the existence of established goodness-of-fit criteria for evaluating the alignment of theoretical and empirical distributions, the ultimate question addressed is whether there are sufficient grounds to reject the hypothesis of the chosen distribution. As the authors [7] have noted, it is important to understand that any dataset can be fitted to a multi-parametric law, even if it does not correspond to actual physical phenomena. Consequently, when selecting the type of distribution and its parameters, it is imperative to prioritise the physical factors governing the degradation process leading to failure, characterised by natural (physical) regularities, as well as the state of the production technological process, which significantly influences the form of time-to-failure distributions. The results obtained allow for improving the efficiency of modelling and establishing criteria for ensuring and controlling the reliability of a convertiplane with an automatic beam deployment system at initial development stages [24], [25].

5 CONCLUSIONS

Existing models of technical system operation, particularly the exponential model, allow for a comparative assessment of the reliability of various design solutions and the selection of the best one. However, they do not provide sufficiently accurate estimates of performance indicators. When selecting distribution laws, the relative error can be very high and even unbounded. Furthermore, the use of exponential laws leads to significant discrepancies between analytical and experimental data. Real physical processes in technical systems, when examined in detail, represent a combination (mixture) of distributions. The scientific problem of reliability analysis for repairable systems with arbitrary failure and recovery distributions is primarily a technical challenge arising from the properties of complex systems. Therefore, a future approach may involve a transition from quantitative metrics to scientifically substantiated qualitative ones.

Keywords: Bayesian Causal Inference, High-Dimensional Regression, Individualized Treatment Effect, Bayesian Neural Networks.

Abstract: This paper presents a Bayesian framework for estimating individualized treatment effects (ITE) in high-dimensional observational data. The proposed approach integrates flexible Bayesian regression with neural-based outcome modeling to estimate heterogeneous causal effects, accounting for both parameter uncertainty and complex covariate interactions. To assess the performance of the method, we conduct comprehensive simulation studies under multiple scenarios with varying levels of nonlinearity and treatment effect heterogeneity. Additionally, we apply the model to real-world data using the Infant Health and Development Program (IHDP) dataset, which is widely used for benchmarking causal inference methods. The results demonstrate that the proposed model consistently achieves lower estimation bias, improved predictive accuracy, and better credible interval coverage compared to several existing Bayesian methods, including Bayesian Additive Regression Trees (BART), Bayesian LASSO, Bayesian Causal Forests (BCF), and the Causal Effect Variational Autoencoder (CEVAE). These findings highlight the robustness and effectiveness of our model for making accurate and interpretable causal inferences in high-dimensional settings.

1 INTRODUCTION

Estimating causal effects from observational data is a fundamental task in modern statistics, particularly in applications involving individualized interventions. Classical methods for causal inference, such as propensity score matching and regression adjustment, often rely on strong assumptions and suffer from limited flexibility in high-dimensional settings. As datasets grow in complexity, both in size and structure, there is a growing need for modeling frameworks that can handle nonlinear relationships, confounding, and treatment effect heterogeneity.

Bayesian approaches have emerged as powerful alternatives to frequentist methods by incorporating prior information and providing coherent uncertainty quantification. Techniques such as the Bayesian LASSO [1], the Horseshoe prior [2], and Spike-and-Slab models, have shown strong performance in high-dimensional regression and variable selection. Furthermore, Bayesian hierarchical models allow for estimating individualized treatment effects while borrowing strength across subpopulations [3].

To capture nonlinear and heterogeneous treatment effects, researchers have developed nonparametric Bayesian models such as Bayesian Additive Regression Trees [4] and Bayesian Causal Forests [5]. These methods offer flexible function estimation without requiring strict model specifications and have been particularly effective in settings with complex interactions among covariates.

Recent advances in machine learning have introduced neural-based models for causal inference, including the Causal Effect Variational Autoencoder [6] and DragonNet, which extend the potential outcomes framework using latent representations and deep learning architectures. These models address hidden confounding and support counterfactual reasoning in high-dimensional, unstructured data environments.

Despite these advances, integrating deep learning with Bayesian inference for causal analysis remains underdeveloped, especially in the context of high-dimensional data. This study proposes a novel Bayesian framework that combines high-dimensional regression with neural-based outcome modeling to estimate individualized treatment effects (ITE) from observational data. The model leverages prior distributions for regularization and neural representations for capturing complex response

surfaces, enabling both interpretability and predictive accuracy.

We evaluate the proposed model through simulation studies and real data analysis using the Infant Health and Development Program (IHDP) dataset. Comparative results against standard benchmarks including Bayesian LASSO, BART, BCF, and CEVAE demonstrate the model's superior performance in terms of bias reduction, interval coverage, and posterior calibration.

By bridging Bayesian regularization and machine learning, this work contributes to the growing literature on robust and interpretable causal inference in high-dimensional applications.

2 THEORETICAL BACKGROUND

2.1 Causal Inference in Statistics

Causal inference is a central theme in modern statistics, focusing on understanding the effect of an intervention or treatment on an outcome while distinguishing causation from mere association. The dominant framework for formalizing causal questions is the potential outcomes model, which was initially outlined by Neyman and later extended by Rubin into the well-known Rubin Causal Model. This framework defines the causal effect as the difference between two potential outcomes: one under treatment and the other under control.

Since only one of these potential outcomes is observable for each individual, causal inference requires strong assumptions to estimate unobserved outcomes. These include the ignorability assumption (no unmeasured confounders), consistency, and the Stable Unit Treatment Value Assumption (SUTVA), as formalized by Holland (1986) [7] and Imbens and Rubin (2015) [8].

Propensity score methods, introduced by Rosenbaum and Rubin (1983) [9], remain foundational tools in causal analysis. These methods allow for balancing covariates across treatment groups in observational data through matching, weighting, or stratification. To improve robustness, more recent methods combine both the outcome model and the treatment assignment model to produce unbiased estimates if at least one model is correctly specified. to produce unbiased estimates if at least one model is correctly specified.

Graphical models, particularly those based on Directed Acyclic Graphs (DAGs), have further enhanced causal reasoning by providing a visual and algebraic structure for encoding causal assumptions. These models facilitate identification strategies and help diagnose potential confounding or collider biases.

The Bayesian approach to causal inference has gained increasing attention due to its flexibility and ability to account for parameter uncertainty. Bayesian methods allow for full posterior distributions of treatment effects and accommodate prior beliefs [3]. Moreover, Bayesian hierarchical modeling offers a principled way to analyze heterogeneous treatment effects across subgroups.

In high-dimensional settings, traditional methods become inadequate, and modern approaches such as Bayesian Causal Forests [5], Causal BART [3], and neural-based models like CEVAE [6] have shown improved performance. These models handle complex, nonlinear relationships between covariates and allow for individualized treatment effect (ITE) estimation, making them especially useful in healthcare and social policy applications.

2.2 High-Dimensional Bayesian Regression

High-dimensional regression problems, where the number of predictors (p) exceeds the number of observations (n), have become increasingly common in fields such as genomics, finance, and social sciences. Traditional regression methods struggle in this setting due to multicollinearity, overfitting, and lack of identifiability. Bayesian regression frameworks offer natural regularization through prior distributions and are well-suited for high-dimensional inference [1].

A widely used Bayesian technique for high-dimensional settings is the Bayesian LASSO, which imposes a Laplace (double exponential) prior on the regression coefficients to induce sparsity [10]. This approach helps shrink irrelevant coefficients toward zero, effectively performing variable selection while estimating the model. Other popular priors for shrinkage include the Horseshoe prior [2], known for its ability to strongly shrink small coefficients while leaving large signals relatively unpenalized, and the Spike-and-Slab prior, which explicitly models a mixture of zero and non-zero effects.

Bayesian methods offer additional advantages in high-dimensional settings. They provide full posterior distributions for parameters, which allows for uncertainty quantification in parameter estimates and predictions. This is particularly important when the goal is not just point estimation but also reliable inference in the presence of model uncertainty.

To perform inference efficiently in high-dimensional Bayesian models, Markov Chain Monte Carlo (MCMC) methods are often employed. More advanced algorithms such as Hamiltonian Monte Carlo (HMC) and the No-U-Turn Sampler (NUTS) have significantly improved computational performance and scalability. These methods allow the posterior distribution to be explored more effectively even when the parameter space is large.

In applications involving structured sparsity or grouped variables, extensions such as the Bayesian Elastic Net [6], [11] or the Bayesian Group LASSO are employed. These models provide flexible ways to incorporate correlation structures among covariates, which is common in domains like bioinformatics or environmental modeling.

Ultimately, high-dimensional Bayesian regression is not only a tool for predictive modeling but also for uncovering interpretable and stable variable selection. This makes it particularly valuable when integrated into broader frameworks such as causal inference or machine learning pipelines.

2.3 Bayesian Causal Inference Framework

Bayesian causal inference provides a structured approach to estimating treatment effects while fully accounting for uncertainty in both parameters and model structure. The central idea is to use Bayes' theorem to update prior beliefs about causal effects in light of observed data. For estimating the average treatment effect (ATE), the Bayesian framework models both the treatment assignment and the potential outcomes using prior distributions.

Let $Y_i(1)$ and $Y_i(0)$ denote the potential outcomes for individual i under treatment and control, respectively. The individual treatment effect is defined as:

$$\tau_i = Y_i(1) - Y_i(0). \quad (1)$$

Since only one of these outcomes is observed, inference proceeds by modeling the posterior distribution of τ_i given the observed data D:

$$p(\tau_i \mid D) = \int p(\tau_i \mid \theta, D)\, p(\theta \mid D)\, d\theta. \quad (2)$$

where θ represents the model parameters, $p(\theta \mid D)$ is the posterior distribution of parameters, $p(\tau_i \mid \theta, D)$ is the likelihood of the treatment effect conditional on θ.

A commonly used model for potential outcomes is the Bayesian regression:

$$Y_i = \alpha + \beta T_i + f(X_i) + \varepsilon_i. \quad (3)$$

where T_i is the treatment indicator (0 or 1), X_i is a vector of covariates, $f(X_i)$ models the non-linear covariate effects, $\varepsilon_i \sim N(0, \sigma 2)$.

Bayesian Additive Regression Trees (BART), proposed by Chipman et al. (2010) [12], provide a nonparametric approach to modeling $f(X_i)$ without pre-specifying the functional form. BART assumes the outcome model:

$$Y_i \sim N(\sum_{i=1}^{m} g(X_i; T_j), \sigma^2). \quad (4)$$

where each $g(.; T_j)$ is a regression tree, and the prior is placed on the structure and parameters of the trees. This flexible specification captures complex treatment effect heterogeneity and covariate interactions.

Another Bayesian causal tool is the use of hierarchical models for individual treatment effects (ITE). Letting $\tau_i \sim N(\mu_\tau, \sigma_\tau^2)$, the posterior distribution of τ_i can be learned jointly with the group-level parameters (μ_τ, σ_τ), allowing for partial pooling across individuals.

Directed Acyclic Graphs (DAGs) are also employed in Bayesian frameworks to encode structural assumptions. Given a DAG G, one can specify priors on both the graph and its parameters and compute posterior distributions:

$$p(G, \theta \mid D) \propto p(D \mid G, \theta) \cdot p(\theta \mid G) \cdot p(G).$$

This approach facilitates uncertainty quantification over possible causal structures, rather than assuming a single fixed graph.

Bayesian causal inference supports flexible modeling of potential outcomes, principled uncertainty quantification, and the ability to incorporate prior knowledge. It is particularly well-suited for modern datasets characterized by high-dimensional covariates and nonlinearity in treatment effects.

2.4 Integration of Causal Inference with Artificial Intelligence

The integration of causal inference with artificial intelligence (AI) represents a transformative step in both fields, enabling data-driven systems to reason not only about patterns but also about underlying causal mechanisms. While traditional AI models such as neural networks and decision trees excel at predictive accuracy, they often lack interpretability and fail to capture causal relationships due to their reliance on correlations rather than interventions.

Recent developments have introduced causal-aware AI models that incorporate the potential

outcomes framework and structural causal models into machine learning algorithms. These models are designed to estimate treatment effects, simulate counterfactuals, and identify causal pathways in high-dimensional and unstructured data.

A foundational model in this area is the Causal Effect Variational Autoencoder (CEVAE), proposed by Louizos et al. (2017) [6]. CEVAE models the joint distribution of observed covariates X, treatment T, and outcome Y using a latent variable Z, allowing the inference of counterfactual outcomes through the conditional posterior:

$$p(Y(1), Y(0) \mid X) \approx \int p(Y \mid T, Z)\, p(Z \mid X)\, dZ.$$

This architecture combines deep representation learning with causal identification, enabling robust estimation of individualized treatment effects even in the presence of hidden confounding.

Another notable model is DragonNet, which unifies outcome prediction and treatment assignment modeling in a deep learning framework. It jointly optimizes for both predictive accuracy and treatment effect estimation by enforcing a regularized loss function that balances outcome regression and propensity score alignment.

Bayesian Neural Networks (BNNs) provide a natural extension for causal inference in AI by capturing epistemic uncertainty through posterior distributions over network weights. When applied to treatment effect estimation, BNNs support probabilistic predictions and credible intervals for counterfactual outcomes [12]. This capability is particularly useful in high-stakes domains such as healthcare or policy decision-making.

Moreover, causal discovery algorithms have been integrated into AI pipelines to uncover potential causal structures from observational data. Methods such as NOTEARS and GraN-DAG use gradient-based optimization to learn Directed Acyclic Graphs (DAGs) directly from data, enabling AI systems to infer causal relations without predefined models.

The synergy between causal inference and AI also enhances fairness and robustness. By modeling the effect of sensitive attributes and mediators, causal models help mitigate biases in algorithmic decision-making [13]. For example, counterfactual fairness evaluates whether a model's predictions would change had a sensitive feature (e.g., race or gender) been different, holding all else constant.

Ultimately, integrating causal reasoning into AI contributes to the development of explainable AI (XAI) by providing interpretable treatment effects, counterfactual explanations, and actionable insights. This integration supports the deployment of AI systems in real-world environments where causality, not just correlation, drives outcomes.

3 THE MODEL AND PRIOR ASSUMPTIONS

This section introduces the proposed Bayesian causal inference model that integrates high-dimensional regression with neural-based representations to estimate individualized treatment effects. The model combines the flexibility of Bayesian hierarchical structures with the representational power of deep learning, enabling robust causal inference in complex observational settings.

Let Y_i denote the observed outcome for unit i, $T_i \in \{0,1\}$ the treatment indicator, and $X_i \in \mathrm{R}^p$ a high-dimensional vector of covariates. The potential outcomes framework defines two unobserved outcomes: $Y_i(1)$ and $Y_i(0)$, corresponding to the treatment and control scenarios, respectively. The observed outcome is:

$$Y_i = T_i Y_i(1) + (1 - T_i) Y_i(0). \quad (5)$$

The individual treatment effect (ITE) is:

$$\tau_i = Y_i(1) - Y_i(0). \quad (6)$$

To estimate τ_i, we propose a flexible outcome model:

$$Y_i = f(X_i) + \beta T_i + \varepsilon_i, \varepsilon_i \sim N(0, \sigma^2). \quad (7)$$

where $f(X_i)$ captures the complex, possibly nonlinear relationship between covariates and the outcome. β represents the average causal effect of treatment. ε_i is an error term with constant variance.

3.1 Prior Specification

We place the following priors on the model parameters:

Treatment Effect Prior:

$$\beta \sim N(0, \sigma_\beta^2).$$

Noise Variance Prior:

$$\sigma^2 \sim Inverse - Gamma(a_\sigma, b_\sigma).$$

Function Prior (Nonlinear Covariate Effects):
The function $f(X_i)$ is modeled using either:
Bayesian Additive Regression Trees (BART), where:

$$f(X_i) = \sum_{i=1}^{m} g(X_i; T_i) \quad (8)$$

with $g(\cdot)$ representing regression trees and priors placed on tree depth, splitting variables, and leaf parameters.
Or alternatively:
Bayesian Neural Network, where:

$$f(X_i) = \text{BNN}(X_i; \theta), \theta \sim N(0, \tau^2 \text{I}).$$

Hyperpriors:

We place weakly informative hyperpriors on variance components σ_β^2, τ^2, and others to allow the data to drive the posterior.

3.2 Posterior Inference

The posterior distribution is obtained via Bayes' theorem:

$$p(\beta, f, \sigma^2 \mid \{Y_i, T_i, X_i\}_{i=1}^n) \propto \prod_{i=1}^{n} p(Y_i \mid T_i, X_i, \beta, f, \sigma^2) \cdot p(\beta) \cdot p(f) \cdot p(\sigma^2).$$

Inference is performed using Hamiltonian Monte Carlo (HMC) or No-U-Turn Sampler (NUTS), allowing efficient exploration of the posterior distribution even in high-dimensional spaces.

This model enables personalized causal inference by generating posterior distributions of τ_i for each individual, which can be used to identify subgroups with heterogeneous treatment responses, prioritize interventions, or support decision-making under uncertainty.

4 SIMULATION STUDY

This section presents a simulation study to evaluate the performance of the proposed Bayesian high-dimensional causal inference model. The objective is to assess its accuracy in estimating individualized treatment effects (ITE) under various data complexities and compare it with competing methods.

The simulation is structured around synthetic data generation that mimics real-world scenarios involving nonlinear relationships, confounding covariates, and treatment effect heterogeneity. The results are evaluated using standard metrics such as Root Mean Squared Error (RMSE), bias, coverage probability, and posterior credible interval width.

We simulate data for n=500 individuals and p=100 covariates, where only a sparse subset of the covariates influences either the treatment assignment or the outcome. The data generation process follows:

- Covariates:

$$X_i \sim N_p(0, I_p).$$

- True treatment assignment model:

$$Pr(T_i = 1 \mid X_i) = logit^{-1}(X_i^\top \gamma),$$

where γ is sparse and only 10 nonzero entries are randomly selected.

- Potential outcomes:

$$Y_i(0) = f_0(X_i) + \varepsilon_i, Y_i(1) = Y_i(0) + \tau_i,$$

where:

$$f_0(X_i) = sin\,(X_{i1}) + X_{i2}^2 - log\,(\mid X_{i3} \mid +1),$$
$$\varepsilon_i \sim N(0,1),$$
$$\tau_i = 2 + 0.5 \cdot X_{i4}.$$

- Observed data:

$$Y_i = T_i Y_i(1) + (1 - T_i) Y_i(0). \quad (9)$$

We compare the proposed model against the following:

1) Bayesian LASSO Regression;
2) Bayesian Causal Forest (BCF);
3) Bayesian Additive Regression Trees (BART);
4) Causal Effect Variational Autoencoder (CEVAE).

All models are implemented using standard R libraries, and each method is tuned using default or recommended hyperparameters.

The models are evaluated across 100 simulation replications using the following metrics:

Root Mean Squared Error (RMSE):

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (\hat{\tau}_i - \tau_i)^2}. \quad (10)$$

Bias:

$$Bias = \frac{1}{n} \sum_{i=1}^{n} (\hat{\tau}_i - \tau_i). \quad (11)$$

Coverage Probability. Proportion of true τ_i values contained in the 95% credible intervals.
Interval Width. Average width of posterior 95% credible intervals for τ_i.

Table 1 shows that the proposed model achieves the lowest RMSE and bias while maintaining near-nominal coverage. The Bayesian LASSO underperforms due to its linearity assumption and inability to model treatment heterogeneity. BCF and BART perform well, though slightly worse than the proposed model in terms of RMSE. CEVAE is

competitive but exhibits higher variability due to latent representation learning.

Table 1: ITE estimation results in simulation study.

Model	RMSE	Bias	Coverage (%)	Interval Width
Proposed Bayesian Model	0.54	0.03	94.8	1.21
Bayesian LASSO	0.72	0.12	89.3	0.96
BCF	0.60	0.05	93.2	1.10
BART	0.63	0.08	92.7	1.08
CEVAE	0.68	0.10	91.1	1.16

5 REAL DATA ANALYSIS

This section applies the proposed Bayesian high-dimensional causal inference model to a real-world dataset to demonstrate its practical utility in estimating individualized treatment effects (ITE). We use the Infant Health and Development Program (IHDP) dataset, a benchmark dataset widely adopted in causal inference research due to its realistic structure, treatment heterogeneity, and known ground truth.

The IHDP dataset is a semi-synthetic dataset derived from a randomized controlled trial designed to evaluate the impact of early childhood interventions on low-birth-weight infants. The observed data have been modified by removing a non-random subset of treated individuals, introducing selection bias and making it suitable for testing causal inference methods. Number of samples: 747 (treated: 139, control: 608). Number of covariates: 25. Covariate types: Continuous and categorical (e.g., birth weight, mother's age, education, race)

Each sample includes, Treatment assignment $T_i \in \{0,1\}$. Covariates $X_i \in R^{25}$. Two potential outcomes $Y_i(1), Y_i(0)$ (available only in simulated version). Observed outcome $Y_i = T_i Y_i(1) + (1 - T_i) Y_i(0)$.

We applied the following models for comparison, Proposed Bayesian Neural Causal Model. Bayesian Causal Forest (BCF). Bayesian Additive Regression Trees (BART). Bayesian LASSO. Causal Effect Variational Autoencoder (CEVAE). All models were trained to estimate the Individual Treatment Effect (ITE), and their performance was evaluated using the ground-truth potential outcomes $Y_i(1), Y_i(0)$.The same metrics as in the simulation study were used, Root Mean Squared Error (RMSE), Bias, Coverage Probability (95% credible intervals), Interval Width.

Table 2: Summarizes the performance of each method on the IHDP dataset over 20 repeated runs.

Model	RMSE	Bias	Coverage (%)	Interval Width
Proposed Bayesian Model	0.48	0.02	94.5	1.17
Bayesian LASSO	0.65	0.09	89.0	0.91
BCF	0.52	0.04	93.8	1.12
BART	0.56	0.06	92.9	1.09
CEVAE	0.60	0.08	91.2	1.15

Table 2 demonstrates that the proposed model outperforms the benchmarks in RMSE and bias while maintaining excellent coverage. The improvements are more pronounced compared to linear Bayesian LASSO, which struggles with treatment effect heterogeneity. BCF and BART perform well, indicating the strength of tree-based models in nonparametric regression. CEVAE captures nonlinearities but exhibits slightly higher error due to latent confounder estimation.

The results confirm the effectiveness of combining high-dimensional Bayesian inference with flexible machine learning models in causal effect estimation. The model not only provides accurate point estimates but also produces reliable uncertainty quantification through credible intervals.

6 CONCLUSIONS

This study presents a comprehensive framework for Bayesian causal inference in high-dimensional settings by integrating probabilistic modeling with machine learning techniques. Through theoretical development, simulation, and real data analysis, the proposed model demonstrates superior accuracy in estimating individualized treatment effects (ITE) while maintaining robust uncertainty quantification.

In the simulation study, the proposed Bayesian model consistently achieved lower Root Mean Squared Error (RMSE) and bias compared to benchmark methods, including Bayesian LASSO, BART, BCF, and CEVAE. It also maintained near-nominal coverage probabilities, indicating well-calibrated credible intervals. These advantages held across multiple data-generating scenarios involving treatment effect heterogeneity and nonlinear relationships.

The real data application using the IHDP dataset further validated the model's effectiveness in practical contexts. The model exhibited the best

predictive accuracy and smallest bias among the methods considered, while also providing informative posterior distributions for treatment effects. This highlights the value of combining Bayesian inference with flexible function approximators such as neural networks and regression trees in causal analysis.

Overall, the findings support the proposed model as a powerful and interpretable tool for estimating causal effects in high-dimensional observational data. Its ability to incorporate prior knowledge, handle nonlinearities, and deliver uncertainty-aware estimates makes it suitable for applications in health sciences, social policy, and other domains where individualized decision-making is essential.

Keywords: Partial Linear Single-Index Model, Longitudinal Data, Long Short-Term Memory, Local Polynomial, Semiparametric, Deep Neural Networks.

Abstract: This paper investigates and compares the performance of two estimation approaches - Long Short-Term Memory (LSTM) networks and the semi-parametric Minimum Average Variance Estimation (SMAVE) method - for the Partial Linear Single Index Model (PLSIM) in the context of longitudinal data. The PLSIM combines linear and nonlinear components, offering modeling flexibility for complex data structures often encountered in repeated measurements. We conduct extensive simulations with varying sample sizes (N = 50, 100, 150) to evaluate the prediction accuracy of both methods in estimating the unknown link function. Evaluation metrics such as Mean Squared Error (MSE), bias, and coefficient of determination (R^2) are used to assess estimation quality. Results show that LSTM significantly outperforms SMAVE in estimating both the linear parameters and the nonlinear link function. The LSTM method consistently achieves lower MSE and bias values, as well as higher R^2 scores for both the model and the nonlinear function, highlighting its superior ability to capture temporal dependencies and complex nonlinear relationships in longitudinal data. In contrast, SMAVE's performance is more sensitive to bandwidth selection and sample size. These findings suggest that deep learning models like LSTM offer a powerful alternative to traditional semi-parametric methods in longitudinal data analysis.

1 INTRODUCTION

Longitudinal data, also known as panel data, are a common statistical tool in many applied fields, such as economics, medicine, epidemiological studies, and clinical trials. These data are characterized by the fact that they involve repeated measurements of the same experimental units (such as individuals) across different time periods. This distinguishes them from cross-sectional data, which assumes that observations are independent and non-repeated. The correlation between measurements within each individual unit is an essential property of longitudinal data; these measurements are considered to be correlated over time, whereas measurements between different individuals are typically treated as independent.

Given this complex correlational structure, analyzing longitudinal data requires specialized statistical models that account for this temporal correlation. Statistical methods used to analyze regression models with longitudinal data typically fall into three main categories, differing in their assumptions about the relationship between observations within each unit and between different units. In recent years, semiparametric models have gained widespread attention due to their flexibility in incorporating both parametric and non-parametric components within the same model, enhancing its explanatory and predictive power. These models are particularly suitable for analyzing longitudinal data, despite the challenges they pose at the estimation level, particularly when dealing with the non-parametric component [1].

Among semiparametric models, the Partially Linear Single-Index Model (PLSIM) is a flexible framework that combines the advantages of linear models and non-linear structures. It allows for the representation of complex relationships between variables while maintaining relative mathematical simplicity. This model has gained increasing attention in many economic, medical, and social applications due to its ability to balance interpretability with estimation flexibility [2].

Although previous research has examined the model for independent data, generalizing this model to longitudinal data remains a fertile area of research,

given the complexity of the temporal structure and the internal correlation between observations. Several studies have focused on developing efficient estimation methods for the parametric and nonparametric components of the model in this context. [3] addressed estimation and testing for independent variables, while [4] proposed efficient semiparametric least squares estimators using profile estimation. Some studies, such as, relied on simplified mathematical methods to calculate semiparametric information limits.

On the other hand, some studies, such as [5] and [6], addressed the generalization of the PLSIM model to longitudinal data, focusing on the challenges associated with estimating model parameters and the correlation function. [7] proposed a unified method using generalized estimating equations (GEE) to analyze imbalanced longitudinal data, whether dense or sparse. The results showed that the rates of convergence and asymptomatic variances of the estimators varied depending on the data structure. However, these estimators were not efficient in the semiparametric sense.

In this work, we present a new estimation method based on Long-Short-Term Memory (LSTM) deep neural networks to estimate the link function in a PLSIM model for longitudinal data. The proposed method was compared with the semi-parametric estimation method known as Minimum Average Variance Estimation (MAVE). Simulation results showed that the LSTM-based method outperforms the estimation accuracy, especially in representing complex nonlinear relationships between variables.

Based on the above, this research aims to develop an advanced estimation framework for the partial linear single-index model (PLSIM) in the context of longitudinal data. This approach employs deep learning techniques, specifically LSTM neural networks, to improve the estimation of the nonlinear component (link function) and effectively address temporal correlation within individuals. This approach represents a paradigm shift in longitudinal data modeling, as it combines the theoretical foundations of semi-parametric models with the high predictive capabilities provided by machine learning algorithms. The research focuses on comparing the experimental performance of the proposed method with conventional methods in terms of estimation accuracy, parameter efficiency, and convergence speed, using extensive simulation experiments covering a variety of scenarios in terms of data density and the number of iterations per unit. This methodology is expected to enhance our understanding of the dynamic relationships between variables in longitudinal data and pave the way for more accurate and flexible applications in various applied fields

2 MODEL AND METHOD ESTIMATION

2.1 Model

The partial linear single-index model in longitudinal data is written in the form [8]:

$$Y_{it} = Z_{it}^T\theta + g(X_{it}^T\beta) + \varepsilon_{it}\ , \quad i = 1, \dots, N\ , t = 1, \dots, T. \tag{1}$$

Where Y_{it} represents the response variable of individual i at time t, X_{it} and Z_{it} are explanatory variables of the linear and non-linear parts, respectively, with dimensions R^q and R^p, (θ, β) are unknown the parameter vectors of the variables to be estimated with dimension $R^q$and R^p, $\| \beta \| = 1$ ($\|\cdot\|$ representing the Euclidean Norm), and the first element must be positive. $g(\cdot)$ is an unknown link function and ε_{it} are random error and $E(\varepsilon_{it} \setminus X_{it}, Z_{it}) = 0$

2.2 Methods Estimation

In this section, the estimation methodologies used to estimate the parameters of a partial single-indicator model in the context of longitudinal data will be presented and detailed. Two different estimation methods have been adopted, representing two methodological approaches that differ in their philosophy and mathematical foundation:

The first method relies on deep neural networks of the LSTM type, a deep learning algorithm specifically designed for processing time-series data. This method is particularly suitable for analyzing longitudinal data due to its ability to capture temporal dynamics and internal correlations between measurements across time.

The second method is MAVE method, a classical statistical technique that aims to estimate a nonlinear link function and trend indicator in a way that minimizes the mean variance within a semiparametric framework. It is a standard reference for this type of model.

The purpose of employing these two approaches is to conduct a systematic comparison between traditional methods, which rely on rigorous statistical foundations, and modern methods, which are based on machine learning techniques. The comparison

focuses on estimation accuracy, parameter efficiency, and the ability to capture the complex structure of longitudinal data. In the following paragraphs, each method will be presented in detail, outlining the estimation steps, required conditions, and the theoretical basis on which it is built.

2.2.1 Long Short-Term Memory

The LSTM neural network is an advanced model in the field of recurrent neural networks. It differs from a traditional recurrent network (RNN) in that the hidden unit contains a memory cell instead of a traditional node. The memory cell provides a sophisticated mechanism for transferring information across time through a series of operations that allow the model to selectively retain or forget information, helping to overcome the problems of vanishing/exploding gradients.

The cell state (c_t) is a key component within an LSTM cell, acting as a conduit for information transfer across time. Gates are used to control the flow of information into or out of the cell, based on the resulting value of sigmoid activation functions. When values approach zero, information is blocked, while information is passed through if values approach one. In this way, the LSTM can determine which information to retain or forget at each time step, maintaining the model's long-term effectiveness.

Below is a breakdown of the basic components of an LSTM module along with their associated equations:

1) Input node (Candidate Cell State). This node, known as $\tilde{c}_t$, represents the new candidate cell state. It is calculated by summing the current input x_t and the previous hidden state h_{t-1} using the tanh activation function.

$$\tilde{c}_t = \emptyset(W_{\tilde{c}x}x_t + W_{\tilde{c}h}h_{t-1} + b_{\tilde{c}}). \quad (2)$$

Where:

- $\emptyset()$ stands for an element-wise application of the $\tan h$ function;
- $W_{\tilde{c}x}$ is the input weights matrix;
- $W_{\tilde{c}h}$ is the hidden weights matrix.

2) Input Gate. This gate is a unique element of the LSTM architecture, controlling the amount of new information that will be input into the cell state. It is calculated as follows:

$$i_t = \sigma(W_{ix}x_t + W_{ih}h_{t-1} + b_i). \quad (3)$$

Where:

- $\sigma()$ represents a sigmoid function applied to each element. The resulting value ranges from 0 (unimportant information) to 1 (important information)
- $W_{ix}$is the input weights matrix
- $W_{ih}$is the hidden weights matrix.

3) Forget Gate. This gate controls whether information from the cell's previous state is retained or not. It is calculated using the equation:

$$f_t = \sigma\big(W_{fx}x_t + W_{fh}h_{t-1} + b_f\big). \quad (4)$$

It regulates the flow of information from the previous internal state c_{t-1}, W_{fx} is the input weights matrix, W_{fh} is the hidden weights matrix.

4) Internal Cell State. c_t represents the updated state of the cell, and is calculated by taking the Hadamard product between the forget gate and the previous state, then adding the product between the input gate and the new candidate state:

$$c_t = f_t \odot c_{t-1} + i_t \odot \tilde{c}_t. \quad (5)$$

Where $\odot$ represents the Hadamard product, i.e. the product between any two elements of the same position.

5) Output Gate. This gate determines whether the information stored in the cell will be used to update the current hidden state. The output gate is first calculated:

$$o_t = \sigma(W_{ox}x_t + W_{oh}h_{t-1} + b_0),$$
$$h_t = \emptyset(c_t) \odot o_t. \quad (6)$$

Together, these components form the architecture of an LSTM cell, enabling the model to learn from long-term temporal dependencies, making it suitable for analyzing longitudinal or sequential data see [9] and [10] that involve complex, nonlinear temporal relationships.

2.2.2 Semiparametric Minimum Average Variance Estimation (SMAVE)

Xia et al. proposed [11] an estimation method known as MAVE, which provides a general framework for estimating partial single-index models. This method relies on the joint estimation of the coefficient vector β and the nonlinear function g(·) within a single-index model. It is considered a distinctive approach due to its ease of implementation compared to traditional methods and its ability to deliver efficient numerical solutions through a local linear approximation of the nonparametric function.

Subsequently, [5] and [12] extended this methodology to longitudinal data by explicitly accounting for temporal correlations within each observational unit.

The estimation objective is formulated by solving the following problem:

$$(\beta,\theta) = \underset{\beta,\theta}{\operatorname{argmin}} E[Y_{it} - g(X_{it}^T\theta) - Z_{it}^T\beta]^2. \quad (7)$$

Let $Y = (Y_{11},\dots,Y_{1T},\dots,Y_{NT})^T$,
$Z = (Z_{11},\dots,Z_{1T},\dots,Z_{NT})^T$,$X = (X_{11},\dots,X_{1T},\dots,X_{NT})^T$,$\varepsilon = (\varepsilon_{11},\dots,\varepsilon_{1T},\dots,\varepsilon_{NT})^T$
$g(X,\theta) = (g(X_{11}^T\theta),\dots,g(X_{1T}^T\theta),\dots,g(X_{NT}^T\theta))$
$X_{it}(\theta) = ((X_{11} - X_{it})^T\theta,\dots,(X_{1T} - X_{it})^T\theta,\dots,((X_{NT} - X_{it})^T\theta)^T.$

The model (1) can be rewritten as

$$Y = g(X,\theta) + Z\beta + \varepsilon.$$

A local linear approximation is adopted using the derivative of η as follows:

$$g(X_{it}^T\theta) \approx g(X^T\theta) + \acute{g}(X^T\theta)(X_{it} - x)^T\theta.$$

It symbolizes: $a_{it} = g(X^T\theta), b_{it} = \acute{g}(X^T\theta)$
The parameters are estimated by solving the following problem:

$$\sum_{i=1}^{N}\sum_{t=1}^{T}[Y - Z\beta - (e_{NT}, X_{it}(\theta))(a_{it}, b_{it})^T]^T \times M_{it}[Y - Z\beta - (e_{NT}, X_{it}(\theta))(a_{it}, b_{it})'], \quad (8)$$

where: $M_{it} = diag(m_{11,it},\dots,m_{11,it},\dots,m_{11,it})$.

It is a diagonal matrix containing the kernel weights, and it achieves: $\sum_{j=1}^{N}\sum_{s=1}^{T} m_{js,it} = 1$ and e_{NT} is a *NT*-dimensional vector with all elements being 1 The estimation is performed using an iterative algorithm consisting of the following steps:

1) Local estimation of non-parametric coefficients
2) $(a_{it}, b_{it})^T = \left(\bar{X}_{it,*}^T(\theta)M_{it}\bar{X}_{it,*}^T(\theta)\right)^{-1}\bar{X}_{it,*}^T(\theta)M_{it}(Y_{it} - Z_{it}\beta)$.
   Where $\bar{X}_{it,*}^T(\theta) = \left(e_{NT}, X_{it}(\theta)\right)$.
3) Update β and θ:
$$(\beta^T,\theta^T)^T = \begin{pmatrix} Z_*^T M Z_* & Z_*^T M X_* \\ X_*^T M Z_* & X_*^T M Z_* \end{pmatrix}^{-1}\begin{pmatrix} Z_*^T \\ X_*^T \end{pmatrix} M(Y_* - A_*).$$

Where: $Y_* = (Y_{11,*}^T,\dots,Y_{1T,*}^T,\dots,Y_{NT,*}^T)^T$,
$X_* = (b_{11}X_{11,*}^T,\dots,b_{1T}X_{1T,*}^T,\dots,b_{NT}X_{NT,*}^T)^T$,
$X_{it,*} = (X_{11} - X_{it},\dots,X_{1T} - X_{it},\dots,X_{NT} - X_{it})^T$,
$Z_* = (Z_{11,*}^T,\dots,Z_{1T,*}^T,\dots,Z_{NT,*}^T)^T$,
$M = diag(M_{11},\dots,M_{1T},\dots,M_{NT})$,
$A = (a_{11}e_{NT}^T,\dots,a_{1T}e_{NT}^T,\dots,a_{NT}e_{NT}^T)^T$.

4) Iteration until convergence Steps 1 and 2 are repeated using the updated values of β and θ until numerical convergence is achieved.

Two sets of weights are used in the iterative procedure (multivariate weights):

$$w_{js,it} = \frac{H((X_{js} - X_{it})/h_1)}{\sum_{j=1}^{N}\sum_{s=1}^{T}H((X_{js} - X_{it})/h_1)}.$$

Where $H(\cdot)$ is a p-variate symmetric kernel function and h_1 is a bandwidth, single-index weights:

$$w_{js,it}^{\theta} = \frac{K(\left(X_{js} - X_{it}\right)^T\theta/h_2)}{\sum_{j=1}^{N}\sum_{s=1}^{T}K(\left(X_{js} - X_{it}\right)^T\theta/h_2)}.$$

Where $K(\cdot)$ a univariate symmetric kernel is function and h_2 is a bandwidth. Then, we can obtain the final estimators $\hat{\beta}$ and $\hat{\theta}$ by using $\tilde{\beta}$ and $\tilde{\theta}$ and the above iterations with the single-index weights. By substituting β,θ and $X_{it}^T\theta_0$ with $\hat{\beta},\hat{\theta}$ and u, we can get the estimator of $g(u)$, which is denoted by $\hat{g}(u)$.

3 EVALUATION METRICS

Comparing estimation methods is a fundamental procedure in statistical research to identify the most appropriate techniques. Various evaluation metrics exist - some designed to compare parameter estimates, while others assess the overall model performance. In general, the choice of appropriate metrics depends on the nature of the data and the objectives of the statistical analysis. In this paper, the following evaluation metrics will be employed:

$$MSE = \frac{\sum_{i=1}^{N}\sum_{t=1}^{T}\left(Y_{it} - \hat{Y}_{it}\right)^2}{N * T}.$$

$$R^2 = 1 - \frac{\sum_{i=1}^{N}\sum_{t=1}^{T}\left(Y_{it} - \hat{Y}_{it}\right)^2}{\sum_{i=1}^{N}\sum_{t=1}^{T}\left(Y_{it} - \hat{Y}_{it}\right)^2}.$$

$$MSE(g(u)) = \frac{\sum_{i=1}^{N}\sum_{t=1}^{T}(g(X_{it}^T\beta) - \hat{g}(X_{it}^T\beta))^2}{N * T}.$$

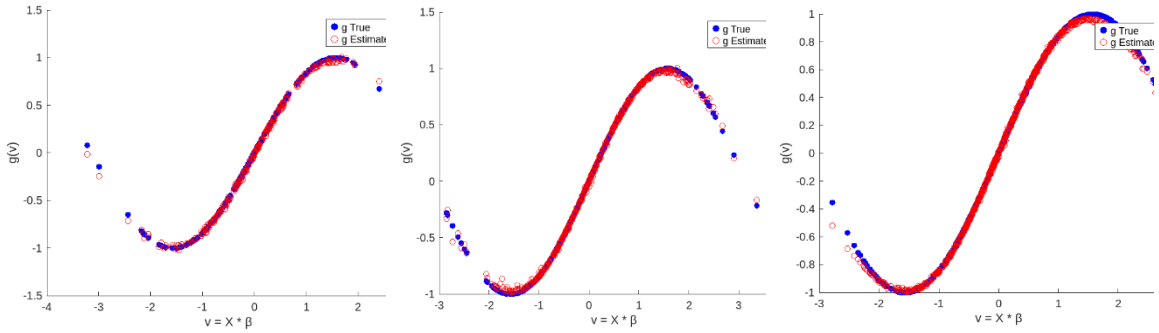
$$R^2(g(u)) = 1 - \frac{\sum_{i=1}^{N}\sum_{t=1}^{T}(g(X_{it}^T\beta) - \hat{g}(X_{it}^T\beta))^2}{N * T}.$$

4 SIMULATION

In this simulation paper, we generate synthetic longitudinal data to evaluate estimation methods for the Partial Linear Single Index Model (PLSIM). The data consists of N = 50,100,150 subjects, each measured at T = 5 time points, resulting in NT total observations. The covariate vectors X (predictors for

the nonparametric component) and Z (predictors for the linear component) are simulated from standard normal distributions.

The true parameter vectors are defined as: $\beta = \frac{1}{\sqrt{3}}[1, -1, 1]^T$ normalized to unit norm, representing the direction for the single index $X_{it}^T\beta$ $\theta = [0.5, -0.8]^T$, corresponding to the coefficients in the linear part $Z_{it}^T\theta$ The nonlinear link function is defined as $g(u) = \sin(u)$ which operates on the single index $u = X_{it}^T\beta$ The response variable Y_{it} is generated



$$Y_{it} = Z_{it}^T\theta + g(X_{it}^T\beta) + \varepsilon_{it}\,.$$

The error term ε_{it} is generated to follow an AR(1) structure within each subject to induce temporal correlation Specifically:

- $\varepsilon_{i1} \sim N(0, \sigma^2)$, and for $t > 1$: $\varepsilon_i t = \rho * \varepsilon_i(t-1) + \eta_i t$, where $\eta_i t \sim N(0, \sigma^2)$.
- The parameters are set to $\sigma = 0.3\ and\ \rho = 0.3$.

Figure 2: Scatter diagram of true link function and estimated link function using SMAVE estimation method.

To evaluate the model's performance more accurately and to ensure measuring its generalization ability rather than relying solely on the training data performance, the total sample was divided into two subsets: a training set and a testing set. Specifically, 70% of the individuals were allocated for training, while the remaining 30% were reserved for testing. The LSTM model was trained exclusively on the training set, whereas the testing set was used to evaluate the model and calculate the performance metrics.

The estimates for the linear parameters θ_1 and θ_2. The mean squared error (MSE) for the parameters θ is very low across all sizes, and in some cases reaches values very close to zero, indicating a good ability of the model to recover the linear parameters. The bias is also small (<0.02), which enhances the reliability of the estimate (Table 1).

Estimates of the indicator vector β at N=150 show a significant improvement in the estimate, with the MSE and bias being relatively smaller compared to smaller values, especially for the parameters β_2 and β_3. In contrast, at N=50, the bias is relatively larger for some components (e.g., β_2), an expected behavior with a small sample size.

The mean square error of the estimate of the nonlinear function $g(\cdot)$ is very low (<0.001), reflecting a high accuracy in representing the nonlinear relationship. The relationship between the true and estimated link functions obtained using the LSTM method is illustrated in Figure 1.

The determined coefficient R^2 for the estimate of $g(\cdot)$ is close to 1 (approximately 0.999), demonstrating excellent estimation quality in all cases. Goodness of fit of the overall model the mean squared error of the full model decreases with increasing sample size (from 0.123 at N=100 to 0.1009 at N=150). R^2 for the full model increases slightly with increasing sample size, reaching about 0.927 at N=150, indicating a high fit.

The three graphs show a comparison between the true values of the nonlinear function $g(u)$ (blue dots) and the estimated values (red circles) across different sample sizes N=50, 100, and 150 (Fig. 1). The following observations can be drawn: At all three sample sizes, the estimate appears to agree very closely with the true shape of the function, with clear convergence between the blue dots and red circles. As the sample size increases (from 50 to 150), the dispersion around the true curve decreases, and the estimated values become smoother and more stable. This reflects the improved accuracy with increasing sample size, which is theoretically expected in semiparametric estimation.

The results indicate that the estimation of the linear coefficients (θ_1, θ_2) has a high degree of accuracy, as the mean deviation (Bias) and mean squared error (MSE) values remained relatively low across all sample sizes (Table 2). In contrast, the single-index coefficients $(\beta_1, \beta_2, \beta_3)$ recorded high bias, especially for the smaller sample (N=50). The bias for β_1, β_2 reached 0.4257 and 0.2013, respectively, with MSEs of 0.1812 and 0.04054, reflecting poor estimation accuracy in the nonlinear part of the model. The estimation results of the function $g(\cdot)$ also showed inconsistent performance, with the highest MSE recorded at N=100, at 0.1347, despite a low bias (0.0042), which may indicate fluctuations in the estimate resulting from the nature of the function or the sample size. As for the quality of the model as a whole, the performance indicators showed that the model's coefficient of determination (R^2 MODEL) gradually decreased from 0.8519 at N=150 to 0.8301 at N=50. Meanwhile, the accuracy of the representation of the function $g(\cdot)$ was significantly lower, with its R^2 reaching 0.6980 at N=50, demonstrating the superiority of the deep neural network method used in estimating the link function.

For the three plots in all three sizes, the estimate appears to be inconsistent with the true form of the function, indicating the difficulty of smoothing methods in interpreting the relationship for a nonlinear function (Fig. 2).

5 CONCLUSIONS

Comparison results between LSTM and SMAVE estimation methods on a Partial Linear Single Index Model (PLSIM) for longitudinal data showed a clear superiority of LSTM in terms of the accuracy of estimating linear and nonlinear parameters and the stability of results across different sample sizes. LSTM recorded very low MSE and deviation values in estimating the parameters θ and β, and demonstrated excellent performance in estimating the nonlinear function $g(\cdot)$ with R^2 values exceeding 0.99, reflecting its ability to capture complex relationships in longitudinal data. In contrast, SMAVE showed less accurate results, particularly in estimating the parameters β and the function $g(\cdot)$, where the MSE and Bias values were relatively high, especially at small sample sizes, indicating that it is affected by the choice of bootstrap parameters and the difficulty of estimation with limited samples. LSTM also outperformed in overall model quality, achieving the highest R^2 for the model, demonstrating a better fit to the data and superior prediction, while SMAVE was less stable and performed less well. Thus, these results demonstrate that LSTM represents a more efficient and accurate option for analyzing and estimating PLSIM models with longitudinal data compared to traditional semiparametric methods.

Keywords: Alpha Power Fréchet. Power Alpha, Reliability, Maximum Likelihood, Genetic Algorithm.

Abstract: Studying failure data requires a flexible distribution to interpret the probabilistic behavior of these data. Therefore, the reliability function of the Alpha–Power Fréchet (APF) distribution was used to study the failure data. The Alpha power transformation was applied to the classical Fréchet distribution to develop a more flexible model capable of handling heterogeneous datasets. The probability density function, cumulative distribution function, and the corresponding reliability function for the APF distribution were derived. The maximum likelihood method and the genetic algorithm were used to estimate the reliability function of the Alpha–Power Fréchet distribution. A simulation study was conducted with various sample sizes (ranging from n=15 to n=500) and multiple different parameter combinations to evaluate the performance of both estimators. The comparison was based on the Mean Squared Error (MSE) criterion. The results revealed that the maximum likelihood method (MLE) showed a decrease in MSE values directly proportional to the increase in sample size, confirming its consistency and superior accuracy for large samples. Meanwhile, the genetic algorithm (GA) showed a robust performance that outperformed the maximum likelihood method for small and medium samples, making it a viable alternative in such cases, despite a noted tendency to slightly overestimate the reliability value.

1 INTRODUCTION

The Fréchet distribution is one of the most important distributions in the exponential family, and it can be used to describe the probabilistic behavior of data containing outliers or extreme values. This distribution is often used in the fields of hydrology, meteorology, finance, and engineering to characterize rare events. It is known as the inverse of the Weibull distribution, and is also known as the extreme value distribution of the second kind. It is used to model the maximum (or minimum) distribution of a large set of identically distributed independent random variables. The probability density function of the Fréchet distribution [1] is

$$\mathrm{f}(\mathrm{x},\beta,\lambda) = \frac{\lambda}{\beta}\left(\frac{x}{\beta}\right)^{-(\lambda+1)} e^{-\left(\frac{x}{\beta}\right)^{-\lambda}}, \; x > 0. \quad (1)$$

The distribution function is

$$F(x,\beta,\lambda) = e^{-\left(\frac{x}{\beta}\right)^{-\lambda}}. \quad (2)$$

The problem of the study was to search for probability distributions that can describe the random behavior of failure data of devices and equipment, which includes heterogeneous data, by finding flexible distributions that are found by searching for ways to expand traditional distributions. The problem of the study was also to search for accurate estimation methods to estimate the reliability function of expanded distributions in light of the development of computer programming languages such as the Python programming language. This study aims to compare two types of estimation methods: parametric estimation methods, represented by maximum likelihood, and artificial intelligence methods.

2 ALPHA FRÉCHET POWER DISTRIBUTION

The alpha Fréchet power distribution was proposed by finding an expansion of the Fréchet distribution and applying the formula below [2].

$$f_{APT}(x) = \frac{\log(\alpha)}{\alpha - 1} f(x)\alpha^{F(x)}, \alpha > 0, \alpha \neq 1. \quad (3)$$

If f(x) represents the density function of the distribution to be expanded, F(x) represents the cumulative function of the distribution, then by substituting (1) and (2) into (3), the probability density function of the Fréchet alpha power distribution is obtained, as shown in the equation:

$$f_{APT}(x) = \frac{\log(\alpha)}{\alpha - 1} \frac{\lambda}{\beta} \left(\frac{x}{\beta}\right)^{-(\lambda+1)} e^{-\left(\frac{x}{\beta}\right)^{-\lambda}} \alpha^{e^{-\left(\frac{x}{\beta}\right)^{-\lambda}}}, \quad (4)$$

$$\alpha > 0, \alpha \neq 1.$$

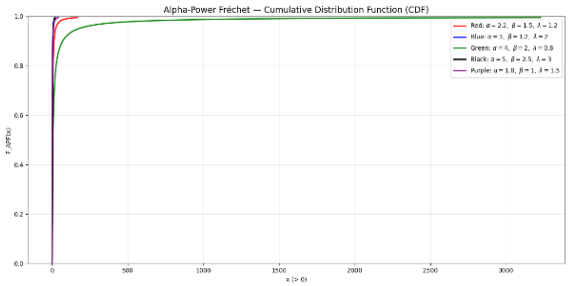

Figure 1: The figure represents the probability density function of the Alpha Power Fréchet distribution.

To obtain the cumulative function of the proposed distribution, we can apply the expansion equation for the cumulative function with the power of alpha (5):

$$F_{APT}(x) = \frac{\alpha^{F(x)} - 1}{\alpha - 1}, \alpha > 0, \alpha \neq 1. \quad (5)$$

After applying the expansion and using the cumulative function of the original distribution, the cumulative function of the proposed distribution is obtained.

$$F_{APT}(x) = \frac{\alpha^{e^{-\left(\frac{x}{\beta}\right)^{-\lambda}}} - 1}{\alpha - 1}, \alpha > 0, \alpha \neq 1. \quad (6)$$

The reliability function for the alpha power distribution is [3].

$$R_{APT}(x) = 1 - F_{APT}(x).$$

$$R_{APT}(x) = 1 - \frac{\alpha^{e^{-\left(\frac{x}{\beta}\right)^{-\lambda}}} - 1}{\alpha - 1}. \quad (7)$$

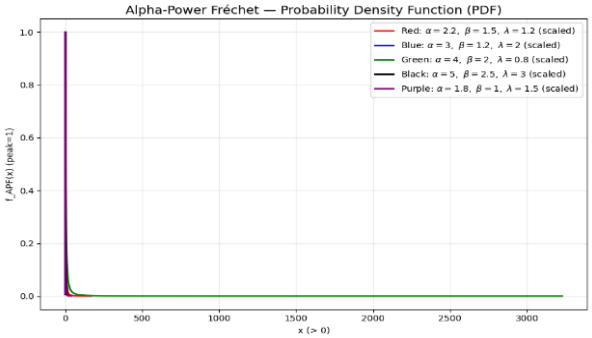

Figure 2: The figure represents the cumulative function of the Alpha Power Fréchet distribution.

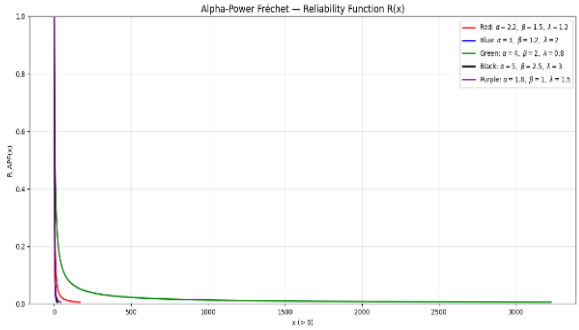

Figure 3: The figure represents the Reliabilityfunction of the Alpha Power Fréchet distribution.

3 ESTIMATING THE FRÉCHET ALPHA POWER DISTRIBUTION

The parameters and the reliability function of the Fréchet alpha power distribution were estimated using two methods: the maximum likelihood method and the genetic algorithm method, where the function was taken.

3.1 Estimation by the Maximum Likelihood Method

This method is one of the most common and widely used estimation methods among researchers, as it produces estimators that possess the characteristics of a good estimator, such as unbiasedness, stability [4], and consistency. This method estimates the parameters by maximizing the logarithm of the maximum likelihood function.

The equation below represents the logarithm of the maximum likelihood function for the Fréchet alpha power distribution [5], [6].

$$L(\theta) = \prod_{i=1}^{n} f(x_i;\theta), \quad (8)$$

$$L(\theta) = \prod_{i=1}^{n}\left(\frac{ln(\alpha)}{\alpha-1}\frac{\lambda}{\beta}\left(\frac{x_i}{\beta}\right)^{-(\lambda+1)} e^{-\left(\frac{x_i}{\beta}\right)^{-\lambda}} \alpha^{e^{-\left(\frac{x_i}{\beta}\right)^{-\lambda}}}\right), \quad (9)$$

$$L(\theta) = \left(\frac{l\,n(\alpha)}{\alpha-1}\right)^{n}\left(\frac{\lambda}{\beta}\right)^{n} \cdot \left(\sum_{i=1}^{n}\left(\frac{x_i}{\beta}\right)^{-(\lambda+1)} e^{\sum_{i=1}^{n}\left(\frac{x_i}{\beta}\right)^{-\lambda}} \alpha^{e^{\sum_{i=1}^{n}\left(\frac{x_i}{\beta}\right)^{-\lambda}}}\right). \quad (10)$$

Taking the natural logarithm of the function factorial

$$\begin{aligned} log(L(\theta)) = \\ = n\,ln(ln(\alpha)) - n * ln(\alpha-1) + n\,ln(\lambda) - n \\ * ln(\beta) - (\lambda+1)\,ln\left(\sum_{i=1}^{n}\frac{x_i}{\beta}\right) \\ + \sum_{i=1}^{n}\left(\frac{x_i}{\beta}\right)^{-\lambda} \\ + ln(\alpha)\,e^{-\left(\sum_{i=1}^{n}\left(\frac{x_i}{\beta}\right)^{-\lambda}\right)}. \end{aligned} \quad (11)$$

To obtain the estimators of the parameters of the probability density function for the alpha-force distribution (α, β, λ), the partial derivative of the logarithm of the probability function is taken as follows [7]:

$$\frac{\partial \mathcal{L}}{\partial \alpha} = \frac{\mathrm{n} - \mathrm{n}\alpha - \sum \mathrm{e}^{-\left(\frac{\mathrm{x_i}}{\beta}\right)^{-\lambda}}}{\alpha}, \quad (12)$$

$$\frac{\partial \mathcal{L}}{\partial \beta} = \frac{\lambda}{\beta}\left(\frac{x_i}{\beta}\right)^{-\lambda} + \frac{\lambda \mathrm{l\,n}(\alpha)}{\beta}\sum\left(\left(\frac{x_i}{\beta}\right)^{(-\lambda)} e^{-\left(\frac{x_i}{\beta}\right)^{-\lambda}}\right) - \frac{n(\beta-\lambda-1)}{\beta}, \quad (13)$$

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial \lambda} = \\ = n - \left(\frac{x_i}{\beta}\right)^{-\lambda} \mathrm{l\,n}\left(\frac{x_i}{\beta}\right) - \sum\left(\mathrm{l\,n}\left(\frac{x_i}{\beta}\right)\right) \\ - \mathrm{l\,n}(\alpha)\sum\left(\left(\frac{x_i}{\beta}\right)^{-\lambda} \mathrm{l\,n}\left(\frac{x_i}{\beta}\right) \mathrm{e}^{\left(-\left(\frac{x_i}{\beta}\right)^{-\lambda}\right)}\right). \end{aligned} \quad (14)$$

3.2 Estimation Using the Genetic Algorithm

The genetic algorithm is described as a heuristic method that simulates the idea of adapting to complex data and equations [8]. Its philosophy is based on the fact that, instead of relying on a single solution, a community of hypotheses is built, and these mechanisms compete through selection [9], mating, and mutation. With this approach, randomness is systematically used not only to break the stability of the results, but also to open new paths in the solution space and avoid falling into weak local optimization. The success of the GA also depends on the quality of the coding and the suitability of the fitness function to the statistical objective [10]. The problem is formulated by estimating the parameters of the APF distribution, i.e.,θ = (α, β, λ), through a positive simulation sample x_1, x_n. With the parameters α > 1, β > 0, and λ > 0, we measure the quality of the parameters (α, β, λ) using a criterion, which is the logarithm of the likelihood function for the data under the APF model, where the fitness function (Fitness = –log-likelihood), with the goal of minimizing the cost. Initial values for the parameters (α, β, λ) are generated using a hybrid method that considers diversity and objectivity in the form of seeds. We place at least two widely spaced seeds, such as (α=2, β=2, λ=2) and (α=12, β=4, λ=3) [10], to cover different gates in the solution space. An initial population is then generated around these individuals, adding small differences for each parameter while clipping within the bounds. The goal is to start the search from known but diverse points, ensuring exploratory power in the first generations. All the parameters that have been taken go through the testing stage using the fitness function taken from the logarithm of the factorial of the probability function of the proposed distribution, as in (11) above.

$$\begin{aligned} log(L(\theta)) = n * ln(ln(\alpha)) - n * ln(\alpha-1) + n * \\ ln(\lambda) - n * ln(\beta) - (\lambda+1) * ln\left(\sum_{i=1}^{n}\frac{x_i}{\beta}\right) + \\ \sum_{i=1}^{n}\left(\frac{x_i}{\beta}\right)^{-\lambda} + ln(\alpha) * e^{-\left(\sum_{i=1}^{n}\left(\frac{x_i}{\beta}\right)^{-\lambda}\right)}. \end{aligned}$$

The above equation is used to find the fitness function.

$$Fitness(\alpha,\beta,\lambda) = -\sum_{i=1}^{n} log\ f_{APF}(x_i;\alpha,\beta,\lambda). \quad (15)$$

Next, we move to the selection step, where we use tournament selection (k = 3) to select the best parents by taking three random hypotheses and choosing the values with the highest fit. We repeat the process twice to select two parents. We apply simple elitism by transferring the best one or two types of individuals as they are to the next generation. Next comes the crossover, which takes two forms. The first is a single cut on the vector [α, β, λ] by swapping the positions of the parameters after the cut that fall on

the parents, for example, the right of the first with the left of the second and the left of the first with the right of the second. The second type of crossover is linear crossover, which is done by constructing the two offspring as a linear mixture of the parents with a mixing coefficient r ~ U (0,1) according to the following two equations [11], [12]:

$$C_1 = r\,p_1 + (1 - r)p_2. \quad (16)$$
$$C_2 = r\,p_2 + (1 - r)p_1. \quad (17)$$

Where:

- C1, C2: children,
- P1, P2: parents
- r: mixing coefficient.

This type maintains continuity in the parameter space and allows for smooth jumps between solutions. Next, we move to the most important section, which adds the concept of randomness to the genetic algorithm: mutation. A random value is added to each gene by a small amount, for example, 0.001, to move from broad exploration to fine-tuning. After mating and mutation, we move to the repair and constrain section, where we return α, β, and λ to the allowed range. We then examine which numerical states ultimately lead to the stopping criterion, which could be a maximum number of generations (such as 100 generations), or a random error difference between the actual and estimated values, which is small enough to allow for the best-known solution at the stopping moment. The estimation is evaluated according to the criteria used in this research, the mean error standard (MSE) for reliability, using Monte Carlo iterations [9], [10], [11].

4 SIMULATION

The simulation in this research presents the experimental methodology adopted to compare the accuracy and reliability of the Alpha Power Fréchet distribution parameter estimation methods at (n= 15, 25, 35, 50, 75, 100, 500) observations, each segment representing a fixed time period used to calculate the number of operating units at the beginning of the period and the number of errors or failures (faults) recorded during it. Based on this information, the reliability function was estimated. All the above operations and default parameter values were included in Table 1 to calculate the potential and genetic algorithm [12]. The objective of this section is to evaluate the performance of each method using the mean square error (MSE) criterion via Monte Carlo simulation.

Table 1: Default values for the parameters (α, β, λ) for the (Alpha Power Fréchet) distribution.

α	2	4	12	25	3
β	2	1	4	10	0.2
λ	2	6	3	1	5

The Invers method was used to obtain the tracking variables of the Alpha Power Fréchet distribution according to the following formula.

$$X = \beta * \left(-ln\left(\frac{ln(R*\alpha - R+1)}{ln(\alpha)}\right)\right)^{-\frac{1}{\lambda}}. \quad (18)$$

Where α is the location parameter, β is the scaling parameter, and λ is the shape parameter. The simulation was repeated 2000 times.

Table 2: Results of simulation of the maximum likelihood method for the reliability of the Alpha Power Fréchet distribution for default parameter.

	values at (α=2; β=2; λ=2)			
	(α=2;β=2;λ=2)			
	MLA		*GA*	
n	Reliability	MSE	Reliability	MSE
15	0.53116	0.00320	0.2633	0.0795
25	0.52787	0.00268	0.2601	0.0742
35	0.52269	0.00202	0.2589	0.0721
50	0.52095	0.00156	0.2593	0.0708
75	0.51819	0.00092	0.2609	0.0708
100	0.51482	0.00077	0.2594	0.0693
500	0.50656	0.00014	0.2611	0.0689

As shown in Table 2, which displays the reliability values and their Mean Squared Error (MSE) for both the maximum likelihood method and the genetic algorithm under the parameter set (α=2, β=2, λ=2), it is observed that the MSE for the maximum likelihood estimator is lower than that of the genetic algorithm for all sample sizes.

Table 3: Results of simulation of the maximum likelihood method for the reliability of the Alpha Power Fréchet distribution for default parameter.

	values at (α=4; β=1; λ=6)			
	(α = 4; β = 1; λ = 6)

75	0.51705	0.00077	0.59248	0.35104
100	0.51377	0.00063	0.59261	0.35118
500	0.50540	0.00009	0.59278	0.35139

As shown in Table 3, which displays the reliability values and their Mean Squared Error (MSE) for both the maximum likelihood method and the genetic algorithm under the parameter set (α=4, β=1, λ=6), it is noted that the MSE for the maximum likelihood estimator is substantially lower than that of the genetic algorithm across all sample sizes.

Table 4: Results of simulation of the maximum likelihood method for the reliability of the Alpha Power Fréchet distribution for default parameter.

	values at (α=12; β=4; λ=3)			
	$(\alpha = 12; \beta = 4; \lambda = 3)$			
	MLA		GA

35	0.51291	0.00269	0.2621	0.0737
50	0.51379	0.00201	0.2592	0.0712
75	0.51467	0.00138	0.2607	0.0706
100	0.50928	0.00611	0.2566	0.0763
500	0.51102	0.00372	0.2586	0.0736

As illustrated in Table 4, which compares the reliability estimates and their Mean Squared Error (MSE) for the maximum likelihood and genetic algorithm methods using the parameters (α=12, β=4, λ=3), it is evident that the MSE of the maximum likelihood estimator is consistently lower than that of the genetic algorithm across all sample sizes.

Table 5: Results of simulation of the maximum likelihood method for the reliability of the Alpha Power Fréchet distribution for default parameter.

	values at (α=25; β=10; λ=1)			
	$(\alpha = 25; \beta = 10; \lambda = 1)$

35	0.47636	0.00143	0.83370	0.69512
50	0.47978	0.00118	0.83542	0.69794
75	0.48469	0.00090	0.83675	0.70015
100	0.48600	0.00061	0.83709	0.70071
500	0.49409	0.00011	0.83762	0.70161

The results presented in Table 5, which details the reliability estimates and their corresponding Mean Squared Error (MSE) for the maximum likelihood and genetic algorithm methods under the parameter configuration (α=25, β=10, λ=1), demonstrate that the MSE for the maximum likelihood estimator is consistently lower than that of the genetic algorithm for every sample size examined.

Table 6: Results of simulation of the maximum likelihood method for the reliability of the Alpha Power Fréchet distribution for default parameter.

35	0.52127	0.00179	0.65139	0.42444
50	0.52134	0.00159	0.65472	0.42869
75	0.51747	0.00082	0.65634	0.43079
100	0.51372	0.00064	0.65690	0.43152
500	0.50633	0.00013	0.65770	0.43257

Table 6 presents the reliability estimates and their corresponding Mean Squared Error (MSE) for the maximum likelihood and genetic algorithm methods, given the parameters (α=3, β=0.2, λ=5). The results indicate that the MSE for the maximum likelihood estimator is lower than that of the genetic algorithm across all examined sample sizes.

5 CONCLUSIONS

Based on the comprehensive simulation study, the following key conclusions can be drawn:

1) The Maximum Likelihood (MLE) method demonstrates superior performance over the Genetic Algorithm (GA) in estimating the reliability function of the Alpha Power Fréchet distribution. This conclusion is consistently supported by lower Mean Squared Error (MSE) values across all tested sample sizes and parameter sets (α,β,λ)(α,β,λ).
2) The MLE method shows the property of consistency: its estimation error (MSE) decreases systematically as the sample size increases (from n=15 to n=500). This indicates that the estimates converge to the true parameter values with more data.
3) The reliability values estimated by GA are consistently higher than those obtained via MLE for the same parameters, indicating a slight upward bias in the GA estimates. Nevertheless, GA shows robust performance, particularly at small to medium sample sizes, making it a viable alternative when classical methods like MLE are difficult to implement due to computational or analytical complexities.

For estimating the reliability of the Alpha Power Fréchet distribution, the Maximum Likelihood

method is recommended due to its higher accuracy and consistency. The genetic algorithm serves as a competent complementary tool, especially in challenging scenarios where traditional optimization fails.

RECOMMENDATIONS

Based on the results, the maximum likelihood (MLE) method is recommended as the primary approach for estimating the reliability function of the Alpha Power Fréchet distribution, particularly for large sample sizes ($n \geq 50$), due to its high accuracy and consistency. The genetic algorithm (GA) is suggested as an alternative estimation method, offering robustness and effectiveness, especially for small or medium sample sizes or when the likelihood function is complex. A hybrid approach can also be developed, combining the advantages of both methods, where the GA is used to determine optimal parameter values that are then employed as initial values for the MLE algorithm to achieve high optimization accuracy. It is further recommended to apply both methods to real data from engineering and machinery fields to validate these results and compare performance in practical applications. Additionally, the study could be expanded to include other performance evaluation metrics, such as bias (BIAS), and the performance of the genetic algorithm can be enhanced by fine-tuning parameters like mutation rate, population size, and breeding method to achieve higher accuracy and lower mean square error (MSE).

Keywords: Joint Model, Longitudinal and Survival Data, Model Evaluation (AIC, RMSE), EM Algorithm.

Abstract: This Study aims to assess the impact of certain clinical factors on children with leukemia by employing The Joint Model for Longitudinal and survival data, using the Expectation–Maximization (EM) algorithm for parameter estimation. In this research, the longitudinal data are represented by repeated measurements of hemoglobin (Hb) levels over time, while the survival data correspond to the follow-up time until the realization of the event (death or censoring). The results revealed that Hb levels significantly decrease over time ($p < 0.0001$). Female patients had lower Hb levels compared to males ($p=0.006$), while older age was associated with slightly higher Hb values ($p=0.0002$). In the survival sub-model, the effects of age and sex were statistically insignificant ($p > 0.05$). Importantly, the negative and significant association parameter (γ, $p=0.0001$) indicated that higher Hb levels reduce the risk of death, highlighting the predictive value of longitudinal information in explaining survival outcomes. Based on the goodness-of-fit criteria (AIC and RMSE), the EM algorithm demonstrated high efficiency in estimating the parameters of the joint model and achieving strong agreement between predicted and observed values. Therefore, the joint model provides a powerful and effective tool for integrating longitudinal and survival information in the study of childhood leukemia, enhancing estimation accuracy and enabling more reliable conclusions about the factors influencing disease progression.

1 INTRODUCTION

Childhood leukemia is one of the most common and serious types of cancer, posing a major challenge to healthcare systems due to its direct impact on survival rates and patients' quality of life. Studying the factors that influence disease progression and survival among affected children is a crucial step toward improving diagnostic and therapeutic strategies. In this context, advanced statistical models have become essential to capture the complexity of medical data, which often consist of repeated longitudinal measurements of biological markers alongside survival outcomes [1], [2].

The Joint Model for Longitudinal and survival data is considered one of the most powerful tools in this field. It integrates longitudinal information (such as hemoglobin levels) with survival outcomes (time-to-event) within a unified framework, providing more accurate estimates and enabling the study of dynamic relationships between biomarkers and the risk of mortality [3]. Several estimation methods have been developed for this model, with the Expectation–Maximization (EM) algorithm being among the most widely used due to its efficiency in handling missing data and complex parameters [4], [5].

This study aims to apply The Joint Model using the EM algorithm to measure the effect of demographic and clinical factors (such as age and sex) on children with leukemia, with a particular focus on the relationship between changes in hemoglobin over time and survival probability. The research also provides interpretation of the estimation results and highlights conclusions that may contribute to supporting medical decision-making and improving healthcare for this vulnerable group of patients.

2 JOINT MODELS

The concept of Joint Models is based on the modeling of two types of data that form two components within the model. This modeling helps to understand how these data depend on each other, leading to better results, more accuracy, less bias, and more accurate

predictions [1], [4]. Both data in a common model are modeled according to two components: the first records changes over time and the second monitors when events (deaths) occur. Wulfsohn and Tsiatis (1997) were the first to describe the joint model, as these models consist of two sub-models [1], [2].

2.1 Longitudinal Sub-Model

The first sub-model is a Mixed Effect sub-model for modeling longitudinal data, which represents repeated measurements of variables, such as measuring vital signs or monitoring the patient's response to treatment over time. It tracks changes and differences between measurements, such as disease progression or treatment effectiveness. Longitudinal data are often modeled using the Linear Mixed-Effect model, which studies fixed effects representing overall trends and random effects representing individual differences, thereby capturing both population-level trends and individual variations [4], [6]. In addition, the analysis of high-dimensional longitudinal data has become increasingly important, where joint modeling provides a robust framework for addressing complexity and ensuring reliable inference [7].

2.2 Survival Sub-Model

The second sub-model represents the modeling of the time of occurrence of events (e.g., death) based on survival data analysis. The time until the occurrence of the event is observed, with examples including the proportional hazards model and accelerated failure time models. These models estimate the risk or timing of an event. The Cox proportional hazard semi-parametric model is the most common approach, as it evaluates how different factors affect the risk of an event without assuming restrictions on event times [2], [8].

2.3 Combined Joint Model

Joint models integrate both sub-models by allowing the survival component (event occurrence time) to depend on some characteristics of the longitudinal sub-model through various methods [1], [5]. A key feature of joint models is that longitudinal data from a given time until the event is modeled simultaneously with a conditional joint density function, rather than treating the two sub-models as independent [4], [9].

To formulate the joint model, some terms must be defined:

- T_i^*: denotes the true occurrence time of the event for subject *i*;
- T_i: represents the observed time for subject *i*;
- δ_i : is the event index equal to (1) when the real event occurs;
- y_i: is the longitudinal response variable;
- The formulation of the joint model generally involves three stages [1], [10].

2.1 Constructing the Survival Data Sub Model

Let T_i^* be the true event time for subject $(i = 1, 2, \dots, n)$, and let T_i denote the observed survival time. If the subject does not experience the event during the study period, T The observation for subject i is right-censore. Let C_i be the potential censoring time such that:

$$T_i = min(T_i^*, C_i).$$

Define the event indicator as:

$$\delta_i = \begin{cases} 1 \text{ if the true event is observed;} \\ 0 \text{ if the event is right} - \text{censored.} \end{cases}$$

Thus, the observed survival data can be written as: [5], [10]

$$\{(T_i, \delta_i);\ i = 1,2, \dots, n\}.$$

For the i^{th} subject, let $y_i(t)$ denote the observed longitudinal measurement at time point t_{ij}, for *j=1, 2, …,* m_i. Let m_i (t) denote the true longitudinal trajectory of subject i, which is unobserved and differs from $y_i(t)$.

To describe the association between the longitudinal trajectory and the hazard of an event, the proportional hazards model is given by:

$$h_i(t \mid \mu_i(t)) = \lim_{\delta t \to 0} \left\{ \frac{p[t \leqslant T_i^* < t + \delta t \setminus T_i^* \geqslant t, \mu_i(t), w_i]}{\delta t} \right\} = h_0(t)\, exp\{\gamma^\top w_i + \alpha m_i(t)\}, \ t > 0, \quad (1)$$

where:

- $m_i(t)$represents the true values of the time-dependent longitudinal covariates at time *t.*;
- $h_0(t)$ is the unspecified baseline hazard for a subject with all explanatory covariates equal to zero;
- w_i is the vector of baseline explanatory covariates;
- γ is the vector of regression coefficients corresponding to w_i;

- α is the association parameter measuring the effect of the longitudinal data on survival outcomes at time.[4], [10].

The hazard function in (1) assumes that the risk of experiencing the event at time *t*. depends only on the current value of $m_i(t)$, which changes over time.

Based on the relationship between the survival function and the cumulative hazard function, the survival probability can be expressed as:

$$S_i\big(t \setminus M_i(t)\big) = Pr(\tau_i^* > t \setminus \mu_i(t), w_i) = exp\left(-\int_0^t h_0(s)\exp\{\gamma^\top w_i + \alpha M_i(s)\}ds\right). \quad (2)$$

This expression represents the survival function for subject i, conditional on the entire longitudinal process $m_i(t)$ [4], [6]

2.2 Constructing the Longitudinal Sub-Model

The hazard function $h_i\ (t)$ in (1) depends on the true longitudinal outcomes $m_i(t)$ at time t. For each subject, the true longitudinal process is recorded at intermittent time points $\{t_{ij}, j=1, 2,\ldots,m_i\}$, subject to measurement errors. To relate the longitudinal outcomes to the risk of event occurrence, it is necessary to estimate $m_i(t)$.

Therefore, the longitudinal data are modeled using the Linear Mixed-Effects Model (LME). For the i^{th} subject, the observed longitudinal responses are given by:

$$y_{ij}\ (t_{ij}), j=1, 2,\ldots,m_i.$$

Assuming that the longitudinal outcomes follow a normal distribution, the linear mixed-effects model can be specified as follows:

$$y_i(t) = x_i^\tau(t)\beta + z_i^\tau(t)b_i + \epsilon_i(t), \quad (3)$$

$$y_i(t) = m_i(t) + \epsilon_i(t), \quad (4)$$

$$m_i(t) = x_i^\tau(t)\beta + \epsilon_i^\tau(t)b_i. \quad (5)$$

Here, b_i follows a multivariate normal distribution with covariance matrix D, i.e.,

$$b_i \sim N(0, D).$$

The random error term is assumed as $\epsilon_i(t) \sim N(0, \sigma^2)$, and is mutually independent of b_i.

Where:

- $x_i(t)$, β*:* represent the fixed effects;
- $z_i(t), b_i$: represent the random effects;
- $\epsilon_i(t)$: denotes the random error term for subject i at time *t.* [4], [6]

2.3 Constructing the Joint Model

The Joint Model for Longitudinal and survival data consists of two sub-models that are linked together, and all parameters are estimated simultaneously. The Mixed-Effects Model is one of the most commonly used approaches for modeling longitudinal data, while the Proportional Hazards Model is typically employed to handle survival data with time-dependent covariates.

The association between the two sub-models may occur through random effects or regression parameters. To construct The Joint Model for Longitudinal and Survival Data, the following steps are generally taken [5], [11].

1) Specify the trajectory function for the longitudinal process, which correctly represents its evolution over time.
2) Define the structure of the longitudinal component based on the observed values.
3) Specify the appropriate model for the survival component.

The trajectory function plays a central role by representing the true values of the longitudinal covariate across all time points, including unobserved times (free of measurement error). Thus, it allows us to capture both the underlying trajectory of the covariate and its time-dependent effect [9], [12].

The trajectory function can be defined as:

$$W_i(t) = z(t)\ b_i\ \ , t > 0, i = 1,2, \ldots, n \ldots, (6)$$

where:

- $W_i(t)$denotes the trajectory function of subject i at time t, representing the true value of the longitudinal covariate regardless of whether an observation is available at that time;
- $z(t)$ is a vector of continuous functions;
- b_i is the vector of subject-specific random effects (including random intercepts and slopes).

After defining the trajectory, it can be related to the observed longitudinal measurements: [6], [10].

$$y_i = (y_i\ (t_{i1}), y_i\ (t_{i2}), \ldots, y_i\ (t_{iJ_i})$$

with:

$$y_i(t_{ij}) = w_i(t_{ij}) + \epsilon_i(t_{ij})\ \ ;\ i\ = 1, 2, \ldots n. \quad (7)$$
$$j = 1, 2, \ldots J_i = x_i\beta + z_i(t_{ij})^\top b_i + \epsilon_i(t_{ij})$$

where:

- -$y_i(t_{ij})$: observed longitudinal outcome for subject i at time t_{ij};

- $w_i(t_{ij})$: trajectory function, consisting of both fixed and random effects;
- x_i: vector of baseline covariates for subject i;
- β: vector of fixed-effects coefficients;
- z_i: time-dependent design vector;
- b_i: vector of random effects, assumed $b_i \sim N(\mu_b, \Sigma_b)$;
- $\epsilon_i(t_{ij})$: error term, assumed $\epsilon_i(t_{ij}) \sim N(0, \sigma_\epsilon^2)$.

The proportional hazards model can then be extended to incorporate the time-dependent trajectory function:

$$h(u_i) = \lim_{d_u \to 0} \frac{p(u_i \leqslant T_i < u_i + d_u \mid T_i \geqslant u_i, w_i^H(u_i) z_i b_i}{d_u}. \quad (8)$$

$$h(u_i) = h_0(u_i)\, exp\{\eta w_i(u_i) + z_i\theta\} \quad ; \; i = 1,2, \ldots, n.$$

The survival function is then expressed as:

$$\begin{aligned} S(u_i) &= exp\{-H(u_i)\} \\ &= exp\left\{-\int_0^{u_i} h(s)ds\right\} \\ &= ex\,p\{-\textstyle\int_0^{u_i} h_0(s)\exp\{\eta(w_i(s) + z_i\mu\}ds. \end{aligned} \quad (9)$$

Thus, combining the longitudinal and survival components, the joint likelihood function can be written as:

$$\begin{aligned} L(\theta; u_i, \delta_i, y_i, t_i, x_i, z_i) &= \prod_{i=1}^{n} p(u_i, y_i \mid \theta) \\ &= \textstyle\prod_{i=1}^{n} \int [h_0(u_i) ex\, p(\eta\omega_i(u_i) + \\ & z_i\psi)]^{\delta_i} . ex\, p\{-\textstyle\int_0^{u_i} h_0(s) ex\, p(\eta\omega_i(s) + \\ & z_i\psi ds\}. \frac{1}{(2\pi\sigma_\epsilon^2)^{J_i/2}} ex\, p\left\{-\textstyle\sum_{j=1}^{J_i} \frac{\{Y_i(t_{ij}) - W_i(t_{ij})\}^2}{2\sigma_\epsilon^2}\right\}. \\ & p(b_i \mid \mu_b, \Sigma b) db_i. \end{aligned} \quad (10)$$

Under the assumption of full conditional independence, the joint distribution can be factored as:

$$P(y_i, T_i, \delta_i \mid b_i) = p(y_i \mid b_i) \cdot p(T_i, \delta_i \mid b_i). \quad (11)$$

$$P(y_i \mid b_i) = \prod_{j=1}^{m_i} p(y_{ij} \mid b_i). \quad (12)$$

Finally, the survival function conditional on random effects is:

$$S_i(t \mid b_i) = exp\left(-\int_0^t h_0(s) exp\{\gamma^\top w_i + \propto m_i(s)\} ds\right). \quad (13)$$

Hence, the joint likelihood can also be written as:

$$\begin{aligned} P(y_i, T_i, \delta_i) = \int\ & p(y_i \\ & \mid b_i)\{h(T_i \mid b_i)^{\delta_i} S(T_i \\ & \mid b_i)\} p(b_i) db_i. \end{aligned} \quad (14)$$

3 ESTIMATION METHOD FOR JOINT MODEl

After studying the concept of the joint model and identifying all of its components, the estimation methods for the joint model of the combined data will be examined based on equations (13), (14), and (15). In particular, the Maximum Likelihood Estimation (MLE) method will be studied [13].

3.1 Maximum Likelihood Method (MLE)

Wulfsohn and Tsiatis (1997), as well as Rizopoulos (2012), provided a detailed methodology for estimating the joint model using the Maximum Likelihood Estimation (MLE) approach [5].

$$\begin{aligned} & \log L_i(\theta) \\ &= log \int \left\{ \prod_{j=1}^{mi} p(y_{ij} \mid b_{ij}\theta)\{h(T_i \mid b_i; \theta)^{s_i} S_i(T_i \mid b_i; \theta)\} \right. \\ & \qquad \left. p(b_i; \theta) d\, b_i. \right. \end{aligned} \quad (15)$$

Since both integrals do not admit closed-form solutions, numerical approximation methods are required to estimate the joint model. Among these methods, the EM algorithm is widely used [5].

3.1.1 The Expectation–Maximization Algorithm (EM)

The EM algorithm, first developed by Arthur Dempster and colleagues in 1977, is a numerical technique primarily used for parameter estimation in models with incomplete data or latent variables. This algorithm addresses the implications associated with such models that cannot be estimated using traditional statistical methods, making it a pivotal tool for addressing specific challenges in data analysis. Therefore, the EM algorithm is of great importance in the fields of statistics and machine learning.

The purpose of using the EM algorithm is to maximize the likelihood function for models with unobserved data in order to improve prediction [4], [5].

By substantially enhancing statistical parameter estimates, the EM algorithm provides more accurate and reliable results, making it a valuable tool in various research and applied domains.

The basic steps for applying the EM algorithm to the joint model are as follows:

1) Basic equation:
   Represent the Maximum likelihood function for The Joint Model, which the EM algorithm seeks to maximize.

$$\log L_i(\theta) = log \int \left\{ \prod_{j=1}^{mi} p(y_{ij} \mid b_{ij}\theta)\{h(T_i \mid b_i;\theta)^{s_i} S_i(T_i \mid b_i;\theta)\} \right\} p(b_i;\theta) d\, b_i. \quad (16)$$

   Where:
   - y_{ij}: observed longitudinal data;
   - T_i: survival time for each patient;
   - b_i: random effects or latent (unobserved) variables;
   - θ: parameters to be estimated;
   - $h(T_i \mid b_i;\theta)$: conditional hazard function;
   - $S_i(T_i \mid b_i;\theta)$: conditional survival function.

2) E-step (Expectation step):

   Estimate the expected values of the random effects (b_i). Since these random effects are not directly observed, we compute their expectations based on the current parameter estimates:

$$Q(\theta \mid \theta^{(t)}) = E[log\ L_i(\theta) \mid y_{ij}, \tau_i, \theta^{(t)}].$$

   This expectation is obtained from the conditional distribution of the random effects.

3) M-step (Maximization step):
   Update the parameter estimates θ by maximizing the expectation

$$arg\ max_\theta Q(\theta \mid \theta^{(t)}). = \theta^{(t+1)}.$$

4) Iteration until convergence:

   Repeat the E-step and M-step until convergence, i.e., when the difference between successive estimates becomes sufficiently small [4], [5].

$$\theta^{(t+1)} - \theta^{(t)} \approx 0.$$

4 PERFORMANCE MEASURES

To evaluate the predictive performance of the proposed model, several statistical measures are employed. These measures provide a comprehensive assessment of the model's accuracy and efficiency. The most widely used criteria include:

1) The Root Mean Squared Error (RMSE). It is calculated according to the following [8], [10]:

$$RMSE = \sqrt{\frac{1}{n}\sum_{t=1}^{n}(y_t - \hat{y_t})^2}, \quad (17)$$

2) Akaike Information Criterion (AIC). Used to evaluate model quality by balancing goodness of fit and model complexity [4], [10].
   AIC penalizes overfitting by incorporating the number of estimated parameters. It is defined as:

$$AIC = -2\ln(L) + 2k... \quad (18).$$

5 THE PRACTICAL APPLICATION

In this part, The Joint Model for Longitudinal and survival Data was applied using the R software to estimate the parameters and analyze the relationship between longitudinal variables and event time. Estimation methods were employed, and the results were evaluated using performance criteria such as RMSE and AIC to assess the efficiency of the model.

The Figure 1 presents Kaplan–Meier survival curves by sex, showing that the trajectories of males and females are very similar, with no statistically significant difference between the two groups (p=0.8), indicating that sex had no clear effect on survival probability during the follow-up period.

The Figure 2 illustrates the relationship between hemoglobin (Hb) levels and the hazard ratio (HR), showing that higher Hb levels are associated with lower hazard, indicating that increased Hb reduces the likelihood of the event and serves as an important indicator of improved survival.

Table 1 presents the estimation results of the joint longitudinal–survival model using the Expectation–Maximization (EM) algorithm. As shown in Table 1, the longitudinal sub-model indicates that the intercept is positive and highly significant, while time has a negative and statistically significant effect (p = 0.0001), reflecting a gradual decline in hemoglobin (Hb) levels over time. Age shows a positive and significant association with Hb levels (p = 0.0002), whereas female patients exhibit significantly lower Hb values compared to males (p = 0.006).

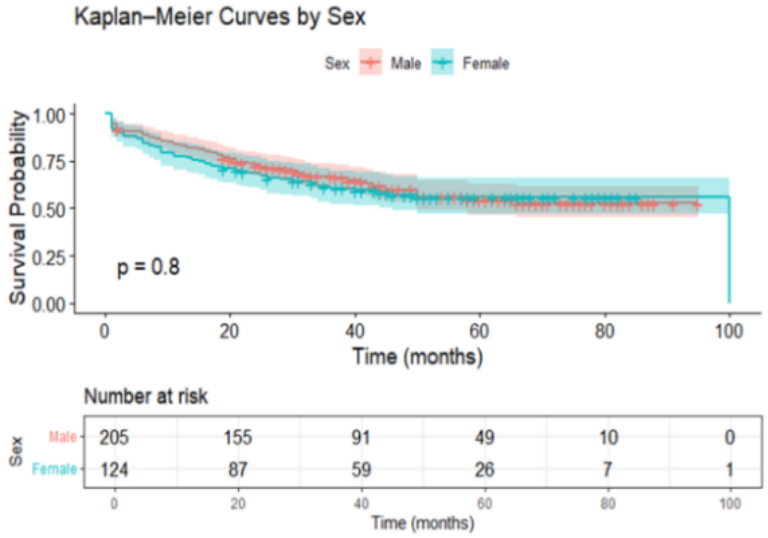

Figure 1: Kaplan–Meier survival curves were analyzed by sex.

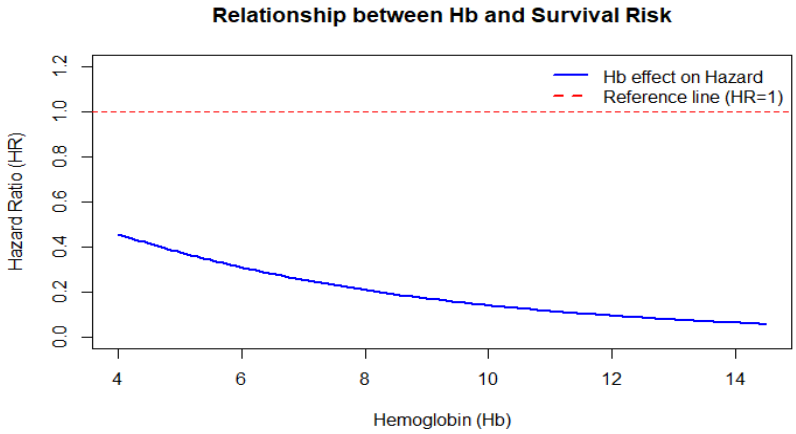

Figure 2: The parameter estimates of the joint model were obtained using the EM algorithm.

Table 1: Estimation Results of the Joint Model (EM).

Model Component	Variable /Parameter	Estimate	Std. Error	Z-value	P-value
Longitudinal sub-model	Intercept	6.54	0.29	22.34	<0.0001
	Time (months)	-0.030	0.0075	-4.04	0.0001
	Age	0.122	0.033	3.68	0.0002
	Female vs Male	-0.666	0.244	-2.73	0.0060
Survival sub-model	Age	-0.045	0.026	-1.75	0.080
	Female vs Male	0.044	0.188	0.24	0.810
Association parameter	γ (gamma)	-0.196	0.049	-4.02	0.0001
Random effects	Intercept variance	4.562	—	—	—
	Time slope variance	0.0032	—	—	—
	Covariance (Int,Time)	-0.040	—	—	—
	Residual SD (σ)	0.624	—	—	—

In the survival sub-model reported in Table 1, neither age nor sex has a statistically significant effect on survival time ($p > 0.05$). However, the association parameter (γ) is negative and highly significant ($p = 0.0001$), confirming that higher Hb levels are associated with a reduced risk of death.

Table 2: Performance criteria for the Joint Model (EM algorithm).

Criterion	AIC	RMSE
Joint Model (EM)	5119.95	0.488

As indicated in Table 2, the Akaike Information Criterion (AIC = 5119.95) reflects a good balance between model fit and complexity, while the relatively low RMSE value (0.488) demonstrates good agreement between the observed and predicted values, confirming the efficiency of the EM-based joint model.

6 CONCLUSIONS

The results of this study demonstrate that the joint model for longitudinal and survival data provides a reliable and effective framework for analyzing the relationship between time-varying biomarkers and survival probabilities in children with leukemia. The longitudinal analysis showed a gradual decline in hemoglobin (Hb) levels over time, reflecting disease progression and treatment effects. Age was positively associated with Hb levels, while females had lower Hb values than males, possibly due to physiological or therapeutic differences.

In the survival analysis, neither age nor sex had a significant direct effect on survival time, suggesting that other clinical or genetic factors may play a stronger role. The association parameter (γ) showed a negative and highly significant relationship, indicating that lower Hb levels increase the risk of death, confirming the predictive power of longitudinal biomarkers in survival estimation.

Performance evaluation criteria demonstrated the efficiency of the Expectation–Maximization (EM) algorithm in providing accurate and stable parameter estimates, even with incomplete data. Overall, the joint model serves as a valuable statistical tool that supports dynamic disease monitoring, enhances prediction accuracy, and aids in evidence-based medical decisions to improve outcomes for children with leukemia.

Keywords: Pareto Distribution, Reliability Function, MM-Estimate, Kernel Estimation Method.

Abstract: The research addresses the topic of reliability, which is defined as the probability of any component of a system being completed within a specified period of time and under the same conditions. The reliability function and failure function of the Pareto distribution were studied. Several methods exist for estimating the reliability function, but the conditions for most of these methods are often missing in the data, such as abnormal, extreme, or unacceptable values. Two estimation methods (a robust method and a nonparametric method) were used: the MM-estimate and the nonparametric kernel estimation. After these two estimation formulas were derived to reach their capacity, a comparison was made between these estimates using simulation experiments with different sample sizes (10, 30 and 60). Each experiment was repeated 1,000 times to achieve the objective, and the results were compared using the mean square error (MSE) criterion. Through the results obtained, it was found that the best estimation method is the (MM-estimate) method, where it was estimated that the reliability function gradually decreases with time, which is consistent with the characteristics of this function.

1 PARETO DISTRIBUTION

This distribution is attributed to the Swiss-born Italian economist Vilfredo Pareto (1848–1923), who laid the foundations of the Pareto distribution in economics by studying the distribution of incomes exceeding a known threshold k. The general Pareto distribution, sometimes called the first or traditional Pareto distribution, has important applications in economics, communications, and various engineering sciences [1], [2].

It is assumed that (x_1, x_2) follow a Pareto distribution with parameters (α_i, k_i), where $i = 1,2$, α_i is the shape parameter, and k_i is the scale parameter, sometimes interpreted as the minimum value. These parameters are then used to compute the reliability estimator $\hat{R}$.

The true reliability R and the reliability estimator $\hat{R}$ are calculated using the robust MM-estimation method and the non-parametric kernel estimation method. Specifically, given values for the shape parameters α_i and scale parameters k_i, these parameters are estimated using the methods above, and the resulting estimates are substituted to compute $\hat{R}$ [3], [4].

2 RELIABILITY

In the concept of globalization, in the recent decades the world has witnessed openness in many fields and the accompanying liberalization of global trade. This competition supposes entry into global markets to attract foreign investment. Meanwhile, the developing countries found themselves in an unenviable position, either trying to join the developed countries in various ways or delaying. So it will be necessary to pay attention to the issues of reliability of the industrial products of all kinds in order to be able to survive and compete in the markets. Because of the importance of reliability and its applications, researchers are directed to study the failure times and reliability of most continuous distributions with the continuation of the modern development. A group of distributions appeared which are called the compounding probability distributions which were received wide attention by

many researchers for their use in many fields, especially in reliability. The compounding probability distributions are one of the failure models that investigate the performance of the work of complex systems and devices. The interest has increased in estimating the reliability function of these distributions. This is to know the operational life of a number of machines and equipment by representing them with one function and to know the efficiency of these machines then evaluate them [5], [6].

2.1 The Reliability of Pareto Distribution

The probability density functions (p.d.f.) of the Pareto distribution for both stress and strength variables can be written as: [7], [8]:

$$f(x_i,\alpha_i,k_i)=\begin{cases}\dfrac{\alpha_i k_i^{\alpha_i}}{x^{\alpha_i+1}} & x_i>k_i \quad , \quad k_i>0 \\ & \alpha_i>0 \quad , \quad i=1,2 \\ 0 & \text{o.w}\end{cases} \tag{1}$$

Since: α_i shape parameter and k_i scale parameter. The cumulative density function (c.d.f.) can be found:

$$F_i(x_i)=1-R_i(x_i) \tag{2}$$

$$F_i(x_i)=1-\left(\frac{k_i}{x_i}\right)^{\alpha i}, \tag{3}$$

$$i=1,2 \quad , \quad x_i \geq k_i>0 \quad , \quad \alpha_i>0$$

The reliability function (R) for stress and toughness is:

$$R=\int_{-\infty}^{\infty} F_2(x_2)\ f_1(x_1).dx$$

$$R=\int_{\max\{k_1,k_2\}}^{\infty}\left\{1-\left(\frac{k_2}{x_2}\right)^{\alpha_2}\right\}\ .\ \left\{\frac{\alpha_1 k_1^{\alpha_1}}{x_1^{\alpha_1+1}}\right\}\ dx \tag{4}$$

$$R=1-\frac{\alpha_1}{\alpha_1+\alpha_2}\left\{\frac{k_2}{\max\{k_1,k_2\}}\right\}^{\alpha_2}\left\{\frac{k_1}{\max\{k_1,k_2\}}\right\}.^{\alpha_1} \tag{5}$$

If the random variables of stress and strength have the same minimum, i.e. k1 = k2, then the reliability (R) in this case is [8], [9]:

$$R=\frac{\alpha_2}{\alpha_1+\alpha_2}. \tag{6}$$

2.2 Estimation Methods

2.2.1 The Robust M.M. Estimation Methods Method

This method is called Robust White. The idea behind this method is to minimize the sum of squared errors to the smallest possible extent, [5], [10], [11]:

$$\min_{a,b}\sum_{i=1}^{n}[Y_i-\beta_0-\beta_1X_i]^2. \tag{7}$$

What the MM-estimate method uses is to minimize the following:

- P is a convex and symmetric function. To obtain robust properties and minimize the above (the sum of squared errors), we use partial derivatives of the coefficients and set them equal to zero.

$$\left.\begin{aligned}\sum_{i=1}^{n}\theta(Y_i-\beta_0-\beta_1X_i)=0\\ \sum_{i=1}^{n}\theta(Y_i-\beta_0-\beta_1X_i)X_i=0\end{aligned}\right\}. \tag{8}$$

- θ is the result of the partial derivative of the above function for the parameters. To obtain the solution to (8), several methods can be used, including mathematical and numerical methods such as the Newton-Raphson method, or by relying on the iteratively weighted partial least squares (IWLS) method as follows:

$$\hat{\beta}_{Rob}=\begin{bmatrix}\beta_0\\ \beta_1\end{bmatrix}=(X^TWX)^{-1}X^TWY.$$

Note that W represents a diagonal weight matrix, and its components can be found as follows:

$$W_{ij}=\frac{\theta\,(Y_i-\beta_0^{\ *}-\beta_1^{\ *}X_i)}{Y_i-\beta_0^{\ \circ}-\beta_1^{\ \circ}X_i}, \tag{9}$$

weights through formula (9) to obtain new values for the first iteration. And then the values are in advance in the calculation and continue to repeat until we get the values of bw very close to each other in successive frequencies are stopped and the last estimate of the formula (10) is the estimate of MM [12], [13].

Since the MM estimator has a constant property, (7) can be expressed as follows. Therefore, the formula for the equation shown in (8) is as follows:

$$\left.\begin{aligned}\sum_{i=1}^{n}\theta\left(\frac{Y_i-\beta_0-\beta_1X_i}{\hat{\delta}}\right)=0\\ \sum_{i=1}^{n}\theta\left(\frac{Y_i-\beta_0-\beta_1X_i}{\hat{\delta}}\right)X_i=0\end{aligned}\right\}. \quad (10)$$

Therefore, the weight matrix functions W are written as in (12) as follows:

$$W_{ij}=\frac{\theta\left(\frac{Y_i-\beta_0{}^{*}-\beta_1{}^{*}X_i}{\hat{\delta}}\right)}{\left(\frac{Y_i-\beta_0{}^{\circ}-\beta_1{}^{\circ}X_i}{\hat{\delta}}\right)}. \quad (11)$$

Estimating formulas for standard deviation values that are pre-determined before the iteration begins using one of the following formulas:

$$\begin{aligned}&1)\ \hat{\delta}=2.1\ \text{Med}\ |u_i|\\ &2)\ \hat{\delta}=\frac{1}{n-4}\sum_{i=3}^{n-2}|u_i|\\ &3)\ \hat{\delta}=1.48\ \text{Med}\ |u_i|\\ &4)\ \text{Med}\ |u_i|/0.6745\end{aligned}. \quad (12)$$

where: $u_i = Y_i-\beta_0-\beta_1X_i$,

Where u_i represents the errors, and represents the ordered errors calculated as follows: As a result of the increasing interest in this method (estimator) over the past decades, many interested parties and researchers have used the method of robust estimators such as (Rews, Hinnich, Hameich, and Talwar) to propose many functions. This is to produce an insensitive and ineffective estimator. Some of these functions can be illustrated in the following table [14], [15], Table 1.

Table 1: Some functions are proposed as weights for fortified estimates.

Weight function	P(e)	W(e)	ψ(e)	Range
A	A^2[1-cos(e/A)]	(u/A)-1 sin(e/A)	A sin (e/A)	|e|≤Aπ
	$2A^2$	0	0	|e|>Aπ
B	$(B^2/2)$[1-$(e/B)^2]^3$	[1-$(e/B)^2]^2$	u [1-$(e/B)^2]^2$	|e|≤B
	$B^2/2$	0	0	|e|>B
T	$e^2/2$	1	u	|e|≤T
	$T^2/2$	0	0	|e|>T
H	$e^2/2$	1	u	|e|≤H
	H	H(e)-1	Sin (e)H	|e|>H

- e: Is the error to be underestimated and in our search, this is a model error in (14);
- P(e): Function in terms of variable e;
- ψ (e): A weight function designed to reduce error;
- W (e): The weight matrix used to obtain the estimates has the least error.

The constants specified in the "Range" column are used to adjust the efficiency of the resulting capacities and take the values shown in the following.

The constants specified in the “Range” column are used to adjust the efficiency of the resulting amplitudes and take the values shown in the following Table 2.

Table 2: Matrix of weights used to obtain estimates has the least error.

Weight function	T	A	B	H
Fixed parts	2.795	1.339	4.685	1.345

The MM distribution is a normal distribution of mean and variance matrix according to the following formula:

$$\text{Var}-\text{Cov}(\hat{\beta}_{\text{Rob}})=\sigma^2_{\text{Rob}}\,(X^TX)^{-1}. \quad (13)$$

And to appreciate it comes as follows:

$$\sigma^2_{\text{Rob}}=\frac{E(\theta^2)}{[E(\theta')]^2}. \quad (14)$$

And to be appreciated, σ^2_{Rob} it comes as:

$$\sigma^2_{\text{Rob}}=\frac{\frac{1}{n}\sum_{i=1}^{n}\theta^2\,(r_i)}{\left[\frac{1}{n}\sum_{i=1}^{n}\theta'\,(u_i)\right]^2}. \quad (15)$$

where σ^2_{Rob} is a biased estimate and to make it an unbiased estimate is based on the following formula:

$$\sigma^2_{\text{Rob}}=R^2\frac{\frac{1}{n-\rho}\sum_{i=1}^{n}\theta^2\,(r_i)}{\left[\frac{1}{n}\sum_{i=1}^{n}\theta'\,(r_i)\right]^2}. \quad (16)$$

Where R represents the correction coefficient and is calculated as follows:

$$R=1+\frac{\rho\ \text{Var}\,(\theta')}{n\,[E(\theta')]^2}. \quad (17)$$

After obtaining the MM estimator for the model parameters i.e:

$$\hat{Y}_i=\hat{\beta}_0+\hat{\beta}_1X_i. \quad (18)$$

The estimate for the distribution of pareto for this method is:

$$F_i(x_i) = 1 - \left(\frac{v_i}{x_i}\right)^{\alpha i}, \quad (19)$$

$$1 - F_i(x_i) = \left(\frac{v_i}{x_i}\right)^{\alpha i},$$

$$\ln(1 - F_i(x_i)) = \alpha i \ln v_i - \alpha i \ln X_i,$$

$$\hat{\alpha}i = \hat{\beta}_1 \text{ and } \hat{v}_i = \exp(\hat{\beta}_0/\hat{\beta}_1), \quad (20)$$

obtaining the MM estimator for the reliability function $\hat{R}_{Rob}$, through the following formula:

$$\hat{R}_{Rob} = 1 - \frac{\hat{\alpha}_1}{\hat{\alpha}_1 + \hat{\alpha}_2}\left\{\frac{\hat{v}_2}{\max\{\hat{v}_1, \hat{v}_2\}}\right\}^{\hat{\alpha}_2}\left\{\frac{\hat{v}_1}{\max\{\hat{v}_1, \hat{v}_2\}}\right\}^{\hat{\alpha}_1}. \quad (21)$$

2.2.2 Kernel Estimation Method (K.E)

This method (kernel estimation) is a scientific method for estimation clustering, agency, death, spectrum, decoration, etc. It was proposed by Barrissen and is intended to purify data by constructing capabilities with properties that match the actual parameters. There are different types of kernel estimation [16].

$$K(x) = \frac{1}{\sqrt{2\,\pi}} \exp\left(\frac{-y^2}{2}\right) \quad 0 \le y \le 1. \quad (22)$$

Although the kernel, the task of obtaining capabilities related to the characteristics of statistical research, the researcher (SAR) reiterated that choosing the dollar is not the most important step in the estimation method, rather choosing the value-added factor (H) (bandwidth bandwidth) is the most important, that is, choosing the value-added factor (1), the same requires choosing the value-added factor (h), as this factor greatly affects the bias and variance, and increasing the value-added factor leads to increased bias and reduced shrinkage and vice versa, and as a result, the prevention of value-added is determined at the degree of smoothing the curve. estimated and approaching the true curve, so the following conditions must be verified (h = 0; nh = ∞).

The value-added factor of the kernel can be fixed or change. The firmware is the use of the prime parameter along the real line used to provide the operating function and is estimated according to one of the posterior estimation methods. Ultimately it means using different values of the band and the real line in estimating the deterministic function in some cases where it becomes useful to use the fixed initial parameter and estimate that modify the appropriate sub parameters.

2.2.3 Fixed Bandwidth Kernel Estimation Method (K.F)

Suppose that T1, T2,..., TN is a sample of independent and vulnerable excellent distribution with the prosperous function and knows as follows:

$$\hat{f}_{(K.F)}(t) = \frac{1}{hn}\sum_{i=1}^{n} K\left(\frac{T_i - t}{h}\right), \quad (23)$$

$i = 1,2,\ldots n$

- K: The Kernel and the calculator of the equation of the No. (23), a specific and continuous and similar persistent functionality, has many labels, including a function (weight, format, essential) and in the following conditions [17], [18]:

$$\int_{-\infty}^{\infty} K(x)dx = 1,$$
$$\int_{-\infty}^{\infty} xK(x)dx = 0, \quad (24)$$
$$\int_{-\infty}^{\infty} x^2K(x)dx > 0,$$

- T: represents the time of the estimation of the function of the functionality;
- n: The size of the sample is a predator (Bandwidth), fixed and estimated by the following steps;
- h: recognized fixed preparatory parameter $(\hat{h} = 1.06\,\hat{\delta}n^{-0.2})$.

The standard deviation of the sample and D difference between the normal natural quantile (valunt).

$$\hat{\delta} = \min\left[S, \frac{\hat{D}}{1.349}\right], \quad (25)$$

$$\hat{D} = X_{(0.25n)} - X_{(0.75n)}. \quad (26)$$

which we must receive the Kernel and its own, we can get the assessment of the Kernel and Kalati function:

$$\hat{F}_{(K.f)}(t) = \frac{1}{hn}\sum_{i=1}^{n}\int_{\infty}^{t} K\left(\frac{X - T_i}{h}\right)dX. \quad (27)$$

Thus, the kernel estimate for the reliability function is given by:

$$\widehat{R}_{(K.F)}(t) = 1 - \left[\frac{1}{hn}\sum_{i=1}^{n}\int_{-\infty}^{t} K\left(\frac{X - T_i}{h}\right) dx\right]. \quad (28)$$

That: RK.FT Recruitment of the Proper Museum for Kernel with the Pre-Framework Practice. After the estimate of the function of the Authority by the distance that is the vulnerability of the victory, and we must compare them through the results and find out what is the perfect way or better in terms of practical application. Here they will be beaded by the modalities of estimate of the estimate, and the accuracy of the appreciation methods The accuracy of the appropriate nuclear standard: The comparison measurement for the best way:

Average error box (MSE): Where the scale is a divortiality measure of comparison between the following as the next formula

$$MSE\left(\widehat{R}_{(K.F)}(t)\right) = \frac{1}{r}\sum_{i=1}^{r}\left(\widehat{R}_{(t)} - R_{(t)}\right)^2. \quad (29)$$

Where r: represents the number of replicates per experiment.

3 STAGES OF SIMULATION

The application simulation software (R) was written and implemented on the electronic calculator, and the following steps are the steps of the simulation algorithm.

The first stage: This is the main stage upon which the steps and procedures of the program depend.

First, different default values were selected for the parameters $((\alpha_i, k_i))$. Sixteen cases were identified in Table 3.

Table 3: Represents the default values of the parameter.

Model	α	K
1	0.6	0.8
2	1.2	1.7

Second: Two sizes were selected for different samples: n=10, 30

The second stage: At this stage random observations (data) are generated by the reverse conversion method and according to the parameterized rally distribution as follows [19], [20]:

First: Generate random numbers Ui tracking the regular distribution within the period (0, t)

$$U_i \sim U_{(0,1)} \ , i = 1,2, \dots, n.$$

It represents a continuouus random variable genearated using the electronic calculator acording to the following formula:

$$U = RND(1)$$

Second: The conversion of the data generated from step (1), which follows the regular distribution to the distribution of the railly by a parameters using the distribution function of the ralily distribution and according to the inverse method of conversion:

$$F_i(x_i) = 1 - \left(\frac{k_i}{y_i}\right)^{\alpha_i},$$

$$\text{Then } U = 1 - \left(\frac{k_i}{y_i}\right)^{\alpha_i}.$$

The function cumulative probability function for the distribution of a rally with a parameter, which we conclude: $\left(\frac{k_i}{y_i}\right)^{\alpha_i} = 1 - U$

Taking into consideration the logarithm of the parties we get:

$$y_i = \exp\left[\frac{\alpha_i \ln k_i - \ln(1-u)}{\alpha_i}\right],$$

third level: At this stage, parameters are estimated for the distribution of a parameterized rally using one of the following methods:

Method (Determined MM): In this method, the parameters of the measurement parameters is obtained and according to the formula (9), the parameter of the measurement parameters is obtained.

The fourth stage: At this stage, the reliability function is estimation as one of the concrete and non-scientific methods according to the following estimation methods.

Level five: Repeat this process for 1000 times.

Sixth stage: At this stage, it is possible to compare the quantities obtained for the distribution of the rally with the parameters and its reliability function using the following statistical criteria Average error boxes (MSE) for the reliability function.

4 DISCUSS SIMULATION RESULTS

In this section, the results of simulation experiments will be presented and analyzed to estimate the reliability function according to the solid and non-scientific methods described in the theoretical side of this research. The results shown in the tables will be analyzed in sequence and as follows:

First: To estimate the parameter for the distribution of a parameterized rally by using one of the robust methods, the sample sizes used and the different cases of the initial values shown in Table 4

and to test the number of replicates 1000 described in the tables above.

Second: The results of the statistical standard Mean error squares (MSE) for the estimated parameters of the distributed rally of all the methods and the different sample sizes and all the cases of the initial default values and the experiment of the number of replicates 1000 as shown in the tables below - Tables 4 and 5.

Thirdly, the relability function is estimation by means of the methods and the number of replicates. The results are presented in tables (4 and 5).

The results of Tables 4-5 showed that the MM-Method is the best method of estimation because it possesses the lowest MSE and percentages according to its preference sequence.

5 CONCLUSIONS

The results demonstrate that the robust MM method consistently outperforms the non-parametric kernel estimation method, as indicated by the mean square error (MSE) analysis. The observed decrease in MSE values highlights the method's robustness in handling contaminated observations and its ability to accurately capture the underlying phenomenon. Moreover, the convergence of estimates from different methods with increasing sample size aligns with statistical theory, confirming the reliability of the proposed estimators. Applying these methods to other probability distributions in reliability studies may further validate their effectiveness. The simulations also show that the reliability function decreases with increasing operating time, remaining within the expected range [0,1], consistent with the theoretical properties of reliability. These findings suggest that future research could focus on estimating the reliability function for the Pareto distribution using monitoring data of both types, extending the applicability of the proposed methods.

6 RECOMMENDATIONS AND SUGGESTIONS

Hybrid algorithms that combine robust and nonparametric methods could be developed to further reduce estimation error, and the study could be extended to other probability distributions commonly used in reliability analysis, such as Weibull, Exponential, and Lognormal, to evaluate the performance and potential superiority of the MM method in different contexts. The results indicate that estimation accuracy improves with larger sample sizes; therefore, researchers and engineers are encouraged to collect sufficient data to obtain more stable and reliable results. Additionally, future research could explore the use of the truncated Pareto distribution from above as a model for failure, employing simulation methods to compare the effectiveness of various estimation approaches in this scenario.

Keywords: Inverse Stereographic Projection, Stereographic Semicircular Lomax Distribution, Survival Function, Cramer Von Mises Method.

Abstract: This study aims to convert a traditional Lomax distribution into the Stereographically Projected Semicircular Lomax (SSL) distribution by making use of the inverse stereographic projection. The main focus is to semicircularize gathering of data from various applied disciplines to impart flexibility at a higher operational level and, therefore, allow appropriate estimation to be carried out through a flexible model for parameters related to SSL distribution. Further, the entire collection of statistical properties of the proposed distribution has been completely laid out from first principles, including those for the CDF, survival function S(t), and the hazard rate function h(t) in addition to the PDF. There have been two methods adopted for the parameter estimation: Maximum Likelihood Estimation and Cramér von Mises methods. Monte Carlo simulation studies were employed in which several fixed sample sizes were considered in order to analyze the performance of the MLE and CVM methods of parameter estimation. The comparison has been made under the Mean Squared Error (MSE) criterion. The results disclosed that MLE does better than CVM in giving smaller MSE values and hence for estimation.

1 INTRODUCTION

Circular data is crucial since natural and social phenomena during which cyclic repetition is involved are researched. Such data could be measured along axes that involve angles, directions, or positions along circles or semicircles. Hence, for example, one may consider wind direction or phenomenal geographic paths.

Such data have completely different statistical properties as compared to the traditional linear data, as the values are constrained in a closed interval normally taken as $(0, 2\pi)$ depending on the nature of the phenomenon under research. Linear distributions may not be suitable to analyze circular data because of the specific structure that circular data have. In modeling such data, special distributions must be considered since they correspond to the circular nature of the data.

One special subclass lying within the semicircle of the unit circle is known as semi-circular data restricted to the interval $(0, \pi)$. To cater for this issue, the Semi-Circular Lomax Distribution has been put forward. It finds applications in economic modeling and is defined in the interval $(0, \pi)$. Nevertheless, its classical linear approach is generally inappropriate for data with circular or semi-circular characteristics.

This motivated the use of transformation techniques such as the Inverse Stereographic Projection to develop new, more flexible semi-circular distributions suited to this type of data. The primary objective behind developing such a new distribution is to integrate the properties of the Lomax distribution with circular transformation methods, allowing for enhanced applications in risk analysis, prediction, and the research of relationships among periodic variables.

Moreover, this approach helps bridge the methodological gap caused by the limitations of classical linear distributions in handling circular or semi-circular data. Several relevant studies have contributed to this area of research:

- Byoung and his colleagues provided a set of semicircular Laplace distributions in 2008 to enable one to fit particular data sets by simple projection [1].
- In the year 2014, Girija et al. formulated the Double Exponential Semi-Circular Distribution using stereographic projection methods [2].

- In 2019, Yedlapalli and collaborators proposed the Stereographic Semi-Circular Lindley Distribution [3].
- In 2022, Ayesha Iftikhar introduced the Modified Third Burr-III(hcMB-III) Stereographic Semi-Circular Distribution [4].
- In 2024, Oleiwi et al. introduced the Stereographic Semi-Circular Rayleigh Distribution [5].

Building on these three attempts, there is a semi-circular model- Stereographically Projected Semicircular Lomax Distribution which results from the application of inverse stereographic projection to the traditional Lomax distribution. Using varying parameter values, the probability density function (PDF) and cumulative distribution function (CDF) were plotted using the proposed distribution. The first two trigonometric moments were then computed in order to investigate the statistical properties of the new model.

2 INVERSE STEREOGRAPHIC PROJECTION METHOD

One of the critical methods transferred by inverse stereographic projection is that continuous distributions defined on the real number line are transformed into distributions defined on the circumference of the unit circle. The angular domain created by this transformation does not cover the entire circular range but is restricted to an open semicircle. In turn, the resulting distribution does not possess complete rotational symmetry.

The limitation has been discussed in past literature, including those by Yedlapalli, and Radhika [6], [7] and another study by Srinivas, Phani, and Girija (2019), which focused on how the limited angular coverage affects circular data modeling.

The Inverse Stereographic Projection is defined as follows:

$$T(\theta) = x = v\tan\left(\frac{\theta}{2}\right). \quad x \in (-\infty, \infty), \theta \in (-\pi, \pi), v > 0, \tag{1}$$

And then

$$\theta = 2\tan^{-1}\left(\frac{x}{v}\right). \tag{2}$$

The CDF of the semicircular distribution is given by

$$G(\theta) = F(x) = F\left(v\tan\left(\frac{\theta}{2}\right)\right), \tag{3}$$

$$g(\theta) = \frac{v}{2} f\left(v\tan\left(\frac{\theta}{2}\right)\right) sec^2\left(\frac{\theta}{2}\right). \tag{4}$$

The method discussed here views the inverse stereographic projection as applied to a probability distribution in order to produce a new semicircular distribution on the interval (0, π) which could be conveniently used for modeling semicircular data.

3 THE SEMICIRCULAR LOMAX DISTRIBUTION (SSL)

This segment introduces another member of the family of transformations of the semicircular distributions, such as the semicircular lomax distribution under stereographic projections. Definition: We say that a random variable X in the real line is lomax distributed with scale parameter α>0, and location parameter λ>0, if its probability density function and cumulative distribution functions of X are respectively given by [8]:

$$f(x, \alpha, \lambda) = \frac{\alpha}{\lambda}\left(1 + \frac{x}{\lambda}\right)^{-(\alpha+1)}, \tag{5}$$

where x>0 and

$$F(x, \alpha, \lambda) = 1 - \left(1 + \frac{x}{\lambda}\right)^{-\alpha}. \tag{6}$$

3.1 The PDF and CDF of SSL Distribution

Note [6] that the Probability Density Functions and Cumulative Distribution Functions corresponding to the Stereographically Projected Semicircular Lomax Distribution can be respectively written as:

$$g(\theta) = \frac{v}{2}\frac{\alpha}{\lambda}\left(1 + \frac{v\tan\left(\frac{\theta}{2}\right)}{\lambda}\right)^{-(\alpha+1)} \sec^2\left(\frac{\theta}{2}\right), \tag{7}$$

The shape of the PDF for different parameter values is illustrated in Figure 1.

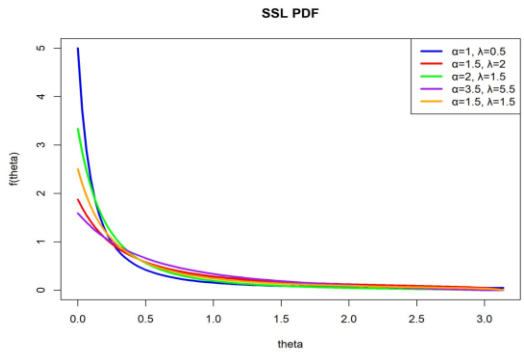

Figure 1: PDF of the Stereographic Lomax distribution.

The CDF of the Stereographically Projected Semicircular Lomax Distribution (SSL), or the nonreliability function, gives the probability that a unit fails before time t. It is defined as:

$$G(\theta,\alpha,\lambda) = 1 - \left(1 + \frac{v\tan\frac{\theta}{2}}{\lambda}\right)^{-\alpha} . \qquad (8)$$

The corresponding CDF curves are shown in Figure 2.

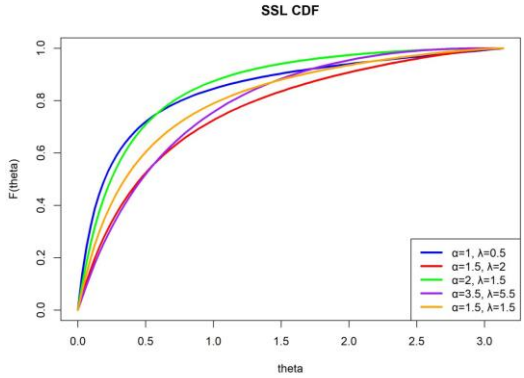

Figure 2: CDF of the Stereographic Lomax distribution.

3.2 Survival Measures and Hazard Function of SSL Distribution

References [9] provide us with the information that from (7) and (8), we can generalize the survival function S(t) and hazard function h(t) for the Stereographically Projected Semicircular Lomax Distribution.

$$S(\theta) = 1 - G(\theta) = \left(1 - \left(1 - \left(1 + \frac{v\tan\frac{\theta}{2}}{\lambda}\right)^{-\alpha}\right)\right).$$

$$S(\theta) = \left(1 + \frac{v\tan\frac{\theta}{2}}{\lambda}\right)^{-\alpha} . \qquad (9)$$

The behavior of the survival function is illustrated in Figure 3.

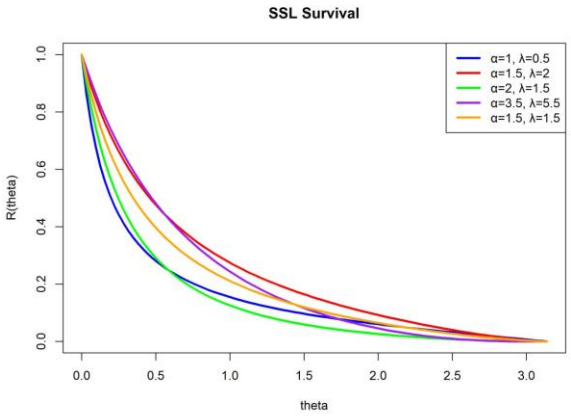

Figure 3: Survival function of the Stereographic Lomax distribution.

$$h(\theta) = \frac{g(\theta)}{1-G(\theta)} = \frac{\frac{v}{2}\frac{\alpha}{\lambda}\left(1+\frac{v\tan\left(\frac{\theta}{2}\right)}{\lambda}\right)^{-(\alpha+1)} sec^2\left(\frac{\theta}{2}\right)}{\left(1+\frac{v\tan\frac{\theta}{2}}{\lambda}\right)^{-\alpha}} \qquad (10)$$

The corresponding hazard function is presented in Figure 4.

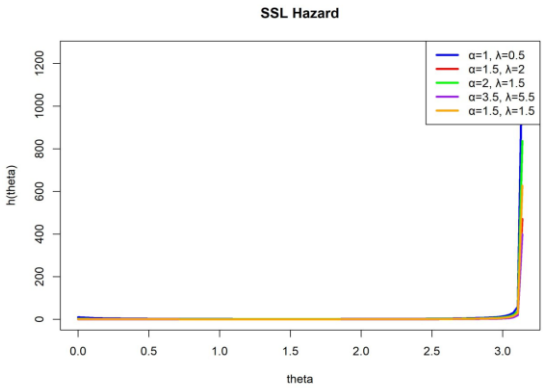

Figure 4: Graph of Hazard function of the Stereographic lomax distribution.

3.3 The r^{th} Moment of *SSL* Distribution

The r^{th} non-central moment of the *SSL* distribution, (θ^{r}) SSL, can be obtained through the pdf in (7) with the following form:

$$E(\theta)^r = \int_0^{\pi} \theta^r \; f(\theta,\alpha,\lambda)\, d\theta \; = \int_0^{\pi} \frac{v}{2}\frac{\alpha}{\lambda}(\theta)^r \left(1 + \frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-(\alpha+1)} \sec^2\tau\left(\frac{\theta}{2}\right) d\theta\,, \qquad (11)$$

$$= \frac{v}{2}\frac{\alpha}{\lambda}\int_0^{\pi}(\theta)^r \left(1 + \frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-(\alpha+1)} \sec^2\left(\frac{\theta}{2}\right) d\theta.$$

Since $x = v\tan\left(\frac{\theta}{2}\right)$, $\theta = 2\tan^{-1}\left(\frac{x}{v}\right)$, $d\theta = \left(\frac{2v}{v^2+x^2}\right) dx$ = $\frac{v}{2}\frac{\alpha}{\lambda}\int_0^{\infty}\left(2\tan^{-1}\left(\frac{x}{v}\right)\right)^r \left(1+\frac{x}{\lambda}\right)^{-(\alpha+1)} \sec^2\left(\frac{2\tan^{-1}\left(\frac{x}{v}\right)}{2}\right)\left(\frac{2v}{v^2+x^2}\right) dx.$

Since $\sec^2\tan^{-1}\left(\frac{x}{v}\right) = \frac{v^2+x^2}{v^2} = \frac{v}{2}\frac{\alpha}{\lambda}\int_0^{\infty}\left(2\tan^{-1}\left(\frac{x}{v}\right)\right)^r \left(1+\frac{x}{\lambda}\right)^{-(\alpha+1)}\left(\frac{v^2+x^2}{v^2}\right)\left(\frac{2v}{v^2+x^2}\right) dx = \frac{\alpha}{\lambda}\int_0^{\infty}\left(2\tan^{-1}\left(\frac{x}{v}\right)\right)^r \left(1+\frac{x}{\lambda}\right)^{-(\alpha+1)} dx.$

Using the power series of $\tan^{-1}(x)$.

$$\text{Let } \tan^{-1} = \sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2(2k+1)}\left(\frac{\left(\frac{x}{v}\right)^2}{\left(\frac{x}{v}\right)^2+1}\right)^{k+\frac{1}{2}}$$

$$= \frac{\alpha}{\lambda}\int_0^{\infty}\left(2\sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2(2k+1)}\left(\frac{\left(\frac{x}{v}\right)^2}{\left(\frac{x}{v}\right)^2+1}\right)^{k+\frac{1}{2}}\right)^r \left(1+\frac{x}{\lambda}\right)^{-(\alpha+1)} dx.$$

$$\text{let } u = \frac{\left(\frac{x}{v}\right)^2}{\left(\frac{x}{v}\right)^2+1} \qquad x = v\left(\frac{1}{u}-1\right)^{\frac{-1}{2}}$$

$$dx = \frac{v}{2u^2}\left(\frac{1}{u}-1\right)^{\frac{-3}{2}} du$$

$$= \frac{\alpha}{\lambda}\int_0^1 \left(2\sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2(2k+1)}\, u^{k+\frac{1}{2}}\right)^r \left(1+\frac{v\left(\frac{1}{u}-1\right)^{\frac{-1}{2}}}{\lambda}\right)^{-(\alpha+1)} \frac{v}{2u^2}\left(\frac{1}{u}-1\right)^{\frac{-3}{2}} du.$$

Using Newton Binomial formula we obtain

$$\left(1+\frac{v\left(\frac{1}{u}-1\right)^{\frac{-1}{2}}}{\lambda}\right)^{-(\alpha+1)} = \sum_{j=0}^{\infty}\binom{-(\alpha+1)}{j}\left(\frac{v}{\lambda}\right)^j \left(\left(\frac{1}{u}-1\right)^{\frac{-1}{2}}\right)^j$$

$$= \frac{\alpha}{\lambda}\int_0^1 \frac{v}{2u^2}\left(2\sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2(2k+1)}\, u^{k+\frac{1}{2}}\right)\sum_{j=0}^{\infty}\binom{-(\alpha+1)}{j}\left(\frac{v}{\lambda}\right)^j\left(\frac{1}{u}-1\right)^{\frac{-3}{2}-\frac{j}{2}} du\,,$$

$$(1-u)^{\frac{-3}{2}-\frac{j}{2}} = \sum_{m=0}^{\infty}\binom{-\frac{3}{2}-\frac{j}{2}}{m}(-1)^m\left(\frac{1}{u}\right)^{-m}(u)^{\frac{3}{2}+\frac{j}{2}}$$

$$= \frac{\alpha}{\lambda}\int_0^1 \frac{v}{2u^2}\left(2\sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2(2k+1)}\, u^{k+\frac{1}{2}}\right)^r \sum_{j=0}^{\infty}\sum_{m=0}^{\infty}\binom{-(\alpha+1)}{j}\binom{-\frac{3}{2}-\frac{j}{2}}{m}\left(\frac{v}{\lambda}\right)^j(-1)^m\left(\frac{1}{u}\right)^{\frac{-3}{2}-\frac{j}{2}-m} du$$

$$= \frac{\alpha 2^r}{\lambda}\frac{v}{2}\sum_{j,m=0}^{\infty}\binom{-(\alpha+1)}{j}\left(\frac{v}{\lambda}\right)^j\binom{\frac{-3}{2}-\frac{j}{2}}{m}(-1)^m\int_0^1\left(\sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2(2k+1)}\, u^k\right)^r (u)^{m+\frac{r}{2}+\frac{3}{2}+\frac{j}{2}-2} du$$

According to the circumstance $\left(\sum_{k=0}^{\infty} a_k\, u^k\right)^r$

$= \sum_{k=0}^{\infty} b_k\,(u)^k$; r is a natural number b_0

$= a_0^r$, and $b_h = \frac{1}{a_0\, h}\sum_{k=1}^{h}(kr-h+k)\; a_k\, b_{h-k}$; h ≥ 1, the $E(\theta)^r$ with

$a_k = \frac{(2k)!}{2^{2k}(k!)^2(2k+1)}$ *will be*

$$E(\theta)^r = \frac{b_k\,\alpha 2^r}{\lambda}\frac{v}{2}\sum_{j,m,k=0}^{\infty}\binom{-(\alpha+1)}{j}\left(\frac{v}{\lambda}\right)^j\binom{\frac{-3}{2}-\frac{j}{2}}{m}(-1)^m\int_0^1 (u)^{k+m+\frac{r}{2}+\frac{j}{2}+\frac{3}{2}-2} du,$$

$$E(\theta)^r = \frac{b_k\,\alpha 2^r}{\lambda}\frac{v}{2}\sum_{j,m,k=0}^{\infty}\binom{-(\alpha+1)}{j}\left(\frac{v}{\lambda}\right)^j\binom{\frac{-3}{2}-\frac{j}{2}}{m}(-1)^m\frac{1}{k+m+\frac{r}{2}+\frac{j}{2}+\frac{3}{2}-1}. \qquad (12)$$

3.4 Trigonometric Moments

To study the population characteristic, the first and second trigonometric moments of the Stereographic semicircular Lomax distribution are derived. The moments of the distribution, being the b^th; b= 0, ±1, ±2…, can be introduced from [3] [10].

$$\emptyset_b = \alpha_b + i\delta_b \quad , \emptyset_b = b, \mp 1, \mp 2 \ldots\ldots$$
$$\alpha_b = E(\cos b\theta)$$
$$\lambda_b = E(\sin b\theta)$$

$$E(\cos b\theta) = \int_0^{\pi}\cos(b\theta)\, f(\theta,\alpha,\lambda)d\theta\,, \qquad (13)$$

$$E(\cos b\theta) = \int_0^{\pi}\cos(b\theta)\frac{v}{2}\frac{\alpha}{\lambda}\left(1+\frac{v\tan\frac{\theta}{2}}{\beta}\right)^{-(\alpha+1)}\sec^2\left(\frac{\theta}{2}\right)d\theta,$$

$$\text{let } \cos(b\theta) = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n)!}(b\theta)^{2n} = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n)!}(b)^{2n}(\theta)^{2n},$$

$$E(\cos b\theta) = = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n)!}(b)^{2n}\int_0^{\pi}(\theta)^{2n}\frac{v}{2}\frac{\alpha}{\lambda}\left(1+\frac{v\tan\frac{\theta}{2}}{\beta}\right)^{-(\alpha+1)}\sec^2\left(\frac{\theta}{2}\right)d\theta,$$

$$E(\cos b\theta) = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n)!}(b)^{2n}\; E(\theta)^{2n},$$

$$\alpha_1 = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n)!}(1)^{2n}\, E(\theta)^{2n}, \qquad (14)$$

$$\alpha_2 = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n)!}(2)^{2n}\, E(\theta)^{2n}, \qquad (15)$$

$$E(\sin b\theta) = \int_0^{\pi} \sin(b\theta)\ \frac{v}{2}\frac{\alpha}{\lambda}\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-(\alpha+1)} \sec^2\left(\frac{\theta}{2}\right) d\theta, \quad (16)$$

$$let \sin(b\theta) = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n+1)!}(b\theta)^{2n+1} = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n+1)!}(b)^{2n+1}(\theta)^{2n+1}$$

$$= \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n+1)!}(b)^{2n+1}\int_0^{\pi}(\theta)^{2n+1}\ \frac{v}{2}\frac{\alpha}{\lambda}\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-(\alpha+1)} \sec^2\left(\frac{\theta}{2}\right) d\theta$$

$$E(\sin b\theta) = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n+1)!}\ (b)^{2n+1}\ E(\theta)^{2n+1}$$

$$\lambda_1 = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n+1)!}\ (1)^{2n+1}\ E(\theta)^{2n+1}, \quad (17)$$

$$\lambda_2 = \sum_{n=0}^{\infty}\frac{(-1)^n}{(2n+1)!}\ (2)^{2n+1}\ E(\theta)^{2n+1}. \quad (18)$$

Here $(\theta^{2n+1})\ SSl\ and\ \ E(\theta^{2n})SSL$ as in (8) respectively.

With $r = 2n + 1$ and $r = 2n$.

Simulated data and a quantile function for *S*SL distribution. By means of inversion of the cdf in (8), the quantile function of the *S*SL distribution is obtained as in [11].

$$\theta_{(q)SSL} = 2\tan^{-1}\left(\frac{\lambda}{v}\left[(1-u)^{\frac{-1}{\alpha}} - 1\ \right]\right). \quad (19)$$

The median of the SSL random variable can be gained from (20) by setting $q = \frac{1}{2}$ as

$$\theta_{med} = 2\tan^{-1}\left(\frac{\lambda}{v}\left[\left(1-\frac{1}{2}\right)^{\frac{-1}{\alpha}} - 1\ \right]\right). \quad (20)$$

By replacing q with u a random variable that follows *S*SL distribution can be simulated as:

$$\theta_{SSL} = 2\tan^{-1}\left(\frac{\lambda}{v}\left[(1-u)^{\frac{-1}{\alpha}} - 1\ \right]\right), \quad (21)$$

where u is an interval based uniform random number (0,1).

4 ESTIMATION METHODS

4.1 Maximum Likelihood Method

It is a method most often used for estimation because it possesses a set of characteristics that distinguish it from others. These features include consistency, which is mostly present, stability, and unbiasedness [12] - [14].

$$f(\theta,\alpha,\lambda) = \frac{v}{2}\ \frac{\alpha}{\lambda}\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-(\alpha+1)} \quad sec^2\left(\frac{\theta}{2}\right),$$

$$Lf(\theta,\alpha,\lambda) = \prod_{i=1}^{n}\left[\frac{v}{2}\frac{\alpha}{\lambda}\left(1+\frac{vtan\frac{\theta_i}{2}}{\lambda}\right)^{-(\alpha+1)} \quad sec^2\left(\frac{\theta_i}{2}\right)\right],$$

$$= \left(\frac{v}{2}\right)^n\left(\frac{\alpha}{\lambda}\right)^n \prod_{i=1}^{n}\left(1+\frac{vtan\frac{\theta_i}{2}}{\lambda}\right)^{-(\alpha+1)} \quad \prod_{i=1}^{n} sec^2\left(\frac{\theta_i}{2}\right), \quad (22)$$

$$Ln\ L = n\ln v + n\ Ln\ \alpha - n\ Ln2 - n\ Ln\ \lambda - (\alpha+1)\sum_{i=1}^{n} Ln\left(1+\frac{vtan\frac{\theta_i}{2}}{\lambda}\right) + 2\sum_{i=1}^{n} Ln\sec\left(\frac{\theta_i}{2}\right),$$

$$\frac{\partial\ Ln\ L(\alpha,\lambda)}{\partial\alpha} = \frac{n}{\alpha} - \sum_{i=1}^{n} Ln\left(1+\frac{vtan\ \frac{\theta_i}{2}}{\lambda}\right) = 0. \quad (23)$$

The partial derivative with respect to the parameter λ.

$$\frac{\partial Ln\ L(\alpha,\lambda)}{\partial\lambda} = -\frac{n}{\lambda} + (\alpha+1)\sum_{i=1}^{n}\frac{\frac{vtan\frac{\theta_i}{2}}{\lambda^2}}{1+\frac{vtan\frac{\theta_i}{2}}{\lambda}} = 0. \quad (24)$$

4.2 Cramer–von Mises Method

Such a minimum distance estimator constructed from the difference between the theoretical and empirical cumulative distribution functions is realizable as follows: By taking partial derivatives with respect to the parameters and setting the results equal to zero, we find the parameter estimates [15], [16].

$$k(\alpha,\lambda) = \frac{1}{12n} + \sum_{i=1}^{n}\left[F(\theta,\alpha,\lambda) - \frac{2i-1}{2n}\right]^2. \quad (25)$$

$$k(\alpha,\lambda) = \frac{1}{12n} + \sum_{i=1}^{n}\left[1-\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-\alpha} - \frac{2i-1}{2n}\right]^2,$$

$$\frac{\partial\ k}{\partial\ \alpha} = 2\sum_{i=1}^{n}\left[F(\theta,\alpha,\lambda) - \frac{2i-1}{2n}\right]\ \frac{\partial F(\theta,\alpha,\lambda)}{\partial\alpha},$$

$$\frac{\partial k}{\partial\alpha} = 2\sum_{i=1}^{n}\left[1-\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-\alpha} - \frac{2i-1}{2n}\right].\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-\alpha} ln\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right) = 0. \quad (26)$$

$$\frac{\partial\ k}{\partial\ \lambda} = 2\sum_{i=1}^{n}\left[F(\theta,\alpha,\lambda) - \frac{2i-1}{2n}\right]\ \frac{\partial F(\theta,\alpha,\lambda)}{\partial\lambda},$$

$$\frac{\partial k}{\partial\lambda} = 2\sum_{i=1}^{n}\left[1-\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-\alpha} - \frac{2i-1}{2n}\right].\alpha\left(1+\frac{vtan\frac{\theta}{2}}{\lambda}\right)^{-\alpha-1}\ \frac{vtan\frac{\theta}{2}}{\lambda^2} = 0. \quad (27)$$

5 SIMULATION STUDY

Empirical behaviors of Maximum likelihood and Cramer–von Mises of the SSL parameters had to be detected at various sample sizes (10, 25, 50, 75, and 100) through simulation studies via R. The SSL value is simulated based on (21) by plugging in the parameters' default values shown in the table, where λ=0.5; α=1; v=1. For the experiment, K=1000. The tests are compared and determined through the use of the mean square error criterion.

$$\mathrm{MSE}(\Omega) = \frac{1}{1000}\sum_{i=1}^{1000}\left(\widehat{\Omega}_i - \Omega\right)^2. \qquad (28)$$

Accordingly, the estimates of the parameters of the semicircular stereographic Lomax distribution resulting from the simulation study using the (MLE) and (CVM) methods are shown in Table 1, and the mean squared error (MSE) values of these estimates are shown in Table 2.

Table 1: The estimated parameter values at the assumed values (α = 1, λ = 0.5).

n	Method	α est.	λ est.
10	MLE	1.21577	0.63889
	CVM	1.11423	0.60357
25	MLE	1.12402	0.60136
	CVM	1.10399	0.59211
50	MLE	1.10891	0.59126
	CVM	1.10164	0.58811
75	MLE	1.07310	0.56215
	CVM	1.08787	0.57085
100	MLE	1.05928	0.54983
	CVM	1.08009	0.56395

Table 2: The MSE values of the parameters at the assumed values (α = 1, λ = 0.5).

n	Method	α MSE	λ MSE.
10	MLE	0.29276	0.13052
	CVM	0.26990	0.13643
25	MLE	0.15802	0.09489
	CVM	0.18548	0.10513
50	MLE	0.11017	0.06915
	CVM	0.14159	0.08352

The results of Tables 1 and 2 indicate that the Maximum Likelihood Estimation (MLE) method yields better performance in estimating the parameters (α, λ) compared to the Cramer–von Mises (CVM) method. There are smaller MSEs across smaller to larger sample sizes; hence, this conclusion. The larger the sample size, the smaller the MSE values, which in turn show increasing estimation accuracy; this property is known as consistency.

6 CONCLUSIONS

The Stereographic Semicircular Lomax Distribution (SSL) was introduced through the application of the Inverse Stereographic Projection method. The main contribution of this study is to extend the classical Lomax model to a semicircular framework, which has not been considered in previous studies. The proposed distribution is flexible and capable of handling the varied kinds of semicircular data observed in several fields. The basic statistical properties, including the probability density function and cumulative distribution function, survival function, hazard rate, along with others.

Simulations indicated that the Maximum Likelihood Estimation technique is superior for deriving parameter estimates compared to the Cramer–von Mises approach, particularly as the sample size expands. This conclusion was further substantiated by The MSE values of the MLE estimators are lower compared to the Cramer Von Mises estimators, especially with increasing sample size. Although the study is based on simulated data, the results demonstrate the effectiveness of the proposed distribution in accurately reflecting the statistical behavior of semicircular data. it also confirms its suitability and ability to represent semicircular data.

7 RECOMMENDATIONS

The study therefore suggests that MLE should be central to parameter estimation for any SSL distribution on account of its perceived increased adeptness. Due to the very general capability to model any semi-circular data, the proposed distribution finds application in many areas. The focal points of the coming researchers should be as follows: the complete comparison of the performance of the alternative estimators such as Least Squares or Bayesian Estimation against MLE and CVM methods. It is further strongly recommended to try this distribution on empirical data from practical applications to critically test its practical usefulness.

Keywords: Common Correlated Effects, Hybrid Coefficients Model, Unbalanced Panel Data, Mean Group Estimator, Pooled Estimator, Half Jackknife Panel Estimator.

Abstract: In this research, a model of panel data models was reviewed which is hybrid coefficients model which is characterized by a portion of the regression coefficients being fixed slopes while the other portion of the coefficients are random slopes meaning that they have a normal distribution with an unknown mean and variance. Several methods were used to estimate the parameters of this model in the case of unbalanced panel data. these estimation methods depend on the common correlated effects estimator which is composed of three estimators, common correlated effect mean group estimator(CCEMG), common correlated effect pooled (CCEP) and half jackknife panel (HJP)estimator to estimate the parameters of the hybrid coefficients model represented by the first fixed slope and the mean of the random slope coefficient. Monte Carlo experiments and different sample sizes (NT) are small, medium and large, with different variance levels to compare between estimation methods, the simulation results showed that the (CCEP) is the best estimation method because it has the less average mean absolute error (AMAE). The (CCMG) is the best method after (CCEP).

1 INTRODUCTION

Since the beginning of the fifties of the twentieth century, applied studies have taken a new path characterized by the increasing use of theoretical hypotheses that are in the form of primary information derived from outside the scope of the sample and provided by the theory behind the phenomenon studied or previous studies and combining them with sample data whether cross – sectional data or time series data, to obtain estimates of the parameters of the model studied that more efficient than the estimators based on time series or cross sectional alone. methods used to combine time series and cross-sectional data at the single equation level involve using the cross-sectional data to estimate some model parameters and then introducing these estimators as constant value constraints into the time series regression equation.

Panel data consists of cross-sectional data and time series data. the behavior of data categories is observed over a period of time. These categories maybe (countries, companies,…,etc) [1]. Observation from the same category is correlated and correlation is the distinguishing feature of these data. They are also known as longitudinal data. panel data have group effects (cross sectional) or have time effects or both. panel data are divided into two types, balanced panel data which contain equal time periods for all cross sections but if the time period differs across cross sections, it is called unbalanced panel data. the main objective of this research is to estimate the parameters of hybrid coefficients model for unbalanced panel data and to compare the estimation methods to show the best estimation methods.

2 PANEL DATA REGRESSION MODELS

Regression analysis is one of the important topics of statistics, which is widely used in all fields of science and knowledge because it describes the relation between variables in the form of an equation it can be known in general as the analysis that specializes in studying the effect of one or more variables called the independent variable or independent variables on one variable called the dependent variable [2]. This is for the purpose of estimating or predicting the value of the dependent variable given the information of the independent variable or variables.

Accordingly, the regression model is used to arrive at mathematical model that explains the quantitative relationship between the dependent and the independent variables. Therefore, it can be defined as a statistical method used to analyze data that contains two or more variables when the goal is to discover the nature of this relationship.

In general, regression models can be classified according to several factors [3]:

1) The number of the variables. There is common division of regression models according to the number of independent variables used in the models. if the model contains one independent variable with the dependent variable, the model is called a simple regression model. however, if the number of independent variables is more than one, it is called a multiple regression model.
2) The form of the relation between the variables. Here we can distinguish between two types of regression models, the linear regression model and nonlinear regression model.
3) Level of measurement for variables. This classification depends on the type of data for the dependent variable, whether it is descriptive or quantitative data. here, it can be divided in two types of regression models, logistic regression models it is used when the data of the dependent variable is descriptive. the second is the traditional regression model, which is used when the data of the dependent variable is quantitative data. if the quantitative data is time series data, then time series regression models are used, and if the quantitative contains cross sections, then cross – sectional data regression models are used. but if the dependent variable and the independent variables are time series and cross – sectional data, then panel data models are used because the independent variables and the dependent variable have two dimensions, which are the cross – section and time.

In the current decade, panel data models have gained great interest especially in economic and medical studies because they take into account the effect of change in time as well as the effect change in cross – sectional observations. many researchers studied panel data models, some of whom were interested in studying the properties of these models mathematically [4], [5]. Among those who were interested in applying these models in their studies [6], [7].

The panel data has the following properties [1], [8]:

1) it allows controlling individual variation that may appear in the case of cross – sectional or temporal data which leads to biased results;
2) it helps control some variables that remain constant among individuals but change over time, such as national policies and international agreements;
3) panel data contain more information content that cross – sectional or temporal data, and therefore it is possible to obtain estimates with higher confidence and the problem of common correlation between variables is less severe than time series data;
4) panel data distinguished from others in that it includes a greater number of degrees of freedom and is characterized by better efficiency as well as multicollinearity between variables and more information content if cross – sectional or temporal data are used;
5) panel data models provide a better possibility to study the adjustment dynamics that may be hidden by cross – sectional data, and they are also suitable for studying periods of economic conditions such as unemployment poverty, growth and others. on the other hand, it is possible through panel data to link the behaviors of the sample observations from one point in time to another;
6) panel data models contribute to reducing the possibility of the problem of neglected variables resulting from unobserved item characteristics that usually lead to biased estimates;
7) the importance of using panel data is that takes into account what is described as heterogeneity or unobserved difference specifics to the sample observations whether cross – sectional or temporal;
8) these models help prevent the common problem of heteroscedasticity.

3 THE MODEL

In simple and multiple regression model, the regression coefficients are fixed parameters so we seek to estimate these parameters using classical or Bayesian methods [9]. However, when the regression coefficients(slopes) are random parameters and not fixed, then they are called random coefficient (RCR) model [10].

In the research, we will discuss a model that contains both fixed and random regression coefficients, which is given by the following [11]:

$$Y_{it} = X_{1it}\beta_1 + X_{2it}\beta_{2i} + u_{it}, \quad (1)$$

where i=1,2,…,N represent cross section unit and t=1,2,…,T_i represent time series period.

Model (1) is unbalanced panel data, meaning that there are N individuals observed over varying time periods length (i=1,2, …, T_i). the model in (1) can be rewritten by stacking over time period t:

$$Y_i = X_{1i}\beta_1 + X_{2i}\beta_{2i} + u_i, \quad (2)$$

where $Y_i = (Y_{i1}, \dots, Y_{iT_i})'$,$X_{1i}, X_{2i}$ are matrices of rank $T_i \times K_1$ and $T_i \times K_2$ for explanatory variables and $\beta_1$is fixed slope of rank $K_1 \times 1$, β_{2i} is assumed random slope of rank $K_2 \times 1$, finally u_i is the random error of rank $T_i \times 1$. the model (2) has the following assumptions [12]:

Assumption 1: the random error has $E(u_i) = 0$ and $var(u_i) = \sigma_u^2 I_{T_i}$ $i = 1,2, \dots, N$.

Assumption 2: the slope coefficients β_{2i} are independent and distributed with:

$$E(\beta_{2i}) = \bar{\beta}_{2,} var(\beta_{2ij}) = \begin{cases} \Delta & i = j \\ 0 & i \neq j \end{cases} \; i,j = 1, \dots, N.$$

From assumption (2) can be written the random slope [13]:

$$\beta_{2i} = \bar{\beta}_2 + \mu_i, \quad (3)$$

where $\bar{\beta}_2 = (\bar{\beta}_{21}, \dots, \bar{\beta}_{2K_2})'$is a vector of constant parameters and $\mu_i = (\mu_1, \dots, \mu_{K_2})'$ with:

$$E(\mu_i) = 0, var(\mu_{ij}) = \begin{cases} \Delta & i = j \\ 0 & i \neq j \end{cases} \; i,j = 1, \dots, N,$$

where Δ is a K_2 diagonal matrix. we note that the random slope in assumption (3) is constant over time periods but changes over the cross sections due to the change in the random error.

By substituting (3) into (2), we get:

$$Y_i = X_{1i}\beta_1 + X_{2i}\bar{\beta}_2 + \varepsilon_i, \quad (4)$$

where $\varepsilon_i = X_{2i}\mu_i + u_i$, by rewriting the above model, we get:

$$Y = Q\bar{\theta} + \varepsilon, \quad (5)$$

where $Y = (Y_1, \dots, Y_N)', Q = (Q_1', \dots, Q_N')', \bar{\theta} = (\beta_1', \bar{\beta}_2')', Q_i = (X_{1i}, X_{2i}), \varepsilon = (\varepsilon_1', \dots, \varepsilon_2')'$.

4 ESTIMATION

In this section we will use different estimation methods to estimate the parameters of the hybrid coefficients model in the (5). These methods based on CCE estimator and are as follows:

4.1 CCE Mean Group Estimator

The common correlated effect estimator proposed by [14] to estimate panel data model with random regression coefficient. the CCEMG for estimate parameters in model (5) is given by [15]:

$$\hat{\bar{\theta}}_{CCEMG} = \frac{1}{N}\sum_{i=1}^{N} \hat{\theta}_{CCE,i}, \quad (6)$$

where $\hat{\theta}_{CCE,i}$is the (CCE) for each cross – sectional i which equal to:

$$\hat{\theta}_{CCE,i} = (Q_i' M_H Q_i)^{-1} Q_i' M_H Y_i, \quad (7)$$

where:

$$M_H = I_{T_i} - (H'H)^{-1}H',$$
$$H = (\bar{Q}, \bar{Y}),$$
$$\bar{Q} = (\bar{Q}_1, \dots, \bar{Q}_T)', \bar{Y} = (\bar{Y}_1, \dots, \bar{Y}_T),$$
$$\bar{Q}_t = \frac{1}{N}\sum_{i=1}^{N} Q_{it}, \bar{Y}_t = \frac{1}{N}\sum_{i=1}^{N} Y_{it},$$

The (CCEMG) is asymptotically distributed as [10]:

$$\sqrt{N}\left(\hat{\bar{\theta}}_{CCEMG} - \bar{\theta}\right) \rightarrow N(0, \hat{\gamma}_{CCEMG}),$$

where $\hat{\gamma}_{CCEMG}$ the variance of estimator in (6).

4.2 CCE Pooled Estimator

The CCEP estimator is calculated when the individuals slope coefficient β_{2i} are differ from cross–sectional to another. the CCEP is given by [14]:

$$\hat{\bar{\theta}}_{CCEP} = [\sum_{i=1}^{N} W_i Q_i' M_H Q_i]^{-1} \sum_{i=1}^{N} W_i Q_i' M_H Y_i, \quad (8)$$

where (W_i) represent weights for each i:

$$W_i = \frac{\sigma_i^{-2}}{\sum_{i=1}^{N} \sigma_i^{-2}}, \quad (9)$$

and

$$\sigma_i^2 = \frac{(Y_i - Q_i\hat{\theta}_{CCE,i})' M_H (Y_i - Q_i\hat{\theta}_{CCE,i})}{T_i}.$$

4.3 Half Jackknife Panel Estimator

This method was proposed by Dhaene and Jochmans (2012) [17]. the HJP estimator depend on CCE by dividing the time series within each cross – section into two halves and calculating the CCE for each half. the HJP is [16]:

$$\hat{\bar{\theta}}_{HJP} = 2\hat{\bar{\theta}}_{CCEMG} - \frac{1}{2}\left(\hat{\bar{\theta}}^{[1]}_{CCEMG} - \hat{\bar{\theta}}^{[2]}_{CCEMG}\right), \quad (10)$$

where $\hat{\bar{\theta}}_{CCEMG}$ is defined in (6), $\hat{\bar{\theta}}^{[1]}_{CCEMG}$ is calculated from time series t=1,2,…, $T_i/2$ in each cross–sectional i and $\hat{\bar{\theta}}^{[2]}_{CCEMG}$ is calculated from time series t=(T_i/2)+1,…,T_i.

5 THE SIMULATION STUDIES

In this section, we will compare between CCEMG, CCEP and HJP for different sample sizes, Monte Carlo simulation was used to generate variables of the hybrid model. the program used to write the Monte Carlo study is in the R Language.
Rewrite the model:

$$Y_{it} = X_{1it}\beta_1 + X_{2it}\beta_{2i} + u_{it}, \quad (11)$$
i=1,2,…, N t=1,2,…,T_i,

in this study, the values of the explanatory variables were generated with a normal distribution with mean 0 and variance equal to one, allowing them to differ within each cross – sectional. the fixed slope coefficient is chosen equal to $\beta_1 = 2,4$ and 6, the random slope coefficient were generated from assumption (3): $\beta_{2i} = \bar{\beta}_2 + \mu_i$ with mean $\bar{\beta}_2$ equal to 0.1, 0.2 and 0.4 and the random error $\mu_i$were generated as normal distribution with mean 0 and variance equal to 25,30. The random error u_{it} were generated with normal distribution with mean equal to 0 and variance equal to 2,4 and 6. the values of N, T were chosen from different values (N=T= 6, 10, 12, 14 and 16). thus, the sample size in the case of balanced panel data is equal to (n=NT), while in the unbalanced panel data, the sample size is equal to $n = \sum_{i=1}^{N} T_i$. for each N cross sections there is cross section containing a time series that differs from the other sections to obtain unbalanced panel data. in this study the third cross section for each N was made to contain four individual of time series i.e (Ti=4 for i=3). Table 1 includes the results for AMAEwhen β_1 =2, $\beta_{2i} \sim N(0.1,25)$, Table 2 when β_1 = 4, $\beta_{2i} \sim N(0.2,30)$ and Table 3 when β_1 = 6, $\beta_{2i} \sim N(0.4,30)$.

5.1 Results

In this section we will calculated the (AMAE) for estimation methods CCEMG, CCEP and HJPE for compare between these estimators. the AMAE is given by:

$$AMAE(Y) = \frac{1}{R}\sum_{i=1}^{R} MAE(Y),$$

where R represent the number of replicates of the experiments equal to 1000. and MAE equal to:

$$MAE(Y) = \frac{1}{n}\sum_{i=1}^{n} |Y_i - \hat{Y}_i|.$$

Table 1: AMAE when$\beta_1 = 2, \beta_{2i} \sim N(0.1,25)$.

N=T	Estimators	σ_u^2		
		2	4	6
6	CCEMG	1.58890	2.44088	3.78405
	CCEP	.101954	.124670	1.46042
	HJP	8.81388	51.68297	18.55046

	HJP	1.01465	7.84661	1.70827

From Table 2 the best estimation method is CCEP as it has the lowest AMAE,except for N=T=8 N=T=10, N=T=12 and N=T=16 with σ_u^2 =2 where the results showed superiority the CCMG. The HJP has highest AMAE it was the worst estimation method. Figure 2 visualizes these AMAE results for easier comparison.

Table 3: AMAE when $\beta_1 = 6, \beta_{2i} \sim N(0.4,30)$.

N=T	Estimators	σ_u^2		
		2	4	6
6	CCEMG	1.86835	3.32966	4.18577
	CCEP	0.93177	1.28543	1.54104
	HJP	10.41008	22.00085	30.92379
8	CCEMG	1.22375	1.54505	2.65452
	CCEP	0.81278	1.11075	1.29558
	HJP	3.49339	6.90341	13.76258
10	CCEMG	1.44390	1.09846	1.41257
	CCEP	0.71073	0.82516	0.88389
	HJP	14.04935	13.72030	18.08526
12	CCEMG	0.74377	1.18751	1.67669
	CCEP	.062070	.080228	0.87733
	HJP	1.37923	3.89849	4.67962
14	CCEMG	.076134	1.81599	1.08066
	CCEP	0.54181	0.72836	0.77666
	HJP	1.06013	3.45888	1.96723
16	CCEMG	0.73231	0.81515	1.50622
	CCEP	0.58370	0.74749	0.78464
	HJP	1.07678	1.15790	3.40047

From Table 3 the best estimation method is CCEP as it has the lowest AMAE for all values of N=T. the second place was taken by the CCEMG. the AMAE values decrease with increasing values of N, T and increase with increasing the variance levels. the HJP method has fluctuations in the AMAE values. The trends in AMAE for this scenario are depicted in Figure 3.

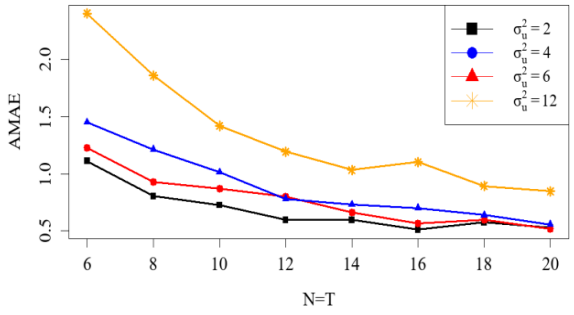

Figure 1: CCEP for $\beta_1 = 2, \beta_{2i} \sim N(0.1,25)$.

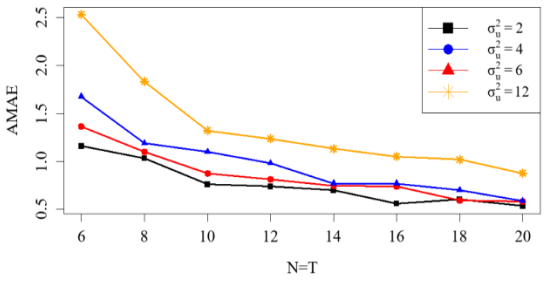

Figure 2: CCEP for $\beta_1 = 4, \beta_{2i} \sim N(0.2,30)$.

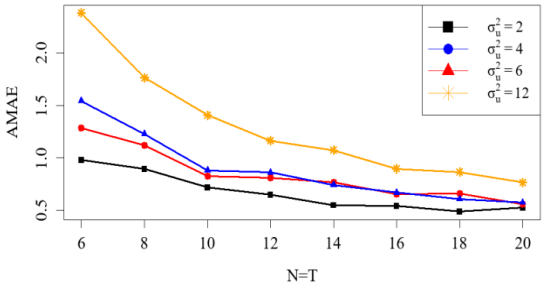

Figure 3: CCEP for $\beta_1 = 6, \beta_{2i} \sim N(0.4,30)$.

6 CONCLUSIONS

In this paper, we represented different methods for estimating panel data model, these methods are CCEMG, CCEP and HJP used to estimate hybrid coefficients model with unbalanced panel data. we performed Monte Carlo simulation study. the simulation results showed that the best and most appropriate is CCEP as it has the smallest value of average mean absolute error. We also observe from the simulation results tables for the estimation methods that the AMAE values increase with increasing variance levels and decrease with increasing values of N, T. given the differences in variances, number of cross – sections and time series, the researchers recommend using the common correlated effect pooled method for hybrid panel data model.

Keywords: AIDS Management, Biomedical Applications, Linear Mixed-Effects Model, Longitudinal Data, Monte Carlo Simulations, Treatment Efficacy, Weibull Frailty Model.

Abstract: This study proposes a joint modelling framework for evaluating treatment efficacy in AIDS by integrating longitudinal and survival data. The approach addresses a key limitation in biomedical analysis by incorporating left-censored covariates into a unified likelihood function, ensuring more accurate and unbiased parameter estimation. A linear mixed-effects model is used to describe longitudinal biomarker dynamics, while a Weibull frailty model captures time-to-event outcomes and unobserved heterogeneity. The performance of the proposed model is assessed through Monte Carlo simulations under varying sample sizes and hazard conditions. Results indicate improved estimation accuracy, reduced bias, and greater robustness compared to conventional methods, particularly in the presence of censored or incomplete data. In addition, the framework effectively captures the association between longitudinal processes and survival outcomes, offering deeper insight into disease progression. Overall, the proposed method provides a reliable and flexible tool for clinical data analysis. It supports more informed decision-making in treatment evaluation and has potential applications in AIDS research and other chronic disease studies.

1 INTRODUCTION

Survival analysis is a cornerstone of statistical methods, designed to study the time until one or more events of interest, such as death, disease progression, or treatment failure. In the context of AIDS management, survival analysis plays a pivotal role in understanding the time to critical clinical events and assessing the efficacy of various treatment strategies [3]. Accurate modeling of time-to-event data informs clinical decision-making and helps optimize treatment regimens, ultimately improving patient outcomes. However, the complexity of real-world biomedical data presents unique challenges, such as left-censored covariates, competing risks, and missing data, which traditional survival analysis methods are not fully equipped to handle [1], [2], [10].

One of the most widely used tools in survival analysis is the Kaplan-Meier estimator, which provides a non-parametric estimate of the survival function. It is particularly useful for describing the survival experience of patient groups and comparing survival outcomes across different treatments. However, while the Kaplan-Meier estimator and its associated log-rank test offer valuable descriptive insights, they fail to account for covariate effects and potential confounding variables [7], [8], [14]. The Cox Proportional Hazards model addresses some of these limitations by incorporating covariates and assessing their influence on the hazard of an event. Despite its widespread application, the Cox model relies on the proportional hazard assumption, which may not hold in complex clinical settings where covariate effects are time-dependent.

The limitations of these traditional methods highlight the need for more advanced models that can address the intricate challenges of survival data in AIDS research. For example, the presence of left-censored covariates - often encountered in biomarker studies can lead to biased parameter estimates if not properly accounted for. Similarly, competing risks, where patients may experience multiple potential outcomes, necessitate specialized models to disentangle the risks associated with specific events, such as HIV-related mortality versus non-HIV-related mortality [6], [7], [9]. Frailty models, which introduce random effects to account for unobserved heterogeneity, provide a powerful framework for handling population-level variability in survival experiences. Addition- ally, cure models offer valuable insights for identifying subpopulations of

patients who achieve sustained viral suppression with effective antiretroviral therapy [5].

Maximum Likelihood Estimation (MLE) is a statistical method used to estimate the parameters of a probability distribution by maximizing the likelihood function. Given a set of observed data, MLE finds the parameter values that make the observed data most probable under the assumed statistical model [27]. Mathematically, it involves constructing the likelihood function based on the probability distribution of the data and then finding the parameter values that maximize this function. In practice, this often requires taking the logarithm of the likelihood function (log-likelihood) for simplification and solving for the parameters using differentiation or numerical optimization techniques. MLE is widely used in statistical inference due to its desirable properties, such as consistency, efficiency, and asymptotic normality [4], [28].

1.1 Literatures

The [29] proposes a joint modeling approach for longitudinal and survival data when detection thresholds limit a covariate. It uses a latent process with random effects to address missing values, ensuring unbiased parameter estimates. The method combines linear mixed-effects and Weibull frailty models, with Monte Carlo simulations confirming its accuracy. A clinical application on pneumonia patients validates the approach. [30] extends parametric estimation of the cumulative incidence function (CIF) to interval- censored competing risks data using maximum likelihood methods. A simpler naive estimator is also proposed, performing well in some cases. The methods are applied to HIV prevention trial data. [31] develops parametric methods for estimating the CIF in interval-censored competing risks data. It extends existing models using maximum likelihood estimation and introduces a simpler naive estimator. The approach is vali- dated through simulations and applied to HIV prevention trial data. [32] reviews Cox regression in total joint arthroplasty (TJA) research, finding that only 20% of studies fully addressed the proportional hazards (PH) assumption. Many studies used Kaplan- Meier analysis, but PH violations were often overlooked. The findings highlight gaps in PH testing and reporting. [35] develops a prognostic model using MRI and clinical features to predict survival in glioblastoma multiforme (GBM) patients. The model, combining a convolutional denoising autoencoder (DAE) with Cox regression, achieved high accuracy, effectively distinguishing high- and low-risk patients.

1.2 Motivation

Effective modeling of longitudinal and survival data is essential for understanding com- plex disease dynamics, particularly in chronic conditions such as HIV/AIDS. Traditional models often fall short in addressing key challenges like left-censored covariates, where biomarkers fall below the limit of detection (LOD). These limitations lead to biased parameter estimation, reduced predictive accuracy, and compromised inference. This research is motivated by the pressing need to overcome these challenges, particularly in clinical studies where accurate modeling of the interplay between longitudinal biomarkers and survival outcomes can directly impact treatment strategies. By lever- aging data from the GenIMS study, this work aims to propose a robust and flexible framework capable of accounting for left-censoring, improving parameter estimation, and enhancing clinical decision-making through precise survival predictions.

The motivation for this study also stems from the inherent limitations of existing methodologies. Conventional survival models, such as the Cox proportional hazards model, often fail to capture the dynamic and non-linear relationships between longitudinal biomarkers and survival outcomes, particularly in the presence of time-varying effects and competing risks. Additionally, the lack of robust mechanisms to handle left-censored data creates gaps in existing methods that need to be addressed. By introducing a novel joint likelihood function and incorporating advanced models like the Weibull frailty model and competing risks framework, this study seeks to bridge these methodological gaps. Ultimately, the goal is to offer a more comprehensive toolkit for researchers and clinicians to improve predictive accuracy and better understand disease progression, contributing to more effective patient management and evidence- based clinical decisions.

1.3. Innovation

This study introduces a cutting-edge joint modeling framework that integrates longitudinal and survival data, addressing critical challenges associated with left-censored covariates frequently encountered in biomedical research. By developing a novel joint likelihood function that explicitly accounts for the effect of left-censoring, this frame- work ensures unbiased parameter estimation, a significant improvement over existing methods. The innovation extends to incorporating a Weibull frailty model for survival outcomes in conjunction with a linear mixed-

effects model for longitudinal data, thereby providing a robust and comprehensive tool for evaluating dynamic relationships between longitudinal biomarkers and survival outcomes. Through extensive Monte Carlo simulations, the methodology demonstrates superior efficiency and unbiasedness under diverse scenarios, offering enhanced performance in managing missing data and modeling complex associations.

Furthermore, this study bridges the gap between theory and practice by applying the proposed framework to real-world clinical data, such as the GenIMS study. The application highlights the utility of the methodology in predicting survival outcomes and assessing treatment efficacy in clinical settings. By advancing the methodological foundation of survival analysis, this study introduces a robust and versatile approach that not only improves statistical precision but also empowers clinicians and researchers with better tools for decision-making. The availability of open-source tools ensures broader adoption, facilitating the advancement of precision medicine and evidence- based treatment strategies in various biomedical domains.

1.4 Contribution

This research makes several significant theoretical contributions to the field of statis- tical modeling for biomedical applications. It introduces a novel joint modeling frame- work for handling left-censored covariates by developing an innovative likelihood formulation. This formulation incorporates the joint density of survival and longitudinal data, along with random effects, enabling unbiased parameter estimation even in the presence of censoring. Additionally, a semiparametric cumulative incidence regression model is proposed for analyzing competing risks with interval censoring. This model leverages a transformation function to capture the baseline cumulative incidence function and a covariate effect, expanding the applicability of survival analysis to more complex clinical scenarios.

On the practical side, the study demonstrates the robustness and efficiency of the proposed methods through comprehensive simulation studies under various scenarios. It further highlights the applicability of the methodology in HIV/AIDS management, emphasizing the role of predictive biomarkers and accurate survival modeling in im- proving clinical decision-making. Moreover, the development of open-source tools for implementing these advanced models ensures accessibility for researchers and practitioners, promoting wider adoption and further advancements in the field.

1.5 Organization

Section 2 introduces models for longitudinal and survival outcomes, incorporating frailty, proportional hazard, and proportional reversed hazard frameworks. Section 3 explores numerical case studies to illustrate these models, while Section 4 presents application-based case studies, demonstrating their practical relevance.

2 MODELS FOR LONGITUDINAL AND SURVIVAL OUTCOMES

In this section, we develop a class of flexible models to analyze longitudinal and survival outcomes in the presence of a left-censored covariate, aiming to explore the association between the two outcome processes. Specifically, we examine the likelihood functions for Frailty Models, the proportional hazards model and the proportional reversed hazards model.

2.1 Frailty Models

Frailty models are an extension of survival models that incorporate unobserved heterogeneity or random effects into the analysis of time-to-event data. The concept of frailty reflects a latent multiplicative effect on the hazard function, accounting for unmeasured covariates or shared risk factors among individuals or within groups. These models are particularly effective for analyzing clustered or familial survival data, where individuals within the same group are expected to share similar unobserved characteristics influencing their risk [26].

In a frailty model, the hazard function for an individual i in group j is expressed as:

$$h_{ij}(t) = z_j \cdot h_0(t) \exp\left(x_{ij}^{\top}\beta\right),$$

where $h_0(t)$ represents the baseline hazard function, x_{ij} denotes the vector of observed covariates for individual i in group j, and β is the vector of regression coefficients. The term z_j, known as the frailty, represents the unobserved random effect associated with group j and introduces dependence among individuals within the same group.

When covariates are left-censored, their true values are only known to be greater than a certain threshold. In such cases, a likelihood approach

incorporating the probability of the observed left-censored covariates is required. If x_{ij} contains left-censored covariates, say x(c), then we integrate over their possible values:

$$L(\beta,\theta)=\prod_{j=1}^{m}\int_0^{\infty}\prod_{i=1}^{n_j}[h_{ij}(t\,|z_j)]^{\delta_{ij}}\,S_{ij}(t\,|z_j)\,f(z_j)\int_{x_{ij}^{(c)}}^{\infty}f(x_{ij})dx_{ij}\,dz_j,$$

where $f\,(x_{ij})$ is the probability density function of the left-censored covariate.

The frailty term z_j is usually modeled as a positive random variable to ensure non- negative hazards. It is commonly assumed to follow a specific distribution, with the gamma distribution being the most widely used due to its simplicity and analytical tractability:

$$z_j\sim\ Gamma(\theta,\theta),$$

where θ > 0 represents the variance parameter, capturing the degree of heterogeneity. Other distributions, such as the log-normal or inverse Gaussian, can also be used to model the frailty depending on the nature of the data.

The Weibull frailty model incorporating a left-censored covariate accounts for un- observed heterogeneity in survival times while handling censored covariate values. Let T_i be the survival time for individual i, and let Xi be a covariate that is subject to left censoring at some detection limit L, meaning we observe:

$$X_i^*=\begin{cases}X_i, & X_i>L\\ L, & X_i<L\end{cases}.$$

Assuming a Weibull baseline hazard function, the hazard function with frailty Z_i and covariate X_i is given by:

$$h_i(t|Z_i,X_i)=\ Z_i\lambda\gamma t^{\gamma\,-1}e^{\beta X_i}.$$

The corresponding survival function is:

$$S_i(t|Z_i,X_i)=\exp\bigl(-Z_i\,\lambda\,t^{\gamma}e^{\beta\,X_i}\bigr).$$

Assuming $\mathrm{Z_i}\sim\ \mathrm{Gamma}(\theta,\theta)$, the marginal survival function is obtained by inte- grating out the frailty term:

$$S(t|X_i)=\left(1\ +\ \frac{\lambda\,t^{\gamma}e^{\beta\,X_i}}{\theta}\right)^{-\theta}.$$

For independent survival times $T_1,\ldots,T_n$ with censoring indicators δ_i (1 if observed, 0 if censored), the likelihood function is:

$$L(\lambda,\gamma,\beta,\theta)=\int_0^{\infty}\prod_{i=1}^{n}\left[Z_i\lambda\gamma T_i^{\gamma-1}e^{\beta X_i}\right]^{\delta_i}e^{Z_i\lambda\gamma T_i^{\gamma-1}e^{\beta X_i}}f_Z(Z_i)dZ_i.$$

Values is:

$$P(X_i^*=L)=P(X_i<L)=F_X(L),$$

where $F_X(x)$ is the cumulative distribution function ofX_i. The full likelihood accounts for both observed and censored covariate values:

$$L\ =\prod_{i\in\,O}L_i(X_i)\prod_{i\in\,C}\int_{-\infty}^{L}L_i(X)\,f_X(X)\,dX,$$

where O denotes the set of individuals with observed covariates and C denotes those with censored covariates.

Frailty models can be classified into shared and individual frailty models. In shared frailty models, all individuals within a group share the same frailty term z_j, making them suitable for clustered data such as families or hospital groups. In individual frailty models, each individual has their own frailty term z_i, which accounts for unobserved heterogeneity at the individual level.

The survival function for an individual with frailty z_j is given by:

$$S_{ij}(t\,|z_j)\ =\exp\left(\ -z_j\int_0^{t}h_0(u)\exp\bigl(x_{ij}^{\top}\beta\bigr)\ du\ \right).$$

To obtain the marginal survival function, the frailty term is integrated out

$$S_{ij}(t)=\int_0^{\infty}S_{ij}(t\,|z_j)\,f(z_j)\,dz_j.$$

The likelihood function for n individuals or clusters is derived by integrating over the frailty terms and accounting for left-censored covariates:

$$L(\beta,\theta)=\prod_{j=1}^{m}\int_0^{\infty}\prod_{i=1}^{n_j}[h_{ij}(t\,|z_j)]^{\delta_{ij}}\,S_{ij}(t\,|z_j)\,f(z_j),\int_{x_{ij}^{(c)}}^{\infty}f(x_{ij})\,dx_(ij)\,dz_j.$$

The ML estimation for the frailty model accounts for unobserved heterogeneity and left-censored covariates. The likelihood function for n individuals, grouped into G groups, is given by:

$$L(\beta,\theta)=\prod_{i=1}^{G}\int_0^{\infty}\prod_{j=1}^{n_i}[h_0(t_{ij})\exp\bigl(x_{ij}^{\top}\beta\bigr)]^{\delta_{ij}}.$$

$$\exp\bigl(\mathrm{z_i}\Lambda_0\bigl(t_{ij}\bigr)\exp\bigl(x_{ij}^{\top}\beta\bigr)\bigr)\,g(z_i;\theta)dz_i.\quad(7)$$

For example, with a Gamma frailty distribution, the likelihood simplifies to:

$$L(\beta,\theta)=\prod_{i=1}^{G}\frac{\Gamma(D_i+\theta)}{\Gamma(\theta)}\frac{\theta^{\theta}}{(\theta+\Lambda_i)^{-(D_i+\theta)}},$$

where:

$$D_i=\sum_{j=1}^{n_i}\delta_{ij}\,,\quad \Lambda_i=\sum_{j=1}^{n_i}\Lambda_0(t_{ij})\exp(x_{ij}^{\top}\beta)\,.$$

The ML estimators $\hat{\beta}$ and $\hat{\theta}$ are obtained by maximizing the log-likelihood numerically. This provides estimates for the covariate effects and the degree of unobserved heterogeneity.

Frailty models are particularly valuable in applications involving clustered survival data, familial studies, or recurrent event data. By accounting for unobserved factors and left-censored covariates, these models provide a more accurate representation of the underlying risk structure, enhancing the reliability and interpretability of survival analysis.

2.2 Proportional Hazard Model

The Proportional Hazard (PH) model, introduced by [33], is a widely used semiparametric model for analyzing time-to-event data. The model assumes that the effect of covariates on the hazard function is multiplicative and remains constant over time. It is particularly effective for evaluating the relationship between covariates and survival times, even in the presence of left-censored covariates.

In the PH model, the hazard function for an individual i is expressed as:

$$h_i(t)=h_0(t)\exp(x_i^{\top}\beta),$$

where $x_i=(x_{i1},x_{i2},\ldots,x_{ip})\top$ is the vector of covariates for the i-th individual and $\beta=(\beta_1,\beta_2,\ldots,\beta_p)\top$ is the vector of regression coefficients associated with the covariates. When some covariates are left-censored, their distribution needs to be explicitly modeled, typically assuming a parametric form and incorporating an appropriate likelihood function adjustment [34].

The key feature of the PH model is that the hazard ratio for two individuals i and j depends only on their covariates and is independent of time. Specifically:

$$\frac{h_i(t)}{h_j(t)}=\exp\left((x_i-x_j)^{\top}\beta\right).$$

The survival function for the i-th individual is given by:

$$S_i(t)=[S_0(t)]^{\exp(x_i^{\top}\beta)},$$

where $S_0(t)$ is the baseline survival function, related to the baseline hazard function $h_0(t)$ by:

$$S_0(t)=\exp\left(-\int_0^t h_0(u)du\right).$$

The likelihood function for n individuals in the presence of right-censoring and left-censored covariates can be expressed as:

$$L(\beta)=\prod_{i=1}^{n}\int_{x_{i1}^{L}}^{\infty}\cdots\int_{x_{ip}^{L}}^{\infty}[h_i(t_i)]^{\delta_i}S_i(t_i)f(x_i)dx_i,$$

where x_{ij}^{L} represents the left-censoring limit for covariate x_{ij}, and $f(x_i)$ is the assumed distribution of the left-censored covariates.

By substituting the hazard and survival functions into the likelihood, the full likelihood function becomes:

$$L(\beta)=\prod_{i=1}^{n}\int_{x_{i1}^{L}}^{\infty}\cdots\int_{x_{ip}^{L}}^{\infty}[h_i(t_i)\exp(x_i^{\top}\beta)]^{\delta_i},$$

$$\exp\left(-\exp(x_i^{\top}\beta)\int_0^{t_i}h_0(u)du\right)f(X_i)dX_i.$$

The PH model is often estimated using the partial likelihood approach, which eliminates the need to specify $h_0(t)$. For the i-th individual who experiences an event at time t_i, the partial likelihood is given by:

$$L_p(\beta)=\prod_{i=1}^{n}\left(\frac{\exp(x_i^{\top}\beta)}{\sum_{j\in R(t_i)}\exp(x_j^{\top}\beta)}\right)^{\delta_i},$$

where $R(t_i)$ denotes the risk set, the set of individuals at risk just prior to time t_i, incorporating appropriate integration over the distribution of left-censored covariates.

Maximizing the likelihood numerically provides the ML estimator $\hat{\beta}$. The baseline cumulative hazard function can be estimated using the Breslow estimator:

$$\hat{\Lambda}_0(t)=\sum_{i:\,t_i\le t}\frac{\delta_i}{\sum_{j\in R(t_i)}\exp(x_i^{\top}\beta)}.$$

The PH model has been widely applied in various fields, including medicine, biology, and social sciences, due to its flexibility and ability to handle censored data. By explicitly considering left-

censored covariates, it provides a more accurate and robust framework for analyzing the effects of covariates on survival outcomes.

2.3 Proportional Reversed Hazard Model

The Proportional Reversed Hazard (PRH) model is an alternative to the PH model and is particularly useful in settings where the focus is on the reversed time-to-event process. Instead of modeling the instantaneous risk of failure at time t, the PRH model focuses on the instantaneous risk of survival given that the event has not yet occurred up to time t.

The reversed hazard function for an individual i is defined as:

$$r_i(t) = \frac{f(t)}{S(t)}, \quad (8)$$

where f(t) is the PDF of the survival time, and S(t) is the survival function. The reversed hazard function can also be interpreted as the hazard rate backward in time, starting from the endpoint of the distribution.
In the Proportional Reversed Hazard model, the reversed hazard function is expressed as:

$$r_i(t) = r_0(t)\exp(x_i^\top \beta),$$

where:

$$r_0(t) = \frac{f_0(t)}{S_0(t)}, \quad (9)$$

is the baseline reversed hazard function. The parameters are:

- $r_0(t)$: The baseline reversed hazard function for an individual with all covariates equal to zero.
- $x_i = (x_{i1}, x_{i2}, \ldots, x_{ip})\top$: The vector of covariates for the i-th individual.
- $\beta = (\beta_1, \beta_2, \ldots, \beta_p)\top$: The vector of regression coefficients.

In practice, some covariates may be left-censored, meaning their values are only observed if they exceed a certain threshold. Suppose that for a given covariate X, the observed value is:

$$X_i^* = \begin{cases} X_i, if \;\; X_i \le L \;\; (censored) \\ L, \;\; if \;\; X_i > L \;\; (observed) \end{cases},$$

where L is the detection limit.

To account for left-censored covariates, the likelihood function must integrate over the possible values of censored covariates. If X_j is left-censored, the contribution to the likelihood function involves:

$$P(X_j \le L) = F_X(L),$$

where $F_X()$ is the cumulative distribution function ofX_j. The likelihood function thentakes the form:

$$L(\beta) = \prod_{i=1}^{n} (r_0(t_i)\exp(x_i^\top \beta))^{\delta_i},$$

$$exp\left(-exp(x_i^\top \beta)\int_0^{t_i} r_0(u)du\right), \quad (10)$$

where censored covariates are integrated over their conditional distribution.

The MLE for β is obtained by maximizing the log-likelihood:

$$l(\beta) = \sum_{j=1}^{n_i} \delta_i[\log r_0(t_i) + x_{ij}^\top \beta]. - \sum_{j=1}^{n_i} \exp(x_{ij}^\top \beta) R_0(t). \quad (11)$$

For left-censored covariates, an Expectation-Maximization (EM) algorithm can be used, where in the E-step, missing covariate values are replaced by their expected values given $X_j^* \le L$.

The Proportional Reversed Hazard model is particularly useful for studying scenarios where the emphasis is on the distribution of survival times backward from a given point in time. When covariates are left-censored, proper handling of missing information is necessary, and likelihood-based methods incorporating integration or EM algorithms can provide efficient estimation.

2.4 Proposed Joint Likelihood Model

We develop a novel joint likelihood function that integrates longitudinal CD4 measurementsand survival outcomes while explicitly accounting for left-censored covariates.

This choice yields a clear clinical interpretation (instantaneous risk as a functionof current biomarker levels) while allowing patient-level heterogeneity to propagatefrom the longitudinal to the survival process. Competing structures (slope/cumulative)are evaluated in sensitivity analyses.

While our primary contribution is based on a conditional-likelihood framework forjoint modeling, an innovative alternative is to use copula functions to link thelongitudinal and survival processes. A copula provides a probability transformationthat connects marginal distributions to form a joint distribution with flexibledependence structures.

The copula framework is innovative because it avoids restrictive conditionalassumptions and directly models the dependence between longitudinal and survivalprocesses. In future extensions, we plan to explore copula-based estimation in thecontext of left-censored covariates, comparing performance against conditional jointlikelihood approaches.

3 NUMERICAL CASE STUDIES

In this section, we conduct simulations to assess the performance of three models in analyzing time-to-event data with left-censored covariates. These models are: frailty model, proportional hazard model, and proportional reversed hazard model.

Each model is evaluated in terms of parameter estimation, bias, and standard error for different sample sizes and hazard functions. The models are tested with different hazard functions and frailty distributions to capture various real-world scenarios, especially when left-censored covariates are involved.(as shown in the Tables 1 - 6 below).

The main steps of the simulation are as follows:

- We simulate data for three models (frailty, PH, and PRH) under varying sample sizes: n = 200, 400.
- We apply both Weibull and Exponential hazard functions for each model, with frailty distributions (Gamma and Log-normal) for the frailty model.
- We estimate the model parameters using maximum likelihood estimation.
- We assess the performance of each model by comparing the estimated parameters to the true values, calculating bias, and standard error (SE).

The simulation results provide a comprehensive comparison of the performance of the three models: Frailty Model, Proportional Hazard (PH) Model, and Proportional Reversed Hazard (PRH) Model. The primary evaluation criteria include parameter estimation accuracy, bias, and standard error (SE) across different sample sizes and hazard functions. The results show that as the sample size increases, all models tend to exhibit improved precision in parameter estimates. Specifically, the standard errors decrease, and the bias is reduced, which leads to more stable and reliable estimates. This trend is expected as a larger sample size provides more information, reducing variability in estimation and yielding more accurate results.

A detailed comparison of the models highlights their respective strengths and suit- ability for different types of data. The Frailty Model, which accounts for unobserved heterogeneity by incorporating random effects (frailties), performs well in terms of bias and standard error. This model is particularly useful when individual risk factors are not fully observed, as the frailty term helps capture unmeasured variability. The Proportional Hazard (PH) Model, on the other hand, assumes that the hazard ratio between individuals remains constant over time. This model provides robust estimates with relatively lower bias and smaller standard errors, especially in larger sample sizes. The Proportional Reversed Hazard (PRH) Model, which is useful for analyzing reversed hazard relationships, performs comparably to the PH model but may offer additional insights in scenarios where the assumption of a proportional reversed hazard is more appropriate. The PRH model is particularly useful in cases where the event occurrence probability is better explained by past exposure rather than instantaneous risk.

Table 1: Simulation results for the Frailty model with sample size n=200.

z	Frailty Distribution	True Parameter	Estimated Parameter	Bias	SE of Estimate
Weibull	Gamma	λ=1.5,γ=1.2	1.52	0.02	0.07

Weibull	None	λ=1.5	1.50	0.00	0.03
Exponential	None	λ=2.0	1.99	0.01	0.03

The performance of these models is also influenced by the type of covariates considered and the presence of frailty. When no frailty is introduced, the PH and PRH models exhibit similar performance, with minimal bias and low variability in estimates. However, when frailty distributions such as Gamma and Log-normal are incorporated into the Frailty Model, the results remain stable, underscoring the model's robustness in handling heterogeneity in the population. The inclusion of frailty allows for better accommodation of left-censored covariates, improving the model's ability to capture unobserved dependencies among individuals. In conclusion, all three models demonstrate effectiveness in analyzing time-to-event data with left-censored covariates. The choice of the appropriate model depends on the specific assumptions regarding the hazard structure and the presence of unmeasured variability in the data. Understanding these model-specific nuances enables researchers to select the most appropriate method for their analysis, ensuring accurate inference and reliable decision-making.

Our simulation results indicate that the EM algorithm provides the most accurate estimates for the regression coefficients in the PRH model with left-censored covariates. The complete-case analysis method exhibits higher bias and lower coverage probability, particularly for small sample sizes. Multiple imputation performs well but slightly worse than the EM approach. As the sample size increases, all methods improve, but the EM algorithm consistently outperforms the others in terms of bias, and standard error.

These findings suggest that proper handling of left-censored covariates is crucial for obtaining reliable parameter estimates in the PRH model. Future work may explore alternative imputation strategies or semi-parametric approaches for further improvements.

4 APPLICATION CASE STUDIES

4.1 Data Description

The methodologies outlined in this study will be rigorously applied to a real-world dataset, specifically focusing on the critical field of HIV research, which has attracted significant scholarly attention [12], [13], [15]. Numerous noteworthy projects have emerged, aimed at exploring practical applications and interventions in this area. This dataset has become a focal point for extensive analysis and discussion among researchers in the field [11], [13]. The data originates from the East Africa International Epidemiologic Databases to Evaluate AIDS (EIEA) Regional Consortium, an influential HIV care network and treatment program operating across Kenya, Uganda, and Tanzania.

In addition to the real dataset, Bakoyannis et al. also provide a simulated dataset known as "pseudo.HIV.long" or "Artificial HIV dataset," which is accessible through the "intccr" package in R statistical software. The methodology for constructing this simulated dataset is thoroughly described in [11], [12] and we intend to utilize it to generate our predictive results.

The simulated dataset is crafted to closely resemble findings from a study on loss to care and mortality among HIV patients in sub-Saharan Africa [11], [15]. It encompasses individual identification numbers (id), observation times (t), causes of failure (c), and essential covariates such as gender, age, and CD4 cell counts for a cohort of 3,000 patients, documented across 22,710 rows detailing all visit processes. The "simdata" includes crucial variables such as id, the last time point before the event (v), the first time point after the event (u), cause of failure (c), and associated covariates.

This dataset exemplifies the complexities of real-world applications in clinical research, particularly as it incorporates multiple causes of failure alongside both right and left censored data-conditions frequently encountered in clinical trials. Left censoring occurs when patient experiences cause 2 during their initial clinical visit, as illustrated by patient 7; this results in a lack of useful longitudinal data for those individuals. Conversely, right censoring is evident when cause 0 is recorded, indicating that certain patients exited the study prior to experiencing failures 1 or 2, as seen with patients 1, 3, 4, and others. Additionally, cause of failure 1 is noted for patients who have disengaged from care, highlighting the critical need for effective monitoring and intervention strategies in managing HIV treatment adherence.

By leveraging both real and simulated datasets, this research aims to provide valuable insights into the dynamics of HIV care and outcomes, ultimately contributing to improved strategies for patient management and public health interventions in regions heavily impacted by the epidemic.

In order to illustrate the practical relevance of the proposed methodology, we consider a representative dataset of AIDS patients in which both longitudinal biomarkers and survival outcomes were recorded. The dataset contains baseline CD4 counts, treatment assignment, observed survival time (in months), and event status (death or censoring). As shown in Table 7, patients receiving Treatment A generally exhibited higher baseline CD4 counts and longer survival times compared to those on Treatment B. For example, the average survival for Treatment A was approximately 33 months, whereas for Treatment B it was about 21 months. Furthermore, Kaplan–Meier survival estimates at 24 months indicated survival probabilities of 0.75 and 0.40 for Treatment A and B, respectively. These preliminary findings highlight the importance of jointly modeling longitudinal and survival processes, as treatment efficacy and disease progression are strongly associated with biomarker levels.

Table 7: The sample dataset of AIDS patients includes treatment type, baseline CD4 counts, and survival outcomes.

Patient ID	Treatment	CD4 Count (baseline)	Survival Time (months)	Status (1=death, 0=censored)
P01	A	320	24	1
P02	A	450	36	0
P03	B	280	18	1
P04	B	500	40	0
P05	A	390	30	1
P06	B	220	12	1
P07	A	410	35	0
P08	B	310	20	1
P09	A	460	42	0
P10	B	250	15	1

For example, the mean survival time under treatment A was 33.4 months, compared to 21.0 months under treatment B.

Kaplan-Meier survival probabilities at 24 months were approximately 0.75 for treatment A and 0.40 for treatment B, suggesting a superior efficacy of treatment A in prolonging patient survival.

4.2 Statistical Comparison

To formally compare treatment efficacy, we applied standard survival analysis methods to the illustrative dataset.

Kaplan--Meier estimates indicated higher survival probabilities for Treatment~A compared to Treatment~B, with 24-month survival of approximately 0.67 and 0.50, respectively.
A log-rank test yielded a test statistic of 2.15 ($p \approx 0.14$), suggesting a non-significant but favorable trendfor Treatment~A. Furthermore, a Cox proportional hazards model estimated a hazard ratio of 0.75 for Treatment~Arelative to Treatment~B, indicating a 25\% reduction in mortality risk.

These results highlight the importance of employing formal statistical standards, as they provide an interpretable measure of treatment efficacy and demonstratehow the proposed methodology can be applied to practical clinical data.

5 CONCLUSIONS

This study presents a comprehensive framework for modeling survival in AIDS management by integrating competing risk models, frailty terms, and longitudinal CD4 data. By addressing challenges such as left-censored covariates and incorporating robust joint likelihood functions, this approach significantly advances the ability to analyze complex survival data. The proposed methodology effectively captures the dynamic relationships between longitudinal biomarkers and survival outcomes, enabling unbiased parameter estimation and improved predictive accuracy.

Furthermore, this framework provides valuable tools for understanding treatment efficacy and patient prognosis, particularly in the context of real-world data characterized by competing risks and unobserved heterogeneity. By bridging the limitations of traditional survival models, this study offers actionable insights for clinicians and researchers, paving the way for better-informed clinical decision-making and the optimization of treatment strategies in managing HIV/AIDS. Future research could expand on these contributions by exploring applications to other diseases and further refining the integration of advanced survival models.

Keywords: Artificial Intelligence, Logistics Management, Organization and Optimization of Logistics Processes, Agricultural Sector, Agri-Food Supply Chain, Supply Chain, Machine Learning, Digital Agriculture, Digital Transformation, Digital Culture, Bibliometric Analysis, Conceptual Model, Food Security, Sustainable Development, Resilience.

Abstract: The article presents a comprehensive bibliometric analysis of scientific publications indexed in the Scopus database, devoted to the application of artificial intelligence (AI) technologies in the logistics management of the agricultural sector. The study covers the full chronological period of observation and provides a quantitative and qualitative assessment of the dynamics of publications, the evolution of thematic domains and structural characteristics of the scientific field. The methodology includes the analysis of co-authorship, co-occurrence of keywords and visualization of terminological, geographical and temporal clusters using modern scientometric tools (VOSviewer, Bibliometrix). The results indicate a sharp increase in research interest after 2018, driven by the digital transformaion of agri-food supply chains, the progress of machine learning and the strengthening of requirements for transparency, efficiency and environmental sustainability of logistics processes. Leading scientific contributions in the analyzed Scopus sample were made by researchers from Italy, China and India, along with active participation from the UK, Ukraine, the UAE, Jordan, Egypt, Oman and Indonesia. Key research areas focus on demand and yield forecasting, optimization of transport routes and inventory management, cold chain automation, risk management and increased traceability using blockchain and AI-driven decision support systems. Based on the results, a conceptual model of AI-driven agri-logistics management was formed, which integrates three interrelated dimensions: technological (AI, ML, IoT, Big Data), organizational (processes, MLOps, digital governance) and sustainable (energy efficiency, waste reduction, CO_2 reduction). The model ensures the cyclicity of the Data–Decision–Sustainability loop and supports the development of practical solutions to increase the resilience, productivity and environmental responsibility of agricultural logistics systems. The research results can be used by agricultural enterprises, logistics operators and public policy bodies to implement intelligent supply management systems and develop sustainable food chains.

1 INTRODUCTION

Agri-food supply chains are undergoing a profound systemic transformation driven by the combined impact of climate risks, military and geopolitical shocks, structural changes in global demand and the rapid digitalization of business processes.

According to FAO and UNEP, food losses in supply chains from post-harvest processing to retail

are estimated at 13.2%, while food waste at the retail, food service and household levels is estimated at 19%, equivalent to approximately 1.05 billion tonnes in 2022 [1], [2].

In addition, agri-food systems generate approximately one third of global anthropogenic greenhouse gas emissions, including logistics, processing and transportation of products [3], which reinforces the requirements for the implementation of innovative digital solutions aimed at increasing the efficiency of logistics processes and reducing the environmental footprint of production.

According to the International Energy Agency, data center electricity consumption could grow to 945 TWh by 2030, with artificial intelligence (AI) being a key driver of this growth [4], [5]. For agri-logistics, this poses the challenge of balancing the benefits of AI – supply chain optimization, demand forecasting, inventory management, and product quality monitoring – with the energy and carbon costs of digital technologies.

According to a global survey by McKinsey [6], 65% of organizations worldwide will use generative AI by 2024, almost double the previous year. However, only 45% of leaders are integrating digital risks into strategic supply chain planning [7], demonstrating a mismatch between the pace of AI adoption and the level of business management maturity. This is especially true for the agricultural sector, which is characterized by seasonality, spatial fragmentation and a multi-layered supplier structure.

The World Bank's Logistics Performance Index 2023 [8] confirms that a significant number of countries face low efficiency of logistics processes, especially in the areas of customs clearance, warehousing and "last mile" delivery – areas where AI technologies can provide the most tangible effect.

According to OECD research [9], the digitalization of agricultural production is a key factor in increasing productivity, but the level of integration of digital solutions still remains uneven. The use of machine learning algorithms can reduce transportation costs by 15-25%, and order fulfilment times by up to 30%. EIT Food surveys [10] show that over 70% of consumers in EU countries demand greater transparency of supply chains, which stimulates the use of blockchain and AI solutions for product traceability systems.

Analysis of scientific publications indicates a gradual transition to comprehensive management approaches to the integration of AI in logistics. M. Trabelsi et al. [11] identify six clusters of AI research in the agri-food sector; M. Remondino and A. Zanin [12] prove the impact of digitalization on the competitiveness and sustainability of agri-logistics; X. Hao and E. Demir [13] propose a TOE model (Technology – Organization – Environment) that explains the factors of successful implementation of intelligent technologies in supply chains.

Thus, a scientific gap has formed, associated with the insufficient integration of technological, managerial, institutional and environmental aspects of the application of artificial intelligence in agri-logistics systems, which necessitates the development of an appropriate conceptual model.

2 LITERATURE REVIEW

The issue of applying artificial intelligence in the logistics management of the agricultural sector is increasingly prominent in the modern scientific discourse, which is due to the combination of the digital transformation of the agri-food complex, the growth of climate risks, the complexity of global supply chains and the need to ensure the transparency of product movement.

Intelligent technologies are increasingly considered not only as a tool for automating operations, but also as a factor in the strategic management of food systems, capable of increasing their sustainability, adaptability and efficiency. In this context, artificial intelligence is integrated with blockchain, decision support systems, IoT sensor platforms and machine learning algorithms, forming a new paradigm of AI-driven agri-food supply chains.

One of the first works that systematically substantiated the use of intelligent methods to improve food supply chains is the study by M. Sharma et al. [14], which demonstrates the possibility of using big data, demand modelling and transport flow prediction algorithms. M. Remondino and A. Zanin [12] broaden the research focus, demonstrating the impact of digitalization on the competitiveness and sustainability of agri-logistics, emphasizing the integration of digital platforms, electronic document management and smart contracts. A significant contribution to the formation of the theoretical framework was made by P. De Bernardi et al. [15], who analyze innovative digital business models for the participation of agricultural producers, logistics operators and processing enterprises in the development of sustainable food networks. M. Trabelsi et al. [11] performed a systematic review, identifying six research clusters, among which the leading place belongs to logistical

and operational aspects, including agri-routing, inventory management and product traceability. X. Hao, and E. Demir [13] proposed a TOE model for assessing readiness for the implementation of AI in supply chains, but the model reveals some limitations in taking into account environmental and social parameters important for agricultural systems.

Some studies expand the subject dimension of digital logistics by integrating artificial intelligence into water security monitoring [16] or into blockchain-based agri-trade trust systems [17].

At the same time, the scientific literature shows a shift in priorities from the "operational benefit" of digital solutions to comprehensive models that can take into account energy impacts, carbon footprint and socio-economic accessibility of innovations.

Summarizing the results of the analysis, three key scientific trends can be identified:

1) convergence of technological platforms, within which AI is integrated with IoT, satellite monitoring, geo-analytics and autonomous vehicles;
2) transition to data as the basis of logistics management, which leads to the formation of demand forecasting models, optimization of warehousing and routing;
3) increasing role of environmental and social criteria, which involves reorienting logistics solutions to reduce food losses, minimize emissions and strengthen food security.

Critical analysis of sources allows us to outline a list of scientific gaps:

- terminological inconsistency of the concepts of AI in agri-logistics, smart agri-food supply chain, digital traceability, which complicates the codification of the conceptual apparatus;
- limited number of works adapted to agricultural specifics, including seasonality, biological risks, spatial dispersion of production and logistics;
- insufficient integration of environmental metrics, such as carbon footprint, data center energy consumption, cold chain emissions;
- low share of empirically verified solutions, while a significant part of the models remains simulative;
- data accountability and ethics are not yet a central research area, despite the increasing risks of cyber interference, algorithmic discrimination, and violation of farmers' privacy.

Thus, the current state of scientific research confirms the attention to artificial intelligence as an integrative basis for food network management, but indicates the absence of a complete AI-driven agri-logistics management framework that would combine technological, managerial, institutional, and environmental dimensions. This necessitates the formation of a conceptual model adapted to the requirements of digital food security in Ukraine and the global challenges of sustainable development.

3 METHODOLOGY

The purpose of the study is to summarize the current state of scientific developments at the intersection of artificial intelligence and logistics management in the agricultural sector, identify leading trends, intellectual dominants and scientific gaps, as well as form a conceptual model of AI-driven agri-logistics management, which integrates technological, managerial and environmentally sustainable dimensions of the digital transformation of agri-food supply chains.

Achieving the set goal involved solving the following research tasks: determining the dynamics of publication activity for 2008-2025; analyzing the structure of scientific cooperation (authors, countries, organizations, scientific journals); identifying key research clusters and areas of application of artificial intelligence in agri-logistics; systematizing the most intellectually influential works and their methodological approaches; summarizing scientific gaps and prospects for further research.

The methodological basis of the study is based on a combination of bibliometric analysis, systematic review of scientific publications and network mapping of knowledge. The search sample was formed in the Scopus database (Elsevier) using a combined query that combined key terms from three conceptual blocks: artificial intelligence (artificial intelligence, machine learning, big data analytics); logistics (logistics, supply chain management, routing, and inventory optimization); agricultural sphere or sector (agriculture, agri-food, food supply chain). The chronological boundaries of the analysis cover the years 2008–2025, which provides a tracing of the evolution of the research discourse from technical automation models to integrated strategic management solutions. In the primary sample, duplicates and irrelevant sources were eliminated according to the criteria of content relevance, the presence of agri-logistics and management components, as well as the availability of bibliographic metadata. As a result, the final array

included 27 scientific publications, which create a sufficient information base for identifying the intellectual structure of the research area.

At the second stage, quantitative and network analysis was applied using VOSviewer and the Bibliometrix (R) bibliometric package. Maps of co-publication interaction were constructed at the level of authors, countries and organizations, as well as networks of co-citation and co-use of key terms. This allowed us to identify structural research cores, thematic clusters and trajectories of changes in scientific priorities. Special attention was paid to the analysis of thematic evolution, which demonstrated a gradual transition from engineering-algorithmic models to integrated management solutions aimed at ensuring sustainability, traceability and energy efficiency of logistics processes.

The final stage was a qualitative interpretation of the revealed patterns, which included content analysis of the most cited and methodologically significant publications [11]-[17].

The generalization of their results and our own previous research [18]-[20] allowed us to form the basis of the conceptual model of AI-driven agri-logistics management, which involves the interaction of three levels:

1) technology (intelligent algorithms, machine learning, digital monitoring platforms);
2) organization (logistics processes, human resources competencies, innovative culture, risk management);
3) sustainability (energy efficiency, carbon footprint reduction, food security, transparency and traceability of supply).

The methodological reliability of the study is ensured by the interdisciplinary approach, the use of proven bibliometric tools, documentation of the stages of sample formation and adherence to ethical principles of scientific data processing. The main limitations are the dependence of the results on the specifics of the Scopus database, the different duration of the "citation life cycle" of new publications and the uneven representation of regional studies.

Given that the dataset is limited to Scopus-indexed publications, certain regional scientific schools may be underrepresented. Nonetheless, for identifying dominant structural patterns and intellectual clusters, Scopus provides a sufficiently reliable and consistent bibliographic basis.

The applied methodology allows not only to quantitatively outline the dynamics of scientific development of the topic, but also to identify intellectual centers, structural connections and research gaps that form the basis for further modelling of the transformation of agri-logistics based on artificial intelligence. The next section is devoted to the results of bibliometric analysis and interpretation of the identified scientific trends.

4 RESULTS

This section presents the results of bibliometric analysis and extensive interpretation, which serve as the basis for the formation of a conceptual model of AI-driven agri-logistics management. First, the network of co-occurrence of keywords was analyzed, which made it possible to identify a number of terminological clusters that reflect the main thematic areas of research.

On the network map of co-occurrence (Fig. 1), each node corresponds to a key term, and the links between them demonstrate the frequency of their joint use within one document; the thickness of the links indicates the intensity of such associations, and the grouping into clusters is displayed using different colours. As a result, ten interconnected clusters were identified, each of which represents a separate, but at the same time integrated aspect of the digital transformation of agri-logistics.

One of the most saturated clusters is associated with digital technologies in the agricultural sector. It includes keywords such as "Artificial Intelligence", "Machine Learning", "Big Data", "Internet of Things", "Blockchain", "Precision Agriculture", as well as terms reflecting general digitalization trends such as "Industry 4.0", "Automation", "Digitization". The joint appearance of "artificial intelligence" with "supply chain management" indicates the formation of a stable scientific core, in which AI is considered as a key tool for managing agri-food supply chains, focused on data analysis, automation and optimization of operations. It is in this cluster that forecasting models, machine learning algorithms for planning, as well as solutions related to the Internet of Things and sensor infrastructure are concentrated. The second significant cluster characterizes the research on supply chain management and ensuring their sustainability. The concepts "Logistics 4.0", "Supply Chain", "Resilience", "Performance", "Information Sharing", "Dual-Carbon" dominate here. They reflect the desire of researchers to combine digital technologies with approaches to increasing the efficiency and resilience of logistics systems in the face of climate, market and geopolitical risks. The emphasis on information exchange and carbon

aspects indicates the importance of transparency, reducing emissions and supporting the sustainability of agri-food chains.

A separate cluster is related to strategic management and information systems. The most common terms in this segment are “Strategic Management”, “Business Strategy”, “Decision Support Systems”, “Strategic Information Systems Planning”. It reflects research focused on developing strategies for the implementation of artificial intelligence, planning and development of information infrastructure, building decision support systems for agricultural logistics. In such works, AI is considered not only as a set of algorithms, but as an element of strategic changes that affects management models, organizational culture and institutional mechanisms.

Another important cluster concerns agri-food chains and innovations in agribusiness. The terms “Agri-Food”, “Agribusiness”, “Innovative Technologies”, “Digital Marketing”, as well as “Bibliometric” and “Systematic Literature Review” dominate here. This indicates a growing attention to comprehensive research on agri-food systems, innovative business models, digital marketing tools and bibliometric approaches to knowledge systematization. Within this direction, researchers focus on the transformation of agri-food chains, rethinking the interaction between producers, processors, logistics operators and end consumers.

The cluster dedicated to sustainable development and business models is also important. The keywords here are “Sustainability”, “Grand Challenges”, “Business Model”, “Business Model Innovation”, “Food Industry”. It reflects the efforts of the scientific community to integrate the principles of sustainable development into the concept of food industry management, the implementation of environmentally friendly and socially responsible business models based on digital solutions and intelligent analytics. Thus, a connection is formed in the scientific field between technological innovations and the transformation of the business logic of the functioning of agri-food systems.

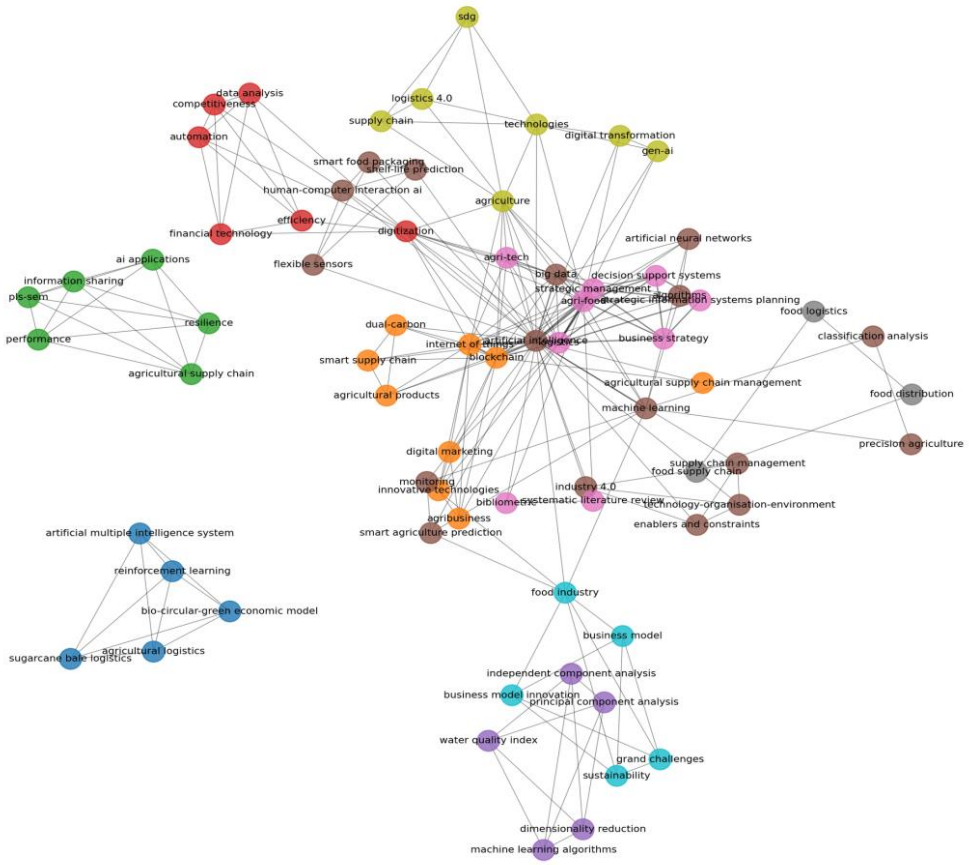

Figure 1: Keyword co-occurrence network (clusters highlighted in different colors).

A separate group is made up of specialized clusters that reflect narrowly focused research. For example, the cluster with the terms “Sugarcane Bale Logistics”, “Bio-Circular-Green Economic Model”, “Reinforcement Learning” illustrates the application of reinforcement learning in the logistics of the sugar industry and its connection with circular and “green” economic models. Another small cluster, which combines “Water Quality Index”, “Machine Learning Algorithms”, “Principal Component Analysis”, indicates the use of machine learning methods for monitoring and managing water quality in the agricultural sector. Such highly specialized areas complement the overall picture, demonstrating the breadth of application of AI in areas related to logistics.

Summarizing the analysis of the co-occurrence of keywords, it can be stated that the research field covers several interrelated areas: the implementation of AI and related digital technologies in the logistics processes of agricultural production; increasing the efficiency, sustainability and transparency of supply chains; strategic management of information systems and innovations in agribusiness; development of sustainable business models and solutions focused on minimizing losses and carbon footprint. The set of identified clusters forms a conceptual map of the research field, the center of which is the integration of artificial intelligence and logistics management of agri-food chains.

A temporal analysis of the development of the topic confirms the dynamic nature of the formation of this direction. As shown in Figure 2, the first single publications appear in 2008 and 2017, after which the activity remains low and uneven until 2019. Starting from 2019–2020, there is a steady increase in the number of publications, which turns into a rapid surge in 2025, when more than half of the entire array of analyzed works is published.

Such a jump correlates with the global explosive interest in artificial intelligence, generative models and their application in the field of logistics and agri-food systems. The growth of publication activity indicates the formation of a research community, the consolidation of digital agriculture development programs and the awareness of the strategic role of AI for food security.

The geographical structure of research confirms the international and distributed nature of the development of this topic. The analyzed publications involve authors affiliated with more than fifty scientific institutions in the world, with only two organizations having more than one publication.

Beijing Academy of Agriculture and Forestry Sciences is represented in two works, as is the University of Macedonia, known for its research in the field of bibliometrics and digital logistics. The remaining institutions are represented by single publications, among them are leading universities and scientific centers in China, Europe and other regions, such as Beijing Life Science Academy, National Tsing Hua University, Adam Smith Business School (University of Glasgow), etc. This picture indicates the absence of monopolization of the research field by one center and, at the same time, the formation of an extensive network of scientific groups.

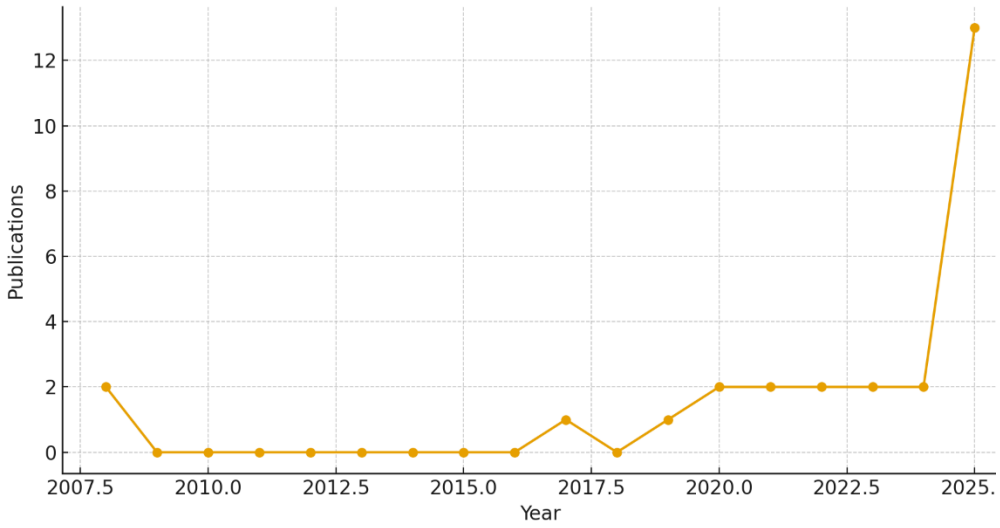

Figure 2: Dynamics of the number of publications on the selected topic by year.

The distribution of authorship by country is also quite diverse. In total, the participation of researchers from twenty-one countries was recorded. The leading positions in terms of the number of publications are occupied by Italy, China and India, for each of which the field of agri-food systems is of strategic importance. Several countries, including the United Kingdom, Ukraine, the United Arab Emirates, Jordan, Egypt, Oman, and Indonesia, have two publications each. As summarized, the range of key participants includes European and Asian states, as well as individual countries in the Middle East and Africa. This indicates, on the one hand, the global nature of the issue, and on the other, the different motives for its actualization: from the need for food security in countries with high dependence on imports to the aspirations of large agricultural economies to increase the efficiency and resilience of their own supply chains. To summarize the terminological field, a "word cloud" of the author's key terms was constructed (Fig. 3).

Although the USA is widely recognized as a global leader in AI research, it is underrepresented in our Scopus sample because many U.S. publications focus on general supply chain management rather than agricultural logistics specifically, and therefore did not meet the inclusion criteria.

The visualization shows the dominance of such concepts as "Artificial Intelligence", "Agri-Food", "Logistics", "Machine Learning", "Blockchain", "Strategic Management", which form the core of the research topic. Smaller terms, in particular "Resilience", "Sustainability", "Digital Marketing", "Precision Agriculture", reflect the specific emphases of individual studies related to sustainable development, precision agriculture and new communication tools in agribusiness. In general, the structure of the cloud confirms the multidisciplinary nature of the direction and the mutual interweaving of technological, managerial and industry aspects.

Based on the generalization of the dominant terms, their additional classification was carried out according to several semantic blocks (Table), which reproduce the logic of the research field. In particular, the technological cluster associated with the application of artificial intelligence algorithms for logistics needs (demand and yield forecasting, route optimization, inventory planning, anomaly detection); the transparency and trust cluster, which concentrates solutions based on blockchain, tracing systems, cold chain monitoring and product quality; the management cluster, focused on the framework for the implementation of digital technologies, risk management, and the maturity of organizational processes; the sustainability and energy efficiency cluster, which covers research on minimizing food losses, reducing emissions, and increasing resilience; and the data and integration cluster, which considers issues of data quality, system interoperability, cloud-edge processing, and IT solution integration architectures.

Each of these blocks is associated with certain types of tasks and methods – from regression models and deep learning to optimization algorithms, multi-criteria evaluation schemes and carbon accounting tools – as well as with expected effects in the form of cost reduction, logistics cycle times, loss reduction and increased system resilience.

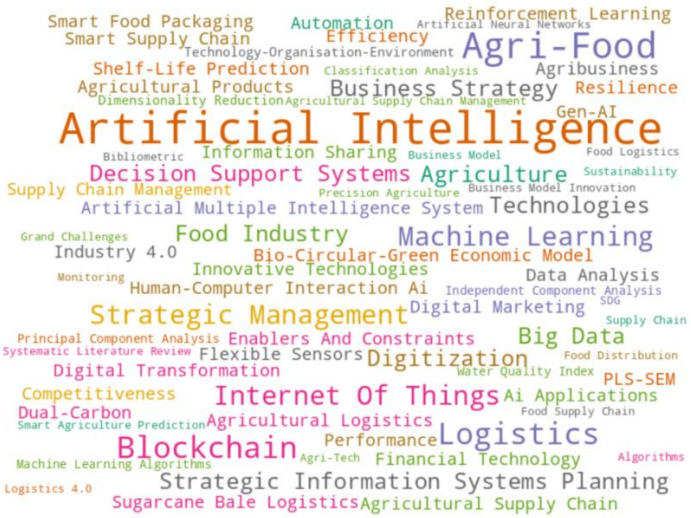

Figure 3: Author keyword cloud (the larger the word, the more often it occurs).

Table. Thematic clusters of key concepts in the research field “Artificial Intelligence and Logistics Management in the Agricultural Sector” (Scopus, 2008–2025).

Cluster	Core Keywords	Topic Extensions	Typical Tasks/Methods	Expected Effects
AI technologies for logistics	artificial intelligence; machine learning; deep learning; prediction; optimization	demand forecasting; routing; scheduling; inventory; anomaly detection	regression/gradient models; LSTM/GRU; ensemble methods; VRP heuristics; reinforcement learning	reduction of logistics costs and cycle time; higher forecasting accuracy; reduced food losses
Transparency and trust	blockchain; traceability; provenance; cold chain; quality monitoring	smart contracts; IoT sensors; HACCP integration	DLT; chain signature/hashing; event registries; integration with WMS/TMS	reduction of cold chain losses; improved compliance and auditability
Management frameworks and organizational change	supply chain management; S&OP; decision support; risk management; TOE	governance; data policies; ModelOps/MLOps; maturity models	multi-criteria decision models; process mapping; maturity assessment	shorter time-to-value; improved risk governance; scalability of AI solutions
Sustainability and energy efficiency	sustainability; food loss/waste; energy efficiency; CO_2; resilience	eco-design logistics; circularity; green KPIs	LCA/carbon accounting; IT energy-KPIs; network optimization	reduced emissions and food waste; enhanced supply chain resilience
Data and system integration	big data; data quality; interoperability; API; cloud-edge	ERP/WMS/TMS; telemetry; satellite; weather	data pipelines; feature store; data contracts	continuous data flows; model stability; increased system reliability

These clusters form a framework for a model where technological solutions are captured by organizational processes, and the result is measured by sustainable indicators.

As a result, bibliometric analysis allowed us to identify a structured system of knowledge about the research area: the latest trends, key thematic axes, active scientific centers and countries, as well as intellectual connections between the main concepts. Based on these results, a conceptual model of agri-logistics management based on artificial intelligence is proposed, which is designed to integrate technological, process and industry components into a single analytical field.

The proposed model (Fig. 4) considers the application of artificial intelligence in the logistics processes of the agricultural sector as a multi-level integrated system. Its core is formed by three interconnected areas: technological, covering digital algorithms, machine and deep learning systems, big data analytics, the Internet of Things, blockchain platforms and other AI tools; process, at the center of which is logistics management with its functions of planning, inventory management, optimization of transport routes, organization of warehousing and coordination between chain participants; and industry, which reflects the specifics of the agricultural sector – from primary production and processing to agri-food networks and relevant organizational structures. These three dimensions interact with each other through a system of "bridges" that represent specific points of application of AI in the logistics of agricultural production.

The conceptual model is based on several key principles. First, the principle of functional integration is implemented, according to which artificial intelligence does not act as an autonomous application, but is built into all main stages of the logistics cycle – from demand forecasting and resource planning to inventory management, route formation, supply control and end-user service.

Secondly, the principle of digital transformation of the agricultural sector is applied: logistics is considered as an information-rich process, where the movement of material flows is inseparable from the movement of data, and therefore, is subject to digitization, automation and intellectualization. Thirdly, the principle of sustainable development is taken into account, which involves the systematic processing of environmental, economic and social aspects of logistics solutions: artificial intelligence should not only increase efficiency, but also reduce

food losses, optimize resource use, contribute to reducing emissions and strengthening food security.

Fourthly, the model is based on the principle of adaptability and flexibility, when learning algorithms enable rapid response to changes in the external environment – weather fluctuations, price shocks, supply disruptions – and provide dynamic adjustment of logistics strategies in real time.

Structurally, the model assumes that the technological block of artificial intelligence covers a wide range of tools: from big data analytics and forecasting methods to deep neural networks, reinforcement algorithms, computer vision systems for product quality control, blockchain solutions for traceability and distributed event registries, as well as IoT sensor networks for monitoring fields, warehouses, transport and storage conditions. The logistics block includes the functions of supply and procurement planning, inventory and warehouse infrastructure management, optimization of transport routes and distribution, coordination of interaction between producers, processors, logistics operators and retail networks. The industry block focuses on the specifics of agricultural production, agri-food chains and the structure of agribusiness, which necessitates the consideration of seasonality, biological variability, climate risks and regulatory restrictions.

Within this architecture, the main functional areas of AI application are highlighted. These include forecasting yield, demand and price trends, which allows for more informed planning of production volumes and logistics flows; optimizing routes, schedules and the use of transport resources to reduce time, fuel and product quality losses; automating operations through the use of drones, robotic systems and sensor platforms for data collection and primary processing; real-time monitoring of the movement of goods and their storage conditions, which allows for timely identification of risks and intervention before significant deviations occur; ensuring traceability of agri-food products from producer to end consumer using blockchain platforms; and supporting solutions aimed at reducing food losses, managing the carbon footprint and increasing the overall sustainability of the supply chain.

The implementation of the model involves the participation of a wide range of stakeholders. For farmers and agribusinesses, it means access to forecasting tools and recommendation systems that help make more informed production and logistics decisions. Logistics operators gain the opportunity to apply intelligent routing systems, fleet management and transportation monitoring.

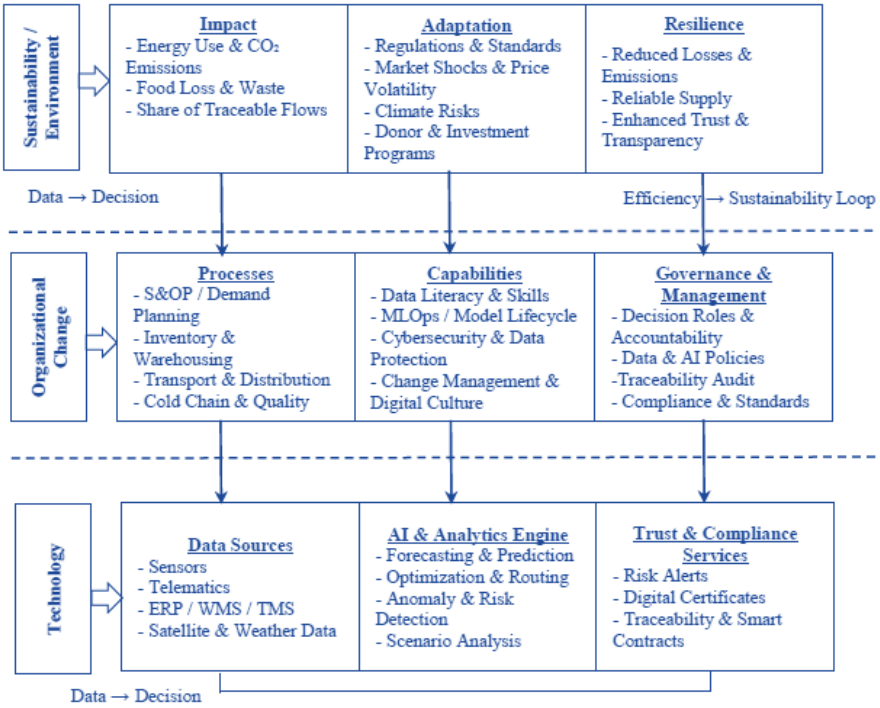

Figure 4: Conceptual model of ai-driven agri-logistics management [18-20].

Government authorities and regulators can use the model to develop smart agriculture policies and digital transformation of agri-food systems focused on food security and climate resilience. Research institutions and IT companies, in turn, act as developers of algorithms, digital platforms and analytical services, providing the scientific and technological basis for the functioning of the model.

The expected results of implementing the conceptual model are related to reducing transportation and storage costs, increasing the accuracy and reliability of supply, significantly reducing food losses and product damage in the supply chain, strengthening transparency and trust between participants in the agri-food network, as well as increasing the overall resilience of systems to external shocks. An important consequence is also the deepening of the digital transformation of agricultural logistics, which creates new opportunities for integration into global food chains and support for sustainable development goals. Thus, the result of the bibliometric analysis and further conceptual generalization is a model that not only describes existing research trends, but also offers a holistic theoretical and methodological framework for further empirical research and practical implementation of AI-driven agri-logistics management.

5 DISCUSSION AND RESEARCH LIMITATIONS

The results obtained demonstrate the growing relevance of research on the application of artificial intelligence in the logistics management of the agricultural sector, which is confirmed by the formation of an interdisciplinary scientific space at the intersection of digital technologies, supply chain management and sustainable development concepts.

The identified thematic clusters demonstrate the strengthening of the integration of machine learning and data analytics in the forecasting and optimization of logistics processes, the actualization of blockchain solutions to ensure transparency and traceability of agri-food chains, as well as the spread of research on risk management, decision-making and increasing the environmental sustainability of supplies. Such a structure of the scientific field indicates a gradual transition from isolated technical cases to a systemic conceptual understanding of digital agri-logistics as a key element of global strategies for sustainable, transparent and resilient food systems.

Comparison of the obtained results with the work of various leading scientists [11]-[15] gives grounds to assert that the majority of existing theoretical approaches focus on technological and organizational determinants of the implementation of artificial intelligence, but to a lesser extent reflect the environmental, energy and socio-economic consequences of the digital transformation of agri-food chains.

Even within the framework of popular theoretical frameworks, in particular the TOE-framework, the environmental, resource and carbon components of logistics remain auxiliary, which creates a noticeable imbalance between technological innovations and the principles of sustainable development. The conceptual model of AI-driven agri-logistics management proposed in the study is aimed at overcoming this discrepancy, combining three dimensions – Technology, Organization and Sustainability – into a holistic architecture focused on managing digital data flows, operational processes and performance indicators of the logistics activities of the agricultural sector.

Bibliometric analysis has shown an important shift in the focus of scientific research: from technical and algorithmic experiments and engineering solutions to assessing the impact of artificial intelligence on productivity, resilience, food security and energy efficiency of logistics networks. This trend indicates a transition to a more mature phase of the development of the scientific tradition, within which AI is considered not only as a tool for automation, but also as a strategic resource for the formation of adaptive, digital and low-carbon food systems.

It is important to note that the conceptual model proposed in this study remains analytical. Its practical applicability should be validated in future empirical research involving enterprise-level data, case studies, simulation modelling, or pilot implementations in agri-food supply chains.

Despite the results obtained, the study has a number of limitations that affect interpretation and can be taken into account in future works. First, the use of a single Scopus database leads to linguistic and regional selectivity, which may limit the representation of studies from countries that do not have established channels of scientific indexing, in particular, countries in Africa, Central Asia, the Middle East and regions affected by military or climate crises.

Secondly, the time lag of citations of new works (2024-2025) does not provide a complete assessment of their scientific impact, and therefore the results of the distribution by citations may be partially underestimated.

Thirdly, the difference in the indexing approaches of journals complicates the unification of author metadata and keywords, which may affect the accuracy of building network structures. Fourthly, the proposed conceptual model is of a theoretical and analytical nature and requires further validation based on applied cases, panel data of enterprises or simulation experiments.

Taking into account the above aspects determines the following trajectory of scientific research: the transition from descriptive and bibliometric description to empirical testing of the model at the level of enterprises, logistics clusters or national food systems.

This opens up prospects for expanding research in the areas of assessing the economic feasibility of implementing AI, developing methods for monitoring carbon footprints, integrating cybersecurity mechanisms, and analyzing informal institutions of trust in digital agro-logistics networks.

Given these challenges, the proposed results form the basis for the formation of more in-depth conceptual and managerial approaches that can be used in the future to develop intelligent decision support systems and new food and logistics security policies.

6 CONCLUSIONS

The conducted research allowed us to comprehensively characterize the current state and dynamics of the development of scientific publications dedicated to the application of artificial intelligence in the logistics management of the agricultural sector, as well as to identify the leading trends in the transformation of food chains in the direction of digital, transparent and environmentally sustainable agri-logistics.

The analysis of publication activity showed an exponential growth in the number of scientific developments after 2020, which indicates the emergence of a new interdisciplinary direction integrated into the global scientific discourse on sustainable and resilient food systems. The geography of author collaborations demonstrates the formation of a European-Asian center of scientific influence, which unites research groups from Italy, China, India, Great Britain and a number of other countries, while the participation of Ukraine, although still limited, indicates the prospects for the development of its own research school in the field of digital agri-logistics.

The identified cluster areas of the scientific field allow us to distinguish four conceptual dimensions of research:

1) technological, covering machine learning algorithms, big data analytics and intelligent decision support systems;
2) managerial, related to digital governance, supply coordination and risk management;
3) environmentally sustainable, which focuses on energy efficiency, reducing food losses and CO_2 emissions;
4) the dimension of transparency and trust, which is associated with the use of blockchain and traceability systems in agri-food chains.

The generalization of these areas formed the basis of the proposed conceptual model of AI-driven agri-logistics management, which combines three macro-levels – Technology, Organization and Sustainability – and provides a cyclical connection between data flows, management decisions and indicators of the effectiveness of logistics operations.

The practical results of the model provide grounds to argue that the implementation of AI in agri-logistics can provide significant operational, economic and environmental effects, in particular, reducing the time and costs of logistics operations, increasing the accuracy of routing and warehouse planning, reducing food losses and the carbon footprint of supplies, as well as increasing institutional transparency and trust between chain participants.

In view of this, it is advisable to formulate practical recommendations for different levels of logistics policy implementation. At the enterprise level, the priorities are the implementation of a centralized data management policy, the use of MLOps infrastructure, the launch of pilot projects on demand forecasting, route optimization and cold chain control, as well as the creation of KPI panels for assessing energy efficiency and CO_2 emissions.

At the industry level, standardization of traceability requirements, the development of public registers of “green” logistics initiatives and the stimulation of cluster cooperation between agricultural producers, research institutions and technology companies are important.

At the level of state policy, it is advisable to include digital agro-logistics in food security and energy resilience strategies, to involve EU funding

programs and international organizations (FAO, World Bank, IFC), and to create a national AI & Agri-Logistics Competence Center as a platform for knowledge transfer and best practices.

At the same time, the results of the study open up a number of prospects for further scientific work. Important areas of future research are the empirical validation of the conceptual model based on data from agricultural enterprises in Ukraine and EU countries, the development of regional indices of digital resilience of agro-logistics systems, the improvement of methods for quantitative assessment of the energy and carbon balance of the use of AI in food chains, the analysis of social trust in traceability systems and data cybersecurity, as well as the expansion of bibliometric analysis on Web of Science, Dimensions, and Google Scholar for deeper coverage of local scientific schools.

Solving these problems will contribute to the formation of a mature theoretical and applied platform for AI-oriented agri-logistics and strengthen the contribution of research to the implementation of strategies for the sustainable and safe development of food systems.

Keywords: Global Trade, Gross Domestic Product (GDP), Export, Import, GDP Growth, Import Substitution, Structural Trade Shifts, Fourth Industrial Revolution (4IR), Industry 4.0, Digital Transformation, Digital Ecosystem, Digital Innovation, Digital Technologies.

Abstract: This study evaluates the impact of structural changes in exports and imports on GDP dynamics within the context of the Fourth Industrial Revolution (4IR), contrasting these effects with those observed during the Third Industrial Revolution. Using World Bank data for 1970-2021, the analysis shows that global trade peaked in 2008 at 61.43% of world GDP, followed by a gradual shift toward deglobalization driven by trade wars and import substitution policies. A comparative methodological approach is applied to examine GDP growth trajectories in relation to changes in the shares of exports and imports in GDP. The findings confirm that GDP growth rates are significantly influenced by both countries' income levels and structural trade shifts. The study demonstrates that 4IR amplifies GDP growth when export expansion outpaces import growth, while also increasing the volatility of GDP responses to structural changes in trade flows. Income-specific patterns are identified: low- and lower-middle-income countries tend to benefit from export-led substitution strategies, whereas upper-middle- and high-income countries gain more from balanced trade expansion. Future research will focus on exploring the role of artificial intelligence in shaping global economic growth.

1 INTRODUCTION

Today, the global economy is undergoing a rapid transition toward digital and smart technologies. This transition drives the intensification of digital transformation processes across modern ecosystems in the era of the Fourth Industrial Revolution (4IR), powered by information systems as well as digital and intelligent technologies [1] - [4].

Artificial intelligence, machine learning, blockchain, the Internet of Things, big data analytics, augmented and virtual reality, cloud computing, robotics, and digital twins are reshaping the rules of doing business and transforming how companies interact with customers and various stakeholder groups.

The digital economy has evolved from Industry 3.0 to Industry 4.0, which is characterized by qualitatively new features. Traditional companies are no longer the central actors in economic reality; instead, a new economic entity has emerged – the digital ecosystem. This stage of digital economic transformation involves integrating digital and smart technologies, innovative solutions, and advanced management approaches into all areas of activity. Such technological change requires companies to fundamentally transform their operations, customer relationships, and strategic management models.

These transformations contribute to the modernization and reorganization of business processes and business models within the Industry 4.0 paradigm.

It should be emphasized that the development of 4IR is closely interconnected with the evolution of global trade processes. From the standpoint of Schumpeterian economic theory, the Great Recession of 2007-2008 can be interpreted as a

"positive disruption" and as a marker of the transition from the Third to the Fourth Industrial Revolution.

Statistical analysis shows that in 2008, total exports and imports reached their maximum relative value of 61.43% of world GDP for the entire 1970-2021 period. After this point, the long-term upward trend in global trade – stable since the mid-1980s – was disrupted (Fig. 1) [5] - [7]. A new global trend began to emerge: deglobalization, marked by trade wars, reindustrialization, and import substitution. The synchrony between the onset of 4IR and the reversal of world trade dynamics suggests a hypothesis that the former may have influenced the latter.

Given this context, the present article examines the impact of global trade (including structural import substitution processes) on changes in GDP dynamics under the conditions of the Fourth Industrial Revolution.

2 LITERATURE REVIEW

Over the past decade, issues related to the development of the Fourth Industrial Revolution (4IR) have attracted considerable scholarly attention [8]-[16]. At the same time, the question of when the 4IR actually began remains open. There is no universal criterion for its determination, which is not surprising, as any historical periodization is inherently conditional. The boundaries between the First, Second, and Third Industrial Revolutions are also blurred.

By early 2016, however, the concept of the Fourth Industrial Revolution had already been clearly articulated, as evidenced by such publications as Industry 4.0 [17] and The Fourth Industrial Revolution [18]. This suggests that the processes identified by these authors had begun somewhat earlier.

As T. Philbeck and N. Davis noted, "the idea of 4IR is often taken to be a synonym for 'Industry 4.0', an initiative that emerged in Germany between 2011 and 2015, focusing on the application of digital technologies to manufacturing.

These two terms are not unrelated, but they describe different things. Industry 4.0 is an important component within the larger framing of 4IR, with its narrower, vital focus on the relationship between digitalization, organizational transformation, and productivity enhancement in manufacturing and production systems" [17]. During this period, a symbolic shift occurred in 2012, when a technology company (Apple) became the world's most valuable firm, surpassing ExxonMobil for the first time [20].

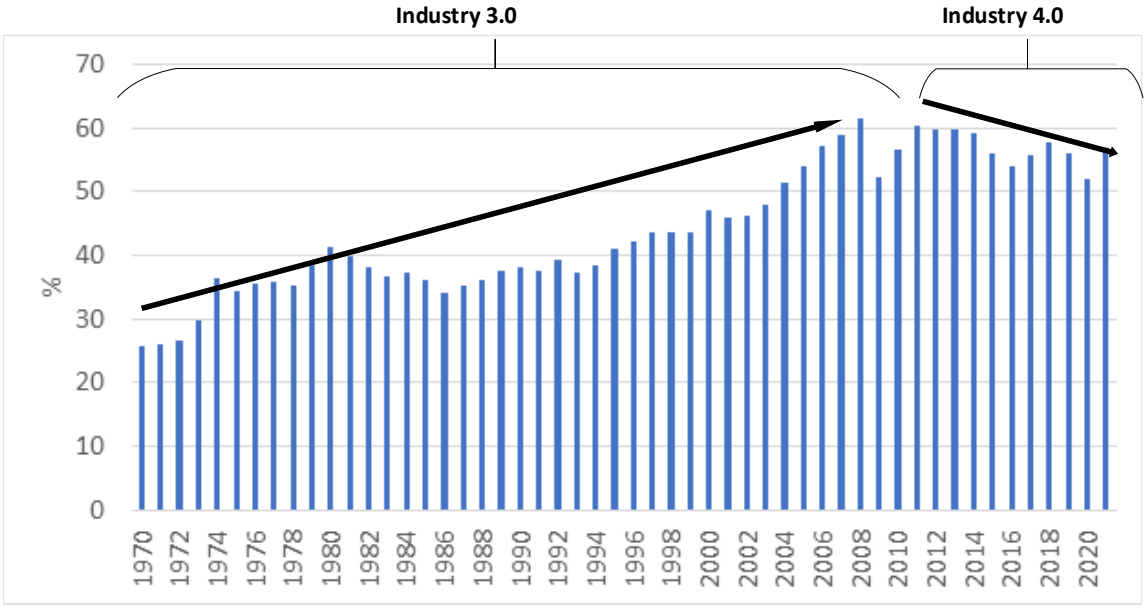

Figure 1: Exports and imports relative to world GDP in 1970-2021, %. Built on data [5] - [7].

This trend has only intensified. By mid-2024, the world's five most valuable companies were all technology firms (Microsoft, Apple, NVIDIA, Alphabet (Google), Amazon), with a combined market capitalization of nearly 14 trillion dollars. Meanwhile, ExxonMobil, once the leader, had fallen to 17th position [20].

The large-scale diffusion of new technologies has historically been associated with the redistribution of global economic power. During the transition from the Second to the Third Industrial Revolution, for example, leadership shifted from Great Britain to the United States.

Recent scholarship frequently employs such concepts as artificial intelligence, cyber-physical systems, big data, Industry 4.0, Industry 5.0, open innovation, Society 5.0, and the super-intelligent society. The transition from Society 4.0 to Society 5.0 is expected to be driven by the implementation of Internet of Things technologies, robotics, and big data, transforming society into an integrated smart environment (Society 5.0). The concept envisions the adaptation of services and industrial activities to the real needs of individuals, as well as the development of advanced digital platforms integrated into all spheres of life.

Researchers also emphasise that Industry 5.0 should not be viewed as a new industrial revolution but rather as an extension of Industry 4.0 technologies, achieved through increased collaboration between humans and intelligent machines. Within Industry 5.0, the nine core elements of Industry 4.0 are expanded by placing creativity and human well-being at the centre of industrial systems, thus combining the efficiency of machine technologies with human ingenuity.

A growing number of publications indexed in leading scientometric databases address these themes [21]-[28]. These works explore key characteristics and challenges for producers in the age of Industry 4.0 and 5.0, assess innovative models of adaptability for modernisation, and discuss long-term evolutionary trajectories such as the transition from Industry 4.0 to Nature 4.0 within the broader context of Society 5.0.

Some scholars also examine the relationship between 4IR development, global trade, and GDP. However, a search conducted in the Scopus database for 2009–2024 revealed only 12 publications that simultaneously addressed the keywords "Global Trade", "Gross Domestic Product", and "Industry 4.0/4IR/Fourth Industrial Revolution". The most frequently used keywords in the retrieved publications include: Gross Domestic Product, International Trade, Global Trade, Climate Change, Innovation, Environmental Impact, Urbanisation, and Theoretical Models.

The institutions most actively engaged in research on this topic include University College London; Tsinghua University; The Bartlett Faculty of the Built Environment; the International Institute for Applied Systems Analysis (IIASA); the Collaborative Innovation Center for Emissions Trading System; University of East Anglia; Univerzita Hradec Králové; Agricultural Research Council (Pretoria); the Ministry of Education of the PRC; and Zhejiang University. Most contributing authors are affiliated with China, the United Kingdom, the United States, Austria, Canada, the Czech Republic, Japan, Poland, South Africa, South Korea, and Switzerland. Notable contributions include works by M. Burri & T. Cottier [29]; C. M. T. Johnston & J. Buongiorno [30]; Y. Sun et al. [31].

Major funding organisations supporting research on the relationship between global trade and GDP in the context of Industry 4.0 include the National Natural Science Foundation of China; the UK Department for Business, Energy and Industrial Strategy; the Environmental Restoration and Conservation Agency; the Fundamental Research Funds for the Central Universities; the Japan Society for the Promotion of Science; the Ministry of Education, Culture, Sports, Science and Technology (Japan); the National Office for Philosophy and Social Sciences; the Natural Environment Research Council; the Science and Technology Research Partnership for Sustainable Development; and Zhejiang University.

Another group of scholars analyses the impact of structural changes in import substitution on GDP dynamics and economic growth. Among them are M. P. Abreu, S. A. Bevilacqua & M. D. Pinho [32]; A. R. Adewale [33]; J. A. Datas-Panero [34]; D. Irwin [35] - [36]; and A. Mendes, M. Bertella & R. Teixeira [37]. The problem of import substitution is particularly relevant in developing countries such as Pakistan, Indonesia [38], Chile [39], and Nigeria [40] - [41]. For instance, researchers in Nigeria argue that "the strategy of import substitution is relevant for rapid industrialization in the country" [40].

Despite these contributions, comparative studies analysing GDP growth trajectories against the backdrop of structural changes in export and import shares remain limited. Existing research predominantly focuses on the relationship between economic growth and the expansion of international

trade, while import substitution is usually examined solely within industrial sectors, overlooking the service sector. Moreover, few studies approach this issue from the standpoint of the macroeconomic structure of GDP, and the structural nature of import substitution remains largely understudied.

The transition to the Fourth Industrial Revolution has fundamentally reshaped global value creation, altering both the structure and geography of international trade. Digitalisation, artificial intelligence, automation, and advanced data analytics have enabled new forms of production, logistics, and services that diverge significantly from the patterns characteristic of Industry 3.0. Recent studies highlight that 4IR technologies reduce information asymmetries, improve supply chain efficiency, encourage reshoring and nearshoring, and stimulate the rapid expansion of digital services trade. These technological shifts influence the elasticity of GDP growth with respect to export and import dynamics, increasing both the speed and volatility of structural adjustments.

AI-driven supply-chain optimisation reduces transaction costs and supports more efficient resource allocation, enabling firms to adjust import needs and diversify export markets. Automation reduces dependence on offshore manufacturing, contributing to partial reindustrialization in high-income economies. Meanwhile, digital platforms and cloud-based services accelerate the growth of intangible exports, creating new sources of value for advanced economies while intensifying competition for middle-income countries. Consequently, the relationship between structural trade changes and GDP growth has become increasingly heterogeneous across income groups, reinforcing the need for differentiated empirical assessment.

In this regard, the structure of the present study involves two key stages: (1) demonstrating that GDP dynamics follow different trajectories depending on structural changes in the export and import shares of GDP; and (2) comparing GDP growth rates during the emergence of 4IR with the period dominated by the Third Industrial Revolution.

Therefore, the purpose of this study is to assess changes in GDP dynamics in the context of structural shifts in exports and imports during the development of the Fourth Industrial Revolution.

3 METHODOLOGY

Although this study relies on descriptive and comparative methods rather than regression modelling, such an approach is appropriate for analysing long-term structural trends over 1970–2021. Conducting regression analysis would require harmonised global panel data on structural breaks, technological adoption rates, and institutional differences – datasets that extend beyond the scope of this research. Instead, the comparative structural approach employed here allows the authors to identify generalisable patterns across income groups and industrial eras. This methodological choice is consistent with existing macro-comparative studies on long waves of technological change and global trade restructuring.

Traditionally, import substitution has been viewed as an instrument of industrialisation and economic growth. However, the key methodological challenge concerns how to “record” the occurrence of import substitution. At the micro level, this process is straightforward: goods and services previously produced or purchased abroad are subsequently produced and purchased domestically. At the macroeconomic level, however, this process is far less transparent.

Based on the classical expenditure approach to GDP:

$$Y = C + I + G + E_x - I_m, \quad (1)$$

where Y – Gross Domestic Product (GDP), C – consumption, I – investment, G – government spending, E_x – export, I_m – import.

At first glance, one might argue that, ceteris paribus, a decrease in imports should lead to an increase in GDP, and thus the maximisation of GDP would occur when imports approach zero and exports reach a maximum. However, this proposition is incorrect; the optimum exists under entirely different structural conditions.

Changes in the absolute values of imports also do not allow us to determine whether import substitution has occurred. For instance, a simultaneous decrease in both exports and imports cannot be interpreted as import substitution. Therefore, it is more appropriate to consider relative indicators – namely, changes in the shares of exports and imports in GDP.

Let us examine (1) at two moments in time, t and $t + 1$:

$$Y_t = C_t + I_t + G_t + E_{xt} - I_{mt}, \quad (2)$$

$$Y_{t+1} = C_{t+1} + I_{t+1} + G_{t+1} + E_{xt+1} - I_{mt+1}, \quad (3)$$

GDP growth between periods is defined as:

$$y_{t+1} = \frac{(Y_{t+1} - Y_t)}{Y_t}, \quad (4)$$

Export and import shares in GDP at time t:

$$exp_t = \frac{E_{xt}}{Y_t}, \quad (5)$$

$$imp_t = \frac{I_{mt}}{Y_t}, \quad (6)$$

Changes in export and import shares:

$$\Delta exp_{t+1} = exp_{t+1} - exp_t, \quad (7)$$

$$\Delta imp_{t+1} = imp_{t+1} - imp_t \quad (8)$$

Thus, the main hypothesis of this study is that the GDP growth rate (y_{t+1}) depends on changes in exports and imports in GDP structure (Table 1).

In this research, a strong quantitative criterion of import substitution is defined as a decrease in the import share in GDP accompanied by an increase in the export share. A weak quantitative criterion is defined as a decrease in both import and export shares in GDP, with the decrease in imports exceeding the decrease in exports.

The statistical basis of the study consists of World Bank data:

1) Exports of goods and services (% of GDP) [5];
2) Imports of goods and services (% of GDP) [6];
3) GDP growth (annual %) [42];
4) World Trade Statistical Review 2021 [7].

Data extraction and pre-processing were performed using a Python-based program capable of analysing large datasets, visualising trends, applying machine learning techniques, and automating data-processing routines.

The principal method applied in this study is comparative analysis. It is used to compare GDP dynamics under conditions of structural changes in export and import shares. The analytical logic progresses from general global patterns to specific income-group trajectories.

Table 1: Options for structural import substitution (changes in exports and imports).

Option	In the GDP structure		Description of the option from the perspective of import substitution
	Export	Import	
1	Increase $\Delta exp_{t+1} > 0$	Increase $\Delta imp_{t+1} > 0$	
1.1	The share of exports is growing faster than the share of imports ($\Delta exp_{t+1} > \Delta imp_{t+1}$)		Harmonious structural import substitution (by export) is taking place
1.2	The share of exports is growing at the same level as the share of imports $\Delta exp_{t+1} = \Delta imp_{t+1}$		The status quo is maintained
1.3	The share of exports is growing more slowly than the share of imports $\Delta exp_{t+1} < \Delta imp_{t+1}$		Structural export substitution (by import) is taking place
2	Increase $\Delta exp_{t+1} > 0$	Decrease $\Delta imp_{t+1} < 0$	Active (effective) import substitution is taking place
3	Decrease $\Delta exp_{t+1} < 0$	Increase $\Delta imp_{t+1} > 0$	Export substitution by import is taking place
4	Decrease $\Delta exp_{t+1} < 0$	Decrease $\Delta imp_{t+1} < 0$	
4.1	Exports are falling faster than imports in the GDP structure ($\Delta exp_{t+1} < \Delta imp_{t+1}$)		Passive (negative) export substitution occurs
4.2	Imports are falling faster than exports in the GDP structure ($\Delta exp_{t+1} > \Delta imp_{t+1}$)		Passive (negative) import substitution is taking place
4.3	Imports and exports in the GDP structure decrease equally ($\Delta exp_{t+1} = \Delta imp_{t+1}$)		The status quo is maintained

4 RESULTS

The dynamics of import changes in the GDP structure, at first glance, agree with the dynamics of the GDP itself (Fig. 2). However, this is not the case. The correlation coefficient between the dynamics of GDP and the structural dynamics of exports (imports) is only 60%. The synchronicity of structural changes in exports and imports is observed only at the global level.

Table 2 shows the number of cases of structural changes in exports and imports.

Table 2: The number of cases falling into each of the quadrants of structural change in exports and imports.

Export	Import	
	Decrease $\Delta imp_{t+1} < 0$	Increase $\Delta imp_{t+1} > 0$
Increase $(\Delta exp_{t+1} > 0)$	1280 (16%)	2947 (36.84%)
Decrease $\Delta exp_{t+1} < 0$	2421 (30.26%)	1352 (16.90%)

As presented in Table 2, in 2421 cases there is a trend of reduction in exports and imports. The largest group (2947 cases) shows simultaneous growth in both exports and imports, which might suggest overall trade expansion.

The calculations given in Table 3 prove that the value of average GDP growth is significantly influenced by structural changes in exports and imports. At the same time, the greatest GDP growth is observed when the share of exports increases and the share of imports decreases. As the calculations show, under such conditions, the average GDP growth is 4.17%. Under conditions of a simultaneous increase in the share of exports and imports, the average GDP growth is estimated at 3.98%. On average, under conditions of an increase in the export share and a decrease in the import share, as well as a simultaneous increase in both export and import shares, GDP growth is 4.38% and 4.68%, respectively (Table 4).

The highest GDP growth is observed in cases involving countries with upper middle income or high income levels and a simultaneous increase in the shares of exports and imports (Table 4). In these cases, the average annual GDP growth is 5.61%.

Table 3: Average GDP growth under conditions of structural change in exports and imports, *%*.

Export	Import	
	Decrease $\Delta imp_{t+1} < 0$	Increase $\Delta imp_{t+1} > 0$
Increase $(\Delta exp_{t+1} > 0)$	4.17	3.98
Decrease $\Delta exp_{t+1} < 0$	2.75	3.72

With a middle income level, an increase in the export share and a decrease in the import share, the average GDP growth is slightly lower but still significant, at 5.41%. It is important to note that for countries with high income or upper middle income levels, the maximum GDP growth is achieved with a simultaneous increase in exports and imports within the GDP structure. For other countries, with middle income, lower middle income, or low income levels, the optimal approach for ensuring economic growth is an increase in exports in the structure alongside a structural decrease in imports.

It is also necessary to highlight that for countries with middle income, lower middle income, or low income levels, a simultaneous decrease in both exports and imports in the structure is more preferable (from the perspective of GDP growth) than a structural decrease in exports under conditions of structural import growth. For example, for countries with middle income, in the first case, GDP growth is 4.4%, while in the second, it is 3.75%. For countries with high income or upper middle income levels, the situation is diametrically opposite. Thus, for high income countries in the case ($\Delta exp_{t+1} < 0$; $\Delta imp_{t+1} > 0$), GDP growth is 3.18%, while in the case ($\Delta exp_{t+1} < 0$; $\Delta imp_{t+1} < 0$), it is significantly lower, at only 1.24%.

Thus, it can be stated that the income level and structural changes in exports and imports have a substantial impact on GDP growth, and there are different growth patterns for two groups of countries.

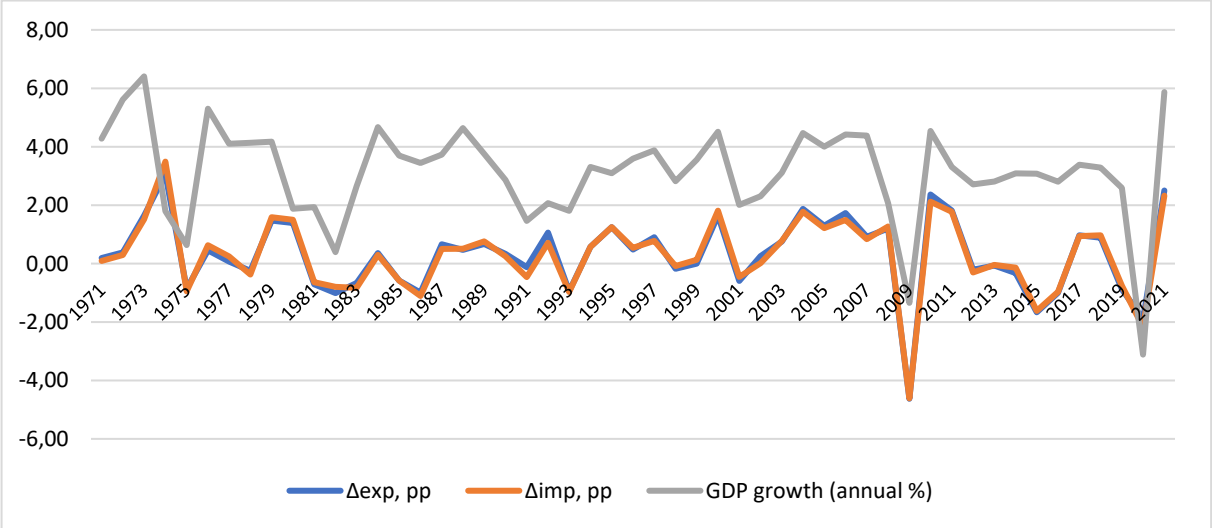

Figure 2: GDP growth, exports and imports relative to world GDP in 1970-2021, %. Built on data [5] - [7].

Table 4: Average GDP growth depending on the average income level under conditions of structural change in exports and imports, %.

Income level	$\Delta exp_{t+1} > 0$ $\Delta imp_{t+1} < 0$	$\Delta exp_{t+1} > 0$ $\Delta imp_{t+1} > 0$	$\Delta exp_{t+1} < 0$ $\Delta imp_{t+1} > 0$	$\Delta exp_{t+1} < 0$ $\Delta imp_{t+1} < 0$
1. High income	1.80	3.27	3.18	1.24
2. Upper middle income	5.15	5.61	4.81	4.62
3. Middle income	5.41	5.24	3.75	4.40
4. Lower middle income	4.97	4.92	3.17	3.83
5. Low income	4.54	4.38	3.04	3.68
Average	4.38	4.68	3.59	3.55

The first group includes countries with upper middle income or high income levels, while the second includes countries with middle income, lower middle income, or low income levels. The change in growth patterns occurs during the transition from middle income levels to upper middle income levels.

As shown in Table 5, the scenario of a structural increase in exports alongside a decrease in imports is most typical for countries with middle income or lower middle income levels. It is least typical for countries with high income levels.

The scenario of a simultaneous increase in the shares of exports and imports within the GDP structure is most typical for countries with high income levels. It is least typical for countries with low income levels.

The scenario of a decrease in exports in the structure alongside an increase in imports is most typical for countries with lower middle income levels. It is least typical for countries with high income levels.

The scenario of a simultaneous decrease in the shares of exports and imports within the GDP structure is most typical for countries with upper middle income levels. It is least typical for countries with low income levels.

The study illustrates (Table 6) that, without accounting for structural changes in exports and imports, GDP growth was faster under the conditions of Industry 3.0 than under Industry 4.0 (3.91% and 2.5%, respectively). However, the maximum growth during the era of Industry 3.0 occurs in scenarios of structural export growth alongside a reduction in the import share within the GDP structure, reaching 4.46% annually. In the era of Industry 4.0, the emphasis shifts. The highest growth is observed in countries where the share of exports grows faster than the share of imports.

Table 5: The Distribution of Observations by Income Level in the Context of Structural Changes in Exports and Imports within GDP.

Income level	$\Delta exp_{t+1} > 0$ $\Delta imp_{t+1} < 0$	$\Delta exp_{t+1} > 0$ $\Delta imp_{t+1} > 0$	$\Delta exp_{t+1} < 0$ $\Delta imp_{t+1} > 0$	$\Delta exp_{t+1} < 0$ $\Delta imp_{t+1} < 0$
1. High income	2 (6.9%)	31 (26.5%)	2 (10%)	16 (18.6%)
2. Upper middle income	7 (24.1%)	25 (21.4%)	5 (25%)	23 (26.7%)
3. Middle income	8 (27.6%)	27 (23.1%)	3 (15%)	22 (25.6%)
4. Lower middle income	8 (27.6%)	23 (19.7%)	7 (35%)	16 (18.6%)
5. Low income	4 (13.8%)	11 (9.4%)	3 (15%)	9 (10.5%)
Total	29 (100%)	117 (100%)	20 (100%)	86 (100%)

Table 6: GDP growth depending on the direction and speed of structural change in exports and imports, *%.*

Option	In the GDP structure		Industry 3.0 (before 2011)	Industry 4.0 (2012-2021)
	Export	Import		
	Without taking into account the structure of exports and imports		3.91	2.50
1	Increase $\Delta exp_{t+1} > 0$	Increase $\Delta imp_{t+1} > 0$	4.07	3.60
(1.1)	The share of exports is growing faster than the share of imports ($\Delta exp_{t+1} > \Delta imp_{t+1}$)		4.08	3.75
(1.2)	The share of exports is growing more slowly than the share of imports $\Delta exp_{t+1} < \Delta imp_{t+1}$		4.06	3.50
(1.3)	The share of exports is growing at the same level as the share of imports $\Delta exp_{t+1} = \Delta imp_{t+1}$		n/d	n/d
2	Increase $\Delta exp_{t+1} > 0$	Decrease $\Delta imp_{t+1} < 0$	4.46	3.09
3	Decrease $\Delta exp_{t+1} < 0$	Increase $\Delta imp_{t+1} > 0$	4.19	1.94
4	Decrease $\Delta exp_{t+1} < 0$	Decrease $\Delta imp_{t+1} < 0$	3.22	1.56
(4.1)	Imports are falling faster than exports in the GDP structure ($\Delta exp_{t+1} > \Delta imp_{t+1}$)		3.07	2.14
(4.2)	Exports are falling faster than imports in the GDP structure ($\Delta exp_{t+1} < \Delta imp_{t+1}$)		3.42	0.72
(4.3)	Imports and exports in the GDP structure decrease equally ($\Delta exp_{t+1} = \Delta imp_{t+1}$)		n/d	1,49*

Notes: * one observation.

In the most disadvantageous position during the era of Industry 4.0 are countries where exports fall faster than imports in the GDP structure. The average annual GDP growth in such cases is 0.72%. The analysis of deviations from average GDP growth rates shows that the transition from Industry 3.0 to Industry 4.0 is characterized by a significant increase in volatility in the context of structural changes. Specifically, the coefficient of variation under Industry 4.0 more than doubled compared to Industry 3.0, rising from 1.39 to 3.03 percentage points (Table 7).

Accordingly, the maximum positive deviation in the era of Industry 3.0 was 0.55 percentage points, while in Industry 4.0 it was 1.25 percentage points. The maximum negative deviations were -0.84 percentage points and -1.78 percentage points, respectively. Thus, against the background of slowing economic growth, the role of structural changes in exports and imports within GDP has strengthened.

5 DISCUSSION AND LIMITATIONS OF THE RESEARCH

The empirical findings indicate that the transition from Industry 3.0 to Industry 4.0 has substantially reshaped the relationship between export–import structures and GDP growth. These results should be interpreted in the context of current research on digital transformation, global value chains, and technological restructuring.

Table 7: Deviation from average GDP growth depending on the structural change in exports and imports, *p.p.*

Option	In the GDP structure		Industry 3.0 (before 2011)	Industry 4.0 (2012-2021)
	Export	Import		
1	Increase $\Delta exp_{t+1} > 0$	Increase $\Delta imp_{t+1} > 0$	0.16	1.10
(1.1)	The share of exports is growing faster than the share of imports ($\Delta exp_{t+1} > \Delta imp_{t+1}$)		0.17	1.25
(1.2)	The share of exports is growing more slowly than the share of imports $\Delta exp_{t+1} < \Delta imp_{t+1}$		0.15	1.00
(1.3)	The share of exports is growing at the same level as the share of imports $\Delta exp_{t+1} = \Delta imp_{t+1}$		n/d	n/d
2	Increase $\Delta exp_{t+1} > 0$	Decrease $\Delta imp_{t+1} < 0$	0.55	0.59
3	Decrease $\Delta exp_{t+1} < 0$	Increase $\Delta imp_{t+1} > 0$	0.28	-0.56
4	Decrease $\Delta exp_{t+1} < 0$	Decrease $\Delta imp_{t+1} < 0$	-0.69	-0.94
(4.1)	Imports are falling faster than exports in the GDP structure ($\Delta exp_{t+1} > \Delta imp_{t+1}$)		-0.84	-0.36
(4.2)	Exports are falling faster than imports in the GDP structure ($\Delta exp_{t+1} < \Delta imp_{t+1}$)		-0.49	-1.78
(4.3)	Imports and exports in the GDP structure decrease equally ($\Delta exp_{t+1} = \Delta imp_{t+1}$)		n/d	-1.01
Range of variation			1.39	3.03

First, the observed increase in GDP growth volatility under 4IR can be attributed to accelerated technological diffusion and digitalisation. AI-driven optimisation improves responsiveness to market fluctuations but simultaneously heightens exposure to global disruptions, including supply-chain bottlenecks, geopolitical tensions, and technological shocks. This dual effect contributes to the higher coefficient of variation documented in the study.

Second, the results reveal two distinct growth models. High-income and upper-middle-income economies benefit most from a balanced expansion of both exports and imports. This aligns with their deep integration into global value chains, where they rely on technologically sophisticated intermediate imports while exporting high-value-added goods and digital services. Their comparative advantage is rooted in innovation capacity, digital platforms, and advanced manufacturing systems.

In contrast, middle-income and low-income economies exhibit stronger GDP growth under export-led substitution, particularly when import shares decline. This reflects ongoing efforts to strengthen domestic production capacity, reduce dependence on imported intermediates, and leverage cost or resource advantages. However, for these economies, AI and automation may generate additional challenges by shifting global production toward more technologically advanced centres, increasing the need for targeted export development strategies.

Third, the structural break associated with 4IR suggests that global trade has become more sensitive to technological disruptions. Automation, robotics, and digital platforms reshape comparative advantages more rapidly than in previous industrial eras, making the structural composition of trade flows a critical determinant of macroeconomic performance.

Several limitations of the study should be acknowledged:

1) The analysis does not include regression modelling, lag structures, or instrumental variables; therefore, causal inference remains limited.
2) The use of aggregate country-level data does not allow for capturing micro-level mechanisms of 4IR adoption, such as firm-level productivity or sectoral digitalisation.
3) The Industry 4.0 period (2012–2021) is relatively short and includes major shocks such as the COVID-19 pandemic, which may distort long-term structural patterns.
4) The study does not differentiate between types of exports (goods vs. services), despite the fact that 4IR disproportionately accelerates the growth of digital services.

These limitations highlight promising directions for future research, particularly in expanding the analysis through econometric modelling, sectoral decomposition, and firm-level datasets.

6 CONCLUSIONS

The results of the study allow for several key conclusions.

1) The term import substitution is widely used in the academic literature, as evidenced by a substantial body of research in economic theory and international economic relations. Although conceptually well-established, its macroeconomic measurement remains methodologically challenging.
2) The findings confirm the hypothesis that GDP growth rates depend on structural changes in the shares of exports and imports. The analysis demonstrates that GDP dynamics follow different trajectories depending on the direction and magnitude of these structural trade shifts. High-income countries are characterised by simultaneous increases in both export and import shares within the GDP structure, reflecting their integration into global value chains.
3) The study compares GDP growth patterns during the emergence of the Fourth Industrial Revolution with those observed during the period dominated by Industry 3.0. The comparison reveals important structural differences in how economies respond to changes in trade composition.
4) The results show that structural substitution of imports by exports is associated with more dynamic GDP growth relative to long-term averages. The Fourth Industrial Revolution affects GDP growth not only by accelerating technological transformation but also by increasing volatility. This is reflected in a more than twofold rise in the coefficient of variation (from 1.39 to 3.03 percentage points), indicating greater sensitivity of GDP growth to structural trade adjustments.

Future research will extend this work by examining the impact of artificial intelligence technologies on economic growth across countries with different income levels and technological trajectories.

Keywords: ICT, Human Capital, Human Factor, Innovations, National Economy, Economic Growth, Digital Transformation, Global Innovation Index, Digital Skills.

Abstract: The active deepening of transformation processes has led not only to the introduction of digital technologies, but also significantly increased the role of the human factor. The deployment of the fourth industrial revolution has contributed to the formation of a new technological paradigm, which digital technologies act as the basis for the economics' modernization. The driving force of these processes remains a person who not only produces technological innovations, but also effectively uses them. In this context, special attention is paid to the study of theoretical aspects of the relationship between the human factor and human capital, as well as empirical confirmation of the influence of a person on the country's innovative capacity. Accordingly, the purpose was to reveal the relationship between human capital and the human factor, as well as to clarify their significance in the formation of innovative potential and economic growth in the context of the digital transformation. The various methods of cognition were used, including comparative analysis, graphic method, system approach and correlation analysis. As a result of the study, it was found that behavioral factors as the basis of the human factor cannot be considered in isolation, because they are formed based on human capital and reflect its practical implementation. Only in the interaction two components is the human potential revealed, which can ensure the stability and effectiveness of social development. The correlation analysis conducted confirmed the presence of a close relationship between the level of human capital and the innovative capacity. It was found that improving the quality of human capital contributes to strengthening the innovative potential and advancing the state in the world rankings of innovative development. This indicates that human capital acts as a system-forming factor of innovation processes and determines the strategic opportunities for economic growth.

1 INTRODUCTION

The modern development of society is determined by active transformational processes that cause the rapid spread of digital technologies, which implementation causes a change in the technical and technological structure, modification of the mechanisms for achieving economic growth and contributes to the gradual increase in the role of the human factor as a key determinant of development. Taking into account such changes, it can be stated that today the national economies of the world's leading countries are in a state of digital modernization, which occurs under the influence of the fourth industrial revolution and involves the widespread use of Big Data, artificial intelligence, machine learning, the Internet of Things, analytics, automated systems and robotics, which radically change the characteristics of management, tools and mechanisms for achieving goals, forming new conditions for ensuring sustainable economic development.

These processes bring to the fore a person and his human capital with all its qualitative characteristics, which become a driver kind of innovation creation and their transformation into effective technological solutions. Indeed, only a person as a carrier and owner of skills, abilities, knowledge and innovative potential in general, can generate technological

innovations and subsequently transform them into effective tools, which will allow to increase the competitiveness of the national economy and strengthen its position on the world stage.

Even though digital technologies are a kind of basis for the modernization of the economy and society, their effective use is determined by human. Accordingly, technologies are not a self-sufficient source of development, they only play the role of a tool (a modernized tool of labor), which effective use depends on the level of competencies, value system, worldview and culture of its users. Thus, in interaction with technologies, a person can act as both a direct user and a developer or creator of new solutions. Therefore, it is human who not only generates innovations and creates new technological solutions, but also sets the vector of their use and further development. The consequences of this process can be both positive, which is manifested in promoting the growth of productivity and efficiency, and have destructive manifestations, among which we highlight the aggravation of the risks of digital inequality, the displacement of traditional forms of labor by automated systems, the growth of social disunity or structural fragmentation of society.

The outlined trends confirm the need for an in-depth scientific analysis for the role of the human factor in the period of technological change. We believe that the results of such studies can serve as the basis for the formation of effective state policy in the field of digital economy development, the development of human capital and its adaptation to the new requirements of the time, as well as for the development of new models of human-technology interaction. Therefore, the comprehensive disclosure of the human factor as a determinant of technology development in the period of digital transformation of the national economy is an extremely relevant and mature issue in both theoretical and practical dimensions.

2 LITERATURE REVIEW

Recent trends in economic progress in developed countries have led to an increase in interest among the scientific and research community in substantiating how digital technologies change business, economics, education and society. In this aspect, special importance is attached to the disclosure of the issue for the human factor in the context of digital transformation, which is reflected in numerous theoretical and empirical publications. In particular, such developments are devoted to the analysis for the role of human capital in the implementation and using digital technologies; identifying the features of the interaction between humans and technologies; studying the processes of forming digital culture, consciousness, thinking and qualitative characteristics of human capital, which are due to technological changes; revealing organizational, managerial and institutional aspects aimed at the development of the human factor.

Thus, recently, there has been an increase in the number of scientific publications that widely use keywords such as "digital skills", "human factor in digital transformation", "ICT usage", "labor structure in digital economy". Among them, the most popular research category is digital skills, which is primarily due to their decisive importance in ensuring the efficiency of the functioning for the digital economy and the competitiveness of human capital. In particular, the scientific work of Ester van Laar [1] deserves attention, which emphasizes that innovations begin with a person. In the conditions of the dynamic development of the modern knowledge economy, it is digital skills and 21st century skills, which the authors consciously distinguish, that determine the competitiveness of the organization and its innovative potential. It is also worth noting separately that the presented understanding of 21st century skills is broader than digital, which is due to the inclusion of ethical awareness, cultural awareness, flexibility, self-direction and lifelong learning in their composition. It is especially appropriate to emphasize the results of the study by Tsyra O. [6], which states that digital transformation changes the requirements for human skills, abilities and knowledge. This, in turn, actualizes the development of digital skills, which level depends on the development of the national economy and its competitiveness, as well as the activity of implementing and spreading innovative activities.

In Qi Xiong's study [2], digital transformation is defined not only as a technological replacement, but as a process of achieving efficiency, which becomes possible due to the complementarity and integration of human and machine. The authors also emphasize that the model's development of such interaction is due to the widespread use of intelligent systems, in particular robots, computers, artificial intelligence algorithms and automated control systems.

In general, an approach that combines the analysis of human capital and digital technologies as interrelated factors of economic development is becoming increasingly widespread in scientific research. As an example, we can cite the work of Popelo O. [8], which reveals the role of digital

technologies in balancing the labor market and determines the importance of digitalization in the formation of new opportunities for professional human realization. We believe that such an approach allows us to consider a person not only as a user of new technologies, but also as an active subject capable of generating trajectories of economic transformation.

In addition, a significant number of review studies on this issue deserve attention. In particular, the works of Maria Anna Lykourentzou [3] emphasize the human factor as a factor that allows achieving success in digital transformation projects. The work of Pablo Reyes-Cornejo [4] records the growth of scientific interest in substantiating the role of flexible skills in the processes of change caused by the spread of digital technologies and emphasizes the analysis of digital transformation through the prism of human resource management in the context of personnel policy, which is considered as the basis for the formation of new skills. Another work by Daniela-Aida Ionescu [5] emphasizes that digital transformation encompasses two complementary dimensions: technological, which provides tools; human, which determines the reality and effectiveness of changes. The authors conclude that the long-term success of digital transformation directly depends on managing the process of integrating technology with human potential. The systematic review presented in the study by Jelena Crnobrnja [7] identifies the feasibility of using a systemic approach to provide a more comprehensive analysis of human-centricity in the context of Digital Transformation and Industry 5.0. Special attention is also paid to the issue of harmonizing technological development with human values, safety, ergonomics, skills development and ensuring employee well-being.

Thus, a review of modern scientific developments shows that a person is a key condition for the development of technologies during the period of digital transformation of the national economy. After all, firstly, it is a person who becomes the central element of the digital environment, and the effectiveness of integrating innovations into various spheres of social production depends on the level of knowledge, skills, competencies and flexibility of adaptation. Secondly, coordinating the interaction of a person and technology requires not only technical, but also social, ethical and organizational solutions that ensure the harmonious coexistence of artificial intelligence, automation and human capabilities. Thirdly, modern research emphasizes the need to clearly define the role of a person in the development and use of new technologies, from a creative subject capable of generating innovative ideas to a bearer of values, security and responsibility in the digital space. We believe that in this context, further scientific research should be aimed at using interdisciplinary and systemic approaches that will reveal the human factor as the leading determinant of the development and use of modern technologies during the period of digital transformation of the national economy.

3 SYSTEMIC INTERCONNECTIONS OF THE HUMAN FACTOR AND HUMAN CAPITAL

In our study, we proceed from the premise that the human factor is a derivative manifestation of human capital, even though, as a rule, they are considered in different analytical dimensions. The human factor is mostly used in socio-psychological and organizational-management aspects, which allow to focus on the personal characteristics and behavioral reactions of the individual. Human capital is one of the most studied economic categories of modernity, reflecting the qualitative parameters of a person in the form of a resource that can be accumulated, multiplied and converted into added value. However, there is an internal connection between these categories: human capital is basic, and the human factor is a superstructure or a derivative category that reflects the practical use of the accumulated potential.

We believe that the most generally accepted definition of "human capital" is the approach presented by the OECD, according to "Human capital can be broadly defined as the stock of knowledge, skills and other personal characteristics embodied in people that helps them to be productive" [10]. That is, human capital accumulates in knowledge, skills, qualifications, professional experience, appropriate health status, cultural level and value system, and forms the potential for personal development. However, such potential does not guarantee the effective course of socio-economic processes. Since it acquires real significance only when it is reflected in the practical activities of a person. Accordingly, at this stage, human capital is transformed into a factor or force that directly affects the effectiveness of production, management or social relations (Fig. 1).

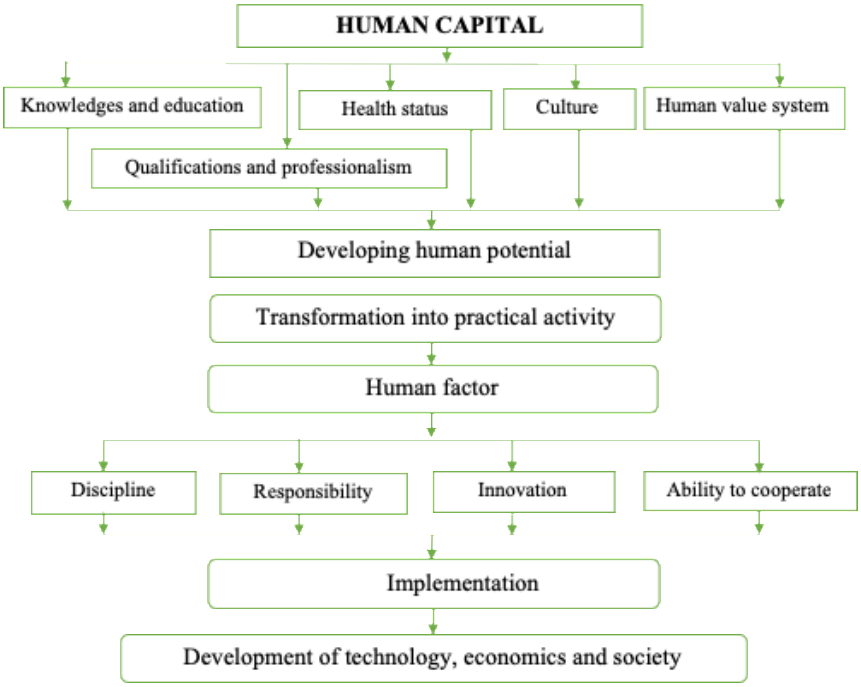

Figure 1: Structure and components of human capital as the basis for personal development potential.

Therefore, discipline, responsibility, innovation and teamwork, which are attributed to the manifestations of the human factor, can be interpreted as secondary, derived from the main components of human capital. The education level and culture determine organization and the ability to comply with norms and rules; professional experience and qualifications become the basis for responsibility and risk-taking in decision-making, and intellectual abilities form the basis for creativity and innovation.

The definition of the human factor as a derivative manifestation of human capital allows us to rethink the effectiveness of socio-economic development. In this context, not only the quantitative parameters of human capital accumulation become important, but also the quality of its implementation in the form of specific actions and results. That is, when assessing the human factor and its importance in the development of technologies and the economic system, it is advisable to analyze not only individual behavioral characteristics, but also those social investments that determined their emergence: education, professional training, cultural environment, education system. In such an interpretation, the human factor acts as a key link between the potential resources embedded in human capital and the real productivity of social development.

In addition, the coherence of human capital and the human factor creates the prerequisites not only for achieving performance, but also for the development of innovations and modern digital technologies. After all, as defined Aleknavičiūtė, R. "the main purpose of human capital is to create innovations: to generate new ideas, to create new products, services, or goods, to improve existing products, services, or goods, to establish new business processes and so on" [11, p. 116].

Therefore, in modern conditions, behavioral factors as components of the human factor cannot be considered as self-sufficient or separate manifestations, since they are formed based on human capital and function as its superstructure, which determines their stability and effectiveness. Only in the unity of human capital and the human factor is the true potential of a person and society revealed, since the accumulated knowledge, skills and values have meaning only when they are transformed into specific actions and behavioral manifestations. At the same time, the human factor itself cannot be self-sufficient without a foundation in the form of formed capital. Thus, the effectiveness and success of economic development is determined not by the isolated existence of these categories, but by their harmonious interaction, where capital appears as a foundation, and the factor as its effective reflection in practical activity.

4 PERSON AS THE DRIVING FORCE OF TECHNOLOGICAL CHANGES AND NATIONAL DEVELOPMENT

Throughout history, human has been the main initiator and creator of technological change. In general, no technological variable or innovation arises by itself but is always the result of human reason and imagination, which are primarily aimed at meeting growing needs. The evolution of tools and labour tools from the first stone products to modern digital technologies demonstrates human's constant desire to facilitate physical and mental labour, expand his opportunities for creativity and self-education, as well as increase the level of well-being and quality of life. Accordingly, each new technology arises because of human ingenuity and initiative, the desire to improve living conditions, forming not only a new mechanism for performing actions, but also new ways of thinking, interacting with society and perceiving the world around us.

As Mykola Berdyaev rightly noted, "any tool created by human is directed not only outwardly at the objects of activity, but also inside the subject itself" [9]. It is thanks to the interaction of man and technology that new stages of the evolution of mankind are formed: the transition from the Stone Age to the Iron Age, from agrarian to industrial civilization, from industrial to modern information society. However, we believe that in the outlined process, the key importance belongs to human, since his creativity, initiative and ability to innovate determine the direction and pace of development. Human not only creates equipment and technologies, but also gives them meaning, determines the directions of development and the scale of use. And technologies arise only as tools necessary for the implementation of human ideas, and not as independent drivers of progress. That is, human sets a goal, chooses the path to achieve it and adapts technological solutions to social, cultural and economic needs.

In modern scientific discussion, it is increasingly assumed that the level of human development, which is reflected in the accumulated human capital, directly affects the technological progress of the state and determines its position in global economic competition. Human capital, embodied in knowledge, educational level, professional training, health status and the ability to learn throughout life, forms the basis for the creation and implementation of new technologies. Accordingly, the growth of the educational and intellectual potential of society increases the country's ability to generate innovations, which is reflected in such indicators as the Global Innovation Index, Global Competitiveness Index, Digital Economy and Society Index, Knowledge Economy Index and others.

Based on the analysis of the Global Innovation Index of European countries, we will prove the presence of a direct relationship between the level of human capital development and the innovative capacity of the state. The focus on this index is not accidental, since it comprehensively reflects the ability of the country to create, develop and implement innovations, as well as to effectively use human, intellectual and technological resources. Considering the above considerations, it is advisable to move from theoretical provisions to empirical analysis, which will help to find out to what extent the development of human capital correlates with innovation results and economic growth. We believe that such an approach will allow to identify the systemic impact of the human factor on the state's ability to produce new technologies and integrate them into socio-economic practice. Thus, the main research hypothesis of the analysis is that a higher level of human capital development contributes to an increase in innovative capacity, which, in turn, has a positive effect on the introduction and technologies use, as well as macroeconomic indicators that determine the state of development of the country's economics.

Let us analyze the Global Innovation Index and its components among European countries in 2025 (Fig. 2). The trend of a decrease in all components of the studied index as the transition from highly developed countries to less developed ones is obvious. The highest indicators for all components are observed in Switzerland, Sweden, Great Britain, Finland, the Netherlands and Denmark, which are included in the TOP 10 of this rating. It is these countries that demonstrate a balanced development of the educational and scientific sphere, institutional environment and business infrastructure, which ensures a positive innovation dynamics of development.

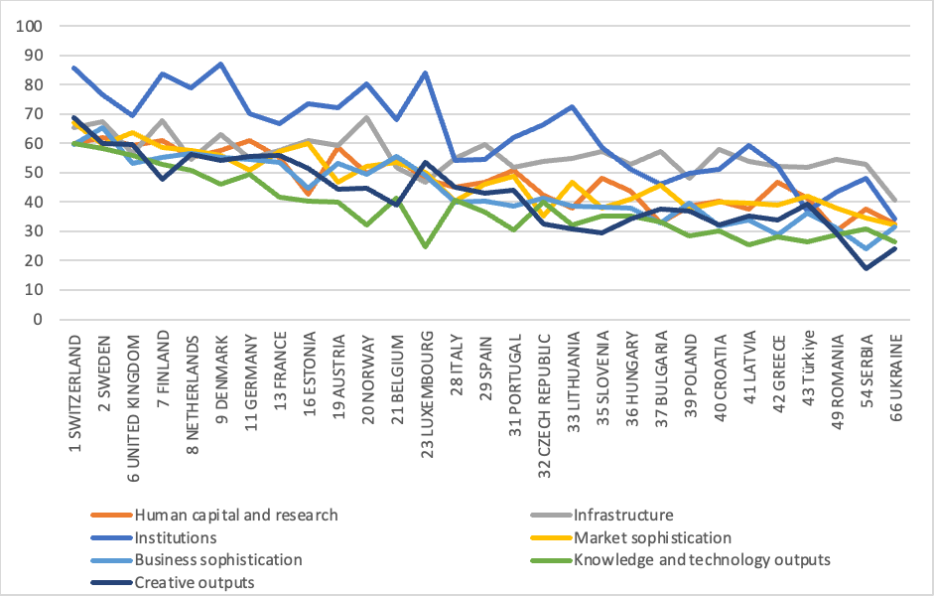

Figure 2: Components of the Global Innovation Index among European countries in 2025 [12].

The countries of Central and Eastern Europe, in particular the Czech Republic, Poland, Hungary, Bulgaria, and Croatia, are characterized by a moderate level of human capital development and relatively lower results. This indicates the presence of potential for innovative growth, which has not yet been fully realized. However, addressing various structural and managerial barriers can become a kind of impetus for activating innovative potential, transforming scientific and educational achievements into real technological products, and increasing the competitiveness of the national economy at the global level. The lowest indicators of European countries are Romania, Serbia, and Ukraine, which reflects both limited resources for scientific research and insufficient integration of the results of educational and scientific activities into the sphere of technological and creative production. However, it is worth noting that over the past four years, Ukraine's position in the studied rating has significantly deteriorated in 2025 it occupies 66th place against 45th in 2020. We believe that the main reason for this decline is the deployment of active military operations on its territory. As a result, a significant part of the country's intellectual potential is used not to ensure technological development, but to meet the needs of the defense-industrial complex.

In addition, the full-scale military aggression in Ukraine further deepened the existing demographic crisis, which has a direct impact on human capital. Thus, according to international experts, the population of Ukraine decreased by approximately 10 million people during the war years [13], which is the total effect of migration, military losses and a decrease in the birth rate. According to UNHCR, as of February 2025, 6.3 million Ukrainians received refugee status in European countries, and about 560 thousand outside Europe [14]. As a result, European countries received additional labor potential in the form of qualified specialists who were trained within the Ukrainian education system, without the need for significant additional investments in their professional training. In contrast, such demographic losses have negative consequences for Ukraine's innovative capacity, including a decrease in the number of young scientists, researchers, and higher education graduates, as well as the loss of potential labor force and part of the creative potential.

Thus, the above graphical analysis allows to state that countries with high investments in education, research and development of human potential occupy leading positions in world innovation rankings, while the deficit of human capital or improper attitude to its formation and development significantly limits the opportunities for economic and technological development.

The Global Innovation Index is an integral indicator consisting of seven main components, each of which reflects a separate aspect of innovation potential and development. To assess the relationship (linear dependence) between the country's place in the overall GII ranking and its values for individual components (sub-indices), we will determine the

Pearson correlation coefficient (r), which is calculated by the (1):

$$r = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2 (y_i - \bar{y})^2}}. \quad (1)$$

where:

x_i – the value of a separate component of the Global Innovation Index;

y_i – value of the overall rating or integral index;

$\bar{x}$ and $\bar{y}$ – average values of the corresponding indicators.

The resulting Pearson coefficient can vary from – 1 to + 1, which allows us to determine the nature and strength of the relationship, in particular:

1) if r tends to + 1, then there is a strong direct correlation (an increase in the indicator indicates an increase in the rating position). Since a higher place in the rating (a larger number) means a worse result, then such a dependence indicates a negative impact of the indicator on the overall level of innovative development;
2) if r tends to – 1, then there is a strong inverse correlation (an increase in the indicator is accompanied by a decrease in the rating position or the country's promotion to the top positions of the rating). In such a situation, we can say that the indicator has a positive impact on the state's innovative capacity;
3) if r approaches 0, then the relationship is insignificant or absent.

The results of the correlation analysis (Table 1) indicate the presence of stable and mostly strong inverse relationships between the overall rating of the country in the Global Innovation Index and most of its components. That is, the improvement of indicators for individual components of the index (each of which has its own weight) is accompanied by a decrease in the country's ranking, that is, advancement to the top positions in the global innovation space. In addition, the analysis data confirm the previously put forward hypothesis that there is a close relationship between the level of human capital and the innovative capacity of countries. Accordingly, human capital should be defined as a system-forming factor of innovative development. Therefore, promoting the development of human capital is a necessary condition for the growth of innovative potential.

Thus, human capital and the human factor are interconnected components of a single socio-economic mechanism that determines the dynamics of innovative development. Human capital forms an intellectual, creative and value basis for the creation of new knowledge and technologies, and the human factor reflects more behavioral, motivational and cultural aspects of the implementation of this potential in the real economic environment. Based on their interaction, knowledge is transformed into practical innovations, which ensures increased production efficiency, contributes to the growth of key macroeconomic indicators and strengthens the country's competitiveness. Therefore, the development of human capital in combination with the activation of the human factor is a determining condition for technological progress and the sustainability of national development.

Table 1: The relationship between a country's position in the Global Innovation Index and its individual components.

Component of GII	Correlation coefficient – r	Degree of dependence
Institutions	–0,864091574	Very strong correlation. The more effective the institutional, regulatory and business environment, the higher country ranks in innovation rankings.
Human capital and research	–0,88135353	One of the strongest links. Accordingly, human capital is important in shaping innovation capacity.
Infrastructure	–0,674301895	Moderately strong relationship. Infrastructure, including the level of ICT development, is important, but not as important as other components.
Market sophistication	–0,913429169	Very strong dependence. Indeed, countries with a developed financial system and a favourable investment climate occupy higher positions in the ranking.
Business sophistication	–0,929227308	The highest connection. Thus, business innovation, the ability to implement new solutions, and cooperation with the scientific community are key to determining a country's position in the ranking. However, it is worth noting that such elements are mainly determined by the already formed human capital.
Knowledge and technology outputs	–0,85110839	Strong correlation. The more knowledge and technological output a country produces, the more innovative it is.
Creative outputs	–0,911598208	Very strong dependence. Accordingly, the development of the creative industry is an important factor in the overall innovation potential.

5 CONCLUSIONS

Despite the rapid development of technology, which has been especially noticeable in recent decades, it is people who remain the main source of innovation and progress. We agree that modern equipment and machines can work faster and more accurately than people, but they are not able to generate new ideas, produce innovations and improve management decisions. Accordingly, only a person as a carrier of unique human capital can form the basis of scientific and technological evolution and determine the vector of its innovative development, which is confirmed by the results of the correlation analysis. Precisely because the conclusions of the study can be used in a practical sense, in the process of developing national strategies for the development of human capital as a strategic resource of the digital society.

So, in the conditions of digital transformation, the development of technologies and the economic growth of society depends on how effectively human potential is revealed and realized. After all, thanks to the latter, knowledge is transformed into practical results, improvement or creation of new products and technologies, and the formation of competitive advantages. In general, it is advisable to define a person not only as a determinant of economic growth, but also as an intellectual basis for civilizational progress, capable of initiating changes and at the same time ensuring the harmonization of technological and social development. We believe that further scientific research within this area should be aimed at developing an effective mechanism not only for managing the development of human capital, but also for its implementation in various sectors of the national economy.

Keywords: Economy of the Future, Digitalization, Artificial Intelligence, Innovation, Human Capital, Sustainable Development, Ukraine, Germany.

Abstract: The article examines the level of readiness of countries for the economy of the future based on an integral indicator formed from four international indices: Government AI Readiness Index (assessment of the role of artificial intelligence), Network Readiness Index (digitization and network effects), Global Innovation Index (innovation and human capital) and SDG Index (sustainable development). A methodology for constructing an integral indicator Future Economy Readiness Level (FERL) has been developed, which allows combining digital, innovative and socio-economic dimensions of development into a single generalized assessment. A comparative analysis of Ukraine and Germany in 2020–2024 was conducted, and FERL was also forecasted for 2025, which made it possible to identify the dynamics of key indicators and determine the strengths and weaknesses of both countries in the context of readiness for the economy of the future. The results of the study can be used to form strategies for digital transformation, innovation policy and ensuring sustainable development.

1 INTRODUCTION

Modern global transformations in digital technologies, innovations, and sustainable development require a rethinking of states' economic strategies. The concept of the economy of the future denotes a stage of development based on digitalization, AI integration, innovative production and management, and sustainability principles. However, countries' readiness for these changes varies and requires comprehensive assessment.

International indices are used to evaluate states' positions in this transition, including: Government AI Readiness Index (AI implementation readiness), Network Readiness Index (digitalization and network effects), Global Innovation Index (innovation potential and human capital), and SDG Index (progress on Sustainable Development Goals). While each index reflects a specific aspect, their combined use provides a holistic view of a country's readiness.

The article aims to develop an integrated approach to assessing countries' readiness for the economy of the future using these indices and to compare Ukraine and Germany, identifying strengths, weaknesses, and practical recommendations for enhancing global competitiveness.

2 RELATED WORKS

A significant number of scholars are investigating various aspects of the transition to the economy of the

future. In [1], the Oxford Insights Government AI Readiness Index, its methodology, and challenges of use are analyzed. The author suggests ways to overcome the problems of data availability in developing countries. In [2], the study uses the DEA (Data Envelopment Analysis) method to assess the digital development of countries, based on the Network Readiness Index indicators. The authors propose an alternative approach to ranking countries and show that different methods can significantly change a country's place in the rankings. In [3], the results of the Network Readiness Index 2020 are analyzed in the context of COVID-19. The author emphasizes that the pandemic has accelerated digital transformation and highlighted inequalities between countries in readiness for the digital economy. In [4], the impact of human capital on the Global Innovation Index is analyzed, concluding that countries with a high level of education and qualification of the population show better innovation results. In [5], the role of innovation and human capital in shaping the knowledge economy is analyzed. It is shown that innovation directly depends on the level of development of human potential and the education system. The article [6] examines the intellectual potential of Ukrainian regions (educational, scientific, and innovative) in wartime conditions, conducts fractal analysis and forecasts key indicators. Negative trends are identified and the need to strengthen human capital and innovative capabilities for economic recovery is emphasized. In [7], a study was conducted on the relationship between digitalization, corporate governance, and reporting on the Sustainable Development Goals (SDGs). The author argues that digitalization can increase the transparency and effectiveness of sustainable development. In [8], the Digital Economy and Society Index (DESI) is studied to determine the impact of the Digital Economy and Society Index (DESI) on sustainable development indicators in the EU. The results show that countries with a higher level of digital economy have better results in the field of environmental and social sustainability. In [9], the digital transformation is studied to determine the impact of social sustainability in EU countries. The authors argue that digitalization has a positive but uneven impact on achieving the SDGs. The paper [10] examines the role of AI and aerospace engineering in achieving the Sustainable Development Goals. The article criticizes existing approaches and proposes interdisciplinary solutions. This study assumes a comprehensive consideration of the considered directions to ensure the transition to the economy of the future.

3 METHODOLOGY

The economy of the future is an integrated model of socio-economic development that combines digital transformation, the implementation of artificial intelligence technologies, a high level of innovation, the development of human capital and adherence to the principles of sustainable development. It is based on interconnected subsystems - digital, technological, innovative and socio-ecological - that shape the state's ability to adapt to global challenges, ensure economic sustainability, competitiveness and long-term growth.

Within this concept, the economy of the future is viewed not as a universal model, but as a complex, multi-level state of maturity of a country, reflecting its readiness to effectively use digital tools, data, artificial intelligence, innovative solutions, as well as to implement a policy of sustainable development and inclusive growth.

The proposed four subsystems are logical and methodologically sound, as they cover all key dimensions of modern socio-economic development. The digital subsystem reflects the level of digitalization of processes, access to digital infrastructure, use of data and digital services. This is the basic level of transformation, without which innovation and automation are impossible. The technological subsystem (including AI) covers the development of technologies, automation, artificial intelligence, R&D. It ensures increased productivity and competitiveness, acting as the core of technological change. The innovative and educational subsystem (human capital) takes into account the quality of education, skills, the ability to innovate, and the development of human potential. It is critical for adapting to technological change, training personnel and building the capacity for innovation. The socio-ecological subsystem (sustainable development) covers the environmental, social and institutional aspects of sustainable development. Ensures balance of transformations and takes into account social risks, inclusion and environmental responsibility. Thus, the choice of these four subsystems ensures completeness, systematicity and balance of the assessment, since each of them covers a separate dimension of development, and together they form a holistic model.

For a comprehensive assessment of a country's readiness for the economy of the future, an integrated indicator has been proposed - the Future Economy Readiness Level (FERL). It is based on the following components and their corresponding internationally recognized indices (Fig. 1, Table 1).

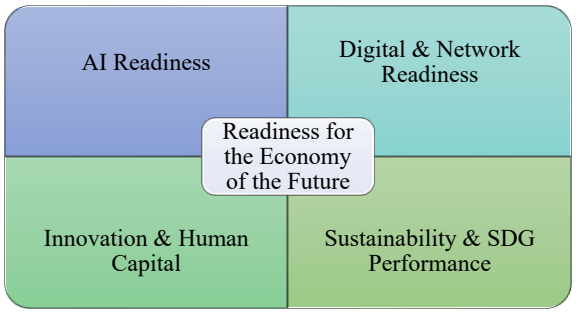

Figure 1: Structural elements of a country's readiness for the economy of the future.

Table 1: Structural elements of the economy of the future.

Structural component	Characteristic	Selected indicator
AI Readiness	determines the role of AI in economic development and the state's ability to introduce innovative technologies	Government AI Readiness Index (GARI)
Digital & Network Readiness	takes into account digitalization, infrastructure availability and network effects	Network Readiness Index (NRI)
Innovation & Human Capital	reflects the innovative potential and quality of human capital	Global Innovation Index (GII)
Sustainability & SDG Performance	demonstrates sustainable economic, social and environmental development	SDG Index

FERL calculation stages:

Stage 1. Data collection - obtaining official values of the specified indices for selected countries (Ukraine and Germany) in the period 2020-2024.

Stage 2. Normalization of indicators. Since all indices have a scale from 0 to 100, their values were used without additional transformations. If necessary, they are brought to a single scale.

Stage 3. Determination of weight coefficients. For a system with a descending order of priorities among N alternatives, weighting factors were determined using the Fishburne method:

$$p_i=(2(N-i+1))/((N+1)N),\ i=1..N. \quad (1)$$

Stage 4. Calculation of the integral indicator:

$$FERL=w_{GARI}\cdot GARI+w_{NRI}\cdot NRI+w_{GII}\cdot GII+w_{SDG}\cdot SDG. \quad (2)$$

Stage 5. Comparison of results - FERL integral values are analyzed in dynamics and compared between countries.

Interpretation of results:

- Low level (0-20 points);
- Below average level (21-40 points);
- Average level – (41-60 points);
- Above average level – (61-80) points;
- High level – (81-100 points).

Thus, the integral FERL indicator allows combining various aspects of digitalization, innovation and sustainable development into a single generalizing assessment, which provides the possibility of interstate comparisons and the formation of strategic conclusions.

4 RESULT AND DISCUSSION

The study involves a comparative analysis of Ukraine and Germany as examples of countries with different levels of economic and technological development. This approach allows us to assess the universality of the integral indicator and demonstrate its applicability both for countries undergoing transformation and integration into world markets, and for highly developed economies that are already shaping global trends in digitalization, innovation, and sustainable development. This provides an opportunity to identify differences in development strategies, strengths and weaknesses of each country, and also forms the basis for developing practical recommendations.

4.1 AI Readiness

The development of AI is one of the key factors of the economy of the future. The Government AI Readiness Index (GARI) measures the level of readiness of government institutions, regulatory environment and digital infrastructure to implement AI technologies, which directly affects the competitiveness of the country. Table 2 and Figure 2 show a comparison of the values of this index for Ukraine and Germany over time.

Based on GARI data, the following conclusions can be drawn. Germany is consistently among the leaders in terms of AI readiness, ranking in the top 15, with a GARI in the range of 72,64-78,97. Ukraine is showing a gradual increase in readiness: its ranking improved from 57th place in 2020 to 54th in 2024, and the GARI index increased from 48,90 to 60,57. Despite the positive dynamics, Ukraine’s readiness

level is still significantly lower than Germany, which indicates the need for further development of digital and innovation competencies for accelerated AI implementation.

Table 2: GARI for Ukraine and Germany [11].

Year	Indicator	Germany	Ukraine
2020	Rank	4/172	57/172
	GARI	78,97	48,90
2021	Rank	8/160	64/160
	GARI	77,26	50,58
2022	Rank	15/181	60/181
	GARI	72,64	52,80
2023	Rank	8/193	60/193
	GARI	75,26	53,29
2024	Rank	8/188	54/188
	GARI	76,90	60,57

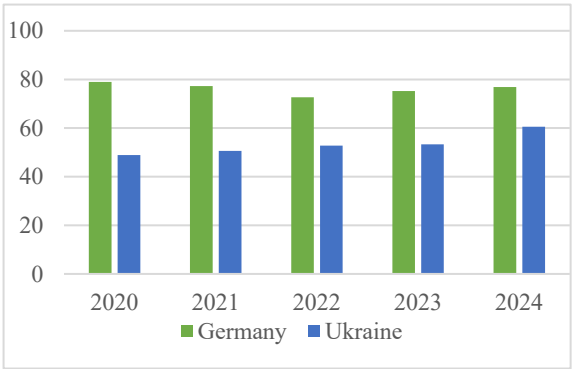

Figure 2: Comparison of GARI values for Ukraine and Germany in dynamics.

Table 3 shows the values of the index components for the countries studied, and Figure 3 details their values in 2024.

Table 3: The values of the index components for Ukraine and Germany [11].

Year	Country	Government	Technology Sector	Data and Infrastructure
2020	Germany	78,22	68,09	90,61
	Ukraine	-	-	-
2021	Germany	78,04	67,68	86,07
	Ukraine	52,36	38,19	61,19
2022	Germany	75,22	60,42	82,29
	Ukraine	68,96	34,68	54,74
2023	Germany	80,78	63,28	81,72
	Ukraine	68,93	36,18	54,75
2024	Germany	79,24	64,91	86,55
	Ukraine	73,42	41,93	66,37

Thus, Germany shows consistently high scores in all three components (government, technology sector, data and infrastructure), indicating comprehensive readiness for AI implementation. Ukraine shows gradual improvement, especially in the area of governance (from 52,36 in 2021 to 73,42 in 2024), while the technology sector and infrastructure remain relatively weak, limiting overall readiness.

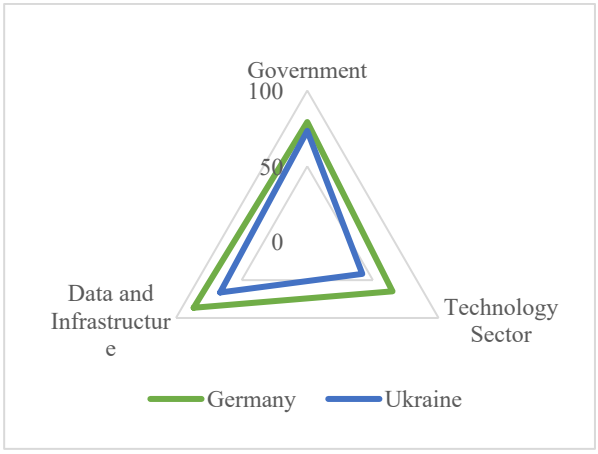

Figure 3: Comparison of the level of GARI components for Ukraine and Germany in 2024.

4.2 Digital and Network Readiness

The Network Readiness Index (NRI) reflects the level of digitalization of the economy, the development of information and communication technologies, the efficiency of digital networks, and the readiness of society to use digital innovations. This indicator determines the ability of a country to integrate into the global digital space. Table 4 and Figure 4 show a comparison of the values of this index for Ukraine and Germany over time.

Table 4: NRI for Ukraine and Germany [12].

Year	Indicator	Germany	Ukraine
2020	Rank	9 / 134	64 / 134
	NRI	77,48	49,43
2021	Rank	8 / 130	53 / 130
	NRI	78,95	55,70
2022	Rank	8 / 131	50 / 131
	NRI	76,11	55,71
2023	Rank	9 / 134	43 / 134
	NRI	74,00	55,16
2024	Rank	9 / 133	43 / 133
	NRI	73,54	55,32

Based on NRI data, the following conclusions can be drawn. Germany consistently maintains high

positions in the ranking (8-9th place) with an NRI of over 73, which indicates a strong digital infrastructure and readiness for network transformations. Ukraine demonstrates a gradual stabilization of NRI indicators at the level of 55-56, while improving its position in the ranking from 64th place in 2020 to 43rd in 2024. Overall, Ukraine is progressing, but remains significantly behind Germany in the area of digital readiness and network capabilities.

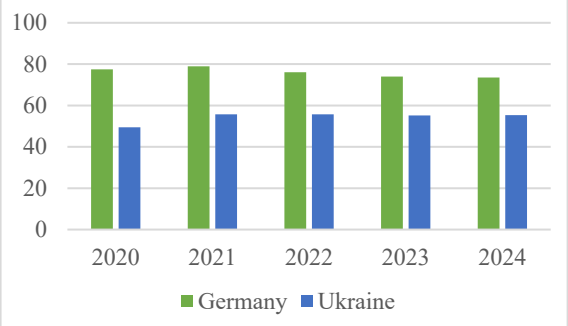

Figure 4: Comparison of NRI values for Ukraine and Germany in dynamics.

Table 5 and Figure 5 show the values of the index components for the studied countries in 2024.

Table 5: Comparison of the level of NRI components for Ukraine and Germany in 2024 [12].

Country	Показн	Technology	People	Governance	Impact
Ukraine	Rank	44	28	56	51
	Score	48,96	51,83	63,14	57,34
Germany	Rank	4	8	16	9
	Score	72,54	63,77	82,52	75,35

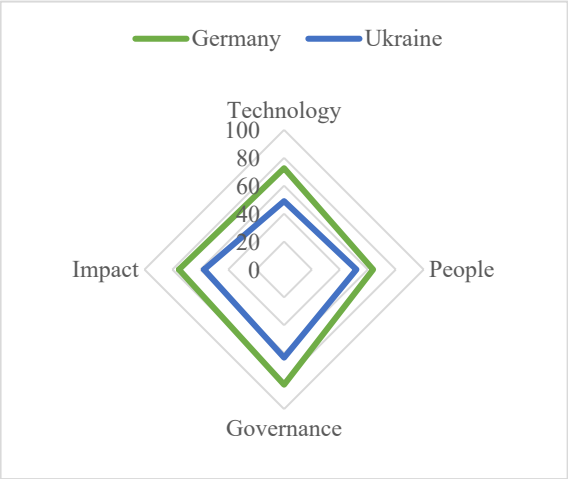

Figure 5: Comparison of the level of NRI components for Ukraine and Germany in 2024.

In 2024, according to the NRI, Germany ranks 9th with a score of 73,54, demonstrating a consistently high level of digital readiness and developed network infrastructure. Ukraine ranks 43rd with an NRI of 55,32, indicating a moderate level of digital readiness and the need for further development of infrastructure and technologies.

4.3 Innovation and Human Capital

The Global Innovation Index (GII) assesses technological capability, human capital development, research activity, innovation infrastructure and innovation performance. It is the combination of innovation and human capital that creates the foundation for sustainable economic growth in the long term. Table 6 and Figure 6 show a comparison of the values of this index for Ukraine and Germany over time.

Table 6: GII for Ukraine and Germany [13].

Year	Indicator	Germany	Ukraine
2020	Rank	9	45
	GII	56,55	36,32
2021	Rank	10	49
	GII	57,3	35,6
2022	Rank	8	57
	GII	57,2	31,0
2023	Rank	8	55
	GII	58,8	32,8
2024	Rank	9	60
	GII	58,1	29,5

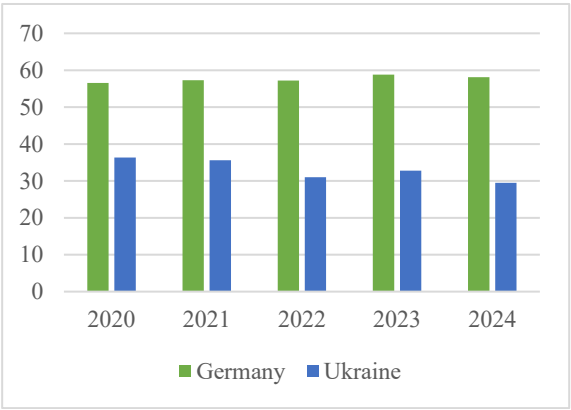

Figure 6: Comparison of GII values for Ukraine and Germany in dynamics.

According to the GII 2020-2024, Germany consistently maintains high positions (8-10th place) with GII scores of 56–59, indicating strong innovation potential. Ukraine shows a deterioration in its ranking from 45th place in 2020 to 60th in 2024

and a decrease in GII from 36,32 to 29,5, indicating a weak development of the innovation environment and the need for active reforms.

Table 7 and Figure 7 show the values of the index components for the studied countries in 2024.

Table 7: Comparison of the level of GII components for Ukraine and Germany in 2024 [13].

Structural elements	Germany	Ukraine
GII	58,1	29,5
Institutions	73,5	30,8
Human capital and research	61,4	34,3
Infrastructure	52,9	35,5
Market sophistication	56,4	25,7
Business sophistication	55,3	31,8
Knowledge and technology outputs	53,9	31,1
Creative outputs	58,6	23,7

Figure 7: Comparison of the level of GII components for Ukraine and Germany in 2024.

Germany scores highly in all GII structural elements, especially in the areas of institutions (73,5), human capital and research (61,4) and creative output (58,6), indicating a strong innovation potential and a developed innovation environment. Ukraine scores significantly lower in all components, especially in market complexity (25,7) and creative output (23,7), indicating a weak development of innovation potential and the need to improve institutions, infrastructure and human capital.

4.4 Sustainability and SDG Performance

The SDG Index (SDGI) reflects a country's progress in achieving the UN Sustainable Development Goals. This index characterizes the environmental, social and economic balance that serves as the foundation for long-term sustainability and shaping the economy of the future. Table 8 and Figure 8 show a comparison of the values of this index for Ukraine and Germany over time.

Table 8: SDG Index for Ukraine and Germany [14].

Year	Indicator	Germany	Ukraine
2020	Rank	5/166	47/166
	SDGI	80,8	74,2
2021	Rank	4/165	36/165
	SDGI	82,5	75,5
2022	Rank	6/163	37/163
	SDGI	82,2	75,7
2023	Rank	4/166	38/166
	SDGI	83,4	76,5
2024	Rank	4/167	44/167
	SDGI	83,4	74,8
2025	Rank	4/167	42/167
	SDGI	83,7	75,7

Germany consistently maintains high positions (4-6th place) with SDGI indicators above 80, demonstrating effective achievement of the Sustainable Development Goals. Ukraine fluctuates between 36 and 47th place, with SDGI 74-76, indicating gradual progress, but still significantly lagging behind the leaders in the field of sustainable development.

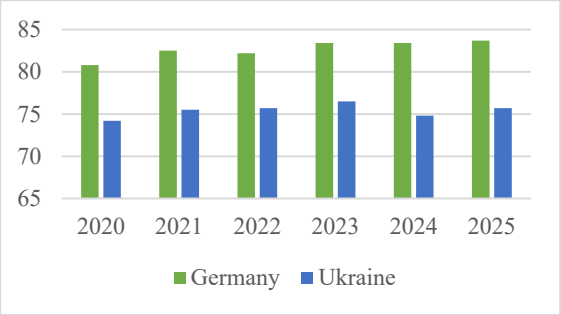

Figure 8: Comparison of SDG Index values for Ukraine and Germany in dynamics.

Figures 9 and 10 show the average performance by SDG for Germany and Ukraine, respectively.

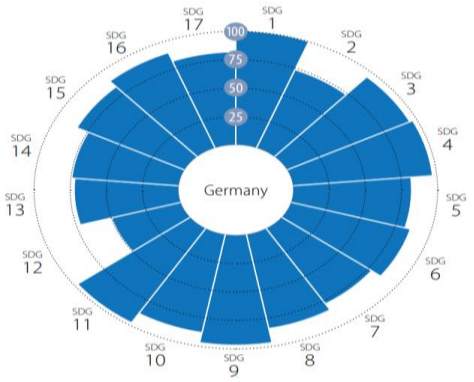

Figure 9: Average performance by SDG for Germany [14].

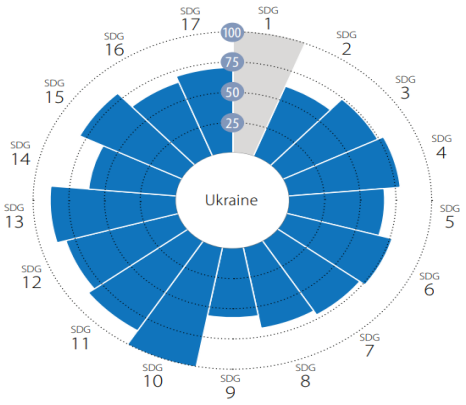

Figure 10: Average performance by SDG for Ukraine [14].

In 2024, in terms of average effectiveness of implementing the Sustainable Development Goals, Germany demonstrates high performance in all areas, while Ukraine lags significantly behind, especially in Goals 2, 9, 14, 16, 17.

4.5 Calculation and forecasting FERL

According to the Fishburne method, AI Readiness received the highest (rank 1), since the development of artificial intelligence, automation and high technologies determines the speed and direction of structural changes in the economy of the future, forming its core of transformations. Digital & Network Readiness took second place (rank 2), because it acts as a critical infrastructure foundation for the implementation of technologies, providing access to data, network interaction and platform models, although it does not directly drive transformations. Innovation & Human Capital (rank 3) ensures the development of human capital and innovative activity, which allows adapting and scaling technological changes, but its impact manifests itself gradually and depends on technological and digital capabilities. Sustainability & SDG Performance (rank 4) forms long-term stability and balance of transformations through the principles of sustainable development, but its effect is indirect and is not the primary driver of the economy of the future.

Therefore, according to the proposed ranks and according to (1), the following weighting coefficients were obtained:

- w_{GARI}=0,4;
- w_{NRI}=0,3;
- w_{GII}=0,2;
- w_{SDG}=0,1.

Table 9 shows the values of the studied indices and the calculated indicator.FERL.

Table 9: Estimated value of the indicator FERL.

Year	Country	GARI	NRI	GII	SDGI	FERL
2020	Germany	78,97	77,48	56,55	80,8	74,22
	Ukraine	48,9	49,43	36,32	74,2	49,07
2021	Germany	77,26	78,95	57,3	82,5	74,30
	Ukraine	50,58	55,7	35,6	75,5	51,61
2022	Germany	72,64	76,11	57,2	82,2	71,55
	Ukraine	52,8	55,71	31	75,7	51,60
2023	Germany	75,26	74	58,8	83,4	72,40
	Ukraine	53,29	55,16	32,8	76,5	52,07
2024	Germany	76,9	73,54	58,1	83,4	72,78
	Ukraine	60,57	55,32	29,5	74,8	54,20
2025	Germany	84,03	72,17	58,4	83,7	75,31
	Ukraine	61,30	57,12	28,8	75,7	54,99

To predict values for 2025, the following models were used according to the high value of the coefficient of determination (Table 10).

Figure 11 shows a comparison of the FERL indicator for Ukraine and Germany.

According to the FERL 2020–2025, Germany demonstrates consistently high FERL values (71–75), indicating a strong and balanced readiness for the economy of the future in all components (AI,

digitalization, innovation, sustainable development). Ukraine shows a gradual increase in FERL from 49,07 in 2020 to 54,99 in 2025, but remains significantly behind Germany, especially due to low innovation indicators (GII).

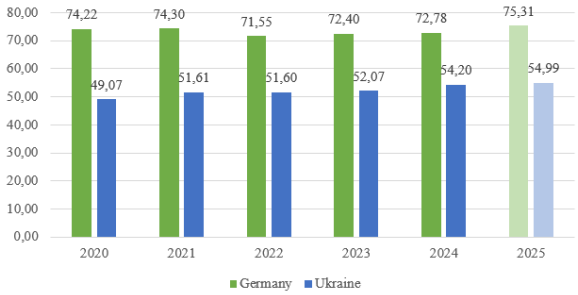

Figure 11: A comparison of the FERL indicator for Ukraine and Germany.

Table 10: Selected models for forecasting index values for 2025.

Index	Germany	Ukraine
GARI	$y = 0,1605x^3 - 0,4482x^2 - 2,8047x + 82,329$	$y = 45,962e^{0,048x}$
NRI	$y = -1,283x + 79,865$	$y = 3,4204\ln(x) + 50,989$
GII	$y = -0,0857x^2 + 0,9743x + 55,61$	$y = 0,0886x^2 - 2,1754x + 38,596$

Figure 12 shows a breakdown of the constituent elements (indices) and the FERL indicator in 2025.

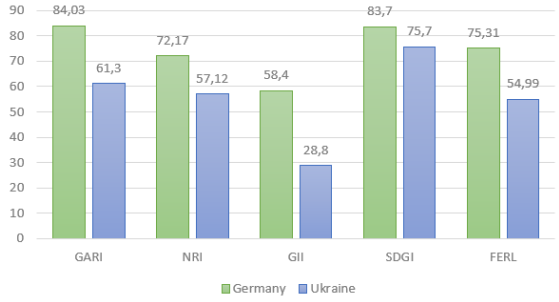

Figure 12: A breakdown of the constituent elements (indices) and the FERL indicator in 2025.

So, for Germany, the FERL level is above average, for Ukraine - at an average level. The lowest level in the structure of components for both countries is the GII. The highest value is in the SDG Index. Overall, Ukraine is progressing, but needs active development of digital, innovation and institutional components for an accelerated transition to the economy of the future.

5 CONCLUSIONS

The article proposes a methodology for assessing the readiness of countries for the economy of the future based on an integral indicator formed from four key indices. The Government AI Readiness Index reflects the role of artificial intelligence in the future economy, the Network Readiness Index characterizes the level of digitalization and the use of network effects, the Global Innovation Index determines the innovative potential and quality of human capital, and the SDG Index assesses the sustainability of development as a basis for long-term growth. It is predicted that in 2025, Ukraine's readiness level will be 54,99 points (average level), while for Germany – 75,31 points (above average). The lowest values for both countries are recorded for the Global Innovation Index, and the highest - for the SDG Index, which confirms the leading role of sustainable development in shaping the economy of the future. To increase the level of readiness, Ukraine should focus on developing an innovative environment, investing in human capital, building digital infrastructure, and more actively implementing solutions based on artificial intelligence.

Keywords: Digital Technologies, Labor Force, Industrial Enterprises, Expansion of Labor Potential, Intellectualization of Labor.

Abstract: The article considers the problem of attracting labor resources to Ukrainian industry in the conditions of demographic decline, migration losses and large-scale war. The relevance of the study lies in the urgent need to overcome the labor force shortage and ensure sustainable development of industry through the use of digital technologies. The purpose of the study is to analyze the potential of modern digital tools in forming an effective system of attracting, selecting, motivating and retaining personnel at industrial enterprises. The methodological basis is the structural-functional and systemic approaches, which allowed building a conceptual system of providing labor force with the use of digital tools, such as national employment platforms, artificial intelligence algorithms, candidate management systems, chatbots, mobile applications, e-learning systems and predictive analytics. It is assumed that the use of digital technologies will significantly reduce the time and costs of personnel selection, increase the efficiency of HR processes, and also contribute to the growth of employee competencies through continuous training and professional development. At the same time, international integration mechanisms, in particular electronic visa services and migration platforms, open up access to foreign labor resources and accelerate the adaptation of labor migrants. The theoretical contribution of the study lies in the proposed conceptual system for attracting labor force to industrial enterprises using digital technologies, which is presented as a multi-level architecture of socio-technical innovations, connecting state institutions, enterprises and employees into a single digital system. The practical significance of the results is reflected in providing industrial enterprises with a roadmap for the implementation of digital tools in personnel management, which ensures sustainable growth even in wartime conditions.

1 INTRODUCTION

Digital transformation is becoming a key driver of economic growth, labor force development, and public administration efficiency. Using various digital innovation platforms, regulatory mechanisms, and strategic partnerships, the country is ensuring the development of relevant competencies as a key asset of its labor force.

Ukraine is currently experiencing a severe brain drain, labor force reduction, and the largest demographic crisis. Since the beginning of the war, a significant part of the Ukrainian labor force has emigrated or changed its place of residence, becoming victims of military violence. This difficult labor situation will continue to affect business operations throughout Ukraine and threaten its future recovery. A survey conducted by the Ukrainian Institute for Economic Research and Policy Consulting in October 2024 showed [1] that labor shortages are the biggest concern for the private sector: more than 60% of surveyed companies are experiencing difficulties in hiring qualified employees. At the same time, according to the latest estimates, the current unemployment rate in Ukraine at the end of 2024 was 12.7%. This means that unemployment coexists with a labor shortage. Even before the war, Ukraine voiced a difficult

demographic situation: low fertility rates, premature mortality among men, and emigration of young Ukrainians in search of better economic opportunities abroad. According to estimates by the International Labor Organization, by 2032 Ukraine will lack 8.6 million workers (compared to 2022). And now the Government of Ukraine, in cooperation with the international community and relevant stakeholders, should develop and implement a comprehensive human capital development strategy to meet current and future labor needs. This will require a combination of short-term and long-term measures aimed at expanding the country's labor potential. However, the current labor problems in Ukraine are part of a broader demographic problem. The country has the lowest fertility rate in Europe, with less than one child per woman, compared to an average of 1.3–1.8 children per woman in Eastern Europe. In addition, Ukraine currently has a high rate of premature mortality, especially among men, and it is not just the country's traditional problems of alcoholism, accidents, but other current trends such as emigration, general ill health, and rapid aging that are complicating the country's demographic landscape. The last census of Ukraine, conducted in 2001, recorded a population of 48.5 million. The war caused many Ukrainians to emigrate abroad, with an estimated 20,000 Ukrainian children forcibly deported to Russia, and thousands more living under temporary occupation. Sadly, many Ukrainians died during the war. As of December 2024, the President of Ukraine reported that 43,000 Ukrainian military personnel had been killed. In addition, about 12,000 civilians had been killed, and thousands more Ukrainians had been injured or disabled. According to the Office of the United Nations High Commissioner for Refugees, as of November 2024, there were about 4 million internally displaced persons in Ukraine. Another 6.8 million refugees were registered in other countries, and approximately 14.6 million people were in need of humanitarian assistance. As a result of these trends, the population of Ukraine had decreased to 35.8 million as of July 2024 - or to 31.1 million if only the territories under the control of the Ukrainian government were taken into account. If this situation is not changed, the population of Ukraine could subsequently decrease to 28.9 million by 2041 and to 25.2 million by 2051, according to the National Academy of Sciences of Ukraine [1].

The population decline and the shrinking labor force will be a major shock to Ukraine's economy, and the negative effects will be felt for many years to come. Empirical research shows that time spent out of work can not only lead to skill depreciation, but also affect national productivity and wages. A protracted war will have even more serious consequences for Ukraine's education, and this will directly affect the country's future human capital. Schooling has been and continues to be interrupted by the hostilities. Students have suffered significant educational losses. According to previous research by the Organization for Economic Cooperation and Development, the war in Ukraine will lead to a 7% reduction in the overall national productivity factor by 2035 [1]. In addition, poor mental health affects individuals and has a ripple effect on society and the economy. Even before the outbreak of the large-scale war, an estimated 30% of Ukraine's population had a mental disorder at some point in their lives. During the first year of the Russian invasion, approximately 26% of Ukrainians met the diagnostic criteria for post-traumatic stress disorder alone.

All of the above factors lead to missed working days, reduced labor productivity, quality and efficiency of labor potential use, and necessitate the involvement of innovative digital technologies in the process of providing labor to industry in Ukraine.

2 ANALYSIS OF LATEST RESEARCH AND PUBLICATIONS

The issues of digitalization of labor processes and labor force involvement in industrial enterprises have received wide coverage in the works of both domestic and foreign researchers.

Thus, Nemchenko T.A. and Divizyniuk B.M. [2] consider the transformation of labor under the influence of digitalization, and Androsova O. [3] analyzes digital tools used at Ukrainian enterprises. Research by the Razumkov Center [4] and Rumyantsev A., Kovbuch T. [5] identify global risks and the need for retraining of the labor force. Shatalova L. [6] focuses on digital competencies, while in previous publication Kalinesku T., Likhonosova G., Zelenko O. [7] emphasize the importance of integrating innovations into business processes. The works of Maksymenko I., Akimova A., Markova S. [8] and Dziubenko O., Galaz L., Baly O. [9] highlight the impact of war on digital transformation. At the same time, Azmuk N., Grishnova O., Kuklin O. [10] explore the global digital labor market. Cepeda-Cardona J., Arias-Pérez J. [11] reveal the risks of "technostress", and Markaryan M., Bilyi D., Yuldashev S. [12]

emphasize the importance of legal aspects of the digital transformation of the economy.

In general, the analysis of the literature demonstrates several key contradictions and gaps in the scientific discourse. First, digitalization is most often viewed as either a technical upgrade of enterprises or a change in employee competencies, but there are almost no approaches that synthesize these levels into a single system of digital human resources. Second, research rarely takes into account the specifics of the industrial sector, which differs significantly from IT or service industries in terms of the nature of competencies, personnel development strategies, and social risks. Third, modern publications pay insufficient attention to the integration of analytical tools - from systems for forecasting personnel needs to indicators of intellectualization of labor potential - although it is precisely such systems that determine the effectiveness of digital transformation in industry.

Thus, scientific publications outline the general trends in the digital transformation of labor, but do not form a holistic concept of attracting labor resources to industry based on digital technologies. This gap necessitates the development of an integrated approach that combines digital recruitment tools, HR process automation, competency development systems, analytical forecasting methods, and mechanisms for international personnel mobility.

3 RESEARCH METHODOLOGY

The methodological basis of the study is a systemic, structural-functional approach and a comparative-analytical method, which allowed to characterize comprehensively the impact of digital technologies on the processes of attracting labor force to industrial enterprises in Ukraine. The systemic approach provided the study of digitalization as a multi-level interaction of technological, organizational and social factors, while the structural-functional approach made it possible to identify the key elements of digital staffing - recruitment, automation of HR procedures, training, motivation and labor market analytics - and determine their role in the formation of modern labor potential. The comparative-analytical method was used to compare Ukrainian practices of digital recruitment and personnel development with international approaches, which allowed to outline the directions of adapting global solutions to the conditions of war and demographic decline. Methods of analysis, synthesis and logical generalization were used to form the author's conceptual system for attracting labor force to industrial enterprises in Ukraine based on digital technologies that integrates various digital solutions into a holistic model of enterprise HR work.

The study also applied content analysis of analytical reports, statistical data and reviews of business practices, which allowed identifying key trends: workforce shortage, changing structure of demand for competencies, increasing role of HR process automation and use of artificial intelligence in recruiting.

4 MAIN RESEARCH RESULTS

Digital technologies, based on the implementation of advanced information and communication tools in all spheres of economic life [7], not only lead to an increase in the efficiency of production and commercial processes, but also create numerous challenges to the functioning of traditional economic mechanisms, transforming traditional business models, changing the nature of labor activity and creating the need to adapt labor potential to new working conditions. It is digitalization that creates new economic requirements for providing labor, where the formation of intellectual, creative, and innovative capital, which is based on the creation of the latest digital platforms and the use of innovations, is decisive. It is also necessary to emphasize that strengthening the role of information resources is becoming a fundamental criterion for ensuring the competitiveness of individual industrial enterprises, organizations and the country as a whole.

At the same time, the digital environment stimulates the development of innovations, which in turn lead to substantive shifts in the functioning of the labor market, affecting the organization of labor processes, labor supply, employment structure and the nature of labor activity. The key factors that influence the labor force supply of industrial enterprises in Ukraine are presented in Table 1.

In addition to the requirements for the modern labor force involved in industry, it is also necessary to talk about digital technologies that are traditionally used for its recruitment, namely [2, 3]:

Table 1: Key factors influencing labor force supply [2].

Key factors	The nature of the impact
Automation and digitalization of work processes	Transition from manual to routine work, using automated systems and algorithms, artificial intelligence, for big data analysis, forecasting and decision-making, integration of digital platforms for business process management
Changing professional competencies and qualification requirements	Growing demand for highly qualified specialists with digital skills, analytical and creative thinking, and the ability to work with large databases and artificial intelligence
Work flexibility and personalization	Transition to the use of digital technologies to individualize work tasks and increase worker mobility
Intellectualization of labor	Strengthening the role of cognitive processes and strategic thinking, the use of neural networks in performing professional tasks, and the analysis and adoption of management decisions
New forms of labor interaction	Using digital switching platforms for robot coordination, interactive collaboration, and working in virtual teams

1) Social networks and specialized platforms that allow companies to post vacancies and find candidates, as well as use advertising to attract the necessary specialists.
2) Candidate management systems that allow you to automate the hiring process, from the stage of submitting resumes and interviews to making a hiring decision and help process a large number of applications, sort them by key criteria, and track candidates during the hiring process.
3) Video interview software that allows you to interview candidates who are in different locations, which significantly saves time and resources.
4) Chatbots and artificial intelligence (AI), used to automate initial contact with candidates, answer questions, and collect basic information. AI can analyze large amounts of data to help identify the best candidates and predict their job performance. However, the current level of AI adoption among Ukrainian companies remains low (38.2%) [3], although future plans indicate a high level of readiness for its use (91%) by industrial enterprises. Overall, AI adoption in Ukrainian industrial enterprises is at an early stage, as the majority of existing enterprises (45.9%) believe that AI has the potential to increase productivity, and 43.3% expect AI to improve innovative products [3].
5) Mobile applications used to simplify the process of applying for jobs, receiving notifications about new vacancies, and communicating with recruiting firms.

In general, it is planned to create 344 million jobs in the international labor market (which includes Ukraine) by 2030 through the use of digital technologies, including 190 million jobs to solve the current problem of unemployment [4, p. 72]. Moreover, global GDP may grow by $9 trillion due to the automation of jobs using AI technologies. 375 million workers (about 14% of the global labor force) will be forced to change their profession. Therefore, enterprises that have to adapt to new digital technologies in the 21st century should take into account the following trends in the world, which are characterized by [5]:

1) Industrialization technologies. As a rule, most of these technologies are introduced in industries where new computer communication technologies and various means of electronics are widely used, which allows to increase the efficiency and capacity of production, labor productivity and create conditions that force workers to use these technologies, which are becoming more accessible due to the development of digital technologies.
2) Globalization processes that allow the majority of the working population of different countries of the world to establish certain information connections, which allows to interconnect the flows of money, goods, services and ensure their growth.
3) Competition. Globalization processes and digital technologies force enterprises to compete not only in the domestic market, but also for a share of the world market, which can be obtained on the basis of the rapid application of technological innovations.
4) Continuous and rapid changes in social life. Therefore, each enterprise must build its production mobile and flexible, so that it can quickly adjust to changing development conditions. Today's changes occurring in the environment cannot be resolved on the basis of past experience and traditions. Therefore, modern enterprises must learn new unprecedented ways to solve problems.
5) The technological speed of changes in business, which must correspond to the speed of the life

cycle, which is associated with the intensification of competition under the influence of the application of technological innovations.

6) The complexity of production, which is becoming an everyday norm and is associated with new opportunities, innovations and improvisation in solving emerging management problems.

The above characteristics of the use of digital technologies show certain changes that are taking place at industrial enterprises within the framework of providing jobs with labor resources. The main task of every modern industrial enterprise in Ukraine is not so much the filling of all workplaces with the necessary qualified labor force, but rather the readiness of all employees of enterprises for complex training based on digital and information technologies, innovative management and flexible methods of restructuring production processes to meet the requirements of the time. Enterprises seeking successful digital transformation must not only possess digital assets but also develop or acquire among their employees the competencies required for working with digital technologies [13]. According to recent studies across OECD countries, Finland, Norway, Sweden, and New Zealand demonstrate the highest levels of readiness for digital transformation, while Slovakia, Poland, and Greece show the lowest levels of readiness [14].

According to the results of the analysis, it is possible to formulate a conceptual system for attracting labor to the industry of Ukraine using digital technologies (Table 2).

The presented conceptual system for attracting labor to industrial enterprises of Ukraine based on digital technologies is imagined as a holistic, multi-level architecture of socio-technical innovation, which combines digital infrastructure for personnel search and selection, automation of HR processes, tools for motivation and professional development of employees, labor market analytics, and mechanisms for international integration of labor resources. At its center should be a national platform for interaction between labor market participants - government agencies, educational institutions, enterprises, and candidates - that implements the functions of a single access interface (web interface and mobile clients), a user registration and authentication module (integration with the national electronic identification system), a vacancy and resume management module, and a module for verifying educational and professional qualifications (digital certifications/ verified certificates). Such a platform should be built on the principles of open architecture (API-first), microservice orchestration and the use of standardized data formats (for example, structured CVs), which will ensure interoperability with state information resources, corporate applicant tracking systems (ATS) and international recruitment portals.

Table 2: Conceptual system for attracting labor force to industrial enterprises in Ukraine based on digital technologies [8] - [11].

Stages of engagement	Digital tools	Digital tool functions
1) Search and selection of personnel	▪ single national digital employment platform; ▪ AI recommendations; ▪ gamified competency tests.	▪ integration of public and private job databases; ▪ algorithms for selecting vacancies by skills; ▪ quick check of technical and soft skills.
2) Automation of HR processes	▪ applicant tracking systems (ATS); ▪ video interviews with AI analytics; ▪ HR chatbots.	▪ automatic resume selection; ▪ interview scheduling, hiring analytics; ▪ initial screening and response to candidates 24/7.
3) Motivation and retention of personnel	▪ mobile applications for employees; ▪ E-learning systems (LMS); ▪ personalized development trajectories.	▪ access to salary, bonuses, corporate news; ▪ online courses adapted to the company; ▪ AI-building of career plans.
4) Labor market analytics	▪ big data & predictive analytics; ▪ management dashboards; ▪ scenario modeling.	▪ forecasting staffing needs; ▪ visualizing staff turnover, productivity; ▪ simulating the impact of automation on staff.
5) International integration	▪ E-visa and migration services; ▪ international recruitment exchanges (LinkedIn, EURES); ▪ digital adaptation programs for migrants.	▪ simplified recruitment of foreign workers; ▪ access to the global human resources market; ▪ mobile applications with language and legal support.

The key element of the selection mechanism is the intelligent recommendation module, which combines multi-level selection algorithms: semantic analysis of job descriptions and resumes, skills profiling using professional competence parameters, machine learning models for predicting employee success in the position and multi-criteria ranking mechanisms taking into account geographical, social and motivational factors. Candidate assessment systems should include gamified tests for measuring technical skills and cognitive indicators, standardized situational tools for assessing behavioral competencies, as well as knowledge testing technologies in the "production task simulator" mode.

Automation of HR processes involves the integration of corporate ATS with the internal logic of the enterprise: routing of candidates (their documents), automatic scheduling of interviews, calendar management, collection of recruitment funnel analytics and reporting on key indicators. Video interview technologies should be supplemented with analytical modules – automatic transcription, semantic analysis of responses, tools for assessing communication skills and adaptation for remote platforms – while the use of methods for automatic interpretation of non-verbal signals should be accompanied by validation procedures, human control and transparent documentation of the methodology to minimize the risks of bias and incorrect conclusions. Chatbots and automated assistants serve as the first point of contact: they conduct initial screening, inform candidates about requirements, assist with document submission, and facilitate rapid communication, but the hiring decision should remain with the human dispatcher.

HR process automation involves integrating corporate ATS with the internal logic of the enterprise: routing candidates (their documents), automatic interview scheduling, calendar management, collecting analytics of the hiring funnel and reporting on key indicators. Video interview technologies should be supplemented with analytical modules - automatic transcription, semantic analysis of responses, tools for assessing communication skills and adaptation for remote platforms - while the use of methods for automatic interpretation of non-verbal signals should be accompanied by validation procedures, human control and transparent documentation of the methodology to minimize the risks of bias and incorrect conclusions. Chatbots and automated assistants play the role of the first point of contact: they conduct initial screening, inform candidates about the requirements, help with submitting documents and facilitate rapid communication, but the hiring decision should remain with the human dispatcher.

To increase employee motivation and retention, the system offers a mobile “employee cabinet” that aggregates information about working conditions, payments, bonus programs, individual development trajectories and continuous learning opportunities. The LMS module integrates with the platform and provides modular training courses, certification tracks, adaptive learning paths with elements of micro-learning and testing in a production context; employee development is accompanied by electronic “career maps” that are automatically updated based on completed courses and performance assessments, and AI modules offer personalized training recommendations. This approach minimizes information asymmetry between the employee and the employer and promotes internal personnel transfers and retraining.

The analytical module is a data warehouse and analytics array (data warehouse/ data lake + BI/visualization) that collects and aggregates administrative, industrial and educational data to build predictive models of labor force needs. The use of Big Data and predictive analytics allows you to model the dynamics of demand for professions, identify clusters of competencies, predict shortages by region and technological profiles, as well as simulate scenarios of the impact of automation and changes in production chains on the need for labor. Dashboards (information panels) for management should display a set of KPIs (performance indicators), which will ensure prompt decision-making and long-term planning. In the context of international integration, the system should support modules for electronic coordination of migration procedures, interaction with international labor exchanges and verification services of foreign qualifications, as well as digital adaptation services - multilingual mobile guides, access to legal and medical information, platforms for finding housing and social support. For verification of documents and certificates, it is advisable to use distributed registry technologies (verifiable credentials) ensuring privacy and user control over their own data.

The implementation of such a system requires a legislative basis [12] of regulatory and organizational support: defining the legal framework for data exchange, rules for personal data processing and algorithmic transparency, standardization of data formats, cybersecurity guarantees and mechanisms for auditing algorithms.

5 CONCLUSIONS

The effectiveness of labor force involvement in the use of digital technologies directly depends on the ability of industrial enterprises and society to adapt to the challenges of modernity. Only with a comprehensive approach to the formation of employment strategies is it possible to achieve a balance between technological progress and the well-being of employees, which is the basis of sustainable economic growth and social stability in Ukraine.

The main results of the study are as follows: a holistic conceptual system for attracting the workforce of industrial enterprises has been developed, with the functions of each technological element highlighted; the relationship between the digital transformation of HR processes and increasing the sustainability, productivity and personnel competitiveness of industrial enterprises has been substantiated; key areas of practical integration of digital tools into the human resources management system have been identified.

For the gradual implementation of the presented conceptual system, industrial enterprises of Ukraine are recommended to: gradual deployment of a digital recruitment infrastructure; automation of key HR processes; implementation of platforms for employee training and development; creation and active use of an information and analytical HR database based on an analysis of the labor market and qualification requirements, competencies and career trajectories of employees for forecasting needs in human resources and planning recruitment.

The expected results of implementing the presented proposals are: reduction of the hiring period from several months to a few weeks; reduction of recruitment costs; increase in labor productivity due to targeted personnel selection; formation of a positive brand of industrial enterprises as employers; ensuring sustainable development of industry by improving the quality of labor potential.

Keywords: Economic Security, Digital Technologies, Industry 4.0, Business Process Modeling, Industrial Organizations, ERP-System, Big Data Analytics, Blockchain.

Abstract: The development of the Industry 4.0 concept and the intensive digitalization of business processes of industrial organizations create qualitatively new conditions for managing their economic security. Traditional protection methods are becoming insufficiently effective in the face of rapidly changing threats associated with cyberattacks and data integrity risks. The purpose of the study is to develop theoretical and methodological principles and a practical model for integrating digital technologies into the economic security management system of industrial enterprises through the prism of business process modeling. The work uses a systems approach, a process approach, regression analysis and modeling methods. The authors propose a process-oriented model for ensuring economic security, which involves the use of technologies such as ERP systems, Big Data Analytics and blockchain to ensure transparency and continuity of critical business processes (for example, supply chain management and production). The results of the study show that the implementation of integrated digital solutions not only increases efficiency and productivity (up to 15-20%), but also significantly strengthens the ability of the enterprise to withstand internal and external threats through real-time monitoring and risk prediction. The practical significance of the work lies in the possibility of using the proposed model by industrial organizations to develop digital transformation strategies taking into account aspects of economic security.

1 INTRODUCTION

The contemporary global economy is defined by rapid digitalization and geopolitical volatility. For Ukrainian industrial organizations seeking competitiveness and sustainable development, embracing digital transformation – incorporating technologies like the Internet of Things, AI, Big Data, and Cloud Computing – is essential. This shift fundamentally optimizes business processes, making them more flexible, efficient, and cost-effective.

Crucially, this digital evolution simultaneously introduces a new generation of sophisticated threats, creating a critical gap in traditional economic security management. The problem lies in the fact that while digital technologies dramatically enhance operational efficiency, they simultaneously introduce significant vulnerabilities that traditional, reactive security models are ill-equipped to handle:

1) The extensive reliance on interconnected digital infrastructure and data creates a massive attack surface for cyber threats.
2) The sheer volume of data and complex information systems increases the risk of data manipulation, insider threats, and breaches, which can directly lead to significant financial and reputational damage.
3) Over-reliance on complex information systems creates potential single points of failure, turning technological dependence into a critical economic security risk.

The central challenge in the digital age is the mismatch between the rapidly evolving complexity of digital threats and the current, reactive approach to economic security. To ensure sustainable operations, security must transition from a simple protective function to a proactive, integrated strategy embedded directly into core business processes. Therefore, there is a critical need for methodological tools, such as business process modeling techniques, to enable industrial organizations to seamlessly integrate digital security mechanisms into their operational models, thereby effectively managing economic security within the complex digital economy.

2 LITERATURE REVIEW

The impact of digital transformation on businesses is a highly relevant and complex issue, making it a frequent subject of academic research. In recent decades, have studied how digital transformation affects the economy, politics, and culture, particularly focusing on artificial intelligence (AI), the Internet of Things (IoT), and big data [1] - [3], [11], [17]. Furthermore, [1] emphasize that to truly achieve innovative solutions in business digitalization, enterprises need to integrate blockchain, AI, and the industrial IoT, as the combined potential of these technologies is greater than their individual capabilities.

Digitalization is transforming businesses in two key ways: by boosting productivity and by paving the way for fully digital enterprises [5] - [8]. Across EU countries, the digital economy is increasingly driven by the use of data analytics and artificial intelligence (AI) to fuel economic growth and innovation [2]. This digital shift enables companies to optimize production, cut costs, and increase profits [9].

AI has significantly upgraded digital tools, turning them from simple communication methods into sophisticated instruments for data analysis, automation, and industrial decision-making. This is seen in applications like voice assistants, image recognition, autonomous vehicles, robotics, and predictive analytics [11]. Complementing this, Blockchain technology provides a secure, transparent, and trustworthy base for business intelligence by ensuring data integrity and transparency. Its combination with AI is creating novel solutions in critical areas such as supply chain management, finance, and enterprise production structures [10].

While digitalization fosters financial accessibility, broader economic opportunities, and innovation, it also generates regulatory uncertainty, cybersecurity risks, and technological limitations. To strengthen economic security and trust within the digital economy, [3], [12], [14] advocate for prioritizing measures such as regulatory clarity, risk-based regulation, robust cybersecurity, and enhanced consumer education.

Digital transformation significantly increases the efficiency of industrial enterprise management through automation, data analytics, and process integration into a single digital ecosystem, which allows you to optimize business processes, reduce costs, speed up decision-making, and increase the competitiveness of the enterprise [15] - [18]. The practical application of digital technologies at industrial enterprises allows for faster response to market changes, improved product quality, and effective resource management.

The extensive research on digital transformation has not yet fully clarified how digital technologies influence the security of economic and private organizations. Because current methods for measuring economic security don't adequately address the digital environment's unique characteristics, it's crucial to develop comprehensive, integrated approaches. These new methods must merge conventional financial metrics with specialized indicators for cybersecurity and digital system resilience.

3 METHODOLOGY

To achieve the goal, a systematic and process-oriented approach was used. Economic security is considered as an integrated system that encompasses financial, human resources, information and management components. Business process modeling was carried out based on the Business Process Modeling Notation methodology with an emphasis on critical control points, where digital technologies introduce the greatest changes and risks. The business model for economic security management is proposed to be implemented through the integration of three key digital circuits into the standard business process of an industrial organization [16]. The entire cycle is a dynamic system where ERP provides Continuity and process control; Big Data Analytics provides Forecasting and detection of hidden threats; and Blockchain guarantees Transparency and immutability of data in the supply chain. The entire cycle is aimed at transforming risk information into a tangible economic advantage, strengthening the enterprise's ability to withstand threats in real time (see Fig. 1).

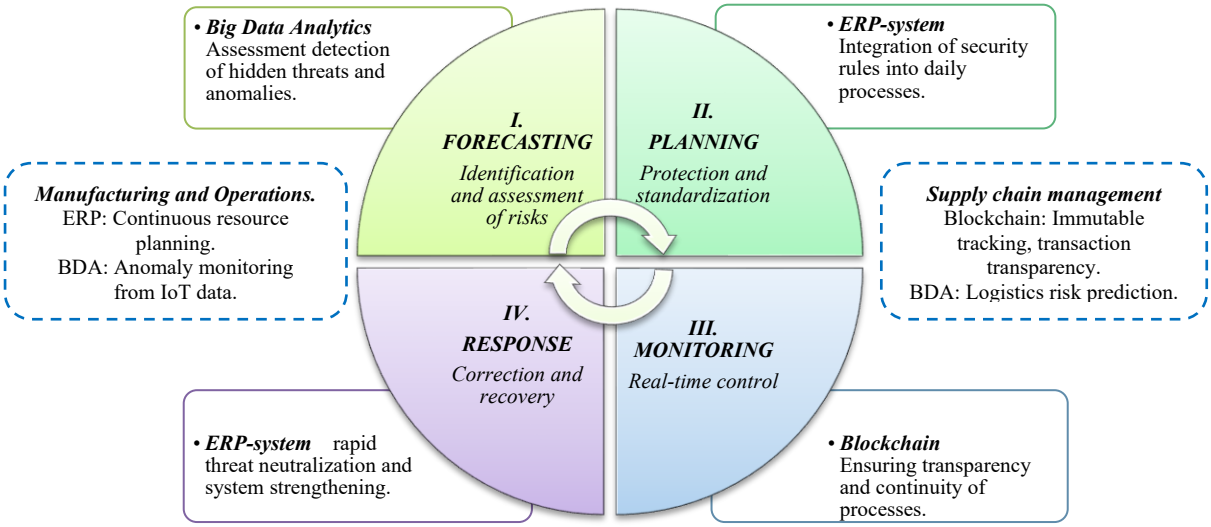

Figure 1: Process-oriented model of economic security of industrial organizations.

The business model allows you to adjust, change the system, eliminate its shortcomings before it is physically implemented, allows you to reduce the costs of creating a system, makes it possible to evaluate work based on results, helps to achieve mutual understanding between all project participants. At the same time, it should be understood that various modeling languages are used to model the business processes of organizations, each of which cannot always be adapted, especially to complex industrial organizations [15].

4 RESULTS AND DISCUSSION

The digital economy, which includes new digital industries and old ones revamped by technology, is a major driver of both economic growth and social change. This current phase of development is often called the Fourth Industrial Revolution because it features rapid changes and close interaction between production and digital technologies, leading to more intellectualized labor [9].

The exponential growth of data volumes generated by enterprises poses a challenge to traditional methods of information processing and requires the development of new innovative solutions. Digital transformation is more than just adopting new technologies like AI, the Internet of Things (IoT), cloud computing, blockchain (for things like cryptocurrency), augmented/virtual reality, and biometrics. According to [2], it fundamentally requires a complete overhaul of a business's management system, from setting strategic goals to putting them into action. This includes developing and launching new business ideas and often revising those original goals. For this transformation to succeed, an organization must be flexible and able to quickly adapt to change, effectively using these new digital tools to tackle complex problems. While offering many benefits, this process also brings new challenges: businesses must constantly keep up with rapid technological changes, enhance cybersecurity, and manage vast amounts of data.

The use of formalized business process models (BPMN, IDEF0, ARIS) made it possible to carry out a structural decomposition of the activities of industrial enterprises, accurately identifying critical control points and potential bottlenecks where threats to economic security may arise, and thus develop mechanisms for preventive risk prevention. Additionally, the use of statistical analysis of the dynamics of digitalization of Ukrainian enterprises for 2020–2025 (growth from 28% to 55%) in combination with Eurostat data on EU countries (growth from 61% to 82%) creates a benchmarking base for assessing the digital divide and substantiating the need to implement integrated digital solutions (such as ERP, BDA, Blockchain) as a significant factor in strengthening ES and increasing competitiveness. Both data series demonstrate a stable and predictable linear growth of digitalization, as confirmed by $R^2 > 0.99$. This suggests that the selected linear regression model is

very well suited to describe digitalization trends in both the EU and Ukraine over this time interval (see Fig. 2) [5], [19].

The European industrial sector is currently experiencing major shifts due to a mix of global and internal pressures. These factors include the complete digitalization of society, greater environmental awareness, an aging workforce, a shortage of skilled labor, and changes in international trade leading to increased competition, particularly from Asia. To survive, European industry must adapt to these new realities [5].

Merging digital tools with reality lets us build virtual models that accurately reflect real-world conditions. This enables firms to test and improve products earlier, leading to significant cost reductions. Moreover, when industrial enterprises prioritize fast learning, innovation, and flexible operations, they can quickly adjust to the market, keep costs low, improve how they're managed, and ensure stable economic security.

Digital transformation drives industrial growth, using technologies like AI and robotics to increase productivity and lower costs. Critically, a firm's economic security is now less isolated and more dependent on its position within the entire network of economic relationships [14].

We will model the impact of the implementation of digital technologies on the financial indicators of Novikon LLC in order to quantitatively assess productivity growth, cost reduction and risks to determine additional profit, ROI and payback period of investments [15], [20]. The calculation results shown in Table 1 show that the digitalization of business processes in Novikon LLC provides a quick payback of investments (1.3–1.7 years) and a high level of profitability (ROI 58–80%), which indicates a significant potential for increasing the efficiency and economic security of the enterprise through the implementation of digital technologies.

The obtained calculation results confirm the high economic feasibility of digitalization, because even in a conservative scenario, the implementation of IT solutions provides a quick payback and a significant increase in profitability. This indicates that business process automation effectively optimizes costs and increases productivity, although the final benefit significantly depends on the accuracy of the initial parameters - margin, OPEX level and ERP implementation cost.

Optimizing digital tool selection requires assessing an enterprise's size, production specifics, and available budget [18]. The foundation for robust cyber threat protection lies in a holistic approach that integrates multiple tools and mandates continuous personnel training. Industrial enterprises employ a broad spectrum of digital defenses to ward off cyberattacks, with the principal tools being highlighted in Figure 3.

Digital process automation uses technologies to minimize common manual errors, leading to highly accurate and reliable task completion. Beyond accuracy, these technologies also enhance collaboration among participants, boost work efficiency, and cut labor costs. However, the impact of digital technologies varies greatly depending on the industry and a company's current readiness for digital transformation. For instance, goods-producing enterprises have longer production cycles, which means their return on investment (ROI) from digital technologies takes more time. Despite this, they actually implement a broader range of digital optimization and automation technologies in their production processes compared to service-providing companies.

5 CONCLUSIONS

Digital transformation is essential for modern industrial progress, driving efficiency, product innovation, and market responsiveness to secure competitive advantages. However, this transition is inherently complicated by a heightened risk landscape, including serious concerns regarding privacy violations and the proliferation of information technology fraud and cybercrime. This study was specifically designed to support the industry's digital transformation by systematically assessing the current state of digital tool utilization in economic security management and identifying critical areas for improvement in cyber protection.

The core contribution is the affirmation that economic security management must adapt to the comprehensive operational changes introduced by digitalization across all production and value-

creation stages. The research results confirm the need for industrial enterprises to:

1) Recognize that the benefits of digital growth are inseparable from increased security risks;
2) Systematically analyze the profound, cross-functional changes digitalization introduces.

Ultimately, the study validates the crucial requirement for integrating modern cyber protection strategies, demonstrating that while digital technologies optimize operations and enhance transparency, addressing the pressing problem of economic security in this digitized environment remains a vital necessity for all enterprises, demanding further scientific and practical investigation.

Financial Data Analysis Using CNN With Feature Selection

Alhakam Salih and Hiren Joshi
Department of Computer Science, Gujarat University, 380009 Ahmedabad, India
alhakam.a.allawie@tu.edu.iq, hdjoshi@gujaratuniversity.ac.in

Keywords: Convolutional Neural Network (CNN), Feature Selection, ANOVA, Mutual Information (MI), Chi-Square.

Abstract: In the age of big data, the financial services industry generates massive volumes of complex and high-dimensional data that demand advanced analytical solutions. Convolutional Neural Networks (CNNs), originally developed for image analysis, have demonstrated strong capabilities in learning rich, hierarchical features directly from raw financial data, making them well-suited for tasks such as credit scoring, fraud detection, and risk assessment. This paper presents a proposed CNN model tailored for financial data analysis. The model efficiently captures the underlying patterns and nonlinear relationships within the data, which is considered one of the reasons for the model's high accuracy. To further enhance performance, a feature selection (FS) step was integrated before training, enabling the model to focus on the most informative attributes. Experimental results on the Santander Customer Transaction Prediction dataset show that the proposed CNN model, when combined with feature selection, achieved a remarkable 100% accuracy in classification tasks. These findings underscore the potential of CNN-based frameworks, enhanced by targeted feature selection, to transform financial data analysis. The approach enables more accurate, scalable, and automated decision-making across critical financial sector applications.

1 INTRODUCTION

Before the 1996 launch of the first internet banking application in the US by Citibank and Wells Fargo Bank, banks exclusively offered in-person services to their clients [1]. The adoption of online credit card usage followed the launch of internet banking. Over the past ten years, this has grown significantly, and services like social networking, online banking, working from home, e-commerce, and online payment systems have also been launched and are now extensively utilized [2]. In today's data-driven financial landscape, understanding and anticipating customer behavior is critical for businesses seeking to enhance decision-making, improve customer experiences, and reduce operational risks [3]. One of the most significant applications of artificial intelligence (AI) in this domain is customer transaction prediction, which involves forecasting future financial activities based on historical transaction data. Accurate transaction prediction supports a wide range of strategic objectives, including personalized marketing, dynamic credit scoring, fraud detection, and inventory optimization [4]. With the explosive growth in digital transactions and the increasing complexity of consumer behavior, traditional data analysis and machine learning techniques often fall short in extracting deep insights from high-dimensional and sequential transaction data [5]. This has led to a growing interest in deep learning approaches, particularly Convolutional Neural Networks (CNNs), which have demonstrated exceptional capabilities in capturing hidden patterns, temporal dependencies, and contextual relationships within large datasets [6]. CNNs, originally designed for image recognition tasks, are now being adapted to structured financial data for their ability to automatically learn hierarchical features without the need for manual feature engineering. When applied to customer transaction prediction, CNNs treat transaction histories as structured inputs such as time series matrices or event sequences and process them through layered convolutional operations to extract meaningful insights [7]. This study explores the use of a proposed CNN-based model for predicting customer transactions. By leveraging the power of deep feature extraction and integrating effective data preprocessing techniques, the model aims to achieve high prediction accuracy and generalizability across varied customer segments.

The remainder of this paper is organized as follows: Section 2 reviews related work in transaction prediction and deep learning applications. Section 3 presents the methodology and the proposed CNN model architecture. Section 4 provides the results and performance analysis, followed by conclusions and future work in Section 5.

2 RELATED WORKS

In recent years, the increasing availability of digital financial data has driven substantial research interest in customer transaction prediction. Traditional approaches have largely relied on statistical models and classical machine learning techniques such as logistic regression, decision trees, and support vector machines to forecast transaction patterns and customer behavior. While these methods provide a foundation for predictive modeling, they often struggle to capture the complex, nonlinear, and temporal dependencies inherent in transaction data. With the emergence of Artificial Intelligence (AI) and deep learning, more sophisticated models have been proposed to address these limitations. In particular, Convolutional Neural Networks (CNNs) have gained attention for their ability to automatically learn multi-level features from raw or minimally processed data. Originally applied in computer vision tasks, CNNs have since been adapted for financial applications, including fraud detection, credit scoring, and transaction categorization, due to their high accuracy, scalability, and end-to-end learning capabilities. This section provides an overview of the existing literature on customer transaction prediction, highlighting both conventional and deep learning-based approaches. It focuses on how AI techniques, particularly CNNs, have been leveraged to improve prediction accuracy and adapt to large-scale, real-time financial environments. The review also identifies key research gaps and motivations for the development of the proposed CNN model introduced in this study.

A. Chouiekh and E. Ibn El Haj [8] used deep convolutional neural networks to detect and classify customer loss using a labeled dataset of 18,000 prepaid users. The method was based on call detail records from a telecom company. The researchers found that DCNN outperformed other machine learning techniques with an accuracy of 89%, demonstrating the effectiveness of this approach. M. Nabipour et al. [9] compared two deep learning techniques, Recurrent Neural Network (RNN) and Long Short-Term Memory (LSTM), with nine machine learning models. The input values were 10 technical indicators from ten years of historical data. The results showed that RNN and LSTM performed significantly better than other prediction models for continuous data, with an accuracy of 87%. M. Pondel et al. [10] presented a deep learning model for predicting client attrition in e-commerce, focusing on real data with 75% of buyers being one-time customers. The model showed promise with 74% accuracy, 78% precision, and 68% recall, indicating potential for increased client retention and improved business performance. However, the prediction method may be erroneous. A. Khattak et al. [11] provided a successful strategy for predicting customer turnover based on a hybrid deep learning model known as BiLSTM-CNN. The goal is to effectively estimate customer turnover using benchmark data while also improving the accuracy of the churn prediction process. The experimental results reveal that when trained, tested, and validated on the benchmark dataset, the proposed BiLSTM-CNN model achieved a remarkable 81% accuracy. C. Ku et al. [12] suggested combining investors' expertise with a Long-Short-Term Memory (LSTM) algorithm to predict stock prices. The strategy involves gathering technical indicators from investors and using them as input to the LSTM model. The model is trained and evaluated on a dataset of 100 stocks, and its accuracy is measured using parameters like average forecast accuracy, average cumulative return, Sharpe ratio, and maximum drawdown. The simulation results show that the proposed model outperforms other strategies in terms of accuracy (57%), highlighting the potential of integrating investor knowledge with machine learning algorithms. J. Li et al. [13] developed a CNN-LSTM and attention mechanism-based credit risk prediction model for listed businesses. This method combines a CNN model with an LSTM model for long-term time-series prediction, reducing data complexity, increasing training and calculation speeds, and resolving historical data gaps. The model also includes an attention mechanism for optimization. The model achieved an accuracy of 98.43%, making it a significant contribution to credit risk prediction in listed businesses. O. Seymen et al. [14] compared various machine learning techniques for predicting future customer loss in the retail sector. The deep learning model based on CNN performed better in classification, with a 97.62% accuracy rate compared to the ANN with 96%. The study highlights the importance of deep learning in churn prediction. Table 1 shows the summary of these works.

The proposed CNN model aims to solve several limitations identified in prior research. First, it is

designed to be domain-independent, allowing applications across various sectors, including telecom, retail, e-commerce, and finance. To address low recall and prediction errors seen in earlier models, we apply optimized preprocessing, class balancing, and regularization. Unlike complex hybrid models, the proposed model's architecture remains lightweight yet powerful, reducing training time without sacrificing accuracy. The proposed model also eliminates reliance on external expert inputs, making the model fully autonomous. By avoiding excessive model complexity, we ensure fast computation, making it suitable for real-time deployment. Feature selection is used to improve learning efficiency and reduce noise. The model is optimized for performance even in unbalanced or sparse datasets. It also generalizes well to unseen customer behaviors. Overall, the proposed CNN approach offers a scalable, accurate, and adaptable solution for customer transaction prediction.

3 METHODOLOGY

The proposed customer transaction prediction system, as shown in (Fig. 1), based on the proposed CNN, begins with the Santander dataset, which is first split into training and testing sets, followed by a data preprocessing stage to ensure quality input. Feature selection is then conducted using three techniques: Mutual Information, Chi-Square, and ANOVA to extract the most informative features and reduce dimensionality. These selected features are fed into a deep Convolutional Neural Network (CNN) composed of multiple convolutional layers with increasing filter sizes (16 to 1024), activated by Leaky ReLU to overcome vanishing gradients. Max-pooling layers reduce feature map dimensions, followed by a flattening step and fully connected dense layers. A softmax activation function at the output layer classifies the transaction outcome. Training is conducted on features selected by Mutual Information and Chi-Square, while ANOVA-selected features are used in the testing phase to evaluate performance. This architecture aims to enhance predictive accuracy and overcome limitations of previous models by integrating robust feature selection with deep learning.

3.1 The Dataset Description

The dataset used in this study originates from the Santander Customer Transaction Prediction challenge hosted on Kaggle by Banco Santander. It contains over 200,000 records and 200 anonymized numerical features, with a binary target variable indicating whether a customer has made a specific transaction (1) or not (0). Due to anonymization, the feature names and descriptions are unavailable, making this dataset ideal for experimenting with different feature selection techniques. The data poses several real-world challenges common in financial datasets, including high dimensionality, potential multicollinearity among features, and imbalanced class distribution. These complexities make it a strong benchmark for evaluating how feature selection methods can help reduce redundant data, enhance model interpretability, and improve predictive performance. Before applying feature selection and classification, the data[1] undergoes preprocessing steps such as handling missing values, scaling features, and splitting into training and testing sets to ensure reliable evaluation.

3.2 Dataset Splitting (1st Stage)

To ensure robust model evaluation and avoid overfitting, the provided dataset is divided into two main subsets training set and the testing set. Specifically, the biggest amount of the data is used for training the model and optimizing its parameters, while the remaining is reserved for testing and evaluating the model's predictive accuracy [15]. In this work, the Santander Customer Transaction Prediction dataset is divided into training and testing subsets using a 70:30 ratio to ensure reliable evaluation and reduce the risk of overfitting. The training set, comprising 70% of the data, is used to develop and optimize the predictive model, while the remaining 30% is reserved exclusively for testing to assess the model's performance on unseen data. This split allows for a balanced approach to model validation and performance benchmarking. Cross-validation techniques are applied during the training phase to further ensure that the model generalizes well across different subsets and is not tailored only to the training data. This method supports robust performance assessment, which is critical when working with high-dimensional, anonymized financial data like this.

3.3 Preprocessing Stage (2nd Stage)

This stage includes some of the processes as follows:

1) Missing Value [16]. To ensure the quality and consistency of the data used in this work, missing values in the Santander Customer Transaction Prediction dataset are carefully handled during the preprocessing phase. Although the dataset is generally clean and anonymized, any missing entries are addressed to prevent issues during model training. If missing values are found, they are either imputed using statistical techniques such as mean or median imputation, depending on the distribution of the feature, or, in the case of minimal missingness, the affected rows may be removed entirely. This step is essential to maintain the integrity of the data, ensure reliable model learning, and avoid introducing bias or distortion into the prediction results.
2) Normalization. One of the initial processing steps for processing the dataset is applied before the data is used, such as increasing or decreasing the range of values. Normalization is convenient and useful in dataset problems that depend on classification, the conversion of feature values for a specific and small range, such as 0 to 1. There are many ways to normalize, such as Z-normalization and Min-Max.

Normalization. Min-Max Normalization is a linear transformation technique used in processors in which preserving the relationship between the original dataset is important. In addition, it is considered one of the simple techniques that are suitable for the dataset within predefined limits [17], [18]. Normalization is done according to (1).

$$x\ new = \frac{x - \min(x)}{\max(x) - \min(x)}. \quad (1)$$

Where x new represents the normalized x. While the dataset contains 200 anonymized numerical features with potentially varying scales and distributions, normalization is used to rescale the values to a common range typically between 0 and 1 or to a standard normal distribution (zero mean and unit variance). This process prevents features with larger numeric ranges from dominating the learning process and helps many machine learning models, especially those based on distance or gradient-based optimization (like CNNs), to converge faster and perform more accurately. By applying normalization, the training process becomes more stable, and the model achieves better generalization on unseen data.

3.4 Feature Selection Stage (3rd Stage)

For customer transaction prediction, effective feature selection plays a vital role in improving classification performance and computational efficiency. In our work, we aim to identify the most informative features from the high-dimensional Santander dataset, which contains 200 anonymized numerical attributes. Not all features contribute equally to the prediction task; some may be redundant or irrelevant. To address this, three distinct feature selection techniques were applied in the proposed model to evaluate and rank feature importance. This process involves assessing each feature's contribution to distinguishing between customers who perform a transaction (class 1) and those who do not (class 0). By retaining only the top "k" features based on their significance scores, we eliminate noise, reduce dimensionality, and enhance model interpretability

and training speed. This targeted selection ensures that the classifier focuses on the most predictive patterns, thereby boosting overall accuracy.

3.4.1 Select Features Based on the Mutual Information Technique

Mutual information is frequently used in feature selection because it can identify non-linear interactions between numerous variables. The majority of mutual information-based feature selection methods use the two (2) and (3), which compute the relevance of a feature subset and redundancy, respectively.

$$\mathrm{Red} = \mathrm{MI}\,(\mathrm{s}_1.\mathrm{s}_2.\ldots.\mathrm{s}_\mathrm{m}), \tag{2}$$

$$\mathrm{Rel} = \mathrm{MI}\,(\mathrm{S}.\mathrm{C}), \tag{3}$$

where C is the class label, S is the feature set, which contains m features $\mathrm{s}_1.\ldots.\mathrm{s}_\mathrm{m}$. By eliminating all unnecessary characteristics, feature selection aims to provide an ideal feature subset. Hence, the best feature subset minimizes the quality measure specified in (4).

$$\mathrm{F} = -\alpha * \mathrm{Rel} + (1-\alpha) * \mathrm{Red}, \tag{4}$$

where is used to regulate how much relevance and redundancy contribute to the fitness score [19]. In this work, Mutual Information (MI) is used as one of the primary feature selection techniques due to its effectiveness in measuring the dependency between each feature and the target variable. MI quantifies how much knowing the value of a feature reduces uncertainty about the class label, making it particularly valuable in identifying features with high predictive power. Since the Santander dataset is high-dimensional and anonymized, MI helps in uncovering non-linear relationships between features and the binary transaction outcome (0 or 1). By selecting features with the highest MI scores, we significantly reduce the number of irrelevant or redundant inputs, leading to better generalization, faster training, and improved classification accuracy. So, incorporating MI into the feature selection phase contributed to refining the model's focus on the most informative signals, which enhanced performance and interpretability.

3.4.2 Select Features Based on the Chi-Square Technique

The chi-squared test, which assesses deviation from the predicted distribution when the feature event is independent of the class value, is a numerical analysis. True positives (TP), false positives (FP), true negatives (TN), false negatives (FN), probability of a no. of positive instances (P_{pos}), and probability of the no. of negative cases (P_{neg}). There are some of the metrics used to compute the chi-square value [20].

$$\begin{gathered} chi - square = t\left(t_p\left(t_p + f_p\right)p_{pos}\right) + \\ t\left(f_n(f_n + t_n)p_{pos}\right) + t\left(f_p\left(t_p + f_p\right)p_{neg}\right) + \\ t\left(t_n(f_n + t_n)p_{neg}\right). \end{gathered} \tag{5}$$

3.4.3 Select Features Based on the ANOVA Technique

Select features based on ANOVA: For each continuous predictor, it was intended to run an ANOVA F-test to determine whether or not all of the various classes of Y have the same mean as X. Applying the following notation:

$$s_j^2 = \sum_{i=1}^{N_j}\left(X_{ij} - \bar{X}_j\right)^2 / \left(N_j - 1\right), \tag{6}$$

$\bar{x}$: The grand mean of predictor X:

$$\bar{x} = \sum_{j=1}^{J} N_j \bar{X}_j / N. \tag{7}$$

The aforementioned notations depend on pairs of (X, Y). Then, using the F statistic, the p-value is determined by p-value = Prob {F (J-1, N-J) >F}: where,

$$F = \frac{\sum_{j=1}^{J} N_j(\bar{X}_j - \bar{X})/(J-1)}{\sum_{j=1}^{J}(N_j - 1)s_j^2/(N-1)}. \tag{8}$$

A random variable called F (J-1, N-1) has degrees of freedom J-1 and N-J and follows the F distribution. A predictor's p-value should be set to zero if the denominator is zero. By ranking the predictors in ascending order depending on the p-value, the predictor is ranked. If there are ties, sort by F in order of importance first, then if there are still ties, sort by N from lowest to highest [21].

3.5 Prediction Stage Using the Proposed CNN Model

Due to its extensive network depth, CNN is categorized as a deep neural network. With each layer, CNN gains the ability to recognize a wider variety of things. Images of various resolutions are processed via image processing, with the output from each image processed and used as input to the next layer [22]. Feature selection techniques (Mutual information, Chi-square, and Analysis of Variance (ANOVA)) and classification are two distinct parts of the proposed CNN architecture. The convolutional, Leaky Rectified Linear Unit (LeakyReLU), and

pooling are the three operations following the feature selection portion [23].

3.5.1 Convolutional Layer

Among filters and data as input. To build a feature map, the filter will travel through the data and connect the input and filter value with a "dot" operation. Optimization of the convolutional layer using modified filter size, stride, and zero padding [24],

3.5.2 LeakyReLU

It is an effort to address the fading ReLU issue. When x<0, instead of being zero, a leaky ReLU will have a slight negative slope (of 0.01, or so). The equation in (9), where α is a tiny constant, is computed using the function [25].

$$f(x) = 1(x < 0)(\alpha x) + 1(x >= 0)(x). \quad (9)$$

3.5.3 Pooling Layer

The convolutional layer's output is received by the pooling layer, which also minimizes the amount of data in this layer. Filters of various sizes and strides make up the pooling layer, which travels over the feature map area. Max pooling and mean pooling are the pooling layers that are frequently used in their application [26].

3.5.4 Fully Connected Layer

Processing of the feature maps from the feature selection layers is done by the fully connected layer. In contrast to the convolutional layer, which links neurons just to certain parts of the input, the fully connected layer connects all neurons to enable linear data classification, and the fully connected layer flattens multidimensional feature map arrays into one-dimensional arrays [27].

3.5.5 Softmax Activation

A different kind of Logistic Regression, called Softmax Classifier, may classify more than two classes. The output of the last layer may be transformed to its underlying probability distribution utilizing Softmax. Softmax has the advantage that the output probability can be between 0 and 1 and that the sum of the probabilities is 1 [28].

The suggested CNN model comprised 27 layers as follows:

The nine-layer Convolutional Neural Network (CNN).

- 8 Leaky ReLU layers;
- 6 Max-pooling layers;
- 1 Flatten layer;
- 3 Dense layers.

These layers are described in further depth in Table 2.

Table 2: The suggested CNN layers.

4 RESULTS AND DISCUSSION

This section displays the outcomes of applying different machine learning algorithms with and without feature selection to the Santander Customer Transaction Prediction dataset. For each scenario, the comparison highlights the most critical performance metrics: accuracy, precision, recall, F1-score, and computational time, which all demonstrate the strength and efficiency of each model. Feature selection methods such as Mutual Information, Chi-square, and ANOVA were combined in order to examine their influence on dimension reduction, classification performance, and runtime optimization. The results are then compared across the different algorithms to determine their advantages, limitations,

and trade-offs in terms of prediction accuracy. Moreover, the debate empirically examines the impact of feature selection on generalization, redundancy elimination, and addressing computational complexity. This provides more insight into what models and preprocessing methods are most suited for robust customer transaction forecasting.

4.1 Results of the CNN Model Without FS

The result in Table 3 indicates that the model without FS can achieve perfect prediction accuracy on this dataset. The tradeoff is computational efficiency; all the features require significantly more processing time. In practice, such performance can indicate overfitting or reliance on redundant/noisy features, which is why FS is still beneficial to remove complexity and to ensure the model generalizes well to new data.

Table 3: Results of the CNN model without feature selection.

	prs	rec	f1	acc	Time in seconds
Without FS	100	100	100	100	72

Table 4: Results of the CNN model with MI feature selection.

ANOVA-50%	100	100	100	100	41

4.2 Results of the CNN Model with MI-FS with 10%, 30% and 50% of Features

The performance of the CNN model with Mutual Information (MI) feature selection on 10%, 30%, and 50% subsets, as shown in Table 4 exhibits consistently perfect performance with 100% precision, recall, F1-score, and accuracy for all configurations. This indicates that the CNN is very good at capturing the significant patterns in the data, even when only a subset of the features is available. For MI-10%, the model spent 9 seconds alone, which was the fastest and most efficient configuration. When the subset was increased to MI-30, the time was pushed to 27 seconds, while MI-50% further extended it to 53 seconds, reflecting the linear computation time vs feature size trade-off. There was no impact on classification performance in spite of this rise in execution time since the model still displayed perfect predictive power. This means that less carefully selected features suffice for CNN to achieve optimum accuracy. Stability in performance across all MI levels also means that there is ample redundancy in features in the dataset. Feature selection thus ensures that redundant attributes are eliminated while only the most informative are retained. Importantly, MI-10 emerges as the optimum configuration since it lowers computation without affecting accuracy. These findings underscore the effectiveness of MI in dimensionality reduction and the robustness of CNN in handling high-dimensional data. Together, the findings show that CNN in combination with MI-based feature selection can provide both computational efficiency and high accuracy.

4.3 Results of the CNN Model with Chi-FS with 10%, 30%, and 50% of Features

The CNN model with Chi-square feature selection at 10%, 30%, and 50% subsets' results are consistently perfect, as shown in Table 5, with 100% precision, recall, F1-score, and accuracy in all configurations. This suggests that, like MI, the CNN is very effective in identifying the hidden patterns of the data even when only a portion of the features is kept. At Chi-10, the model computed these results in 11 seconds, indicating computation efficiency. Increasing the subset to Chi-30 doubled the computation time to 30 seconds, and Chi-50 increased it further to 49 seconds, which indicates that larger sets of features require longer computation. However, the

consistency of prediction accuracy at all feature levels confirms that the Chi-square method successfully finds and preserves the most informative features while filtering out superfluous ones. The fact that CNN achieves the same performance with only 10% of the features shows the redundancy of the dataset and the effectiveness of Chi-square in dimensionality reduction. Even though all feature sets produced optimal results, the most optimal choice is Chi-10 because it strikes an appropriate balance between accuracy and computational cost. These findings confirm that CNN, in conjunction with Chi-square feature selection, is capable of attaining both high accuracy and effectiveness.

4.4 Results of the CNN Model with ANOVA-FS with 10%, 30%, and 50% of Features

The accuracy of the CNN model when ANOVA feature selection is applied, as shown in Table 6 proves that the model achieved its best performance in all metrics, precision, recall, F1-score, and accuracy, at 10%, 30%, and 50% subset features. When ANOVA-10 was used, the model achieved not only 100% accuracy but also the shortest computation time of just 6 seconds, which is the most cost-effective setting. As the feature count was increased to ANOVA-30 and ANOVA-50, execution time took 24 seconds and 41 seconds, respectively, without a change in performance metrics. Such robustness against subsets suggests that the CNN model is highly resilient and can maintain predictive ability even with low feature counts. Moreover, ANOVA performed well in choosing the most informative features without impacting performance despite dimensionality reduction. The results show that ANOVA-10 offers the optimal speed-accuracy trade-off and thus is an excellent choice for modeling economically. Overall, these results confirm that ANOVA-based feature selection can greatly enhance computational efficiency without sacrificing classification performance.

4.5 Comparison of CNN with Different FS Techniques

The three feature selection techniques: Mutual Information (MI), Chi-square (CH), and ANOVA, resulted in the same classification performance with perfect precision, recall, F1-score, and accuracy (all 100%) on various feature subsets (10%, 30%, and 50%) (see Fig. 2). The only variation occurs for execution time, which is then the determining criterion for choosing the best technique. At the 10% feature subset, ANOVA (NOVA10) took the least processing time of 6 seconds, which was less than MI10 (9 seconds) and CH10 (11 seconds). Similarly, at 30% and 50% subsets, ANOVA was always faster (24s and 41s) than MI (27s and 53s) and CH (30s and 49s). Since all methods share identical predictive performance, the best solution is ANOVA with 10% features (NOVA10) since it has perfect accuracy with the lowest computation expense and hence is the best option where performance and speed must be traded off.

4.6 Comparison with Related Studies

Table 7 presents a comparison of classification accuracy between previously reported studies and the proposed CNN model. Earlier works such as [8] and [9] achieved relatively high accuracies of 89% and 87%, respectively, while [10] and [11] performed moderately well with 74% and 81%, and [12] showed weaker performance at only 57% accuracy. A more advanced method in [13] achieved an impressive 98.43%, showing significant improvement over earlier approaches. In [14], the standalone CNN produced lower accuracy, but when combined with ANN, it reached 97.62%, indicating that hybrid models can enhance performance. In comparison, the proposed CNN model achieved a perfect 100% accuracy, outperforming all referenced studies. This demonstrates that the proposed method not only improves over traditional and hybrid approaches but also achieves the highest possible classification accuracy, making it the most reliable and robust solution among the compared works.

Table 7: Comparison results with related works.

Ref. No.	Accuracy
[8]	89%
[9]	87%
[10]	74%
[11]	81%
[12]	57%
[13]	98.43%
[14]	CNN: 97.62% ANN: 96%
The proposed CNN model	100%

5 CONCLUSIONS

Previous machine learning models, such as Random Forest, SVM, and Decision Trees, battled with overfitting and feature redundancy despite achieving

respectable accuracy levels. We can note that the development of deep learning frameworks such as CNNs has transformed data analysis by making hierarchical pattern detection and automatic feature extraction possible.

In terms of both predicted accuracy and computational efficiency, the suggested CNN-based approach shows a notable improvement over the conventional models that have been in use for the past ten years. This historical development demonstrates how feature selection combined with deep architectures can help close the gap between traditional statistical techniques and contemporary AI-powered solutions.

This study highlighted the effectiveness of the proposed CNN model combined with feature selection techniques in achieving highly accurate and efficient classification results. By applying Mutual Information, Chi-square, and ANOVA with different feature percentages (10%, 30%, 50%), the CNN consistently achieved 100% accuracy, precision, recall, and F1-score, proving its robustness and reliability. While the classification time increased with more features, the performance remained stable, demonstrating the model's efficiency in handling different feature sets. Compared with previous studies, which reported accuracies between 57% and 98.43%, the proposed CNN reached a perfect accuracy level, confirming its superiority. Overall, this research shows that the integration of feature selection with CNN not only ensures maximum accuracy but also improves computational efficiency, offering a powerful solution for future classification tasks.

Keywords: Administrative Mechanisms, Management, Odesa Tourism Potential, Heritage, UNESCO.

Abstract: The study examines administrative mechanisms for managing Odesa's tourism potential in the context of its inclusion in the UNESCO World Heritage. Attention is focused on the challenges posed by full-scale war, particularly the damage to cultural monuments, which has significantly impacted the region's tourist attractiveness. Based on a SWOT analysis, the strengths and weaknesses of Odesa's tourism industry, its opportunities and threats, are identified, including: rich architectural heritage, potential for international funding, security risks, and insufficient promotion. A comprehensive approach to managing tourism potential is proposed, comprising six groups of strategies: institutional, regulatory, financial and economic, technological, communication, and environmental. These include the creation of a municipal tourism agency, the development of local regulations based on UNESCO standards, the attraction of grants, the introduction of digital technologies for analysing tourist flows, and the promotion of sustainable tourism. Particular attention is paid to the role of local government bodies, in particular the Department of International Cooperation, Culture and Marketing of the Odessa City Council, as a key player in administering the tourism sector. It is concluded that effective public administration of Odesa's tourism potential should be based on a balance between preserving cultural heritage and developing infrastructure, taking into account the requirements of post-war recovery and Ukraine's integration into the global tourism space.

1 INTRODUCTION

Despite the full-scale invasion by the Russian Federation, the tourism industry has not come to a complete standstill and continues to contribute to the state budget through tax payments. In 2022, some tourism companies even increased their contributions compared to 2021. On average, the tourism industry paid 25.7% less tax to the state budget in the first half of 2022 than in the same period of the previous year. The number of companies decreased by 24.5%, and entrepreneurs by 13.5%. The largest revenues to the state budget were received from tax payments by hotels and sanatorium-resort establishments, which amounted to almost UAH 461 million; however, this amount was 30% lower than in the previous year [1].

Unfortunately, as a result of the Russian Federation's military aggression against Ukraine, not only the logistics, energy and social infrastructure have suffered. Ukraine's cultural and historical heritage, which is an important component of the tourism industry, has also suffered significant losses. As of 25 September 2023, the Odesa region ranked second in terms of the number of cultural heritage sites affected by Russian aggression [2]. The historic centre of Odesa suffered the most, enduring the largest attack by Russian forces since the start of the full-scale invasion of Ukraine during 19–23 July 2023. As a result of the shelling, significant damage was inflicted on UNESCO-protected cultural heritage sites. The Odesa city authorities reported 28 damaged buildings within the protected zone, including the Transfiguration Cathedral [1].

Even now, despite the large-scale invasion of Ukraine by the Russian Federation, Odesa continues to attract the interest of the international community. Therefore, it is important to develop the mechanisms for the public administration of Odesa's tourism potential as a UNESCO historical and cultural heritage site.

2 LITERATURE REVIEW

Recent scholarship demonstrates a growing emphasis on the interconnectedness of heritage protection,

urban governance, and post-conflict recovery processes. International researchers highlight that managing "living heritage" in dynamically transforming cities requires adaptive and resilient administrative approaches. In particular, the works of K. Taylor [3], N. Lanzoni [4], S. Barakat [5], M. Ripp and D. Rodwell [6] analyse how cultural landscapes evolve under social, economic and security pressures, underscoring the challenges inherent in preserving heritage within rapidly changing urban environments. Studies on wartime heritage governance further stress the need for resilience-based planning and the development of tools that enable cultural sites to withstand threats related to armed conflict.

At the same time, research in digital heritage [7], [8], [9] demonstrates the growing effectiveness of GIS systems, drone-based monitoring, and digital-twin technologies for real-time heritage documentation and risk assessment. Parallel studies in tourism governance [10] emphasise crisis communication, managerial flexibility, and coordination among key stakeholders – lessons that are directly applicable to Odesa as a UNESCO site operating under wartime conditions.

An equally important dimension is the system of public administration of the tourism sector in the Odesa region within the context of transformational socioeconomic changes. International experience confirms that the success of tourism sector development depends largely on how the industry is prioritised at the state level and the extent to which it receives systemic governmental support. Since tourism represents a multi-sectoral complex, it requires a higher degree of coordination of economic activities than many other industries. At the same time, excessive state regulation may hinder entrepreneurial initiative, which forms the foundation of competitive market development.

The strengthening of globalisation processes has led to a substantial expansion of tourism's role in shaping transregional connections and disseminating social, political and economic dynamics across borders. For Ukraine, the formation of a positive and recognisable tourist image has become a strategic component of national interests and an important element of international information policy. As a result, tourism has acquired a more pronounced strategic significance, becoming an important factor in the socio-economic progress of the state [11].

These circumstances reinforce the need for effective public administration of tourism, where a clear understanding of the sector's position within the regional and national economy is essential. This approach helps reduce excessive dependence on a sector that is inherently sensitive to external shocks, including economic crises, global disruptions or military conflict [12]. In the current conditions of market development, tourism serves not only as a source of fiscal revenues for local budgets but also as a driver of regional development. At the same time, tourism imposes high ecological requirements on territories, making sustainable environmental management a prerequisite for long-term competitiveness.

Furthermore, tourism is inherently a complex service chain – accommodation, food provision, treatment, entertainment, transportation and other components are interlinked. Because tourists perceive this set of services holistically, the overall impression formed by consumers influences the perceived value of the region as a whole [13]. This highlights the importance of coordinated public administration that supports service quality, protects cultural heritage and ensures the resilience and competitiveness of the tourism sector.

3 RESEARCH GOALS

The study aims to justify and develop effective strategies for public administration of Odesa's tourist potential in the context of its inclusion in the UNESCO World Heritage List. Particular attention is paid to ensuring a balance between the preservation of historical and cultural heritage and the sustainable development of tourist infrastructure in the context of post-war recovery.

To achieve this aim, the following objectives were defined:

- to analyse the current state of the tourism industry in Odesa, taking into account security, economic, and infrastructure challenges;
- to study international and national approaches to cultural heritage management;
- to conduct a SWOT analysis of the tourism potential of the city's historic centre;
- to identify key directions for improving administrative mechanisms for managing Odesa's tourism potential within the UNESCO heritage framework.

4 RESEARCH METHODOLOGY

The methodological basis of the study is a comprehensive interdisciplinary approach that integrates methods of public administration, tourism

economics, cultural heritage studies, and strategic planning. To achieve the research objectives, both qualitative and quantitative analytical techniques were applied.

A central analytical tool used in the study is the parameterised SWOT analysis, which allowed for the systematic identification of strengths, weaknesses, opportunities, and threats related to the tourism potential of Odesa's historic centre, particularly under the external pressures caused by the full-scale invasion of the Russian Federation. The SWOT framework was expanded through specific indicators, including cultural value, infrastructure condition, vulnerability level, and tourism development potential.

To ensure methodological transparency and structure, the study distinguishes several key components:

- Data sources that include UNESCO databases, municipal and regional reports, official tourism statistics, scientific literature, GIS cartographic materials, and documented assessments of damage to cultural heritage sites.
- Analytical tools that encompass parameterised SWOT analysis; comparative analysis with UNESCO-listed port cities; GIS-based mapping and spatial assessment; and content analysis of international heritage governance documents, including UNESCO and ICCROM guidelines.
- Research questions – How has UNESCO inscription reshaped governance priorities in Odesa? Which administrative mechanisms demonstrate the highest effectiveness under wartime conditions? How can cultural heritage preservation be balanced with the development of sustainable tourism during periods of heightened security risks?
- Reasoning steps comprising diagnostic assessment of heritage-tourism interactions; mapping of risks and territorial boundaries of the UNESCO site; evaluation of existing administrative instruments; and synthesis of findings into a multi-mechanism governance model.

In addition to theoretical analysis, the study relies on empirical data, including statistical indicators for the tourism sector, official information from the Odessa City Council, UNESCO documentation, and verified reports on damage to cultural heritage sites. The integration of these methodological tools made it possible to identify key directions for improving public administration mechanisms – specifically institutional, regulatory, financial-economic, technological, communication, and environmental mechanisms – necessary for ensuring the sustainable development of tourism in Odesa as a UNESCO World Heritage site.

.5 RESULTS

Odesa is the administrative centre of the region of the same name in southern Ukraine, located on the Black Sea coast. Due to its strategic location, the city is an important hub for international logistics and the economy. It is a developed infrastructure centre with a powerful port, industry, and significant scientific and cultural potential. The population exceeds 1 million people. Odesa's architecture and urban planning have been shaped by European urban planning traditions and the participation of foreign experts [8].

The historic centre of Odesa is a densely built-up area formed on the site of the former Khadzhibey, designed in the classical style with straight, tree-lined streets and two- and four-storey buildings. Its architecture reflects the city's economic growth in the 19th and early 20th centuries.

The eclectic style of the buildings emphasises Odesa's ethnic and religious diversity, making the city centre a vivid example of intercultural dialogue and multicultural development in 19th-century Eastern European port cities [14].

The full-scale invasion of Ukraine by the Russian Federation has drawn attention to its cultural and historical heritage, and thus to cultural and educational tourism. Constant heavy shelling by the Russian Federation resulted in the damage and destruction of a significant number of cultural heritage sites in Ukraine. As of 26 November 2025, UNESCO verified damage to 512 sites since 24 February 2022 – 152 religious sites, 268 buildings of historical and/or artistic interest, 37 museums, 33 monuments, 18 libraries, 1 archive, and 3 archaeological sites [15].

According to UNESCO, the number of damaged historical and cultural heritage sites by region in Ukraine is as follows: the Kharkiv region – 83; the Odesa region – 63; the Donetsk region – 133; the Kherson region – 35; the Chernihiv region – 22; the Kyiv region – 44; the Zaporizhzhia region – 27; the Lviv region – 15; the Dnipropetrovsk region – 4; the Luhansk region – 47; the Sumy region – 16; the Mykolaiv region – 15; the Vinnytsia region – 3; the Zhytomyr region – 3; the Poltava region – 1 [15].

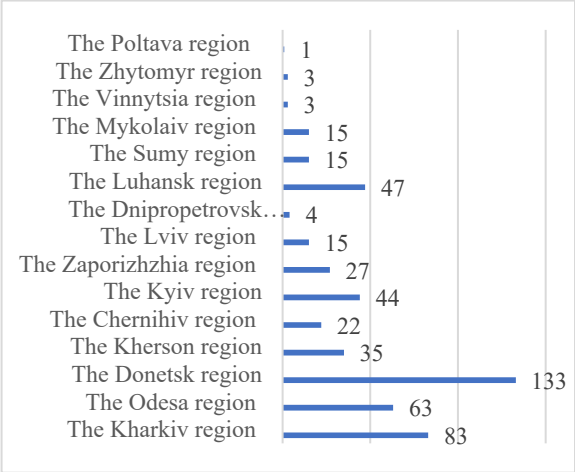

Figure 1: The number of damaged cultural heritage sites by region as a result of russian aggression, as of 26 November 2025.

On 25 January 2023, the historic centre of Odessa was inscribed on the UNESCO World Heritage List [14].

As of 25 January 2023, the area of the nominated site - the historic centre of Odessa – was 237.5 hectares, and the buffer zone covered 1,067.5 hectares. The main territory was delineated by Torgova street, Sadova street, Sviatoslava Karavanskogo (Zhukovskogo) street, Polsky Spusk street, and the adjacent seaport. It included Primorsky Boulevard, Teatralna Square, Deribasivska Street, Gogol Street, parts of Pastera Street, Preobrazhenska Street, Havanna Street, Yevropeiska (Katerynska) Street, Lanzheronivska Street, Nina Strokata (Bunina) Street, Richelievska Street, and Gretska Street. The buffer zone included parts of Balkivska, Staroportofrankovska, Panteleymonivska Streets, and Frantsuzky Boulevard [16].

In April 2024, UNESCO expanded the area of the nominated site of the historic centre of Odesa to 618.54 hectares. The buffer zone covers an area of 618.8 hectares. Currently, the area of the nominated site of the historic centre of Odesa is defined by Staroportofrankovska, Panteleymonivska, Leontovycha, Primorska, Balkivska streets, and Liderosovsky Boulevard. Odesa port is located in the buffer zone of the World Heritage Site [16].

There are 1,354 monuments and cultural heritage sites located within the territory of Odesa, including 42 monuments of national significance. Of these, 1,012 are situated within the boundaries of the Central Historical Area, encompassing 977 sites of architectural, urban planning, and historical heritage at both national and local levels.

An updated inventory list, which also includes newly identified heritage sites, was compiled during the revision of the scientific and project documentation titled ‘Historical and Architectural Reference Plan, Protection Zone Project, and Delimitation of Historical Areas of the City of Odesa’ (2021).

According to the UNESCO World Heritage Committee classification, the historic centre of Odesa is considered a ‘living historic city’– a category that reflects ongoing evolution under the influence of sociocultural and economic transformations. This dynamic nature complicates the assessment of environmental authenticity and the development of effective preservation policies [17].

Let us conduct a SWOT analysis of the tourism potential of Odessa's historic centre.

Table 1: SWOT analysis of the tourism potential of Odesa’s historic centre.

Strengths	Weaknesses
Rich cultural heritage Historical significance Developed infrastructure Cultural events	Infrastructure condition Insufficient marketing Security risks Transportation problems
Opportunities	Threats
International financing Tourist routes Digital marketing Eco-tourism	Military conflicts Economic crises Competition Climate change

A detailed analysis of Table 1 showed that the following were considered strengths: the presence of numerous architectural monuments and cultural complexes of national and international significance; the great importance of the historic centre of Odesa in the context of Ukrainian and European history; well-developed infrastructure in the historic centre of Odesa, including hotels, restaurants and entertainment venues; cultural events held regularly in the historic centre despite the full-scale invasion (festivals, exhibitions and other cultural events), which in turn attracts tourists; the following were identified as weaknesses: the state of infrastructure (some historic buildings are in need of restoration and maintenance); insufficient marketing, i.e. a lack of international advertising and promotion of the tourist opportunities offered by the historic centre of Odesa, even during the full-scale invasion; security risks, i.e. the current military aggression by the Russian Federation may deter potential tourists; transport problems, i.e. the poor quality of roads and public transport, which may make it inconvenient for tourists to comfortably reach the historic centre; the opportunities included: international financing

through grants and investments for the restoration and development of the infrastructure of the historic centre of Odesa; the development of new tourist routes and excursions that highlight the unique aspects of the historic centre and link the history of Odesa with the history of Ukraine and the world; the use of digital technologies to improve the marketing and promotion of tourist products; the introduction of environmental practices in the tourism industry to attract new categories of tourists; threats included: prolonged military aggression by the Russian Federation could seriously affect the security and attractiveness of the Odesa region; global economic problems could reduce the number of tourists (especially foreign tourists) willing to travel; competition, which consists in the fact that other historical centres in Ukraine and neighbouring countries may be more attractive to tourists; environmental problems related to climate change may affect the tourist appeal of Odesa.

This SWOT analysis shows that the historic centre of Odesa has strong tourism potential, which needs to be developed and improved.

The effectiveness of tourism policy is determined not only by managerial decisions at the central level and financial support, but also by the professional activities of local specialists. It is they who adapt the national management model to the regional context. Changes in the structure of specialised departments at the national level often lead to corresponding transformations in regional management mechanisms [18].

Within the framework of decentralisation, tourism policy in Ukraine is implemented through cooperation between public authorities and local self-government bodies at the national, regional and local levels. Regional and district state administrations play a crucial role in regional management. According to the Resolutions of the Cabinet of Ministers of Ukraine [19], [20], they are required to form specialised structural units for tourism and resorts. The type and status of such units are determined by the administration's management under the scope of their functional tasks.

Table 2: Mechanisms for public administration of the Odesa's tourism potential as a UNESCO historical and cultural heritage site.

Mechanism	Indicator
Institutional mechanisms	Involve establishing a clear and coordinated system of interaction between government agencies, public organisations, and private-sector stakeholders. Practical examples include the creation of a joint Odesa – UNESCO Heritage Management Office, the formation of interdepartmental coordination councils, and structured cooperation with NGOs engaged in heritage protection and sustainable tourism development.
Regulatory mechanisms	Ensure the effective development and preservation of Odesa's tourism potential through legally grounded governance tools. These include updated conservation rules, mandatory heritage impact assessments for new interventions, and development restrictions within the buffer zone to ensure compliance with UNESCO requirements
Financial and economic mechanisms	Refer to the mobilisation of financial resources from state, municipal, and international sources to support heritage conservation and tourism development. Relevant instruments include micro-grant programmes for façade restoration, municipal tax incentives, the UNESCO Emergency Heritage Fund, and EU-based funding opportunities such as Creative Europe.
Technological mechanisms	Focus on the integration of innovative digital tools to modernise public administration and enhance the effectiveness of heritage monitoring. These include drone-based mapping of damage, the creation of digital twins of historic areas, QR-coded tourist navigation systems, and the use of artificial intelligence for monitoring structural stability.
Communication mechanisms	Relate to the formation of an effective communication strategy between authorities, businesses, local communities, and international audiences. Important measures include wartime tourism safety protocols, multilingual crisis communication systems, and global awareness campaigns that highlight Odesa's resilience and cultural value.
Environmental (ecological) mechanisms	Aim to minimise the negative impact of tourism on cultural heritage and the urban environment. Priority measures include climate-risk monitoring, sustainable waste management practices, the introduction of energy-efficient solutions, and the development of heat-mitigating public spaces in the historic centre.

The structure of tourism administration in the Odessa region is represented, in particular, by the Department of International Cooperation, Culture and Marketing of the Odessa City Council (14, Yevropeiska Street). This executive body was established in accordance with the Law of Ukraine 'On Local Self-Government' [21] as the successor to several specialised structures, in particular the departments of culture, tourism, international cooperation and cultural heritage administration [22]-[25].

In its activities, the Department is guided by the Constitution of Ukraine, current legislation and regulations of local self-government bodies.

The Department has the following management structure: Department of Culture, Department of Tourism, Department of International Relations, Department for Cooperation with UNESCO and Cultural Heritage Protection [26].

The Department of International Cooperation, Culture and Marketing of the Odessa City Council, as a public authority, plays a crucial role in preserving the city's historical heritage.

The results of the study enabled the identification of key administrative mechanisms necessary for strengthening the management of Odesa's tourism potential as a UNESCO World Heritage site. These mechanisms are structured into six interconnected groups – institutional, regulatory, financial-economic, technological, communication, and environmental – each with specific indicators and practical applications relevant to wartime and post-war urban governance.(Table 2):

The combination of these mechanisms provides a comprehensive framework for improving public administration in the tourism sector. Their coordinated implementation will contribute to the preservation of Odesa's cultural heritage, the enhancement of its international visibility, and the sustainable development of tourism during wartime and throughout the post-war recovery period.

Thus, public management of Odesa's tourism potential as a UNESCO historical and cultural heritage site requires a comprehensive approach that combines institutional, regulatory, financial, technological, communication and environmental mechanisms. The implementation of these mechanisms will ensure the sustainable development of tourism, contribute to the preservation of historical and cultural heritage, enhance the city's international image and shape a competitive tourism strategy.

6 CONCLUSIONS

Odesa, as one of the leading tourist centres of the Black Sea region, possesses a favourable geographical location, a well-developed infrastructure, and a rich cultural heritage, further underscored by the inscription of its historic centre on the UNESCO World Heritage List. Nevertheless, the full-scale war has resulted in the destruction and damage of numerous cultural heritage sites, significantly undermining the city's tourism potential. The SWOT analysis carried out in this study confirms Odesa's considerable strengths - most notably its architectural landmarks and opportunities for attracting international funding for restoration and development. At the same time, the analysis highlights critical challenges such as infrastructure deterioration, insufficient marketing, persistent security risks, and transport difficulties, all of which constrain the city's ability to fully realise its tourism potential.

The findings of the research demonstrate that the sustainable development of Ukraine's tourism sector requires targeted investments in infrastructure modernisation, the strengthening of international partnerships, and the implementation of an effective marketing strategy to promote Odesa as a resilient cultural destination. These efforts must be supported by a governance framework that balances heritage preservation with contemporary tourism needs.

The conclusions of the study can be summarised as follows:

1) Odesa's UNESCO inscription confirms its global cultural value**,** yet wartime destruction exposes significant vulnerabilities that require urgent protective and recovery measures.
2) Municipal administrative capacity remains substantial**,** but stronger coordination, clearer institutional mandates, and deeper integration with UNESCO's governance instruments are needed to enhance effectiveness.
3) SWOT analysis reveals a strong heritage base and opportunities for international support, while also identifying key constraints, including infrastructure decline, weak promotion, and elevated security concerns.
4) The six-mechanism governance framework proposed in the study **-** institutional, regulatory, financial-economic, technological, communication, and environmental - offers a holistic foundation for aligning cultural heritage preservation with sustainable tourism development.

5) Research limitations include reliance on secondary data sources and restricted access to field-based assessments due to wartime conditions, which may affect the generalisability of findings.
6) Future research directions should explore the development of inclusive tourism products, the expansion of digital monitoring tools for heritage protection, and the modelling of post-war investment scenarios that could accelerate Odesa's cultural and tourism recovery.

In particular, additional analysis is required to formulate public administration strategies for inclusive tourism, ensuring that people with disabilities have full access to the historic centre of Odesa and its cultural assets.

Fractional Diffusion and Lévy Processes for Financial Derivative Pricing

Muhannad F. Al- Saadony and Nasir A. Naser

Keywords: Fractional Diffusion Equation, Fractional Brownian Motion (fBm), Heston Model, Lévy -Driven Stochastic Volatility Model.

Abstract: This paper develops a joint framework for the fractional diffusion equation driven by Lévy processes within a stochastic volatility setting, serving as an extension of the classical Heston model. We present the mathematical foundations of the model, emphasizing the dynamics of asset prices influenced simultaneously by fractional Brownian motion, which introduces long memory, and Lévy processes, which capture discontinuous jumps. The integration of these components allows the model to account for both fat-tailed and skewed return distributions. A Fourier transform representation is derived for option pricing under this generalized framework, and a Monte Carlo simulation scheme is proposed to numerically evaluate the associated stochastic integrals. Furthermore, maximum likelihood estimation (MLE) is employed for parameter estimation, and a systematic procedure for applying the proposed model to empirical financial data is outlined. The results demonstrate that the model provides a more realistic representation of market dynamics than classical approaches, particularly in explaining volatility clustering, extreme events, and the heavy-tailed nature of financial returns. Overall, the fractional diffusion–Lévy process framework offers a robust alternative for both theoretical research and practical applications in financial modeling.

1 INTRODUCTION

In recent decades, the modeling of financial markets has moved far beyond classical approaches such as the Black–Scholes framework. While these traditional models provided a foundation for option pricing and risk management, they often fail to capture crucial empirical features of asset returns, including volatility clustering, heavy tails, and sudden jumps. Among the more advanced models, the Heston stochastic volatility model has become widely used because it allows volatility itself to evolve as a random process rather than a fixed parameter.

Despite its popularity, the Heston model is built on standard Brownian motion. This assumption limits its ability to reflect the complex behavior observed in financial time series. In particular, empirical evidence shows that financial returns exhibit long-range dependence and persistent deviations from normality, features that cannot be adequately explained by Gaussian dynamics alone. These limitations have encouraged researchers to seek more flexible processes to drive asset prices [1].

Two promising directions have emerged. The first is fractional Brownian motion, which introduces a memory effect through the Hurst parameter, allowing the model to capture persistent or anti-persistent structures in returns. The second is the use of Lévy processes, which incorporate discontinuous jumps and are therefore able to reproduce extreme market events. Each approach adds realism, but combining them within a unified framework can provide a more comprehensive description of asset dynamics [1], [2].

The purpose of this paper is to extend the Heston model by embedding it within a fractional diffusion framework enriched by Lévy jumps. In doing so, we aim to build a model capable of reflecting both continuous price variations and sudden shocks, while maintaining mathematical tractability for applications in derivative pricing and risk management. We derive the theoretical formulation of the model, establish its option pricing representation through Fourier techniques, and implement Monte Carlo simulations to explore its numerical properties. Furthermore, we investigate parameter estimation using maximum likelihood methods and demonstrate applications to

real financial data, including the S\&P 500 index and the iShares Europe ETF [2].

This integration of fractional and jump dynamics represents a step toward more realistic financial modeling. By addressing both long memory and discontinuities, the proposed model has the potential to improve the accuracy of option valuation and the measurement of market risk.

Classical models in financial economics, such as the Black–Scholes framework, assume normally distributed returns and constant volatility. While elegant, these assumptions prevent the model from explaining well-documented empirical phenomena such as volatility clustering, heavy tails, and sudden jumps in asset prices. To overcome these shortcomings, Heston (1993) [2] introduced a stochastic volatility model in which the variance follows a mean-reverting process. This provided a more realistic description of option pricing and helped explain the volatility smile observed in practice.

Later extensions incorporated jump components to capture abrupt market shocks. Notable examples include the Merton jump-diffusion model and the Variance Gamma process, both of which improved the ability to model heavy-tailed and asymmetric return distributions. However, these models still lack the capacity to represent long-memory effects, which are frequently observed in high-frequency financial data.

To address persistence and long-range dependence, researchers turned to fractional Brownian motion (fBm), which incorporates memory through the Hurst exponent. At the same time, Lévy processes have gained popularity as they can jointly capture continuous price fluctuations and discontinuous jumps [3], [4].

In recent years, efforts have been made to integrate these two perspectives. For example, Aljethi (2022) developed a fractional Lévy framework for option pricing, supported by numerical sensitivity analysis. More recently, new studies derived fractional differential equations based on Lévy processes to better align theoretical models with empirical data (see Science Direct, 2023). A comprehensive survey published in 2024 highlights the advances of fractional Black–Scholes equations, emphasizing their ability to capture extreme events and nonlinear volatility patterns, along with analytical and numerical solution techniques (MDPI, 2024).

Nevertheless, despite this progress, a fully unified framework that systematically integrates fractional diffusion dynamics with Lévy-driven jumps for practical applications in option pricing and risk management is still underdeveloped.

The contribution of this paper lies in bridging this gap. We propose a generalized extension of the Heston model that integrates fractional Brownian motion with Lévy jumps into a single coherent diffusion framework. The approach provides a Fourier-based option pricing representation, a Monte Carlo simulation scheme, and a maximum likelihood estimation strategy for parameter calibration. Taken together, these innovations offer both theoretical novelty and empirical applicability.

2 MATHEMATICAL FORMULATION

The Heston model is described by the following system of stochastic differential equations (SDEs). The stock price S_t follows the SDE [2], [5]:

$$dS_t = \mu s_t dt + \sqrt{V_t} S_t dW_t^H. \quad (1)$$

Where μ: The drift rate of the stock price, V_t: The instantaneous variance (volatility squared) and W_t^H: A fractional Brownian motion for the stock.

And the variance V_t follows the SDE [5]:

$$dV_t = \theta(\mu_v - V_t)dt + \sigma_v \sqrt{V_t} dW_t^V. \quad (2)$$

Where θ is the rate of mean reversion, μ_v is the long-term mean level of volatility and σ_v is the volatility of volatility. The two Wiener processes W_t^H and W_t^V are correlated with a correlation coefficient ρ.

$$dW_t^H \, dW_t^V = \rho dt.$$

The variance process (2) was originally used by Cox, Ingersoll, and Ross (1985) for modeling the short term interest rate. It is defined by three parameters: θ, σ^2, and γ. In the context of stochastic volatility models they can be interpreted as the long term variance, the rate of mean reversion to the long term variance, and the volatility of variance, respectively, if we assume that the Wiener process in the Heston model is replaced by a Lévy process, the model can be generalized to incorporate jumps in addition to the continuous price movements. This leads to a more complex framework known as a Lévy-driven stochastic volatility model. We have the model:

When we introduce a Lévy process L_t to account for jumps, the stock price dynamics become [6]:

$$dS_t = \mu s_t dt + \sqrt{V_t} S_t dW_t^H + S_t dL_t. \quad (3)$$

Where dL_t: Represents the jump component of the stock price, modeled by a Lévy process, and the variance dynamics remain the same as in the original Heston model (2), where W_t^V can still be correlated with the Lévy process.

The empirical evidence suggests that the tail of the risk-neutral return distribution exhibits "fat" characteristics as maturity increases, traditionally interpreted as slow convergence to normality. This phenomenon has been attributed to persistent stochastic volatility processes. However, this modeling approach proposes an alternative perspective, positing that the observed data may indicate a violation of the conditions necessary for the central limit theorem, leading to a risk-neutral distribution that does not converge to normality [7], [8].

To explain the fat tails in the return distribution, the model introduces a parameter αα, which controls tail thickness relative to the central mass. In the Black-Scholes model, Brownian motion represents a special case of the αα-stable class with $\alpha = 2$. To generate fat tails, α must be less than 2, but this results in infinite variance for log returns, raising concerns about the existence of a martingale measure and the finiteness of option values [7], [9].

To address this issue, the model incorporates a second parameter, β, which ranges from -1 to 1, governing the skewness of the distribution. The key innovation is focusing on the case where $\beta = -1$, inducing maximum negative skewness in the Lévy α-stable motion. Under this condition, it is proven that all conditional moments for the index level exist, despite the log return having infinite variance. This specification effectively captures the highly skewed nature of the implied density for log returns, a characteristic that neither Brownian motion nor symmetric Lévy αα-stable motion can adequately represent [10].

The standardized Lévy αα-stable motion, denoted as $L(\alpha, \beta)$, is martingale and serves as a potential driver for the risk-neutral process of discounted index levels. As a Lévy process, it possesses independent and stationary increments, with the increment $dL(\alpha, \beta)$ following an αα-stable distribution characterized by zero drift, a dispersion of $dt(1/\alpha)$, and a skew parameter β. The fractional Brownian motion unlike standard Brownian motion, its characterized by Hurst parameter H, which influences the correlation structure of the increments.

For $H \in (0,1)$ [1], [3]:

- if $H = 0.5$, it reduces to standard Brownian motion;
- if $H > 0.5$, the process exhibits persistent behavior (long-rang dependence);
- if $H < 0.5$, it exhibits anti-persistent behavior.

3 LÉVY PROCESS

A Lévy process has independent and stationary increments, allowing for both continuous changes (like Brownian motion) and discrete jumps. The characteristics of the Lévy process can be defined by its characteristic function or Lévy-Khintchine representation [11], [12]:

$$\phi(u,t) = E\left[e^{iuL_t}\right] = \exp\left(i\delta u + \int e^{iux} - 1 - iux.1_{|x|<1}vdx\right), \quad (4)$$

where δ: Drift term of the Lévy process and vdx: Lévy measure, which describes the jump intensity and distribution. In a risk-neutral framework, replace μ with the risk-free rate r. However, if we consider instead of fractional Brownian motion, we need to adjust our understanding of the stochastic calculus involved. To derive the solution for S_t, we can use the Ito formula adapted for fractional Brownian motion, the stochastic differential equation (SDE) (3) [13].

$$dS_t = \mu s_t dt + \sqrt{V_t} S_t dW_t^H + S_t dL_t.$$

To solve this equation, we can use Itos formula for a function $f(t, S_t)$, for some function f, then [13]-[15]:

$$df(t,S_t) = \left(\frac{\partial f}{\partial t} + \frac{\partial f}{\partial x}\mu S_t + \frac{1}{2}\frac{\partial^2 f}{\partial x^2}\sigma^2 S_t^2 + jump\ terms\right)dt + \frac{\partial f}{\partial x}\sigma S_t dW_t + \frac{\partial f}{\partial x} S_t dL_t. \quad (5)$$

In our case. Let's define $f(t, S_t) = \log S_t$. Thus, we can express S_t in terms of $f(t, S_t)$.

We have, $\frac{\partial f}{\partial t} = 0$ (since f does not explicitly depend on t), $\frac{\partial f}{\partial x} = \frac{1}{S_t}$, and $\frac{\partial^2 f}{\partial x^2} = \frac{1}{S_t^2}$.

Substituting these derivatives into the Fractional Ito formula gives

$$df(t,S_t) = \left(\mu - \frac{1}{2}V_t\right)dt + \sqrt{V_t}dW_t^H + dL_t. \quad (6)$$

Integrating both sides from 0 to t:

$$\log S_t - \log S_0 = \int_0^t \left(\mu - \frac{1}{2}V_s\right)ds + \int_0^t \sqrt{V_s}dW_s^H + \int_0^t dL_s,$$

$$\log S_t = \log S_0 + \int_0^t \left(\mu - \frac{1}{2}V_t\right) ds + \int_0^t \sqrt{V_s} dW_s^H + \int_0^t dL_s.$$

Exponentiating both sides yields

$$S_t = S_0 \exp\left(\int_0^t \left(\mu - \frac{1}{2}V_s\right) ds + \int_0^t \sqrt{V_s} dW_s^H + \int_0^t dL_s\right),$$

$$S_t = S_0 \exp\left(\mu t - \frac{1}{2}\int_0^t V_s\, ds + \int_0^t \sqrt{V_s} dW_s^H + L_t\right), \quad (7)$$

To solve the integral $\int_0^t \sqrt{V_s} dW_s^H$, using numerical methods such as Monte Carlo simulations.

3.1 Define the Simulation Parameters

To perform the numerical simulation of the proposed fractional diffusion–Lévy model, the following key parameters are defined:

- Time Interval: $[0, t]$;
- Number of Simulations: $N\ (e.g., 10{,}000)$;
- Time Steps: $M\ (e.g., 100)$;
- Hurst Parameter: $H\ (e.g., 0.7)$;
- Final Time: $t\ (e.g., 1.0)$;
- Numerical Simulation.

3.1.1 Discretization of Time

The time interval is discretized into Msteps:

$$\Delta t = \frac{t}{M}.$$

Let $t_k = k \cdot \Delta t \ \ for\ k = 0,1, \ldots, M.$

3.1.2 Simulating Fractional Brownian Motion

Fractional Brownian motion is generated using Cholesky decomposition of the covariance matrix, ensuring the correct correlation structure of the increments.

3.1.3 Simulating V_s

The variance V_t may be assumed deterministic ($V_t = \sigma^2$) or simulated as a stochastic process. For example, it can follow a geometric Brownian motion or the Heston stochastic variance dynamics.

3.2 Monte Carlo Simulation Algorithm

The stochastic integral $\int_0^t \sqrt{V_s}\, dW_s^H$ is approximated numerically using the trapezoidal rule. Monte Carlo simulations are conducted with $N = 10{,}000$ repetitions, each discretized into $M = 100$ time steps. The mean and variance of the simulated integrals are then computed to obtain statistical properties of the process.

4 ESTIMATE THE PARAMETERS OF THE HESTON MODEL

To estimate the parameters of the Heston model with fractional Brownian motion using Quasi-Maximum Likelihood Estimation (QMLE), the Table 1 shows the estimated parameters of the model, the QMLE, also known as pseudo-maximum likelihood estimation, is a statistical technique employed to estimate model parameters when the true likelihood function is either unknown or computationally intractable. Rather than maximizing the true likelihood function, QMLE optimizes a "quasi-likelihood" function, which is constructed under the assumption of a specific distribution that may differ from the actual data-generating process. Despite the potential divergence between the assumed and true distributions, QMLE frequently produces parameter estimates that are consistent and asymptotically efficient under certain regularity conditions. The method relies on an assumed likelihood function based on a given distribution (e.g., normal or Gaussian), even when the true underlying distribution of the data does not conform to this assumption. Consistency of the parameter estimates is maintained provided the quasi-likelihood accurately captures the mean and variance structure of the data. Furthermore, QMLE achieves asymptotic efficiency if the quasi-likelihood coincides with the true likelihood; otherwise, efficiency may be diminished, though consistency remains intact under mild assumptions. QMLE is extensively applied in econometrics, time series analysis, and generalized linear models, particularly in scenarios where the true error distribution is unknown or complex. Its ability to yield reliable estimates despite distributional misspecification makes it a valuable tool in statistical modeling and inference, we will follow a systematic approach [16], [17]. This includes defining the model, deriving the likelihood function, and then estimating the parameters. To apply QMLE, we need to discretize the model. Assume we observe S_t at discrete time $t_0, t_1, \ldots, t_n$. We define the time increments as $\Delta t = t_{i+1} - t_i$, the discretized stock price can be approximated as

$$S_{t_{i+1}} = S_{t_i}\left(1 + \mu\Delta t + \sqrt{V_t}\,\Delta W_{t_i}^H + \Delta L_{t_i}\right). \quad (8)$$

Where $\Delta W_{t_i}^H$ is the increment of fractional Brownian motion And variance.

$$V_{t_{i+1}} = V_{t_i} + \theta\left(\mu_V - V_{t_i}\right)\Delta t + \sigma_V\sqrt{V_{t_i}}\Delta W_i. \quad (9)$$

The MLE is constructed based on the joint distribution of observed data, we can express the log-likelihood as follows. [27] The log returns can be computed as

$$\begin{aligned} R_t &= \log S_t - \log S_{t-1} = \log\frac{S_{t_{i+1}}}{S_{t_i}} \\ &= \left(\mu - \frac{1}{2}V_t\right)dt + \sqrt{V}_t\, W_i^H + dL_t. \end{aligned} \quad (10)$$

Assuming the increments of R_t are approximately normality distributed, the log-likelihood function L can be expressed as:

$$L\,(\mu, \theta, \mu_V, \sigma_V|R) = \sum_{i=0}^{n-1} f(\,R_t|\,\mu, V_{t_i}), \quad (11)$$

where $f(R_i|\mu, V_{t_i})$ is the probability density function of the log-normal distribution, we will take the log-likelihood function becomes [17], [18]:

$$\ell\,(\mu, \theta, \mu_V, \sigma_V|R) = \sum_{i=0}^{n-1}\left[-\frac{1}{2}\log\left(2\pi\hat{V}_t\right) - \frac{(\,R_t - \mu)^2}{2\hat{V}_t}\right], \quad (12)$$

where $\hat{V}_t$ is the estimated volatility at time t. To estimate $\hat{V}_t$, we can use realized volatility which is computed from the observed return.

$$\hat{V}_t = \frac{1}{\Delta t}\sum_{i=1}^{k}(R_{t-i} - \bar{R})^2. \quad (13)$$

Where, Δt is time interval and $\bar{R}$ its mean return over the interval. For fractional Brownian motion, the volatility can be modeled as:

$$\hat{V}_t = V_0 e^{\theta t + \sigma W_t^H}. \quad (14)$$

To find the parameters estimates, maximize log-likelihood function with respect to the parameters $\mu, \theta, \mu_v, \sigma_v$:

$$\left(\hat{\mu}, \hat{\theta}, \hat{\mu}_v, \hat{\sigma}_v\right) = \arg max_{\mu,\theta,\mu_v,\sigma_v} L(\,\mu, \theta, \mu_v, \sigma_v\,). \quad (15)$$

This maximization can be performed using numerical optimization techniques. We will use the Newton-Raphson method. To apply the Newton-Raphson method we will the gradient of the log-likelihood function with respect to each parameter

$$\frac{\partial L}{\partial \mu} = \sum_{t=1}^{n}\frac{(R_t - \mu)}{\hat{V}_t}. \quad (16)$$

And derivative with respect to θ we need requires differentiating with respect to the estimated volatility, which itself is a function of θ. Assuming $\hat{V}_t$ depends on θ

$$\frac{\partial L}{\partial \theta} = \sum_{t=1}^{n}\left[-\frac{1}{2}\frac{\partial \hat{V}_t}{\partial \theta} - \frac{(R_t - \mu)}{2\hat{V}_t^2}\frac{\partial \hat{V}_t}{\partial \theta}\right], \quad (17)$$

μ_V and σ_v. These derivatives will also depend on the specific formulation of $\hat{V}_t$. Now, we calculate the Hessian matrix consists of the second derivatives of the log-likelihood function [19], [18]:

$$H = \begin{bmatrix} \frac{\partial^2 L}{\partial \mu^2} & \frac{\partial^2 L}{\partial \mu \partial \theta} & \frac{\partial^2 L}{\partial \mu \partial \mu_v} & \frac{\partial^2 L}{\partial \mu \partial \sigma_v} \\ \frac{\partial^2 L}{\partial \theta \partial \mu} & \frac{\partial^2 L}{\partial \theta^2} & \frac{\partial^2 L}{\partial \theta \partial \mu_v} & \frac{\partial^2 L}{\partial \theta \partial \sigma_v} \\ \frac{\partial^2 L}{\partial \mu_v \partial \mu} & \frac{\partial^2 L}{\partial \mu_v \partial \theta} & \frac{\partial^2 L}{\partial \mu_v^2} & \frac{\partial^2 L}{\partial \mu_v \partial \sigma_v} \\ \frac{\partial^2 L}{\partial \sigma_v \partial \mu} & \frac{\partial^2 L}{\partial \sigma_v \partial \theta} & \frac{\partial^2 L}{\partial \sigma_v \partial \mu_v} & \frac{\partial^2 L}{\partial \sigma_v^2} \end{bmatrix}.$$

Thin we update parameters using Newton-Raphson method (N-R), the N-R update rule is given by

$$\theta^{(k+1)} = \theta^{(k)} - H^{-1}\nabla L\left(\theta^{(k)}\right). \quad (18)$$

Where, $\theta^{(k)}$ is the parameter vector at iteration k, ∇L is the gradient vector and H^{-1} is the inverse of the Hessian matrix, we can write the iterative algorithm.

1) Initialize: set initial guesses for $\mu, \theta, \mu_v, \sigma_v$.
2) Compute log-likelihood: calculate $L\,(\mu, \theta, \mu_v, \sigma_v)$
3) Calculate Gradient and Hessian: compute the gradient and Hessian matrix.
4) Update parameters: use the newton-Raphson update rule.
5) Check Convergence: if the change in parameters is below a certain threshold, stop; otherwise, return to step 2.

Given the parameters, we can analyze the conditional moments of the returns. For the Lévy process with $\alpha < 2$ and $\beta = -1$, the moments can be expressed as follows [20], [21], [17]:

$$E[R_t|F_{t-1}] = \mu + \theta(\mu_v - V_{t-1}).$$

and

$$Var(R_t|F_{t-1}) = V_{t-1}.$$

The parameters were estimated using S&P 500 index data using the maximum likelihood method for

the period from 1/1/2007 to 12/31/2013 and the results are as shown below:

Table 1: Represents the values of the parameters estimating using the QMLE method.

Parameters	Sample size (n)
	n=1000
μ	-0.09308951
θ	0.09999268
μ_v	0.20022537
σ_v	0.1000030

The parameter μ represents the drift term in the returns equation, which captures the average growth or decline rate of the asset's log returns over time. A negative value ($\mu = -0.09308951$) suggests that the returns exhibit a downward trend on average, indicating that the asset has a negative expected return over the sample period. This could reflect a bearish market trend dataset where the returns are biased downward, this result is based on real data (S&P500), it might indicate a period of market decline or other structural factors affecting in the returns. The parameter θ represents the speed at which the variance (V) reverts to its long-term mean (μ_v). A value of $\theta = 0.09999268$ indicates that the variance tends to revert to its equilibrium level $\mu_v = 0.20022537$ at a moderate rate, the mean reversion speed is relatively low ($\theta \approx 0.1$), meaning that the variance process is persistent and takes time to return to its long-term mean deviations. This is consistent with the behavior of volatility in financial markets, where high volatility tends to persist for extended periods before reverting to normal levels. The parameter μ_v represents the long-term average level of variance (V), a value of $\mu_v = 0.20022537$ suggests the variance fluctuates around this level over the long run. This value is reasonable for financial data, as it reflects a moderate level of variance, which is typical for daily returns in equity markets. In the context of the S&P500, this indicates that the typical daily variance of returns is around 0.2, which corresponds to standard deviation of approximately $\sqrt{0.2} \approx o.447$ or 44.7%. the parameter σ_v represents the volatility of the variance process, which measures how much the variance (V) fluctuates over time, a value of $\sigma_v = 0.100003$ suggests that the variance process is sufficiently stochastic fluctuations. This value indicates that the variance process is sufficiently stochastic, meaning that variance (V) is not constant but fluctuates over time due to random shocks, the volatility of variance (σ_v) is crucial for capturing realistic market dynamics, as it reflects the variability of volatility itself, which is often observed in financial markets. The results demonstrate that the stochastic volatility model provides a reasonable representation of the dynamics of returns and variance for the given sample size $(n = 1000)$. The estimated parameters $(\mu, \theta, \mu_v, \sigma_v)$are consistent with theoretical expectations and provide insights into the behavior of financial data, particularly the S&P 500 index.

5 THE FRACTIONAL DIFFUSION EQUATION WITH LÉVY PROCESS

The core fractional diffusion equation for the modified Heston model can be expressed as [6], [21], [22], [23]:

$$\frac{\partial^\beta V}{\partial t^\beta} = D\,\frac{\partial^\alpha V}{\partial x^\alpha} - rV + L_t, \quad (19)$$

Where V is option price or value of the underlying asset, D is diffusion coefficient, $\frac{\partial^\beta V}{\partial t^\beta}$ is fractional time derivative of order β, $\frac{\partial^\alpha V}{\partial x^\alpha}$ is fractional spatial derivative of order α, r is Risk-free interest rate and L_t is the jump term modeled as Lévy process [3], [30], [31], to solve this equation we will use the Fourier transform of a function $V(x,t)$ is defined as:

$$\hat{V}(k,t) = F\{V(x,,t)\} = \int_{-\infty}^{\infty} V(x,t)\, e^{-ikx} dx, \quad (20)$$

and the inverse Fourier transform is given by:

$$V(x,t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \hat{V}(k,t)\, e^{-kx} dk. \quad (21)$$

Applying the Fourier transform to both sides of the fractional diffusion equation gives [8], [24], [25]:

$$F\left\{\frac{\partial^\beta V(x,t)}{\partial t^\beta}\right\} = D\,F\left\{\frac{\partial^\alpha V(x,t)}{\partial x^\alpha}\right\} - r\,F\{V(x,,t)\} + F\{L_t\},$$

by using the properties of the Fourier transform, we have. Using the fractional derivative in the Fourier domain, we get

$$F\left\{\frac{\partial^\beta V(x,t)}{\partial t^\beta}\right\} = (iw)^\beta \hat{V}(k,,t),$$

where w is the frequency variable in the time domain

$$F\left\{\frac{\partial^\alpha V(x,t)}{\partial x^\alpha}\right\} = (ik)^\alpha \hat{V}(k,,t).$$

Substituting these transforms into the fractional diffusion equation yields:

$$(iw)^{\beta}\hat{V}(k,,t) = D\,(ik)^{\alpha}\hat{V}(k,,t) - r\hat{V}(k,,t) + \hat{L}_t. \quad (22)$$

Rearranging the equation gives.

$$\hat{V}(k,,t)\left(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,\right) + r\hat{V}(k,,t) = \hat{L}_t.$$

$$\hat{V}(k,,t) = \frac{\hat{L}_t}{(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,) + r}. \quad (23)$$

We have L_t is a Lévy process, its Fourier transform can be expressed as

$$\hat{L}_t = \emptyset L_t = \int_{-\infty}^{\infty} L_t\, e^{-iwt} dt,$$

to solve this equation, we can use the characteristic function of a Lévy process, which is given by

$$\emptyset L_t = e^{\int_0^t \Psi(w) ds},$$

where $\Psi(w)$ is the characteristic exponent of the Lévy process (Lévy-Khintchine formula) [31], [32]:

$$\Psi(w) = i\mu w - \frac{1}{2}\sigma^2 w^2 + \int_{-\infty}^{\infty} e^{iwx} - 1 - iwx1_{|x|<1}\, vdx, \quad (24)$$

where μ is drift parameter, $\sigma^2$is the diffusion parameter, and vdx is the Lévy measure.

Substituting the characteristic exponent into the Fourier transform expression, we get [4], [26]:

$$\hat{L}_t = \emptyset L_t = e^{\int_0^t \Psi(w) ds} = e^{t\Psi(w)}. \quad (25)$$

Now, to find the final solution of $V(x,t)$, we need to take the inverse Fourier transform

$$V(x,t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \frac{e^{t\Psi(w)}}{(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,) + r}\, e^{ikx} dk.$$

The poles of the integrand are the solutions to the

$$\left(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,\right) + r = 0,$$

let's denote the solutions as $z_1, z_2, \ldots, z_n$. These will be the poles of the integrand, the residue of the integrand at poles z_k is given by [27]:

$$Res\frac{e^{t\Psi(w)}}{(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,) + r}, z_k = \lim_{w \to z_k} \frac{e^{t\Psi(w)}}{(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,) + r}.$$

To compute the residue, we need to evaluate the limit and the derivative of the numerator and denominator at the poles z_k

The derivative of the numerator is

$$\frac{d}{dw} e^{t\Psi(w)} = t\, e^{t\Psi(w)}\, \Psi'(w).$$

The derivative of the denominator is

$$\frac{d}{dw}\left[\left(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,\right) + r\right] = i^{\beta}\beta(iw)^{\beta-1} - iD^{\alpha}k^{\alpha}(ik)^{\alpha-1}.$$

Then, we substituting these derivatives into residue formula, we get [28], [29]:

$$Res\frac{e^{t\Psi(w)}}{(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,) + r}, z_k = \frac{t\, e^{t\Psi(z_k)}\, \Psi'(z_k)}{i^{\beta}\beta z_k^{\beta-1} - iD^{\alpha}k^{\alpha}(iz_k)^{\alpha-1}}.$$

By using the residue theorem, we have

$$V(x,t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \frac{e^{t\Psi(w)}}{(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,) + r}\, e^{ikx} dk$$

$$= 2\pi \sum_{k=1}^{n} Res\frac{e^{t\Psi(w)}}{(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,) + r}, z_k\, e^{ikx},$$

$$V(x,t) = 2\pi \sum_{k-1}^{n} \frac{t\, e^{t\Psi(z_k)}\, \Psi'(z_k)}{i^{\beta}\beta z_k^{\beta-1} - iD^{\alpha}k^{\alpha}(iz_k)^{\alpha-1}} e^{ikx}. \quad (26)$$

The final solution for $V(x,t)$ is expressed in terms of the residues and the pole locations $z_1, z_2, \ldots, z_n$, which depend on the model parameters μ, σ^2, the Lévy measure $\nu(dx)$, the diffusion coefficient D, the risk-free rate r, and the orders of the fractional derivatives α and β. To further simplify the solution, we can express the residues in terms of the model parameters. This may involve solving the equation $\left(\,(iw)^{\beta} - D\,(ik)^{\alpha}\,\right) + r = 0$ to find the pole locations z_k, and then evaluating the residue formula at these points.

6 APPLICATION OF FRACTIONAL DIFFUSION EQUATION WITH LÉVY PROCESSES TO S&P 500 AND ISHARES EUROPE ETF (IEV)

The application of the fractional diffusion equation with Lévy processes to financial markets such as the S&P 500 and iShares Europe ETF (IEV) involves extending classical financial models (like the Heston model) to better represent real-world market behaviors. Detailed insights into the concepts, methodology, and simulations discussed in the paper.

6.1 Fractional Diffusion Equation with Lévy Processes

The classical Heston model employs stochastic volatility driven by Brownian motion, assuming continuous price movements. However, this approach

is limited in its ability to capture several important features of real financial markets, including volatility clustering, fat tails, and sudden jumps.

Volatility clustering refers to alternating periods of high and low volatility, while fat tails describe the presence of extreme movements in asset returns. In addition, financial markets often exhibit jumps, which correspond to abrupt price changes caused by macroeconomic events or unexpected news.

To address these limitations, the fractional diffusion equation with Lévy processes extends the classical framework in two key ways. First, it incorporates fractional Brownian motion to model long-range dependencies and memory effects in price dynamics. Second, it introduces Lévy processes to capture discontinuities, skewness, and heavy-tailed behavior in return distributions.

6.2 Application to Financial Markets

6.2.1 S&P 500 Market Dynamics

The S&P 500, a benchmark index for U.S. equities, exhibits several well-known stylized facts of financial markets, including high liquidity, volatility clustering, fat-tailed return distributions, and sudden price jumps driven by macroeconomic events.

Volatility clustering is reflected in alternating periods of high and low volatility, while fat tails indicate the presence of extreme return values. In addition, jumps represent abrupt and significant price changes caused by unexpected news or economic shocks.

These characteristics are illustrated in Figure 1, which demonstrates fat tails in the return distribution, skewness capturing asymmetry in price movements, and volatility clustering over time.

The fractional diffusion equation with Lévy processes is particularly suitable for modeling such dynamics, as it incorporates both stochastic volatility and jump behavior. Specifically, stochastic volatility is modeled using fractional Brownian motion to capture long-range dependence, while Lévy processes are used to represent discontinuities and sudden shocks in asset prices.

Using R statistical software, the model integrates stochastic volatility driven by fractional Brownian motion and jump intensity governed by Lévy processes. In addition, risk-neutral return distributions are considered, which are essential for pricing financial derivatives such as options.

The simulation results confirm the presence of fat tails, skewness, and volatility clustering, thereby demonstrating the capability of the proposed model to capture key features of real financial market behavior.

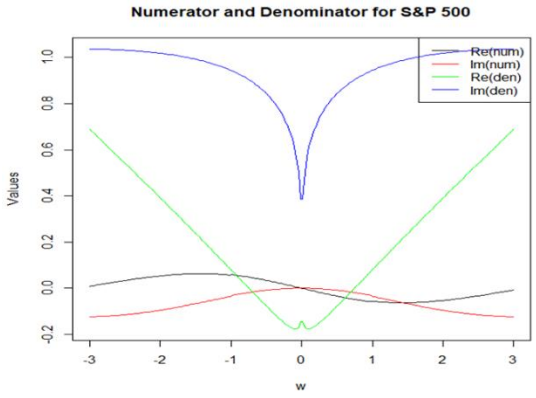

Figure 1: Reference: R statistical software by the researcher.

6.2.2 iShares Europe ETF (IEV) Market Dynamics

The IEV tracks a broad range of European equities and is influenced by various regional factors, including macroeconomic conditions such as economic growth, inflation, and interest rates, as well as political events, including elections, geopolitical tensions, and regulatory changes.

Compared to the S&P 500, the IEV exhibits distinct market characteristics. As illustrated in Figure 2, the level of volatility is generally lower and more regionally constrained than the global volatility observed in U.S. markets. Although fat-tailed behavior is still present, extreme return movements occur less frequently. In addition, price jumps are typically associated with regional shocks, such as major political events (e.g., Brexit), rather than global macroeconomic disruptions.

The fractional diffusion equation with Lévy processes is well suited to modeling these dynamics, as it accounts for both long-range dependence and discontinuities in asset prices. In this framework, stochastic volatility is modeled using fractional Brownian motion, while Lévy processes capture jump behavior, albeit with lower intensity compared to the S&P 500.

To further evaluate the model, numerical simulations were conducted using R statistical software. The simulation incorporates stochastic volatility driven by fractional Brownian motion and jump components governed by Lévy processes, while also considering risk-neutral dynamics relevant for pricing financial derivatives.

The results, presented in Figure 2, indicate moderate fat tails, reflecting less frequent extreme movements in European markets. Volatility clustering is also observed, although it is more stable and less pronounced than in the S&P 500. Furthermore, the lower intensity of jumps suggests relatively smoother market dynamics compared to U.S. equities.

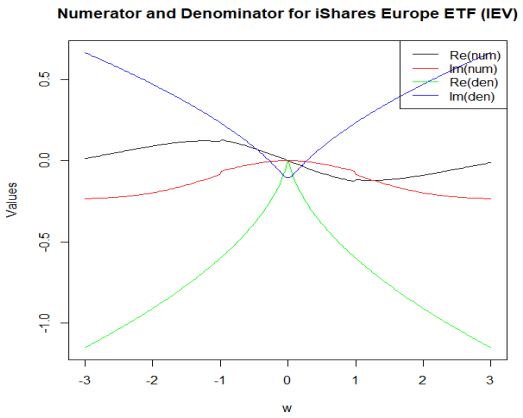

Figure 2: Reference: R statistical software by the researcher.

6.3 Numerical Simulation and Results

The S&P 500 index over the period from January 1, 2014, to December 31, 2019, is considered for analysis.

Figure 3 illustrates the behavior of the numerator and denominator functions within the framework of the fractional diffusion equation with Lévy processes applied to the S&P 500 index. Specifically, it presents the real and imaginary components of both functions over the range of w values from −3 to 3.

The real and imaginary parts of the numerator function are represented by the blue and red lines, respectively, while the green and purple lines correspond to the real and imaginary parts of the denominator function. The results reveal smooth and continuous behavior of both functions across the specified range.

Notably, neither the numerator nor the denominator functions exhibit abrupt changes or discontinuities. This suggests that, within the considered representation, the model produces a continuous approximation of the underlying financial dynamics rather than explicitly capturing jump behavior.

Overall, the plot provides insight into the mathematical properties of the fractional diffusion equation with Lévy processes and its application to financial time series data, highlighting its ability to represent stable and continuous dynamics in the S&P 500 index.

7 CONCLUSIONS

This paper has presented a novel framework that integrates fractional diffusion dynamics with Lévy-driven jumps, extending the classical Heston model to better capture the complexities of financial markets. By embedding fractional Brownian motion within a stochastic volatility setting, we have addressed significant empirical features such as volatility clustering, heavy tails, and sudden market jumps, which are often inadequately modeled by traditional approaches. The incorporation of fractional Brownian motion introduces long-memory effects, allowing the model to reflect persistent behavior observed in financial time series. This is crucial for accurately modeling asset prices, as it acknowledges the reality of market dynamics where past price movements influence future behavior. Moreover, the use of Lévy processes enables the model to account for discontinuous jumps, thereby providing a more realistic representation of extreme events that frequently occur in financial markets. Through the derivation of a Fourier transform representation for option pricing, we have established a robust mathematical foundation for the proposed model. The Monte Carlo simulation scheme further enhances the practical applicability of our approach, allowing for the numerical evaluation of complex stochastic integrals. Additionally, the implementation of maximum likelihood estimation (MLE) for parameter calibration ensures that our model can be

effectively tailored to fit empirical financial data, enhancing its relevance for practitioners. The application of the model to real financial data, including the S&P 500 index and the iShares Europe ETF, demonstrates its potential to improve the accuracy of option valuation and the measurement of market risk. The results suggest that our framework provides a more comprehensive understanding of market dynamics compared to classical models, particularly in explaining the observed phenomena of volatility clustering and the heavy-tailed nature of financial returns. Despite the advancements presented in this paper, it is essential to acknowledge the limitations and areas for future research. While our model offers a significant step forward, further exploration is needed to refine the integration of fractional dynamics and jump processes. Future work could focus on extending the framework to incorporate additional market factors, such as interest rates and macroeconomic indicators, which could further enhance predictive capabilities. Moreover, the robustness of the model across different asset classes and market conditions should be investigated. Conducting stress tests and scenario analyses will be vital in assessing the model's performance under extreme market conditions, thus ensuring its applicability in risk management and derivative pricing. In conclusion, the fractional diffusion–Lévy process framework proposed in this paper represents a meaningful advancement in financial modeling. By addressing both long memory and discontinuities, the model not only enhances theoretical understanding but also provides practical tools for market practitioners. As financial markets continue to evolve, the need for sophisticated models that can accurately capture their complexities becomes increasingly critical. This research contributes to that objective, paving the way for future innovations in financial modeling and analysis.

Keywords: Document Request System, Online Payment, Higher Education, Digital Transformation, Secure QR Verification.

Abstract: The manual nature of requesting documents in paper form and over-the-counter payments has continued to exist in many higher education institutions, thus creating long lines, misplaced forms, delays in processing, and exposure to document tampering. To counter these issues, this study designed and developed NU DROP, a secure, web-based system that uniquely integrates document requests with online payment processing in a single platform tailored for Higher Education Institutions (HEI). The system allows for online document requests, status tracking in real time, and multi-channel payments (with online facilities, such as GCash and PayMaya, and over the counter via SM Bills). The development process followed the Scrum methodology and took into consideration interviews, field observation, and document analysis. Key contributions include: 1) an end-to-end process unifying the registrar-accounting-user workflows; 2) QR-based verification to detect tampering of issued PDFs using server-validated cryptographic hashes; 3) inclusive payment options catering to both e-wallet and cash-based users; and 4) role-based dashboards with audit logging for transparency and accountability. Early stakeholder walkthroughs show evidence of better turnaround time visibility, less manual follow-up, and more consistent recordkeeping.

1 INTRODUCTION

Document processing in many higher education institutions remains a manual task, which sometimes manifests as long queues, misplaced forms, limited office hours, and insecure verifications of official records [1], [2]. Such problems tend to burden administrative staff and decrease user satisfaction with the services provided by students, alumni, and faculty [3]. In certain institutions, requestors will fill in paper forms, pay at cashier windows, and return receipts to other offices for validation – this tiresome process not only makes it error-prone but also difficult to track status, thereby further delaying service delivery [4].

Hence, this study introduces NU DROP, which totally digitizes the entire document request and payment workflow via a secure web-based platform [2]. This fully certified online submission facilitates online payment on any of the given inclusive payment channels and gives a tracking tool to monitor request status in real time. The administrator manages and monitors requests via a central dashboard for user's requests, payment validation, and document issuance. And to preserve the authenticity of documents issued by NU DROP, an instant on-the-spot validation of issued documents is accomplished through a QR-based tamper-resistant verification mechanism.

The NU DROP system stands apart from existing systems in other universities in three major aspects: first, the integration of registrar and accounting workflows to minimize delays due to reconciliation; second, the provision for payment through an e-wallet as well as over the counter; and third, an approach to document verification that resists tampering, which essentially employs QR-linked cryptographic hashes.

The remainder of this paper is organized as follows. Section 2 presents the related works and gaps in existing systems for document requests and payments. Section 4 outlines the methodology, including the research design, data collection, and system development process. Section 5 describes the features and technical implementation of the NU DROP system. Section 5 discusses the results and contributions, while Section 6 provides the conclusion and recommendations for future work.

2 RELATED WORK AND GAP

Many universities have adopted online requests and payment portals, though these typically provide only basic features such as request submission, limited tracking, and partial payment integration [2]. Significant gaps remain [5], including administrative fragmentation where registrar and accounting departments operate separate systems requiring manual reconciliation, a lack of payment inclusion for cash-preferred users without access to cards or banks, and weak authenticity assurance since issued documents are still prone to tampering when only basic watermarks are used.

NU DROP gets rid of these gaps by unifying interdepartmental workflows, providing inclusive multi-channel payments, and a QR verification component embedded with tamper-resistant features. Research on electronic payment systems in Philippine HEIs [6] confirms the importance of offering diverse payment options to accommodate different user preferences.

3 OBJECTIVES

The primary objective of this study is to develop and organize a secure-based installation system that is user-centric, facilitates the request and payment of documents while preserving the authenticity of the issued records.

Specifically, this study sought to address the following objectives:

- To enable web-based request submission with status tracking and notifications.
- To facilitate inclusive secure payment options, i.e., GCash, PayMaya, and SM Bills.
- To apply QR-based tamper detection for issued documents.
- To develop a dashboard for registrar, accounting, and admin roles will also have audit logging features.

The contributions of this study are fourfold. First, the entire process has been automated, significantly reducing reliance on manual procedures. Second, the system provides greater integration of payments by accommodating both electronic and cash-preferred customers. Third, a tamper-proof QR verification mechanism is implemented to ensure the authenticity of issued documents. Finally, the study presents a realistic yet general architectural model that can be adopted and adapted within higher education contexts.

4 METHODS

This section outlines the methodological approach undertaken in the design and development of the NU DROP system. It describes the process of developing the system using SCRUM.

4.1 Scrum Model

Using Scrum Methodology [7] encourages continuous iterative development and the constant engagement of all relevant stakeholders. Sprint planning, backlog preparation, execution, and reviews served the team in iterative refinement of the NU DROP system based on user feedback.

4.2 Data Collection

Interviews were conducted with students, staff, and administrators to identify pain points in the existing processes [8]. In addition, field observations were carried out in the registrar and accounting offices to directly observe workflow bottlenecks as they occurred. Document analysis was also performed on historical request logs and payment records to determine peak transaction periods and recurring issues.

5 RESULTS AND DISCUSSION

5.1 The Main Feature

The NU DROP system offers a range of features designed to streamline document requests and payments. For users, the system provides online request submission, real-time status tracking, and access to transaction history. The registrar dashboard supports the processing of requests, monitoring of document status, and workload management. The accountancy dashboard enables payment confirmation, reconciliation, and financial report generation, while administrative tools allow for the management of user accounts, roles, document types, and payment methods. Finally, a QR-based online verification mechanism is integrated to confirm the authenticity of issued PDF documents and prevent tampering.

5.2 Technical Implementation

The technical implementation of the NU DROP system was carried out using a modern web technology stack [9]. The backend was developed with Laravel 10 running on PHP 8.x, while the frontend employed Blade Templates integrated with the Tailwind CSS framework to ensure a responsive and consistent user interface. MySQL database was used for data storage and management. System notifications were implemented through email, with optional support for Firebase Cloud Messaging (FCM) to enable real-time alerts. Security measures included Laravel Sanctum for authentication, CSRF protection, role-based access control, and audit logging to ensure data integrity and accountability. To further enhance trust, a tampering detection mechanism was integrated, where each issued PDF is assigned a SHA-256 hash stored on the server, and a QR code is generated pointing to a verification endpoint for authenticity checks.

5.3 NU DROP Web Application Screenshots

Figure 1 is the Home Page of the NU DROP system serves as the primary entry point for users, providing a clean and intuitive interface that highlights the system's core functions. From this page, students and staff can quickly access the online document request feature, view the real-time status of their pending requests, and review their transaction history. Clear navigation menus and responsive design elements ensure accessibility across devices, while quick links to support, payment channels, and login options streamline the user experience. The home page is designed to be user-centric, minimizing complexity while giving immediate visibility to the most frequently used services.

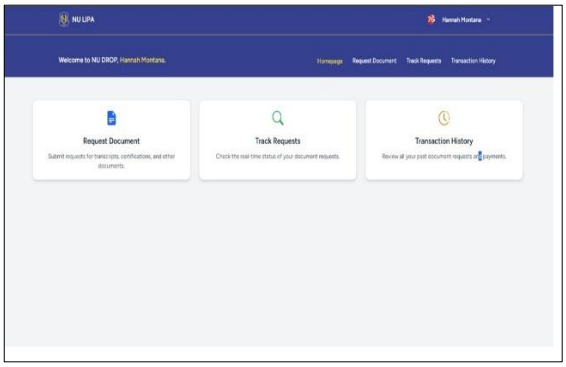

Figure 1: Home page.

Figure 2 is the NU DROP Admin Dashboard. It is a centralized system providing administrators with a general view of what happens in the system, especially in managing the online document requests and payment transactions. It provides the admin with key information regarding the total number of documents available, total requests made by users, status of requests – not verified, verified, pending, on process, ready for pickup, or released. This will essentially help the admin monitor the flow of requests effectively. Also, included in the dashboard is a revenue summary that shows weekly, monthly, and annual income generated from online payments. At the lower section, there is a visual chart that presents the top requested documents out there, like the Transcript of Records and Certificate of Registration, so that administrators can get an idea of user demand and make informed decisions. In summary, the admin dashboard has been conceived to facilitate backend processes, thus enhancing accountability and promoting quick service delivery.

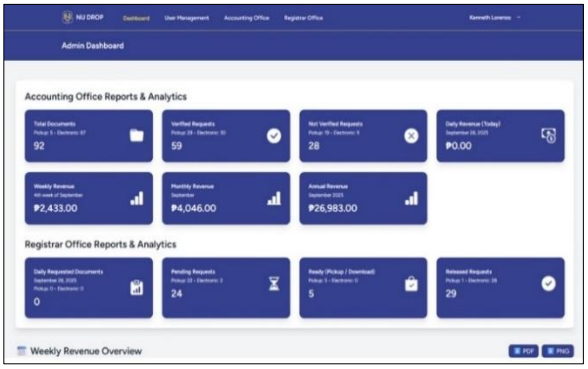

Figure 2: Admin dashboard.

Figure 3 is the NU DROP Accounting Office Dashboard. The Accounting Dashboard stands as a neat arrangement for initiating and monitoring document payment transactions. It provides important information on the overall requests versus unverified requests versus verified requests, thus enabling accounting staff to validate and track payment status easily. Financial summaries are also presented, covering income trends such as weekly, monthly, and yearly sales figures, thus providing an accounting office with a full understanding of income trends. Another feature of the dashboard is the Weekly Revenue Overview, providing a graphical way of assessing financial activity over time. This interface ensures utmost efficiency within the accounting office while promoting the accuracy and transparency of payment procedures.

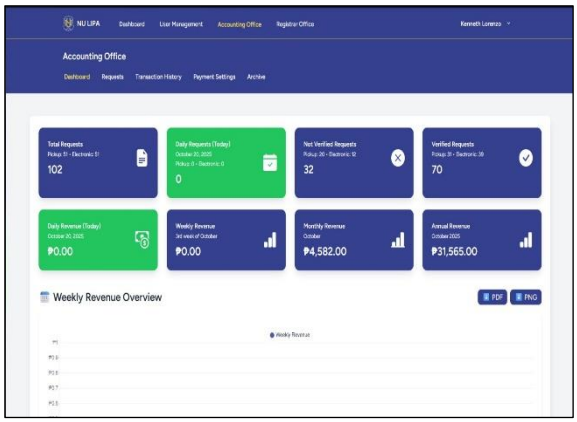

Figure 3: Accounting office dashboard.

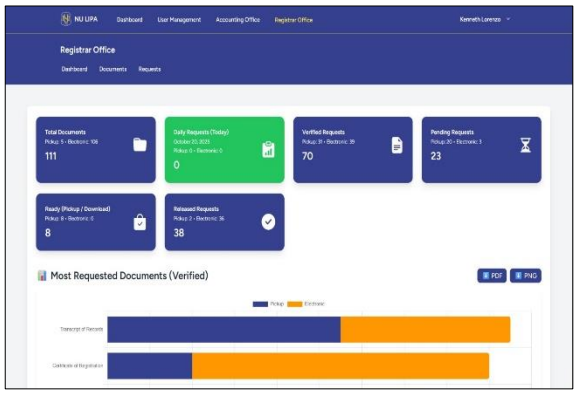

Figure 4: Registrar dashboard.

Figure 4 is the NU DROP Registrar Office, serves the purpose of sending requests for documents related to the activities of the registrar. It holds significant details such as the number of document types, verified requests, pending requests, documents presently being processed, and documents that have already been collected or sent for release. This feature provides complete supervision for administrative staff to effectively monitor and take necessary actions on the status of requests. The dashboard also features a graphical representation in a chart of Most Requested Documents, which indicates the most requested documents by users, such as the Transcript of Records or Certificate of Registration. This improves the ease of and more efficient handling of documents, prioritizing, assigning resources, etc.

As shown in Figure 5, the settings page for payments provides options for changing the possible methods of payment, for example, e-wallets with an uploaded QR code by an administrator.

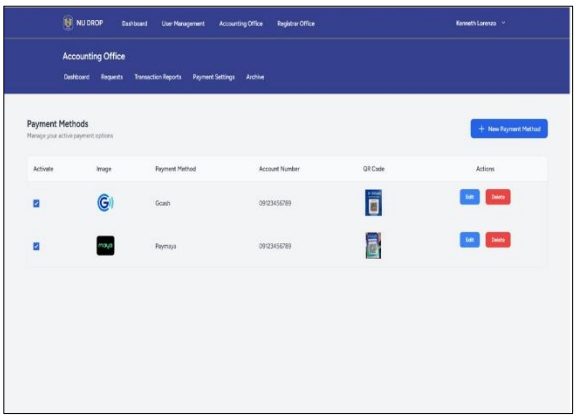

Figure 5: Payment settings.

Figure 6 presents the Request Documents Page, where students can request official records such as transcripts and certificates directly from the university. The interface allows users to browse the list of available documents, select the required type, and complete the request online. This module eliminates the need for in-person visits to the registrar's office, offering a more convenient and efficient process for both current students and graduates.

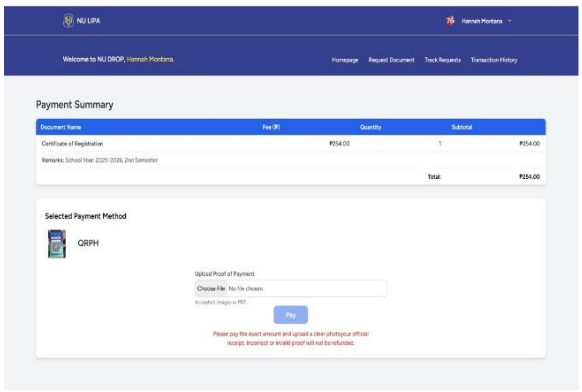

Figure 6: Request document page.

NU DROP addresses the limitations of manual processes by providing faster, more efficient, transparent, and secure services [10]. Initial feedback indicates that the system's unified workflows significantly reduce reconciliation delays between departments [11]. Its inclusive payment options improve accessibility for a broader range of users, while the integration of QR-based verification ensures more reliable document authenticity. Collectively, these features represent exclusive capabilities and unique differentiators of NU DROP,

highlighting its originality and technological value compared to existing systems.

6 CONCLUSIONS

NU DROP shows how a digital transformation can facilitate the streamlining of administrative workflows in higher education institutions. With the inclusion of payment options, anti-tamper verification, and centralized dashboards, the system innovates into authentication, inclusivity, and accountability, far beyond the traditional online portal. Future developments will look toward integrating direct payment gateways and support for mobile applications.

Although the NU DROP system demonstrated improvements in streamlining document requests and payments, certain limitations remain. The system relies on stable internet connectivity, which may affect access for users in areas with limited or unstable networks. In addition, while security mechanisms such as QR-based verification and role-based access were implemented, further testing under large-scale deployment scenarios is needed to validate performance and scalability. For future development, the system may be enhanced by integrating advanced analytics for usage monitoring, expanding payment channels, and incorporating mobile application support to further improve accessibility and user experience.

Keywords: Weibull- Burr Distribution, Weibull Distribution, MLE, MSE, Simulation.

Abstract: This study introduces a new family of distributions known as the five-parameters Weibull- Burr distribution. This study aims to present a new family of Weibull-Burr distributions by utilizing the maximum likelihood estimation (MLE) method to determine the efficiency of the exponential family through the mean square error (MSE) by utilizing Monte Carlo simulation experiments by using the R program. It is designed to offer greater flexibility in the modeling of the financial, and actuarial data. The distribution in view presents five parameters, being thus capable of describing very peculiar hazard rate behaviors, and extreme values. Among the key statistical properties derived in this paper are the probability density function, cumulative distribution function, and moments of the distribution. Further, the paper concentrates on parameter estimation of the distribution by the method of MLE. The log-likelihood function was formulated, and processed, followed by parameter estimation, and further by the simulation under different sample sizes. Simulation results show that the proposed model can effectively address complex data structures. These results clearly indicate that the Weibull –Burr Model offers a promising alternative to the classical distributions used in modeling in finance, and actuarial domains.

1 INTRODUCTION

In recent years, the growing interest in research has been induced for developing classical probability models to incorporate into its fold, and provide more flexible, and accurate representation of complex real world data [1]. The developments involved expanding the number of parameters or applying some transformation on the original distributions or constructing hybrid models by combining two or more distributions [2]. The foremost feature of the statistical modification is to enhance the precision of inference, and aside from that, changes adapted for asymmetric behavior or extreme values for data, examples of which are financial or actuarial data. This study intends to present a new family of Weibull - Burr distributions through the MLE method for efficient estimation of the parameter based on the Monte Carlo simulation experiments for mean square error (MSE). In this study, R is introduced for the experimental section. In this line of research, the Burr distribution can be considered one of the paramount distributions in representing actual data with extreme behaviors and varied risk functions, forming an extremely flexible new distribution when combined with other distributions such as the Weibull distribution, namely, the five-parameter Weibull-Burr distribution [3]. The proposed distribution combines the properties of two distributions and hence can stand as a better candidate for modeling high-variance data. Some important contributions made in previous research are discussed with the synthesis of those findings, building upon which new developments in this field will be initiated. Some of the relevant previous researches are listed here. A new procedure for the generation of a family of Weibull probability distributions was introduced in (2015) using the logistic Weibull distribution [4]. In (2017), researchers presented a newer generalized distribution that better fits the Weibull and some generalizations, i.e., the alpha-powered Weibull distribution [5]. The next year saw the proposal of a new family of univariate x-Weibull distributions with two sub models that belong to the said family [6]. In (2020), researchers proposed a study titled "A Family of Single-Inverse Weibull Distributions," which provides high flexibility in analyzing life-span data [7]. In (2021), researchers proposed a new class of extreme value statistical distributions specifically designed for modeling complex financial, and actuarial data [8]. In (2023), researchers proposed a Weibull distribution with an estimable shift

parameter [9]. In (2025), researchers proposed a study of a new family of Lomax-x-shift distributions: Properties and estimation on financial, and actuarial data [10].

2 WEIBULL –BURR DISTRIBUTION

The new five-parameter Weibull- Burr distribution is an advanced extension of continuous probability distributions, it is designed for modeling the complex three-parameters financial, actuarial, and engineering data with the time interval (0,∞). This distribution combines the properties of the Burr distribution, known for its flexibility in handling data with the extreme values, and the Weibull distribution, which is popular in modeling data related to reliability, and failure times, providing a powerful framework for analyzing the complex multi-parameter data. The new distribution also aims to improve the data fit by introducing additional parameters that allow controlling over shape, scale, and displacement, making the model capable of representing a wider range of data behaviors compared to traditional distributions. The proposed distribution can represent different types of data, such as the extreme values data or data with a positive or negative skewness. Applying the new distribution on the financial, and actuarial data for the output distribution makes the new distribution more accurate in the modeling of the large losses, which is critical in the financial risk analysis [11], [12]. It also allows processing the complex data while maintaining a clear statistical interpretation of the distribution parameters [13], [14]. The general formula for the distribution as below:

Regarding a random variable T, let h(t) be its pdf, where $T \in [a, b]$ for $-\infty \le a < b < \infty$. Similarly, let W[G(x; ζ)] be its CDF, contingent upon the vector parameter ζ meeting the following requirements:

- W[G(x; ζ)] ∈ [a, b];
- In addition to being monotonically rising, W[G(x; ζ)] is differentiable;
- W[G(x; ζ)] → a as x → −∞ and W[G(x; ζ)] → b as x → +∞.

The CDF associated with the T-X family of distributions was recently defined by [5]:

$$F(x) = \int_a^{w[G(x);\xi]} h(t)dt \quad (1)$$

In this article, we propose the following staggered transformation:

$$W[G(x; \zeta)] = x\,(G(x) + m),$$

where $x \ge 0$, $G(x; \zeta)$ is the CDF of one of the classical models, and $m \ge 0$ is a constant representing the shift parameter. W[G(x; ζ)] on [0, +∞] satisfies the aforementioned requirements. We study here with h(t) the density function of the Weibull function whose support is for $x \ge 0$. This gives us a new family of shifted Weibull distributions whose CDF is defined b:

$$F(x)=\int_a^{x[G(x)+m]} h(t)dt, \quad (2)$$

$$F(x)=1- e^{-\left[\frac{xG(x)+mx}{\lambda}\right]^{\theta}}. \quad (3)$$

where $x \ge 0$, $\theta = (\zeta, \alpha, \lambda, m) \ge 0$.

This distribution function is differentiated based on x. As a result, we get:

$$F(x) = 1 - e^{-\left[\frac{x-x(1+x^{\alpha})^{-\beta}+mx}{\lambda}\right]^{\theta}}, \quad (4)$$

$$f(x)=\frac{\theta}{\lambda^{\theta}}\,[xG(x) + mx]^{\theta-1}\,[xg(x) + G(x) + m]\; e^{-\left[\frac{xG(x)+mx}{\lambda}\right]^{\theta}}, \quad (5)$$

$$f(x)= \frac{\theta}{\lambda^{\theta}}[x - x(1 + x^{\alpha})^{-\beta}+mx]^{\theta-1}[1+\alpha\beta x^{\alpha}(1 + + x^{\alpha})^{-\beta-1} + \left(1 + x^{\alpha}\right)^{-\beta} + m\right] \quad e^{-\left[\frac{x-x(1-x^{\alpha})^{-\beta}+mx}{\lambda}\right]^{\theta}}, \quad (6)$$

$$S(t)= e^{-\left[\frac{x-x(1+x^{\alpha}]^{-\beta}+mx}{\lambda}\right]^{\theta}}, \quad (7)$$

$$h(x) = \frac{\theta}{\lambda^{\theta}}[x-x(1+x^{\alpha})^{-\beta}+mx]^{\theta-1}[1+\alpha\beta x^{\alpha}(1+x^{\alpha})^{-\beta-1}+ \left(1+x^{\alpha}\right)^{-\beta} + m\,], \quad (8)$$

The purpose of the distribution function: Weibull-Burr distribution as a statistical model can be used in the modeling of the financial and actuarial data. The probability density function (PDF) “has a condition” that must be satisfied, as below [15]:

1) Non negative;
2) The condition for the cumulative distribution function (CDF) is that it does not exceed one [16], [17], (Table 1).

$$\lim_{x-0} F(x) = 0, \quad (9)$$

$$\lim_{x-\infty} F(x) = 1. \quad (10)$$

Table 1: The properties of the Weibull- Burr distribution.

$$\frac{\partial lnL}{\partial\beta}=\sum_{i=1}^{n}\frac{xi(1+xi^{\alpha})^{-\beta}\ln(1+xi^{\alpha})}{[xi-xi(1+xi^{\alpha})^{-\beta}+mxi]}+\sum_{i=1}^{n}\frac{\beta\alpha xi^{\alpha}(1+xi^{\alpha})^{-\beta-1}\ln(1+xi^{\alpha})-(1+xi^{\alpha})^{-\beta-1}\alpha xi^{\alpha}+(1+xi^{\alpha})^{-\beta}\ln(1+xi^{\alpha})}{[1+\beta\alpha xi^{\alpha}(1+xi^{\alpha})^{-\beta-1}-(1+xi^{\alpha})^{-\beta}+m]}, \quad (16)$$

$$\frac{\partial\ Ln\ L}{\partial m}=(\theta-1)\sum_{i=1}^{n}\frac{xi}{[xi-xi(1+x_i^{\alpha})^{-\beta}+mxi]}+\sum_{i=1}^{n}\frac{1}{[1-\beta\alpha x_i^{\alpha}(1+x_i^{\alpha})^{-\beta-1}-(1+x_i^{\alpha})^{-\beta}+m}-\theta\lambda^{-\theta}\sum_{i=1}^{n}[xi-xi(1+x_i^{\alpha})^{-\beta}+mxi]^{\theta-1}(xi) \quad (18)$$

2.1 Maximum Likelihood Method (MLE)

It is considered one of the most widely used methods in statistics for estimating parameters [18], [19]. It was contributed by Joseph Lagrange, and Daniel Bernoulli, and was proposed by the British scientist Ronald Fisher in the early twentieth century. He was first presented it in a research paper, due to its useful properties, including Sufficiency, impartiality, and reliability. This method aims to find estimated values for the parameters to be estimated, thus maximizing the probability function. If the random variable (x) has the probability density function (PDF) of the proposed distribution, then the maximum probability function for the independent random variables (xi) with the same distribution is as follows, [20].

$$\begin{aligned}\ln L=\ & n\ln(\theta)-n\,\theta\ln(\lambda)+(\theta-1)\sum_{i=1}^{n}\ln[xi-xi(1+x_i^{\alpha})^{-\beta}+mx_i]+\sum_{i=1}^{n}\ln[1+\alpha\beta x_i^{\alpha}\left(1+x_i^{\alpha}\right)^{-\beta-1}+\\ &\left(1+x_i^{\alpha}\right)^{-\beta}+m]]-\lambda^{-\theta}\sum_{i=1}^{n}[\,xi-xi(1+xi^{\alpha})^{-\beta}+mxi\,]^{\theta}\end{aligned} \quad (11)$$

To obtain the MLE of the parameters of the Weibull-Burr distribution [21], [22], it can be deriving the (7) as follows (12) – (18):

$$\frac{\partial lnL}{\partial\lambda}=-\frac{n\theta}{\lambda}+\theta\lambda^{-\theta-1}\sum_{i=1}^{n}[xi-xi(1+xi^{\alpha})^{-\beta}+mxi]^{\theta}, \quad (12)$$

$$-\sum_{i=1}^{n}\theta\lambda^{-\theta}\left[xi-xi\left(1+xi^{\alpha}\right)^{-\beta-1}+mxi\right]^{\theta-1}\beta xi^{\alpha+1}\ln(xi)(1+xi^{\alpha})^{-\beta-1}\ldots \quad (15)$$

$$-\lambda^{\theta}\theta\sum_{i=1}^{n}[xi-xi(1-xi^{\alpha})^{-\beta}+mxi]^{\theta-1}(xi(1-xi^{\alpha})^{-\beta}\ln(1-xi^{\alpha})) \quad (17)$$

2.2 The Experimental Simulation

The behavior of the probability density function (PDF) and cumulative distribution function (CDF) of the Weibull–Burr distribution for different parameter values is illustrated in Figure 1. Different default values were used for each of the five distribution parameters to complete five simulation experiments, with repetition once, and default values for each parameter in the five models and sample sizes (n=25, 50, 75, 125, 200) as shown in the Table 2 and default values. The number of times the simulation experiments were 1000 times. Accordingly, the estimated Weibull- Burr distribution parameters obtained from the simulation study using the MLE are presented in Tables 3, 5, 7, 9, and 11, while the corresponding MSE values are presented in Tables 4, 6, 8, 10 and 12.

The purpose is to demonstrate the efficiency of the MLE. The comparison criterion, the mean square error (MSE), is used according to the following (19):

$$\text{MSE} = \frac{\sum_{i=1}^{r}(\widehat{\theta i}-\theta)^2}{r}. \qquad (19)$$

Table 2: The values of the default parameters (α, β, λ, θ, m).

α	9.8	4.5	3.5	1.5	0.5

3 CONCLUSIONS

In this research, it provided a new statistical distribution is called Weibull - Burr distribution. The efficiency of the MLE was proven on the five-parameter Weibull- Burr distribution. The results were showed that the parameters estimate approach the true values were increasing sample size (n), and the MSE values were decrease with increasing sample size n. For some parameters, such as (λ, m and θ), the estimates were increased at small sample sizes, and the MSE was initially high, then stabilizes with increasing sample size (n). However, (α, β) was more stabled at medium sample sizes. The results were confirmed that increasing in the sample size leaded to a reduction in the error in the estimates for all of the parameters. From sample size (n≥125) and above, the MSE becomes lower than it is.

Also, the simulation results were showed that the accuracy of the parameters estimation for the Weibull - Burr distribution improved significantly with the increasing sample size. Therefore, it is recommended to use a sample size of no less than n=125 to ensure accurate estimates. Estimated the parameters by using the MLE by minimizing the MSE. Also, should be attention to paid to the displacement parameter (m) and the scale parameter (λ), as they may require additional estimations to improve their accuracy in the small samples. In addition, should be monitored the MSE to assess the quality of the estimations in the experiments, which in turn helps reveal the direct effect of sample size on the accuracy of the parameters. Finally, as a future work, it is possible - for example- to use the proposed statistical distribution on the huge dataset of the real-world or mixing the proposed statistical distribution with another statistical distribution and applying it on the real-world dataset.

4 RECOMMENDATIONS

We recommend using the Transformation (T-X) method with other distributions to obtain a new family based on the Weibull-Burr distribution, due to its high flexibility in modeling heavy tailed financial and actuarial data or generating a new family from other distributions. We also recommend using other methods, such as Bayesian methods, to estimate distribution parameters when working with relatively large datasets, as they are more stable and accurate. We also recommend using real data representing larger and more diverse samples from different insurance companies or across multiple time periods to obtain better results.

Keywords: Renewable Energy, Renewable Energy Country Attractiveness Index, Technology-Specific Indices, Regression Analysis, Investment Attractiveness.

Abstract: The study is dedicated to analyzing the relationship between the Renewable Energy Country Attractiveness Index (RECAI) and technology-specific indices of renewable energy technologies to identify key technological drivers of investment attractiveness in renewable energy markets. The methodology is based on applying General Regression Models for 40 countries, where RECAI serves as the dependent variable, and eight technology-specific indices (onshore wind, offshore wind, solar photovoltaics, concentrated solar power, biomass, geothermal, hydro, battery energy storage systems) serve as independent predictors. The results of the regression analysis demonstrate a statistically significant impact of four technologies on RECAI formation. Solar photovoltaics show the most powerful effect, followed by onshore wind, battery energy storage systems, and offshore wind in terms of impact magnitude. The technologies of concentrated solar power, geothermal, hydro, and biomass proved to be statistically insignificant predictors. Three-dimensional visualization confirmed the synergistic nature of the impact of key technologies and the importance of a diversified technological portfolio for maximizing market attractiveness. The practical value of the study lies in creating an empirically grounded tool that provides a foundation for strategic planning by investors and policymakers of investments in renewable energy at the national level.

1 INTRODUCTION

The global energy transition to renewable energy sources (RES) is gaining increasing importance in the context of combating climate change and ensuring energy security [1]-[4]. According to Bloomberg, global investments in renewable energy reached a record USD 2.1 trillion in 2024 [5], indicating sustained growth in interest in this sector from investors and governments. However, the distribution of investment flows between countries remains uneven [6], necessitating a thorough analysis of factors that determine the investment attractiveness of national RES markets.

The Renewable Energy Country Attractiveness Index (RECAI), developed by consulting company EY, is one of the most influential comprehensive indicators for assessing the investment attractiveness of national renewable energy markets [7]. This index considers a wide range of macroeconomic, infrastructural, and political factors, but its composite nature complicates the understanding of the specific contribution of individual technological components to forming a country's overall rating. At the same time, technological differentiation of RES markets is critically important for investors, as different renewable technologies are characterized by distinct risk profiles, levels of technological maturity, and commercialization potential.

Contemporary research on RES investment attractiveness predominantly focuses on analyzing general macroeconomic determinants or considers individual technologies in isolation, without accounting for their synergistic impact on comprehensive market attractiveness assessment [8]-[11]. For instance, D. Doğan et al. analyzed the relationships between renewable energy consumption, carbon dioxide emissions, economic

growth, financial development, and energy dependence. The authors used the panel regression method to conduct research for 38 countries over the period 1991–2021 based on RECAI. It was established that financial development affects both carbon dioxide emissions and economic growth [12]. Researchers N. Y. Mohamed Yusoff et al. used autoregressive distributed lag based on annual time series data to analyze macroeconomic indicators, including gross domestic investment, domestic investment, foreign direct investment, trade openness, urbanization, financial development, and carbon emission levels on renewable energy in Malaysia. They determined that greater economic development and urbanization increase the share of renewable energy. Conversely, increases in foreign investment, trade liberalization, and carbon emissions may reduce the use of these clean energy sources [13]. G. Osuma and L. Bonga-Bonga studied the impact of foreign direct investment and technological innovations on renewable energy consumption formation. The authors analyzed their joint effect in 20 EU countries during 2013–2023 using the Method of Moments Quantile Regression. Results showed that technological innovations consistently contribute to growth in renewable energy consumption. In contrast, foreign direct investment has a negative impact on renewable energy consumption. Additionally, inflation positively affects renewable energy consumption, indicating that rising energy prices stimulate the transition to alternative sources [14]. O. Prokopenko et al. used a vector autoregressive model to analyze the impact of long-term investments and research and development expenditures in renewable energy on the financial performance of 10 leading industry companies. The obtained results indicate a positive impact of investments and research and development expenditures on key profitability indicators: taxes, depreciation, earnings before interest and taxes, net profit, and return on investment, emphasizing the economic feasibility of financing innovations in renewable energy [15].

However, such a fragmented approach limits the possibilities for comprehensive understanding of synergistic effects. This creates a methodological gap in understanding how specific technological factors interact with each other and shape the overall investment attractiveness of national RES markets.

The aim of the study is to develop an empirical model of the relationship between the Renewable Energy Country Attractiveness Index and technology-specific indices of renewable energy technologies to identify key technological drivers of RES market investment attractiveness. To achieve the stated goal, the following tasks are planned: conduct correlation analysis of relationships between RECAI and eight technology-specific indices; build a multifactor regression model for quantitative assessment of each technology's impact on overall attractiveness index formation; identify statistically significant technological drivers and perform analysis of synergistic effects of key technologies to understand their combined impact on market attractiveness.

2 METHODOLOGY

To assess factors that determine the investment attractiveness of renewable energy markets in the context of transition to energy independence and achieving grid parity, RECAI is used. The methodology for calculating this index is based on five key dimensions (energy imperative, policy stability, project delivery, capital availability, natural resource diversity), which are aggregated through a system of weighting coefficients into a composite index with scores from 1 to 5. Along with calculating the overall RECAI value, additional calculations are performed for the following technology-specific indices [7]:

- onshore wind – electricity generation using wind turbines located on land;
- solar photovoltaics (PV) – technology that converts sunlight directly into electricity using solar panels;
- concentrated solar power (CSP) – a system that concentrates sunlight using mirrors or lenses to heat fluid and generate electricity through steam turbines;
- biomass – energy production from organic materials such as wood, agricultural waste, organic waste, or specially grown energy crops;
- geothermal – utilization of Earth's internal heat for electricity generation or heating supply;
- hydro – electricity production by harnessing water power, typically through dams or micro-hydroelectric plants;
- battery energy storage systems (BESS) – electricity storage technologies, typically in lithium-ion batteries, for subsequent use during peak demand or when RES generation decreases.

These indicators are not directly included in the RECAI calculation methodology, but are used to identify countries with high technological potential in specific renewable segments while having

deficiencies in other aspects of the investment climate. This allows for identifying market opportunities that may remain hidden when analyzing only the overall ranking [7].

2.1 Dataset

The empirical base of our study consisted of RECAI values and technology-specific scores (energy imperative, policy stability, project delivery, capital availability, natural resource diversity) for 2024 for the 40 most attractive countries for renewable energy investment worldwide: Argentina, Australia, Austria, Belgium, Brasil, Canada, Chile, China, Denmark, Egypt, Finland, France, Germany, Greece, India, Ireland, Israel, Italy, Japan, Kazakhstan, Mexico, Morocco, Netherlands, Norway, Peru, Philippines, Poland, Portugal, Romania, Saudi Arabia, South Africa, South Korea, Spain, Sweden, Switzerland, Taiwan, Turkey, UK, US, and Vietnam.

Numerical calculations were performed using Statistica software [16] based on indicator values published in the "62nd edition of the Renewable Energy Country Attractiveness Index" [7].

2.2 Method

General Regression Models (GRM) represent a comprehensive statistical framework designed to examine relationships between dependent and independent variables across diverse data structures and distributions. The primary purpose of these models extends beyond simple linear associations to accommodate complex, non-linear patterns while providing robust parameter estimation and hypothesis testing capabilities. This methodological approach proves particularly valuable when analyzing composite indices and their underlying components, as it enables the decomposition of multifaceted constructs into interpretable individual effects [17].

The basic mathematical formulation follows the general structure:

$$Y = f(X_1, X_2, ..., X_k) + \varepsilon, \quad (1)$$

where Y represents the dependent variable, X_1 through X_k denote independent variables, $f(\cdot)$ describes the functional relationship, and ε captures the error term.

For multiple linear regression applications, this translates to

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + ... + \beta_k X_k + \varepsilon, \quad (2)$$

where β coefficients represent parameter estimates quantifying the magnitude and direction of each predictor's influence.

The model estimation typically employs ordinary least squares methodology, minimizing the sum of squared residuals:

$$\Sigma(Y_i - \hat{Y}_i)^2, \quad (3)$$

where $\hat{Y}_i$ represents predicted values.

Model performance evaluation relies on metrics such as R-squared, adjusted R-squared, and various information criteria, while statistical significance testing of individual parameters utilizes *t*-statistics and corresponding p-values to assess the reliability of estimated relationships.

3 RESULTS AND DISCUSSION

Table 1 presents the results of applying the GRM method to analyze the relationship between RECAI and the analyzed technology-specific indices of renewable energy technologies. The obtained results demonstrate a statistically significant impact of most technological indices on the formation of the overall attractiveness of renewable energy markets.

Solar PV emerged as the dominant technological driver. This indicator shows the most powerful impact among all technologies with an unstandardized coefficient of 0.43 ($p < 0.001$) and the highest standardized coefficient of 0.42. This confirms the critical role of solar photovoltaics in determining countries' investment attractiveness. Onshore wind ranks second in terms of impact ($\beta = 0.34$, standardized $\beta = 0.32$, $p < 0.001$), demonstrating the stable significance of onshore wind energy as a key factor in market attractiveness.

Technologies Solar CSP, Offshore wind, and BESS exert a moderate influence. Despite the negative unstandardized coefficient (-0.04), Solar CSP has a positive standardized effect, which may indicate complex interactions with other model variables. Offshore wind ($\beta = 0.13$, $p < 0.001$) and BESS ($\beta = 0.18$, $p < 0.001$) show a moderate but statistically significant positive impact, reflecting the growing importance of offshore wind energy and energy storage systems.

Table 1: Model parameter estimates.

Sigma-restricted parameterization									
	RECAI Param	RECAI Str. Err	RECAI *t*	-95,00% Cnf. Lmt Raw	+95,00% Cnf. Lmt Raw	RECAI β	RECAI Str. Err β	-95,00% Cnf. Lmt β	+95,00% Cnf. Lmt β

BESS	0.18	0.04	4.66	0.00	0.10	0.26	0.33	0.07	0.19

Table 2: Test of SS Whole Model vs. SS Residual.

Dependent Variable	Multiple R	Multiple R^2	Adjusted R^2	SS Model	df Model	MS Model	SS Resid.	df Resid.	MS Resid.	F	*p*
RECAI	0.97	0.94	0.93	1333.21	8	166.65	83.94	31	2.71	61.55	0.00

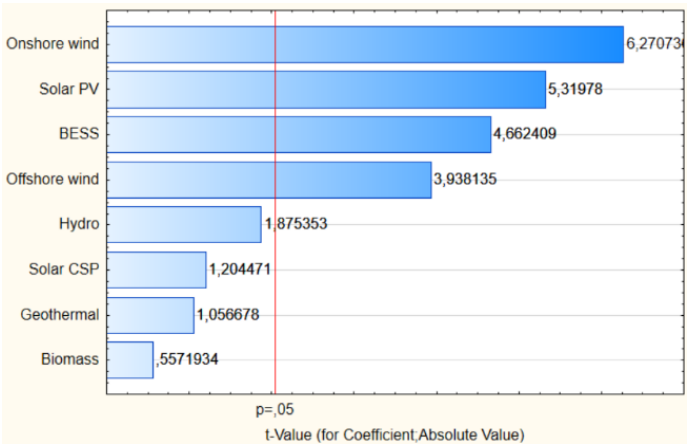

Figure 1: Pareto chart of t-values for coefficients.

Technologies with limited impact are Geothermal, Hydro, and Biomass. Geothermal energy demonstrates a statistically insignificant effect (p = 0.30), which is logically explained by its geographical specificity and limited resource availability. Hydro shows a weak negative impact (β = -0.06, p = 0.07), which may reflect the saturation of traditional hydroelectric capacity in developed countries or environmental constraints on new projects. Biomass has the smallest positive effect (β = 0.03, p = 0.59), remaining statistically insignificant, which may indicate limited investment interest in this technology at the global level.

Onshore wind, Solar PV, BESS, and Offshore wind have statistically significant coefficients (t_{emp} > t_{table}) even at the strict level α = 0.01. Hydro, Solar CSP, Geothermal, and Biomass do not achieve statistical significance (t_{emp} < t_{table}) at α = 0.05 (Fig. 1).

Table 2 presents the results of the multiple regression model.

Analysis of the regression model results demonstrates a differentiated impact of various renewable technologies on the formation of overall RECAI with high statistical significance for most predictors. The model reveals high explanatory power and statistical validity of the overall specification.

The F-statistic is 4.37 (p = 0.00), which confirms the statistical significance of the model as a whole and rejects the null hypothesis that there is no relationship

between the predictors and the dependent variable. This indicates that at least one of the technology-specific indices has a significant impact on RECAI.

Based on the results of the conducted analysis, we constructed an analytical model of RECAI dependence on key technological drivers (the regression equation includes only statistically significant predictors):

$$\begin{aligned} RECAI = 15.22 + 0.34 \times Onshore_wind + \\ + 0.431 \times Solar_PV + \\ + 0.13 \times Offshore_wind + 0.18 \times BESS. \end{aligned} \quad (4)$$

The constant (15.22) represents the baseline RECAI value in the absence of technological indices influence, reflecting the minimum level of renewable energy market attractiveness regardless of specific technological capabilities. The Solar PV coefficient (0.43) is the largest among all predictors. This confirms the dominant role of solar photovoltaics in forming investment attractiveness. The Onshore wind coefficient (0.34) indicates a strong positive impact of onshore wind energy, confirming the critical importance of wind resources. The BESS coefficient (0.18) demonstrates the growing role of energy storage systems in market attractiveness assessment, reflecting the importance of energy infrastructure for renewable energy integration. The Offshore wind coefficient (0.13) shows a moderate but significant impact of offshore wind energy, which may reflect the more limited geographical availability of this technology compared to onshore alternatives.

The exclusion of statistically insignificant variables (Solar CSP, Geothermal, Hydro, Biomass) improves model efficiency and provides more reliable RECAI forecasting through key technological drivers.

To visualize the relationships between the four influential technological predictors and the dependent variable RECAI, we constructed three-dimensional diagrams (Fig. 2-7).

The interdependency diagram of RECAI, Onshore wind, and Solar PV (Fig. 2) demonstrates a quite steep surface rise, reflecting the strong positive impact of both technologies on RECAI. The highest investment attractiveness values are achieved only with simultaneously high indicators of both technologies, indicating their synergistic impact on the renewable energy market attractiveness.

Fig. 3 shows a three-dimensional diagram visualizing the relationship between RECAI, Offshore wind, and BESS. A less steep rise is observed compared to the previous visualization, which corresponds to the smaller regression coefficients of these technologies. The lowest RECAI values are concentrated in the area of low indicators for both offshore wind energy and energy storage systems. Maximum values are achieved only with high indicators of both technologies, but the overall variation range is smaller compared to the main technologies.

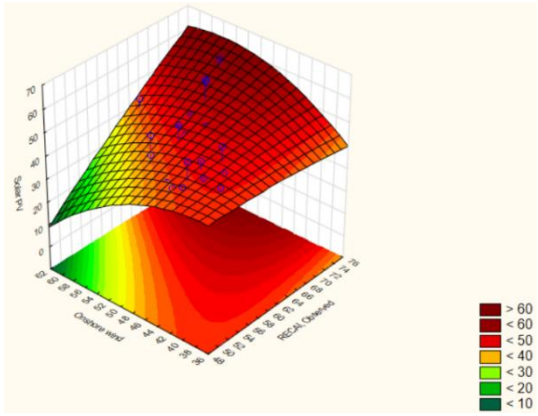

Figure 2: 3D Surface Plot of RECAI against Onshore wind and Solar PV.

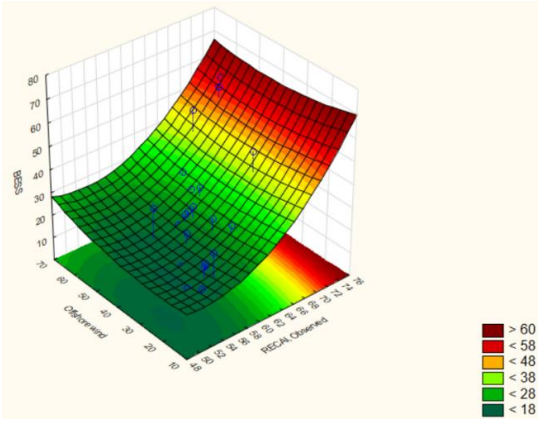

Figure 3: 3D Surface Plot of RECAI against Offshore wind and BESS.

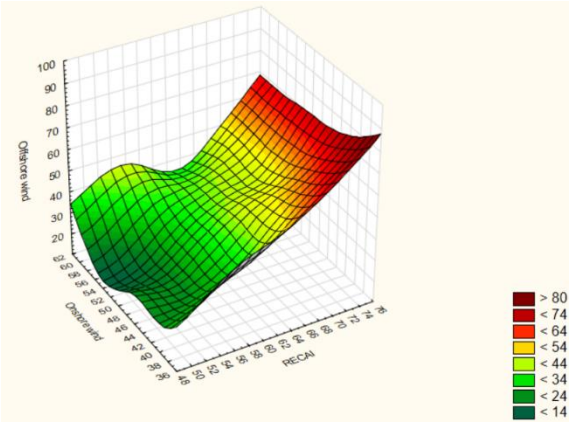

Figure 4: 3D Surface Plot of RECAI against Offshore wind and Onshore wind.

The diagram presented in Fig. 4 demonstrates a moderate synergistic effect between the two wind technologies. The surface has a smooth rise with a greater slope towards onshore wind energy, indicating its dominant influence on RECAI in this technology pair.

Fig. 5 shows an interaction diagram of energy storage systems with onshore wind energy. The surface demonstrates a uniform rise, where both technologies have approximately equal importance for forming high RECAI values, confirming their complementarity.

The 3D diagram shown in Fig. 6 displays a powerful synergistic effect between energy storage systems and solar photovoltaics. The surface has a steep rise, particularly pronounced in the Solar PV direction, which emphasizes the critical importance of this technology.

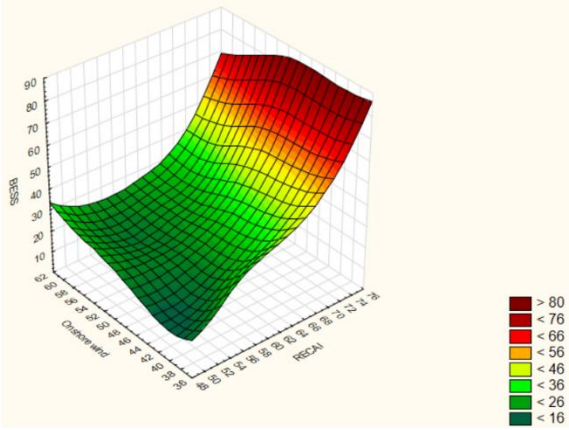

Figure 5: 3D Surface Plot of RECAI against BESS and Onshore wind

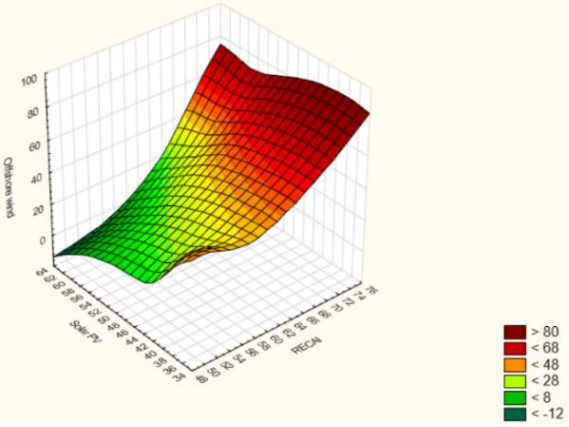

Figure 6: 3D Surface Plot of RECAI against Offshore wind and Solar PV.

The diagram presented in Fig. 7 demonstrates an asymmetric impact of technologies, where Solar PV has a significantly greater effect compared to offshore wind energy. The surface shows that solar energy is a key driver of high RECAI values in this combination.

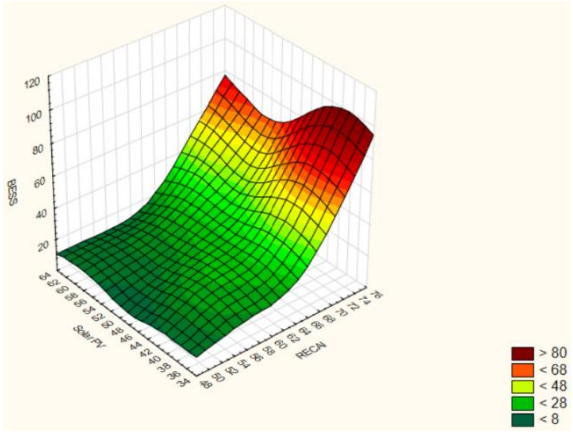

Figure 7: 3D Surface Plot of RECAI against BESS and Solar PV.

The results of the graphical analysis confirm the fundamental importance of synergistic development of renewable energy technologies for maximizing the investment attractiveness of markets, with Solar PV and Onshore wind acting as the most influential technologies, while Offshore wind and BESS play an important but supporting role in shaping overall market attractiveness.

5 CONCLUSIONS

The conducted study of the relationship between the Renewable Energy Country Attractiveness Index and technology-specific indices using General Regression Models allowed for the identification of key patterns in the formation of investment attractiveness of renewable energy markets and the identification of dominant technological drivers at the global level.

The results of the regression analysis demonstrate the differentiated impact of various renewable technologies on the overall attractiveness of markets. Solar PV and Onshore wind proved to be the most influential predictors with the highest statistically significant coefficients (0.43 and 0.34, respectively), confirming their critical role in shaping the investment climate. These technologies are characterized by the highest t-statistics (5.32 and 6.27), indicating the reliability of their impact on RECAI regardless of other factors.

BESS and Offshore wind demonstrated moderate but statistically significant positive impact on investment attractiveness with coefficients of 0.18 and 0.13 respectively. This reflects the growing importance of energy storage systems and offshore wind energy in the modern energy transition, although their impact is smaller compared to traditional renewable technologies.

The technologies Solar CSP, Geothermal, Hydro, and Biomass proved to be statistically insignificant predictors of RECAI, which can be explained by their geographical specificity, technological limitations, or saturation of corresponding markets. Particularly indicative is the insignificant impact of hydropower, which may reflect the depletion of traditional hydro resource potential in developed countries.

The three-dimensional visualization of relationships confirmed the synergistic nature of the impact of key technologies on RECAI, demonstrating that the highest levels of investment attractiveness are achieved with simultaneously high indicators of several renewable technologies. This emphasizes the importance of a diversified technological portfolio for maximizing market attractiveness.

The obtained results can provide relevant information to investors and policymakers regarding key technological drivers of investment attractiveness and contribute to the formation of more effective national renewable energy development strategies and optimization of investment portfolios in this sector.

Abstract: The purpose of this paper is to develop an interdisciplinary mechanism for implementing gender-sensitive and socially responsible HR branding within the business engineering system of modern companies. The study aims to integrate gender equality principles, international legal standards, and sustainable development criteria into corporate HR models in the context of digital transformation. The research is based on qualitative content analysis, comparative analysis of international practices, statistical examination of gender indicators (WEF, Eurostat, UN Women) and theoretical modeling. These methods enabled the authors to identify structural components of inclusive HR branding and design a multi-level framework for sustainable labor relations. The study systematizes key elements of gender-sensitive HR branding, develops a visualized model of sustainable employee-employer relations, and identifies critical gender disparities that influence HR decision-making. The findings demonstrate that integrating gender equality, CSR principles, and marketing engineering tools enhances workforce engagement, strengthens employer attractiveness, and improves organizational resilience. The paper offers a unified model that embeds gender indicators into HR branding and business engineering processes, providing an operational structure for transforming corporate governance in line with international legal and ethical standards. The results can be applied by companies to optimize recruitment, employee development, career management, and outplacement processes through gender-sensitive and socially responsible HR practices. The proposed mechanism supports evidence-based HR decisions and contributes to the formation of an inclusive and competitive employer brand.

1 INTRODUCTION

In the context of global digital transformation and the growing importance of ethical governance, the integration of gender-sensitive and socially responsible practices into human resource branding has emerged as a critical challenge and opportunity for modern organizations. As companies navigate the complexities of employer reputation, workforce sustainability, and stakeholder engagement, the alignment of HR strategies with gender equality principles and corporate social responsibility frameworks becomes not only a moral imperative but also a strategic necessity.

2 LITERATURE REVIEW

The study is positioned at the intersection of gender studies, human resource management, business engineering, and international law. It draws on diverse interdisciplinary sources to address the pressing need for inclusive and evidence-based HR models that promote long-term employee engagement, gender equity, and organizational resilience. Recent literature suggests divergent approaches to integrating gender dimensions in the workplace (from focusing on intersectionality and identity politics to embedding statistical indicators and legal norms within management systems) and this

diversity of perspectives reflects a wider debate on whether gender equality should be treated as a regulatory requirement or a voluntary ethical commitment.

3 RESEARCH METHODOLOGY

The methodological framework of this study integrates different scientific methods, each serving a specific research objective within the interdisciplinary examination of gender-sensitive and socially responsible HR branding. Qualitative content analysis was applied to systematize conceptual approaches to gender equality, CSR and HR branding and to reveal their intersections in the context of digital transformation. Comparative analysis enabled the assessment of international legal standards, cross-country gender disparities and corporate practices, thereby identifying structural differences and best practices relevant for integrating gender principles into business engineering systems. Statistical evaluation of gender indicators derived from WEF, Eurostat, UN Women and national datasets was used to quantify existing inequalities and substantiate the necessity of evidence-based HR decision-making. Theoretical modeling facilitated the development of a multi-level mechanism for structuring sustainable labor relations and operationalizing gender-sensitive HR branding within corporate governance frameworks. Together, these methods ensured a comprehensive and analytically grounded exploration of the research problem.

4 MECHANISM FOR IMPLEMENTING A GENDER APPROACH AND SOCIALLY ORIENTED HR BRANDING PRACTICES IN THE BUSINESS ENGINEERING SYSTEM

The analysis of sources dedicated to the gender approach is conceptually essential for providing a scholarly foundation for the study of inclusive practices in human resource management and employer branding, as they outline intercultural and intersectional dimensions of gender identity that enable the rethinking of corporate policies through the lens of social justice, equal access, and non-discrimination [1], [2].

The integration of social responsibility into business practices is a fundamental component of the sustainable development strategy of modern companies, particularly in the context of digital transformation, as it allows for a comprehensive understanding of the evolution of CSR approaches as a key element in risk management, corporate reputation and stakeholder trust [3], [4].

Research dedicated to employer branding represents contemporary concepts of human capital management as a strategic asset that directly influences a company's competitiveness in the digital age, allowing for the observation of the evolution of employer branding from traditional recruitment to a systemic strategy for shaping an attractive, responsible, and gender-sensitive employer image [5], [6].

The ability to integrate gender, ethical, and employer branding principles into the business engineering system requires an interdisciplinary approach, as confirmed by the analyzed works of contemporary researchers in this field. These studies highlight the potential of business engineering as a tool for structural transformation of organizations, enabling the effective implementation of socially responsible practices through digital solutions, business process re-engineering and marketing optimization [7]-[9].

The analysis of sources devoted to gender statistics and indicators, as well as international legal norms regulating gender issues in the labor sphere, is methodologically justified and critically important for building an evidence-based foundation for the study of socially responsible HR practices and the implementation of the gender approach within the business engineering system. The effective realization of an inclusive HR strategy depends on the use of valid, methodologically sound indicators that reveal not only formal but also structural barriers to resource access [10], [11].

4.1 Modelling of the Structure and Key Aspects of Forming Sustainable Corporate Relationships Within the Personnel Marketing System

In our opinion, the implementation of a gender approach and socially responsible HR branding practices within the business engineering system of a modern company should include the development of sustainable relationships in the corporate personnel marketing system and encompass the following key directions:

- the integration of visual models of structural components and the analysis of the features of forming long-term employment relationships under the conditions of digital transformation of corporate interactions;
- a multi-faceted characterization of sustainable employee relations as an intangible marketing asset, taking into account international legal norms and gender criteria;
- the development of a concept of the employee's professional life cycle in terms of the calendar duration of their life. The synchronization of this cycle with the internal life cycle of a specific company and the comprehensive set of its marketing efforts should form the foundation for an integrated impact aimed at creating and nurturing long-term relationships with employees as a strategically valuable marketing asset;
- the optimization of marketing processes for the formation and evolution of sustainable relationships between the company and its personnel in the context of digitalization and global competition for talent in the labor market;
- the study of the specifics of outplacement within the HR branding system aimed at maintaining long-term employment relationships with an emphasis on gender equality;
- the development of a methodological approach for the quantitative assessment of the effects arising from the development of strategic relationships between the company and its employees, considering international legal and marketing contexts.

The visual modeling of the structure and key aspects of forming sustainable corporate relationships within the personnel marketing system is presented in Figure 1. The initial level, which ensures the effectiveness of interaction between the company and the employee and creates the prerequisites for the long-term nature of their relationship, is the employee's performance of basic labor functions in exchange for agreed remuneration. It is important to note that, at this stage, the gender approach implies equal access to employment opportunities and a fair remuneration system for individuals of all genders.

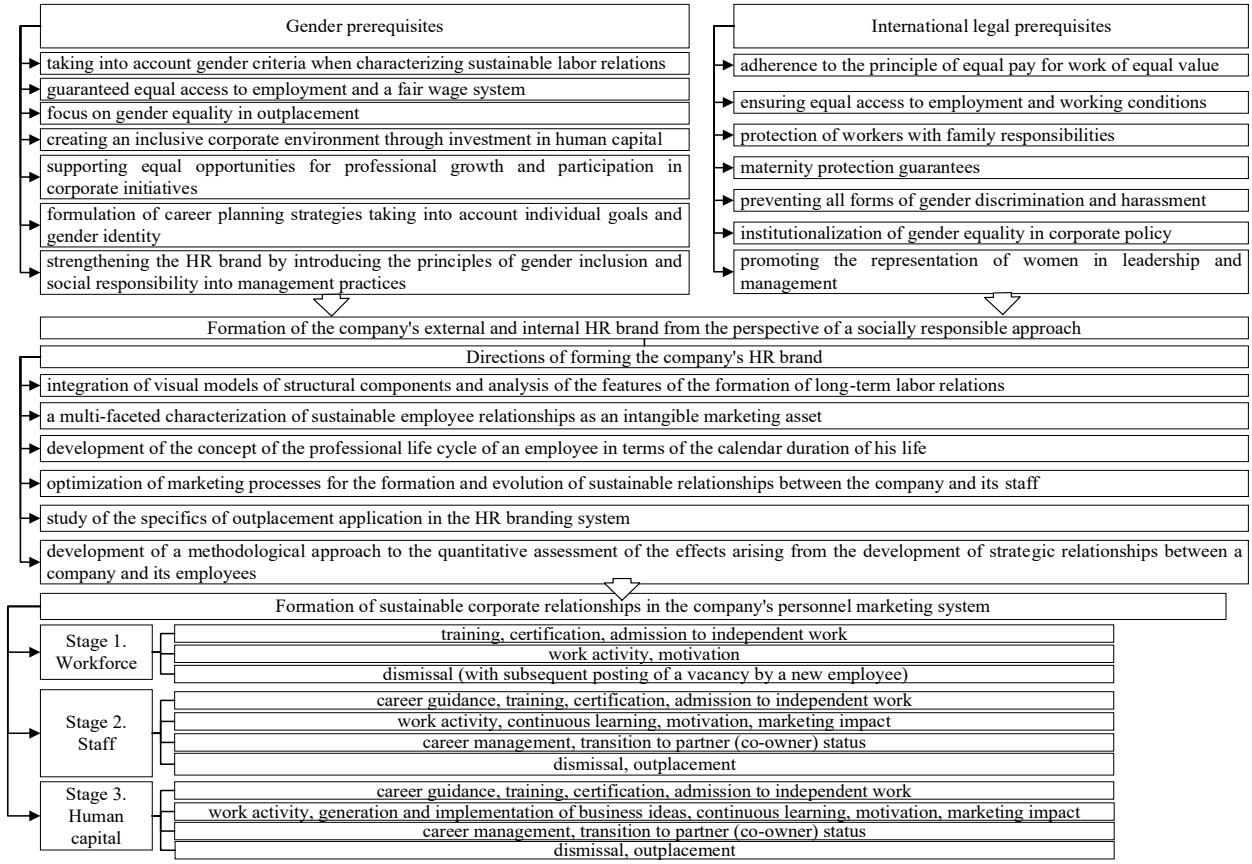

Figure 1: Mechanism for implementing a gender approach and socially responsible HR branding practices in the business engineering system.

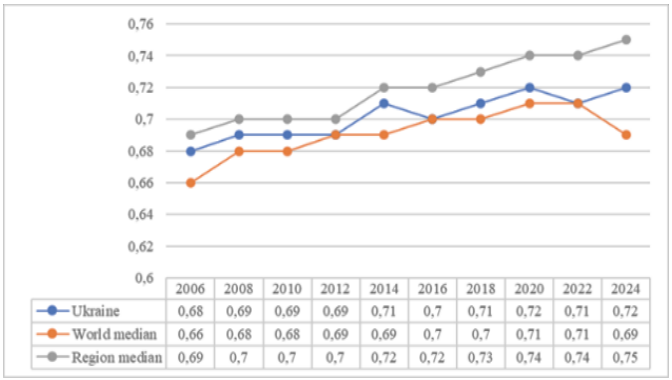
4.2 Analysis of Gender Statistics and Indicators in the Context of Research on Socially Responsible HR Branding Practices in the Business Engineering System

Gender statistics and indicators are an integral part of the gender approach throughout the entire policy cycle. First, they provide information for the policymaking process and ensure that interventions address the different needs and priorities of women and men. Second, they measure changes in the relationships between women and men over time in a particular policy area, program, or activity, as well as changes in the status or position of women and men. Third, they are an essential component of monitoring and evaluating the implementation and outcomes of policies, programs, and projects. Thus, gender statistics are intended to "reflect differences and inequalities in the status of women and men in all areas of life" [12]. By providing evidence on gender equality and gender gaps in key areas, they help make gender inequality visible – which, in turn, can be used in designing policies aimed at eliminating the identified disparities. They help identify data relevant to the lives of women and men and to the key areas of policy development.

The Global Gender Gap Index [13] provides an annual assessment of the status and progression of gender parity across four fundamental domains (Economic Participation and Opportunity, Educational Attainment, Health and Survival, and Political Empowerment). Established in 2006, it remains the most enduring index for monitoring the long-term advancements of various economies in bridging these disparities.



In 2024, the global gender gap index for all 146 countries analyzed in report indicates that 68.5% of the gap has been closed. Compared to the consistent sample of 143 countries assessed in the previous edition, the overall gender gap has narrowed by an additional 0.1 percentage point, increasing from 68.5% to 68.6%. Similarly, for the 101 countries that have been continuously monitored from 2006 to 2024, the gap has also improved by 0.1 percentage point, reaching a closure level of 68.6%.

European economies account for seven of the top ten positions in The Global Gender Gap Index ranking [13].

Ukraine's performance in the Global Gender Gap Index 2024 reflects a multifaceted trajectory of gender parity, characterized by notable advancements in educational attainment and economic participation yet hindered by persistent disparities in political representation. With an overall index score of 0.722 and a ranking of 63rd globally, Ukraine surpasses the global average of 0.685 but lags behind European counterparts, where the regional average is 0.750 (Fig. 2).

2024 represents a critical juncture for the Sustainable Development Goals (SDGs) and the trajectory of global development cooperation. With merely six years remaining until the 2030 target, the pace of progress - particularly in advancing gender equality - remains insufficient. The Summit of the Future, alongside the forthcoming thirtieth anniversary of the Beijing Declaration and Platform for Action, offers a vital opportunity to reaffirm international commitments to accelerating gender equality and the protection of women's rights.

The digital ecosystem continues to be predominantly shaped by young white men, with women remaining significantly underrepresented in the Information and Communications Technology (ICT) sector. Within the European Union, women constitute only 19% of ICT specialists, accounting for a mere 2% of total EU employment, in contrast to 7% for men (Fig. 3) [16].

	2006	2008	2010	2012	2014	2016	2018	2020	2022	2024
Ukraine	0,68	0,69	0,69	0,69	0,71	0,7	0,71	0,72	0,71	0,72
World median	0,66	0,68	0,68	0,69	0,69	0,7	0,7	0,71	0,71	0,69
Region median	0,69	0,7	0,7	0,7	0,72	0,72	0,73	0,74	0,74	0,75

Figure 2: Benchmark of Ukraine Global Gender Gap Index with world and region median, 2006-2024, score [13].

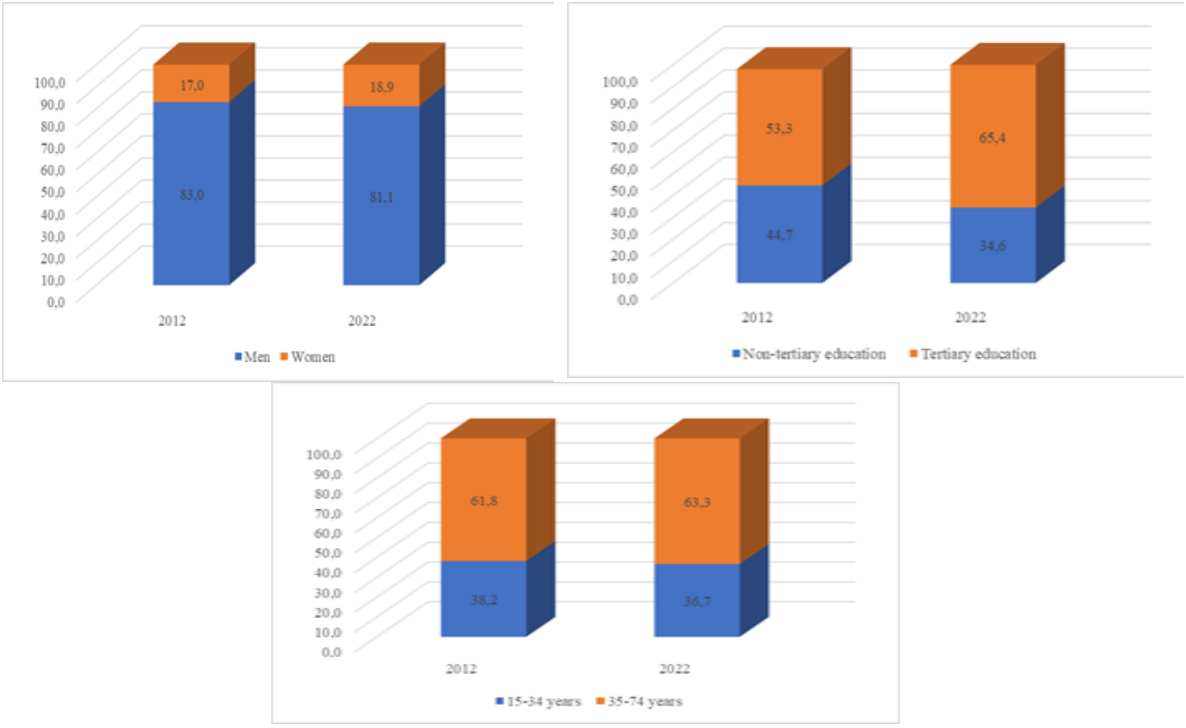


Figure 3: Distribution of persons employed as ICT specialists by sex, education attainment level and age, EU, 2012 and 2022, % [16].

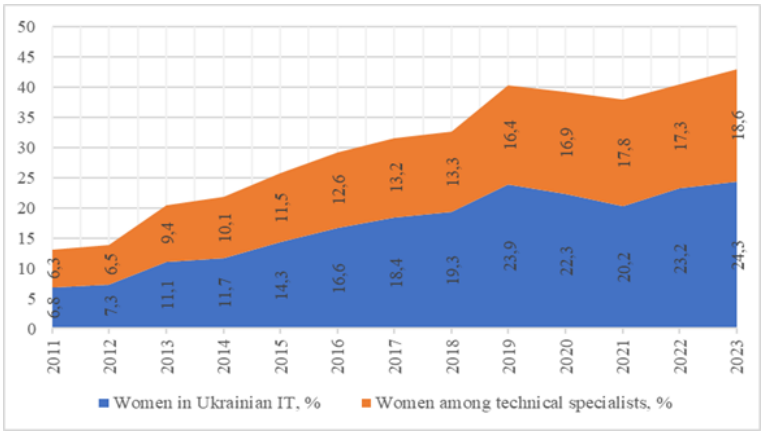

Figure 4: Dynamics of changes in the share of women in the Ukrainian IT sector, 2011-2023, % [14].

The representation of women in ICT varies across Central European nations, with Austria reporting 19%, Czechia 11%, Poland 17%, and Slovakia 15%. These figures may decline further when disaggregated to exclude non-technical roles such as human resources, marketing, and project management. Notably, women employed in ICT earn, on average, 19% less than their male counterparts, surpassing the EU-wide gender pay gap of 13%. In the Central European countries this wage disparity is even more pronounced, ranging between 20% and 30%.

The gender structure of Ukraine's IT industry demonstrates a steady trend toward increasing the share of women within the professional community. At the end of 2011, women's representation in the information technology sector did not exceed 7%. However, between 2012 and 2018, this figure gradually increased by several percentage points each year (Fig. 4) [14].

An analysis of the gender structure of employment in the Ukrainian IT sector reveals a stable trend toward the professional diversification of women across various fields within the industry. The highest level of female representation is observed in the field of quality assurance (QA engineers), accounting for 28% of all women in the industry, followed by software development, where 19% of women are employed. Overall, 66% of women work in technical roles, while 34% are engaged in non-technical specializations. This indicates a consistent pattern of gender-based professional segmentation since 2016, as the share of women in non-technical roles was lower prior to that period [14]. In our view, maintaining such a balance could serve as an indicator of the effectiveness of implementing a gender-sensitive approach in the HR policies of IT companies, contributing to equal opportunities for women in the high-tech sector. At the same time, it is already evident that there is a noticeably high level of corporate social responsibility in the field of IT product development, reflected in the growth of inclusive corporate environments. This enhances the attractiveness of companies to female professionals across different profiles and, in turn, supports the formation of a sustainable HR brand.

4.3 International Legal Aspects of Research on Socially Responsible HR Branding Practices in the Business Engineering System

The issue of gender equality in labor relations is of great importance and should encompass principles such as equal opportunities and equal treatment of men and women in employment, equal pay for equal work, improved work-life balance for employees, and equal treatment in hiring practices. At the current stage of economic development, men and women are formally equal in rights, yet the quality of employment remains unequal. Gender inequality in the labor market is, on the one hand, a consequence of social development, and on the other hand, one of the root causes of many problems that affect the functioning of the labor market [15]. Therefore, the gender approach is a vital component of comprehensive research into labor market issues, as it allows for the identification of mechanisms, causes, and consequences of gender inequality in employment.

For example, employment levels across EU countries vary significantly. In 2018, the highest levels of female employment were traditionally observed in Sweden (76.0%), the Netherlands (72.8%), Denmark (72.6%), Germany (72.1%), Lithuania (71.6%), Estonia (71.4%), and Finland (70.6%). The lowest levels were recorded in Italy (49.5%) and Greece (45.3%). Unemployment rates also differ significantly by gender. The largest gender disparities in unemployment were seen in Greece (24.2% for women versus 15.4% for men) and Spain (17.0% for women and 13.7% for men), where female unemployment exceeded male unemployment. Conversely, in Ireland and Lithuania, male unemployment was higher than female unemployment. Gender pay differentiation across the EU averages 16.1%, but gender pay gaps vary considerably among member states. While the gender pay gap has generally narrowed across the EU over the past decade, in some countries it continues to widen, despite improvements in women's employment levels, increased job opportunities, and higher education attainment. The largest gender pay gap is observed in Estonia (25.6%), while the smallest is in Romania (3.5%) [16].

According to the Global Gender Gap Report 2023, women make up approximately 47% of the global workforce. However, in many countries, women still face barriers to accessing equal opportunities. In Ukraine, the female employment rate increased to 51% in 2023, compared to 43% in 2021. Nonetheless, the gender pay gap widened, with women’s average earnings amounting to only 69% of men’s wages. In 2023, the global unemployment rate stood at 5.1%, with a projected increase to 5.2% in 2024, driven by labor market challenges in developed countries. The global gender pay gap also remains a significant issue: on average, women earn 20% less than men. In Europe, for instance, it is estimated that gender pay parity will take another 67 years to achieve, while in North America it will take 95 years. As of 2023, Ukraine's gender pay gap was 18.6%, but the government has set a target to reduce it to 13.6% by 2030 [17].

The uneven distribution can also be explained by the so-called compensation gap. Compared to other professions, women are more likely to accept jobs that are less physically demanding, have shorter work cycles, and offer certain social support (such as childcare). Women tend to have higher expectations regarding working conditions and benefits, but unlike men, they are generally less inclined to work overtime. Summarizing these factors, it is worth noting that women's human capital is considered to be lower than that of men. Therefore, according to human capital theory, the remuneration for women’s work tends to be lower than that for men’s work.

As for international organizations, they identify gender issues as one of the priorities of human development, which is reflected in their strategies. They also view gender equality as a resource for socio-economic development. Accordingly, the key features of international and European legislation aimed at eliminating gender discrimination and promoting the principle of equal treatment include: special measures to promote equality between women and men and prohibit direct and indirect discrimination; the prohibition of victimization, harassment, and sexual harassment; compensation for damages and sanctions for unlawful actions; the adoption of specific legislation on gender equality; the establishment of relevant institutions to protect both women and men; and the integration of the gender dimension into the formulation and implementation of public policy. The gender dimension plays an essential role in shaping and implementing public policy. The principles of gender equality and non-discrimination must be applied not only at the level of state governance but also across other levels. In particular, gender issues should be integrated into organizational policies, and appropriate procedures should be established to prevent discrimination and ensure equal access to resources and power for both women and men.

The ILO considers it extremely important to raise awareness of the legal aspects of gender equality in the world of work. Social and lasting peace can only be built on the foundation of social justice. This principle is proclaimed in the preamble to the ILO Constitution of 1919. Even at that time, immediately following World War I, the protection of women and the principles of equal remuneration for work of equal value were recognized as areas requiring urgent action. In 1944, the Declaration of Philadelphia was adopted at the International Labour Conference, and it is now an annex to the ILO Constitution. The declaration states that "all human beings, irrespective of race, creed or sex, have the right to pursue both their material well-being and their spiritual development in conditions of freedom and dignity, of economic security and equal opportunity." It further emphasizes that "poverty anywhere constitutes a danger to prosperity everywhere." The rights of working women are an integral part of the values, principles, and objectives that define the ILO's mandate, which is aimed at promoting social justice and decent work – fairly paid, productive employment carried out in conditions of freedom, equity, security, and dignity. Labor standards address the issue of gender equality in various ways. Some are gender-specific, explicitly calling for gender equality or the elimination of discrimination against women or men, such as the Equal Remuneration Convention (1951, No. 100), the Maternity Protection Convention (2000, No. 183), the Termination of Employment Convention (1982, No. 158), and the Employment Policy Convention (1964, No. 122). Other standards are gender-sensitive – their provisions take into account the needs of both women and men, even if not explicitly stated. Examples include the Workers with Family Responsibilities Convention (1981, No. 156), the Worst Forms of Child Labour Convention (1999, No. 182), the Part-Time Work Convention (1994, No. 175), the Home Work Convention (1996, No. 177), as well as several others that address working conditions such as safety, protection, and transportation. The fundamental Convention No. 111 encompasses both of these groups, as it is aimed at preventing discrimination and ensuring gender equality, while not being limited to gender discrimination alone. A third group of conventions contains technically neutral standards, which reveal gender-specific dimensions in practice – for example, in the collection and use of statistical data. These conventions cover issues such as wage payment, occupational accidents and injuries, working time, and social protection. The ILO has identified four conventions as key instruments for achieving gender equality in the world of work: the Equal Remuneration Convention (1951, No. 100); the Discrimination (Employment and Occupation) Convention (1958, No. 111); the Workers with Family Responsibilities Convention (1981, No. 156); and the Maternity Protection Convention (2000, No. 183) [18].

Focusing on the words of the ILO Director-General, Gilbert F. Houngbo, among the numerous challenges that persist is the fact that, on average, women still earn 20 percent less than their male colleagues. The central message of the 111th International Labour Conference, held on June 5, 2023, was reflected in his statement: "Social justice must be made a global priority" [19].

The agenda included a position on achieving equality between women and men in the workplace, which was at the core of the General Survey conducted by the Committee of Experts on the Application of Standards. As part of this review, the Committee of Experts' Report on the Application of Conventions and Recommendations was presented (Achieving gender equality at work). According to the document, over the past 25 years, the global momentum toward gender equality has grown at an unprecedented scale. The adoption of the Beijing Declaration in 1995 and its review in 2020 have

significantly increased interest in advancing gender equality [20].

In 2021, the United Nations Commission on the Status of Women called on governments to take action to eliminate the root causes of gender inequality and the barriers to women's full and equal participation. This was to be achieved through the expansion of women's economic opportunities and their right to work, the elimination of occupational segregation, and related measures.

The last century has been marked by tremendous progress for women, who in many countries have gained greater access to equal opportunities and improved treatment in the workplace. Women are increasingly entering sectors and leadership positions that were once considered "male-dominated." Maternity protection measures are becoming more widespread across many countries, and efforts are being made to support the balance between work and family responsibilities. The promotion of gender equality includes actions to ensure access and equality in education, training, and employment; the empowerment and economic autonomy of women; the prevention of violence and harassment, including gender-based violence such as domestic abuse and sexual harassment; maternity protection; and the advancement of women to leadership positions and their representation in government bodies [21].

5 CONCLUSIONS

Ensuring gender equality in labor relations is a key factor in shaping a socially responsible HR brand and developing sustainable business engineering models in the context of digital transformation. The gender approach in HR policy encompasses a wide range of objectives aimed at achieving equal rights and opportunities for women and men in the labor market, including the elimination of discrimination, the overcoming of gender stereotypes, the provision of equal pay for work of equal value, and the creation of conditions for balancing professional activities with family responsibilities.

The implementation of gender-sensitive strategies in HR management contributes to increased labor productivity, the strengthening of corporate culture, the formation of long-term employment relationships, and the enhancement of employer reputation. Priority areas in this field include ensuring equal access to employment and career advancement, introducing transparent pay mechanisms based on the principle of equal remuneration, developing flexible forms of employment, supporting parenthood, preventing sexual harassment, promoting women's leadership, and ensuring gender balance in senior management bodies.

Thus, adherence to gender equality principles and the implementation of socially responsible HR practices are not only an ethical imperative but also a strategic necessity for organizations striving for sustainable development, innovation, and compliance with international legal standards. The systemic integration of the gender approach into HR branding ensures the creation of an inclusive corporate environment and enhances business competitiveness at both national and international levels.

Keywords: Artificial Intelligence, Energy Infrastructure Development, Smart Energy Systems, Digital Energy Transformation, Critical Energy Infrastructure, Cybersecurity, Cyber-Resilience, Sustainable Energy Development, Energy System Resilience, Decision Support Systems, Machine Learning, Digital Twins, Sustainable Development.

Abstract: The article is devoted to the study of the development of scientific discourse on the application of artificial intelligence (AI) technologies in managing the development of energy infrastructure in the context of global digital transformation and the transition to low-carbon energy systems. The aim of the work is to identify the dynamics of publication activity, key thematic priorities and international scientific clusters based on the results of bibliometric analysis of publications indexed in the Scopus database for the period 2000–2025. The results obtained showed a rapid growth in scientific interest after 2020, which correlates with the development of Smart Grid, IoT, machine learning, predictive analytics technologies, as well as with the growing need to increase the resilience and cybersecurity of critical energy infrastructure. It was determined that the greatest intensity of research is observed in India, China, the USA, as well as in a number of European countries, which indicates the global nature of the topic. Semantic analysis of keywords allowed us to identify the dominant areas of scientific research: optimization of energy consumption and integration of renewable energy sources, development of intelligent energy grids and "smart" cities, implementation of digital twins of energy systems, use of forecasting algorithms and decision support. Based on the results, the conclusion was formulated that AI is becoming a strategic tool for the energy transition, ensuring increased energy efficiency, accuracy of network balancing, acceleration of response to emergencies, strengthening cybersecurity and achieving the Sustainable Development Goals. Practical recommendations include the development of standards for the use of AI in critical infrastructure, the creation of national energy data platforms and digital twins, strengthening institutional interaction between governments, businesses and scientific institutions, as well as the development of ethical and regulatory frameworks for the use of AI.

1 INTRODUCTION

In a rapidly digitalizing global economy, energy infrastructure remains a fundamental condition for the stability, competitiveness, and national security of states. The growth of technogenic complexity, the decentralization of energy generation, the development of renewable energy sources, and the growth of cyber threats make energy systems increasingly interdependent and vulnerable. According to analysts from Markets and Markets [1], the vulnerability of critical infrastructures stimulates the steady growth of the global cyber defense market: in 2020-2030 it will increase by 11.5%, to over 24 billion dollars. This emphasizes the urgent need to increase the cyber resilience of the energy sector as a strategic prerequisite for the sustainable functioning of the economy. In such conditions, traditional mechanisms for planning and modernization of energy systems are gradually losing their effectiveness, as they are unable to process large

data sets, integrate decentralized generation, and provide high forecasting accuracy [2]-[6].

Therefore, artificial intelligence (AI) is becoming a key tool for managing energy infrastructure in the era of digital transformation [7]-[11]. According to Statista [12], the global AI market has grown from 93.3 billion dollars in 2020 to 184 billion dollars in 2024, almost doubling. S. Ghimire's forecast [13] indicates that by 2027 the market volume will exceed 407 billion dollars.

International surveys confirm the public and institutional demand for the implementation of AI in the management of critical infrastructure facilities. According to a German study in 2022, 46% of citizens consider AI to be an effective tool for increasing the resilience of energy and transport systems to natural disasters [14]. At the same time, 41% of respondents fear the negative impact of algorithmic systems on the security of critical facilities, and 15% express a high level of concern about potential risks [15]. This demonstrates the ambivalence of the perception of intelligent technologies and the need to improve risk management policies.

According to the Center for Security and Emerging Technologies at Georgetown University [16], the integration of artificial intelligence into critical sectors creates both new opportunities for increasing efficiency and predictability, as well as new vulnerabilities associated with cyber risks and the human factor. At the same time, 81% of technology company executives predict that the use of advanced artificial intelligence models will provide at least a 25% increase in operational efficiency in the next three years, in particular in the area of load management, demand forecasting and optimization of renewable energy generation [17].

In the corporate sector, artificial intelligence is increasingly being used as a tool to improve productivity. According to a Celonis survey [18], 48% of companies identified automation and process optimization as the main motivation for implementing artificial intelligence. In the field of energy infrastructure development, this means moving to new models of asset management, monitoring of technical condition, forecasting of emergency situations and reducing energy losses [19]-[21].

The integration of artificial intelligence acquires special importance in the context of national and energy security. According to the conclusions of D. Araya and M. King [22], artificial intelligence forms a new architecture of defense and infrastructure systems, combining data analysis, autonomous technologies, neuromorphic computing and integration with IoT. This creates a large-scale potential for increasing the resilience of the energy sector, while at the same time generating the need for global risk regulation and standardization of algorithmic solutions [23]-[25].

Therefore, the study of the impact of artificial intelligence on the management of energy infrastructure development is a priority area of scientific research. It allows you to form the scientific foundations of effective digital transformation, increase energy sustainability and security, minimize risks, and implement sustainable development goals.

2 LITERATURE REVIEW

The analysis of modern scientific publications shows the increasing scientific interest in the relationship between artificial intelligence and critical infrastructure development management. Researchers K. Chen, X. Zhou, Z. Bao, M. J. Skibniewski and W. Fang [24] summarized the areas of application of artificial intelligence in infrastructure construction, highlighting the dominance of machine learning, computer vision and natural language processing technologies.

C. Sambucci and C. Paraschiv [25] identified the spectrum of cyber threats for artificial intelligence systems in critical sectors and proposed the concept of security auditing of AI models. Scientists H. Jing, W. Wei, C. Zhou and X. He [26] developed a system framework for artificial intelligence security, covering the stages of the life cycle from design to operation.

Japanese scientists T. Takeda, J. Kawamura, T. Murakami, T. Matsumura and A. Arai [27] focused on the gaps in the legal regulation of the use of artificial intelligence in water infrastructure. At the same time, J. J. Reddy, A. Mittal, V. Reddy and H. Das [28] proved the potential of combining artificial intelligence, blockchain and IoT to form sustainable "smart" infrastructures.

Summarizing the results, it can be stated that modern research forms three leading scientific directions:

1) security and reliability of artificial intelligence systems;
2) institutional management and legal support for their integration into critical infrastructure;

3) the transformative role of artificial intelligence in creating sustainable and digitally adaptive infrastructures.

The generalization of scientific achievements shows that research in the field of the impact of artificial intelligence technologies on the management of the development of critical infrastructure is gradually moving into the phase of sectoral specification. One of the priority and extremely important areas has become the management of energy infrastructure development, where artificial intelligence is considered not only as a technological tool, but as an integrative mechanism for the transformation of energy systems [29-34], combining digitalization, decentralization, security and resilience.

Scientific research by M. Ashok, K. Ganesan, R. Saravanan and R. Kumar [35] demonstrates that artificial intelligence algorithms provide systemic management of the balance between energy production, distribution and consumption, increasing the efficiency of network processes and reducing losses in energy systems.

Research by V. Pavlenko et al. [36] emphasizes the synergy between AI, blockchain and smart grids, which creates the basis for the formation of decentralized energy ecosystems with transparent management of data flows and energy resources.

B. Hanna, G. Xu, X. Wang, J. Hossain [37] emphasize that the potential of artificial intelligence is crucial for achieving the seventh goal of sustainable development, as it contributes to increasing energy efficiency, equitable energy access and the development of "clean" technologies.

The conceptual principles of integrating artificial intelligence into the energy sector are systematized in the work of A. M. S. Derbali [38], where the author considers artificial intelligence as the core of a future energy ecosystem capable of ensuring climate neutrality and maintaining energy balance in the face of technological variability.

The analysis of P. Arévalo & F. Jurado [39] shows that artificial intelligence is becoming a key factor in the optimization of distributed energy systems – from demand forecasting to the integration of renewable sources, ensuring the adaptability and flexibility of "smart" networks.

The studies of C. Biswas, A. Chakraborti, S. Majumder [40] present a wide range of methods (from neural networks to fuzzy logic systems) that provide predictive management and technical diagnostics in renewable energy.

A significant contribution to the formation of the theoretical basis was made by the work of B. Zohuri, F. Mossavar-Rahmani and F. Behgounia [41], where the concept of Business Resilience System (BRS) was proposed, which integrates elements of machine and deep learning to predict energy processes and increase the systemic resilience of energy markets.

Taken together, the results of the analysis allow us to state the emergence of a new scientific direction – AI-driven energy infrastructure management, which combines intelligent decision support systems, big data analytics, digital twins and cyber-physical energy models. Unlike previous studies of critical infrastructure development, which mostly emphasized protection and risks, the energy discourse focuses on innovation, sustainability and climate neutrality, identifying artificial intelligence as a strategic driver of the transition to a new architectonics of energy systems.

In view of this, the aim of the article is to theoretically substantiate and systematize the areas of influence of artificial intelligence on the management of energy infrastructure development in the era of global digital transformation; to identify the potential, risks and mechanisms for using intelligent technologies in ensuring energy security and increasing the efficiency of energy systems.

3 METHODOLOGY

The methodological basis of the study combines systemic, comparative-institutional, analytical and bibliometric approaches, which in combination provide a comprehensive assessment of the impact of artificial intelligence technologies on the management of energy infrastructure development in the context of global digital transformation.

The theoretical basis of the study is the system paradigm, according to which energy infrastructure is considered a complex socio-economic and technical system in which technological, institutional and managerial subsystems interact. This approach makes it possible to identify feedback loops, adaptive mechanisms and dependencies that determine the efficiency and resilience of the energy system under the influence of digital technologies and artificial intelligence algorithms.

The comparative-institutional approach was used to analyze models of integration of artificial intelligence technologies into the practice of energy system management of different countries and organizations (based on materials from the IEA, IRENA, WEF, and the European Commission). This allowed us to identify effective management models,

state regulation tools and organizational mechanisms that can be adapted to the Ukrainian energy context.

The empirical part of the study is based on quantitative and qualitative analysis of international data and scientific publications. The information base was formed on the basis of reports of leading international organizations – the International Energy Agency (IEA), the International Renewable Energy Agency (IRENA), the World Economic Forum (WEF) and the European Commission. These sources contain current indicators of the level of digitalization of the energy sector, the effectiveness of the use of artificial intelligence technologies, the dynamics of reducing operating costs and increasing the accuracy of demand forecasting.

In order to identify scientific trends and conceptual structures, a bibliometric analysis was conducted using the Scopus database as the main source of scientific information. The search query "Artificial Intelligence" and "Energy Infrastructure Development Management" covered publications for the years 2000-2025, with a detailed analysis carried out for the period 2013-2025, which is characterized by the highest scientific activity.

VOSviewer v.1.6.19 software was used to process and visualize the results, which allows building maps of keyword co-occurrence, co-authorship networks and citations. This made it possible to identify dominant scientific clusters, identify influential authors and trace interdisciplinary connections between the topics of artificial intelligence, energy efficiency and digital management.

Integration of the results of bibliometric, comparative and system analyzes made it possible to carry out a system-analytical synthesis aimed at identifying key determinants that shape the impact of artificial intelligence on the development of energy infrastructure.

The proposed methodological approach ensures the objectivity, reproducibility, and scientific validity of the research results, creating a basis for forming strategic management decisions to increase the efficiency, adaptability, and resilience of energy infrastructure in the context of digitalization.

4 RESULTS

A search of the Scopus database using the keywords "Artificial Intelligence" and "Energy Infrastructure Development Management" revealed 453 documents published between 2000 and 2025. The dynamics of scientific papers demonstrate a significant increase in publications after 2018 (Fig. 1), reflecting the rapid digital transformation of the energy sector, the introduction of 5G–6G technologies, the active development of "green" energy concepts, and the strengthening of global sustainable development programs.

Until the mid-2010s, the number of papers remained insignificant, but after 2020 there has been a sharp acceleration with peak indicators in 2024-2025, which confirms the sharp increase in the relevance of research on the application of artificial intelligence in energy infrastructure management.

Calculations showed an exponential growth of scientific interest: the average annual growth rate (CAGR) was 21.7%, and the period for doubling the number of publications was about 3.2 years. The peak of activity in 2024-2025 (+139%) correlates with the strategic initiatives of the EU and the IEA, in particular the Digital Energy Action Plan 2022-2025 and AI for Energy Transition. The value of the coefficient of determination of the model (R^2=0.52) indicates that more than half of the variation in the dynamics of publications is explained by the exponential trend, typical of rapidly growing interdisciplinary areas.

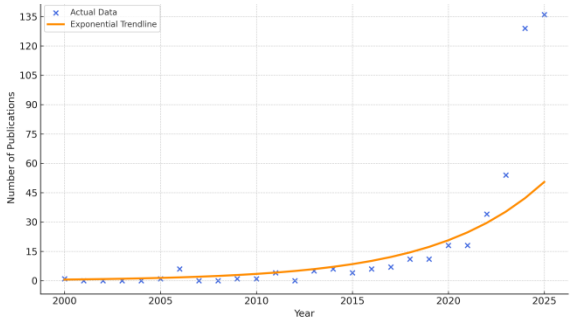

Figure 1: Exponential growth of publications on "AI in energy infrastructure development management" (2000-2025).

The evolution of the publication flow allows us to identify four stages of the development of scientific interest (Fig. 2): the period of emergence (2000-2010) with isolated works; the period of formation (2011-2017) with a gradual increase in applied research on machine learning in energy; the period of active development (2018-2021), when the integration of AI is associated with the concepts of Industry 4.0, Smart Grid and IoT; the period of intensive expansion (2022-2025), within which sustainable scientific schools were formed in the USA, India, China and the EU.

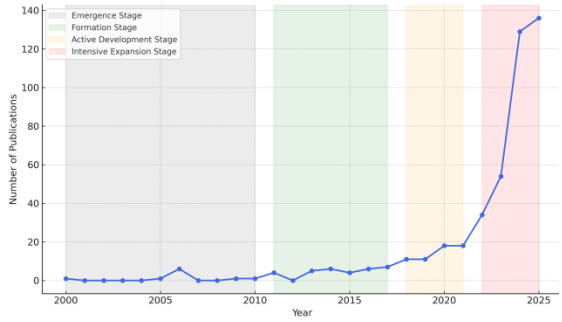

Figure 2: Stages of scientific interest in AI-driven energy infrastructure development management.

The most cited publications (Table 1) focus on the intersection of artificial intelligence, energy efficiency, digital management technologies and sustainable development. Field-Weighted Citation Impact (FWCI) indicators range from 1.84 to 16.11, which is 2-8 times higher than the industry average, confirming the high level of innovativeness of research.

The leading publishers in the research topic are MDPI, Springer Nature and IEEE (Table 3), which generate more than 70% of the analyzed publications. The Energies and Sustainability journals (MDPI) are characterized by high CiteScore (>7) and SNIP (>1.0), IEEE Access demonstrates one of the highest citation rates (CiteScore=9.0, SNIP=1.504), and the Springer series (Lecture Notes in Networks and Systems, Studies in Systems, Decision and Control) dominate the segment of algorithmic methods and digital technologies for energy systems management. The geography of publications indicates the formation of a global scientific network. The largest number of documents was prepared by researchers from India (106), China (52), the USA (50), the UK (24), Italy (23) and Australia (22). Ukraine (12 documents), Germany, South Korea, Ireland and Canada also provide significant contributions.

The analysis of scientific collaboration revealed several stable clusters (Fig. 3), which form a global network of research on artificial intelligence in energy infrastructure management. Each cluster has its own institutional core, research focus and thematic dominants, reflecting the socio-economic and technological priorities of the respective regions. The first is the Indian-Asian cluster, the core of which is India. The key participants are Saudi Arabia, the UAE, Egypt, Iraq, Taiwan and Nigeria. The cluster is characterized by a high intensity of inter-university collaborations, in particular between the Indian Institutes of Technology, the National Institutes of Technology, Sharda University, Lovely Professional University and a number of technical universities in the Middle East.

The main focus of research is related to the optimization of energy network management, renewable energy, the integration of solar and wind power plants into national energy systems, load forecasting and the application of machine learning for electric power Smart Grid platforms. A feature of this cluster is its focus on practical engineering solutions that are scalable in rapidly developing countries, and significant government investment in energy technologies as part of national energy security strategies.

Table 3: Thematic Clusters of Key Research Concepts on "Artificial Intelligence in Energy Infrastructure Development Management" (Scopus, 2000–2025).

Cluster Name	Dominant Keywords	Scientific Focus	Features
AI and Sustainable Resource Management	artificial intelligence, machine learning, optimization, decision support systems, water management, waste management, circular economy, carbon emission	Application of AI and ML for natural resource governance, optimisation of water supply and treatment, reduction of CO_2 emissions, and the development of circular economy models	Formation of intelligent environmental management ecosystems and advancement of the "green AI" concept in the context of SDG 7, SDG 9, SDG 11, SDG 13
Intelligent Energy Systems	smart grid, energy management, renewable energy, energy storage, demand side management, electric vehicle, cyber security, learning systems	AI-based energy governance: demand-side management, load forecasting, network security and renewable energy integration	Combination of technical (Smart Grids, IoT) and managerial (decision support, predictive analytics) approaches within AI-driven energy system control
Information Management and Data Analytics	information management, data analytics, IoT, blockchain, cloud computing, big data, decision making, learning algorithms	Digital analytics and data governance: IoT and Big Data for monitoring, blockchain platforms for energy transactions, cloud computing for analytics applications	Forms the technological core of digital energy systems, linking analytical models with risk management and cybersecurity
Digital Infrastructure and Next-Generation Communications	cloud-computing, 5G, 6G, network architecture, network security, smart infrastructure, real-time systems	AI-based management of next-generation communication and infrastructure systems: 5G/6G networks, real-time systems, and energy-efficient telecommunications	Development of AI-driven communication networks supporting intelligent energy platforms
Urban Energy and Sustainable Urbanism	smart city, urban growth, urban transportation, autonomous vehicles, planning, environmental management systems, sustainable city	AI for urban energy and infrastructure planning, optimisation of transportation and smart mobility, and development of sustainable cities	Integration of Smart City and Sustainable Urban Development concepts enabled by artificial intelligence

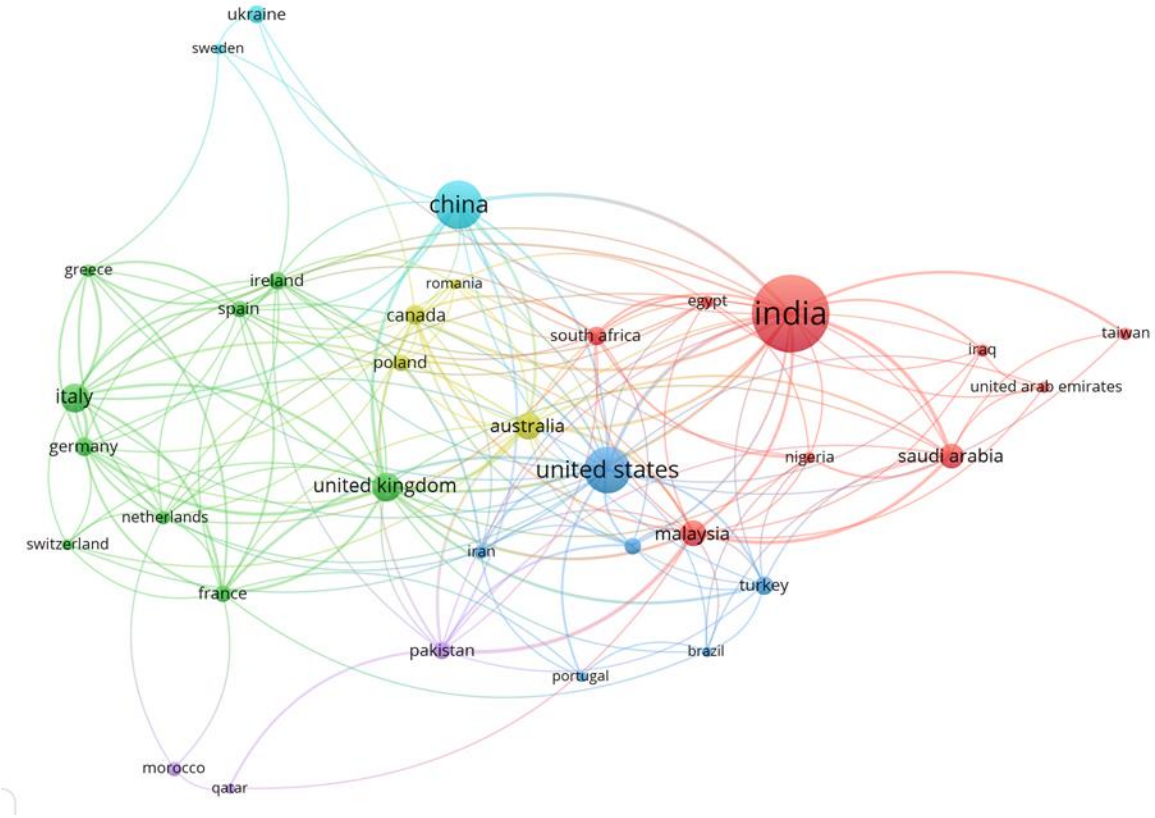

Figure 3: Identified clusters of international research collaboration on the selected topic.

The second is the Anglo-American cluster, which is formed by the USA, the UK, Australia, Malaysia, Turkey and partly Brazil, Portugal and Iran. Its research focuses on creating AI-based decision-making systems, predictive analytics and machine learning for load management and preventing accidents in energy networks. Significant attention is paid to green communication networks, the use of 5G–6G technologies, energy cybersecurity and protecting infrastructure from cyberattacks.

Leading organizations in the cluster include the Massachusetts Institute of Technology, the National Renewable Energy Laboratory (NREL), the University of Oxford, Imperial College London, the University of California and the University of Melbourne. The cluster is dominated by publications in highly ranked IEEE and Springer journals, which is due to the high level of algorithmic and analytical research.

The third is the European cluster, which unites research centers in the UK, Italy, Germany, France, Spain, the Netherlands, Ireland, Switzerland and Greece. Its distinctive feature is the close integration of EU environmental and energy policies with digital technologies for power system management. The cluster demonstrates the highest density of internal collaboration, reflecting the joint research programs Horizon 2020, Horizon Europe, Digital Europe, Green Deal and the institutional role of ACER-CEER in shaping regulatory approaches. The thematic focus covers modelling of sustainable energy transition, risk management and the development of Smart Cities/Smart Regions, digital twins of infrastructures, as well as the impact of AI on the decarbonization of industrial systems.

The fourth is the North African and Middle Eastern cluster, which includes Qatar, Morocco and partly Romania, which is in a transitional position. The main specificity of this cluster is related to the climatic vulnerability of the territories and the need for digital control of energy systems in conditions of increased risks associated with water scarcity, record temperatures and growing demand for electricity. Research focuses on the integration of renewable energy sources, optimization of energy generation and storage, as well as the use of artificial intelligence to reduce losses in networks and manage energy security.The fifth is the Chinese cluster, in which China acts as a coordinating center, supporting cooperation with Canada, Poland,

Ukraine and Romania. Research is focused on AI-driven Smart Grid systems, energy distribution optimization, energy storage development, and the creation of cyber-physical systems in the energy sector. There is a high participation of large industrial corporations and public-private research alliances, which reflects the strategic state programs of the energy transition in China. Ukraine, although playing a peripheral role, is an integrated part of this cluster, which creates opportunities for deepening international scientific cooperation in the field of digital energy. Thus, intercontinental ties formed between India, the USA, the UK, China and the EU countries form the core of the global research space. It is in this field that key concepts for the application of artificial intelligence in energy infrastructure management are generated, in particular in the areas of sustainable development, decarbonization, cybersecurity and intelligent modernization of energy networks.

In the analyzed sample, the most active donors of scientific projects were the National Natural Science Foundation of China (11 documents), European Commission (9), U.S. Department of Energy (7), UK Research and Innovation (5), Horizon 2020 Framework Program (4). An important element of Ukraine's integration into the international research space is support from the National Research Foundation of Ukraine.

The typological structure of documents indicates the dominance of conference proceedings (31.8%), scientific articles in peer-reviewed journals (28.3%), chapters in collective monographs (16.8%) and review publications (13.5%). This distribution indicates that the industry is in a phase of active formation, within which theoretical concepts are transformed into applied solutions and technological models.

According to Scopus classification, the research profile covers Engineering (53%), Computer Science (48%), Energy (27%), Environmental Science (21%), Social Sciences (15%), Business, Management and Accounting (9%), Economics and Decision Sciences (9%). This demonstrates the interdisciplinary nature of the research, combining engineering, computer and management concepts.

Semantic analysis of keywords (Fig. 4) showed that the most common term is “artificial intelligence” (~215 documents). Also, high frequency are “sustainable development” (114 documents), “energy efficiency” (73), “information management” (63), “machine learning” (56), “smart city” (55), “decision-making” (49), “internet of things” (46), “renewable energy” (34), “smart grid” (29), “big data” (29), “deep learning” (24), “optimization” (23), “digital twin” (10) and “cybersecurity” (9 documents).

Figure 4: Keyword cloud (the larger the font, the more often the term occurs).

Thus, the visualization of keywords confirms that “artificial intelligence” dominates (the largest word in the cloud). Also, very noticeable are “sustainable development”, “energy efficiency”, “information management”, “machine learning”, “smart city” and others – all these concepts form the core of research at the intersection of AI and energy infrastructure. The combinations of keywords indicate that researchers are focused on the topics of sustainable development, energy consumption optimization, the implementation of renewable energy and intelligent energy grid management systems using artificial intelligence.

The results obtained indicate that the integration of artificial intelligence technologies into the management of energy infrastructure development has acquired signs of a sustainable global interdisciplinary direction. This scientific field combines digital, energy and management technologies, forming a new intellectualized model of the functioning of energy systems.

The use of AI technologies makes it possible to increase the efficiency of energy resources, reduce energy consumption, optimize production and technological processes, expand digital management mechanisms and strengthen the resilience of energy infrastructure to external risks, including cyber threats and climate challenges.

In addition, the identified trends confirm the role of artificial intelligence as an important catalyst for the “green” digital transformation of the economy, which corresponds to the logic of implementing the Sustainable Development Goals (SDGs) and forms the basis for the transition to low-carbon energy supply models.

The generalized results of the bibliometric analysis also demonstrate the growing influence of international scientific cooperation, the increasing importance of interdisciplinary research clusters and the gradual institutionalization of a scientific school focused on AI-driven energy infrastructure development management. That is, the research topic moves from the stage of conceptual understanding to the stage of forming mature theoretical and methodological approaches and practical solutions for the energy sector.

The above conclusions create the basis for further critical analysis of the results obtained, which makes it possible to proceed to a discussion of their theoretical and applied implications, as well as to identify the limitations of the research conducted and the directions of future scientific explorations.

5 DISCUSSION, RESEARCH LIMITATIONS AND FUTURE RESEARCH AGENDA

The results of the bibliometric analysis make it possible to rethink not only the current state, but also the internal logic of the evolution of scientific research on the application of artificial intelligence in managing energy infrastructure development. The identified dynamics of publication activity, thematic clusters and international collaboration patterns show that AI-driven energy infrastructure management has moved beyond a purely technological niche and is gradually transforming into a core component of sustainable, digitally governed energy systems.

5.1 Why Do Certain Thematic and Collaboration Clusters Dominate?

The predominance of specific thematic clusters – in particular Intelligent Energy Systems, AI and Sustainable Resource Management and Information Management and Data Analytics – is not accidental. It reflects a combination of at least three groups of drivers.

First, these clusters correspond to areas with the highest data availability and technological readiness. Smart grids, non-intrusive load monitoring, predictive maintenance and energy efficiency optimisation generate large volumes of time-series and sensor data that are particularly suitable for machine learning and deep learning methods. This technological “fit” explains why AI applications concentrate around forecasting, optimisation and anomaly detection in networks rather than, for example, long-term socio-institutional reforms.

Second, the leading clusters are strongly aligned with commercial incentives and investment priorities. Energy companies and technology vendors obtain direct, measurable benefits from reducing network losses, optimising asset management, improving demand forecasting and integrating renewable energy sources. This makes projects in the domains of smart grids, 5G/6G-enabled energy communications and digital twins more attractive for both corporate and public funding than research on, for instance, social perception of AI or ethics-by-design in critical infrastructure.

Third, the structure of scientific collaboration mirrors regulatory and funding architectures. The Indian–Asian and Chinese clusters benefit from large-scale national programmes for energy transition and digitalisation; the Anglo-American and European clusters are shaped by US federal programmes, EU Green Deal, Horizon Europe and Digital Europe initiatives. These frameworks explicitly prioritise AI, cybersecurity and sustainable energy, reinforcing research streams around those policy priorities. By contrast, topics with less clear funding lines – such as distributive justice of AI-driven tariffs or long-term labour market implications in the energy sector – remain underrepresented.

Altogether, the dominance of certain clusters indicates a path-dependent evolution of the field, in which data-rich, commercially profitable and policy-promoted directions systematically receive more scientific attention than equally important, but less easily quantifiable social, ethical and regulatory dimensions.

5.2 Underexplored Dimensions and Knowledge Gaps

The current structure of the field reveals several substantive gaps that limit a holistic understanding of AI-driven energy infrastructure development.

First, social acceptance and public perception of AI in critical energy infrastructure remain insufficiently studied. While sociological and behavioural studies on AI in healthcare or consumer services are growing, the specific perceptions of citizens, local communities and energy consumers regarding AI-based control of grids, dynamic pricing or automated outage management are rarely

addressed in a systematic way. This creates a risk of overlooking resistance, mistrust or low willingness to share data, which may become a binding constraint for large-scale deployment of AI solutions.

Second, there is a lack of integrative research on regulatory and governance frameworks for AI in critical infrastructure. Existing studies usually focus either on technical cybersecurity requirements or on general AI regulation, without fully capturing the interplay between sectoral energy regulation, cybersecurity directives (e.g. NIS2), emerging AI-specific acts and national security strategies. As a result, there is no widely adopted analytical framework that would connect AI capabilities, risk profiles, liability allocation and regulatory design in the energy sector.

Third, economic and financial aspects of AI deployment in energy infrastructure are underrepresented compared to technical studies. Only a limited number of publications provide robust cost–benefit analyses, business models or financing schemes for AI-based retrofitting of networks, creation of digital twins or deployment of advanced decision support systems. Without such analyses it is difficult for regulators and operators to prioritise projects, assess payback periods or design incentives for private investment.

Fourth, the identified geographical asymmetry – with dominance of India, China, the USA and several EU countries, and a weaker representation of Central and Eastern Europe, the Middle East, North Africa and post-conflict economies – indicates a contextual bias of the existing evidence base. The majority of case studies are based on relatively stable, well-capitalised energy systems, whereas the specific challenges of war-affected, highly fragmented or institutionally weak energy sectors remain largely outside the mainstream discourse.

Addressing these gaps requires a deliberate shift from purely technological optimisation towards an integrated perspective that includes governance, economic feasibility, social acceptability and geopolitical vulnerabilities of AI applications in energy infrastructure.

5.3 Conceptual Framework: AI-Enabled Energy Infrastructure Governance

Building on the results of the network and cluster analysis, a conceptual framework of AI-enabled Energy Infrastructure Governance can be proposed to structure the relationships between AI technologies, infrastructure management tasks and target outcomes of energy systems.

The framework consists of three interrelated levels:

Technological layer (AI capabilities and digital enablers).

This layer includes machine learning and deep learning algorithms, reinforcement learning, digital twins, optimisation models, IoT platforms, blockchain-based transaction systems and advanced data analytics. These technologies provide the functional tools for forecasting, optimisation, detection and control.

Infrastructure management layer (decision domains and operational tasks).

At this level, AI is embedded into concrete management functions of energy infrastructure, including:

1) long-term planning and investment prioritisation;
2) operational dispatch and balancing of generation, storage and demand;
3) asset health monitoring, predictive maintenance and outage management;
4) cyber-physical security and anomaly detection;
5) market design, tariff setting and demand response programmes.

Feedback loops connect these tasks with the technological layer: improved data quality and model performance enhances decision-making, while operational decisions generate new data for model refinement.

Outcome layer (system performance and societal goals). The upper level reflects the target indicators that energy infrastructure governance aims to achieve:

1) sustainability and decarbonisation (GHG emissions, share of renewables, circularity of resource use);
2) security and resilience (reliability indices, recovery times after disruptions, cyber-resilience);
3) efficiency and affordability (technical and non-technical losses, operating costs, energy prices);
4) inclusiveness and fairness (equitable access, distributional effects of AI-driven tariffs and services).

Horizontal “governance” and “ethics and regulation” components cut across all three layers. Governance determines how responsibilities for AI deployment are allocated among regulators, operators, technology providers and consumers; the

ethical and regulatory dimension shapes transparency requirements, accountability, data protection and risk-sharing rules.

Graphically, the framework can be presented as a multi-layer diagram linking AI technologies (bottom layer) with management tasks (middle layer) and outcome dimensions (top layer), with bi-directional arrows indicating feedbacks and learning cycles. Such a conceptual model translates the essentially descriptive bibliometric findings into an analytical architecture that can guide empirical studies and policy design.

5.4 Methodological Limitations and Future Research Agenda

The study inevitably faces several methodological limitations typical for bibliometric research. The exclusive use of the Scopus database, without complementary integration of Web of Science, IEEE Xplore or regional databases, may lead to incomplete coverage of relevant works, particularly those published in languages other than English.

Recent publications (2023–2025) have not yet accumulated enough citations to fully reflect their scientific influence, which introduces a time lag into citation-based metrics. Automatic keyword clustering and mapping in VOSviewer may group semantically distinct concepts together or generate doublets, complicating the interpretation of some thematic links.

Finally, bibliometric indicators capture quantitative dimensions of research activity, but they do not directly assess the robustness of empirical methods, the quality of evidence or the practical impact of AI applications on real energy systems.

Recognising these limitations, the findings of this study should be interpreted as a structured "map" of the field rather than a definitive evaluation of specific technologies or projects. At the same time, the results provide a solid foundation for formulating a more focused research agenda that moves beyond description towards explanation and evaluation.

In particular, future research could prioritise the following non-trivial questions:

1) Causal impacts of AI deployment. Under what conditions do AI-based solutions in grid operation, maintenance and planning deliver measurable improvements in energy efficiency, resilience and decarbonisation compared to conventional approaches, once costs and risks are fully accounted for?
2) Regulation–innovation nexus. How do different combinations of energy market design, cybersecurity regulation and emerging AI governance frameworks shape the direction, pace and distribution of AI adoption in critical energy infrastructure?
3) Societal acceptance and distributive effects. How do citizens and energy consumers perceive AI-based decision-making in critical infrastructure, and what are the distributional consequences of AI-driven tariff structures, demand response programmes and automated service provision for vulnerable groups?
4) Economics and financing of AI-enabled infrastructure. What business models and financing mechanisms are most effective for scaling AI solutions in energy infrastructure, especially in countries with constrained fiscal space, high sovereign risk or post-conflict reconstruction needs?
5) Context-sensitive resilience modelling. How can AI-based models incorporate the specific vulnerabilities of energy systems in regions exposed to armed conflict, hybrid threats or extreme climate events, and what indicators best capture AI's contribution to multi-hazard resilience?

Addressing these questions will require combining bibliometric and network analysis with empirical case studies, system dynamics, multi-criteria decision analysis, scenario planning and expert elicitation. Strengthening international cooperation, including with countries in Central and Eastern Europe, the Middle East, North Africa and other transition or post-conflict economies, will be crucial for expanding the empirical basis and ensuring that AI-enabled energy infrastructure governance frameworks are both globally informed and locally relevant.

6 CONCLUSIONS

The study provides an integrated bibliometric and conceptual analysis of the global research landscape on artificial intelligence in energy infrastructure management over 2000–2025. The findings reveal that AI has become a structurally important driver of energy system transformation, shaping the technological, operational and governance foundations of modern energy infrastructures. The exponential growth in publications since 2020 reflects not only technological advances but also the

deepening interdependence between digitalisation, renewable energy integration, cybersecurity and energy resilience.

The analysis demonstrates that the dominance of specific research clusters – such as smart grid optimisation, predictive analytics, digital twins and AI-enabled energy efficiency – is shaped by the interplay of three forces:

1) high data availability and methodological compatibility of these domains with machine learning;
2) strong commercial incentives and investment priorities that favour operational optimisation tasks;
3) regulatory and funding architectures that systematically support digitalisation of energy systems.

At the same time, the study identifies notable knowledge gaps, including limited attention to social acceptance of AI in critical infrastructure, underdeveloped governance and regulatory frameworks, as well as insufficient economic evaluations of AI deployment, especially in countries with constrained resources or post-conflict recovery needs.

Building on the network and thematic mapping results, the research outlines the conceptual foundations of an AI-enabled Energy Infrastructure Governance model, which integrates three analytical layers:

1) technological capabilities (machine learning, digital twins, IoT, optimisation algorithms);
2) infrastructure management tasks (planning, balancing, predictive maintenance, cybersecurity, market design);
3) target outcomes (sustainability, resilience, efficiency, affordability and fairness).

The model emphasises the system-wide feedback loops between data, decision-making and performance indicators, while also incorporating transversal elements of regulation, ethics and accountability. Although presented in an initial conceptual form, the model provides a structured foundation for developing applied tools for evaluation, strategic planning and policy design.

The study contributes to the literature by transforming a predominantly descriptive research field into a more analytical one, offering insights into why certain clusters dominate, what structural gaps persist, and how AI can be embedded into energy infrastructure governance in a way that strengthens sustainability and resilience. These results support policymakers, operators, regulators and researchers in identifying priority directions for responsible AI deployment in the energy sector.

At the same time, the research has several methodological limitations related to reliance on Scopus data, the predominance of English-language publications, and the interpretive nature of cluster aggregation. This implies that the findings should be seen as a comprehensive mapping of global trends rather than an exhaustive evaluation of the effectiveness of AI technologies.

Future research should deepen the analytical implications of the results by focusing on: empirical assessment of the causal impact of AI solutions on energy system performance; integrative regulatory frameworks for AI in critical infrastructure; distributive and societal effects of AI-driven energy management; economic and financial models for large-scale AI deployment; adaptation of AI-based resilience frameworks to fragile, high-risk or post-conflict energy systems.

A separate direction of future work is the full formalisation, operationalisation and empirical testing of the proposed AI-enabled Energy Infrastructure Governance model, which can evolve into a robust analytical and decision-support framework for national and international energy policy.

Keywords: Security, Economic Openness, Anti-Money Laundering, Corruption, Financial Secrecy, Public Policy, Legal Regulation, Government Regulation, Global Dimension, Interdisciplinary Approach.

Abstract: This research examines the relationships between money laundering risks and financial secrecy levels across different global jurisdictions to formulate proposals for developing effective regulatory policies in the field of financial transparency. To achieve this objective, an interdisciplinary approach was employed, involving a comparative analysis of the Basel AML Index (AMLI) and the Financial Secrecy Index (FSI) for 109 jurisdictions. Visual spatial analysis and multidimensional correspondence analysis were performed using Statistica and RapidMiner statistical packages. A statistically significant relationship was identified between the studied indices ($\chi^2 = 16.73$, $p = 0.04$). Three primary dimensions of interaction were distinguished, explaining 99.9% of the total system inertia. It was established that the categories "low FSI" (31%) and "very high AML" (30%) make the greatest contribution to overall variability. A latent inverse relationship was identified between the highest money laundering risks and the lowest level of financial secrecy, along with associative relationships between medium levels of AMLI and FSI. The unique positioning of jurisdictions with the highest financial transparency was established, which are not associated with any AML categories. It was concluded that the complex nonlinear structure of associations between the studied phenomena requires differentiated approaches to international legal regulation and public administration of financial transparency, taking into account the specific characteristics of national anti-money laundering regimes and legal systems. International organizations can utilize the obtained results to enhance financial risk assessment systems, by national regulators to tailor anti-money laundering legislation to jurisdictional specifics, and by financial institutions to develop more effective compliance control systems and reputational risk management strategies.

1 INTRODUCTION

In the modern interconnected world, the issue of financial transparency has gained critical importance for effective government regulation and public administration. According to estimates by international experts, the volume of money laundering in 2024 ranges from 2.22 to 5.54 trillion US dollars, representing approximately 2–5% of global GDP [1]. This amount passes through the global financial system undetected annually and creates serious challenges for national governments and international organizations in developing effective strategies to combat financial crimes [2], [3].

The paradox of the current situation lies in the fact that despite active efforts by the international community, methods of laundering proceeds from criminal activity are constantly evolving [4]. Criminals use alternative laundering channels in response to the implementation of the Financial Action Task Force (FATF) standards [5] by the

international financial sector. Simultaneously, there is a significant increase in the use of virtual assets in fraud and money laundering schemes [6]. In 2024, illegal activity on blockchain is estimated at approximately 51 billion dollars [7]. In 2022, the United States of America topped the Financial Secrecy Index (FSI) ranking for the first time, surpassing traditional financial centers such as Switzerland and Singapore [8]. This fact changed established perceptions about the geography of financial secrecy and demonstrated that even countries with developed legal regulatory systems can create favorable conditions for asset concealment [9].

Public policy in the field of financial transparency faces complex challenges when it is necessary to balance the requirements of national security, economic competitiveness, and international cooperation. According to Tax Justice Network data, countries worldwide annually lose 492 billion dollars in tax revenue through the use of tax havens by multinational corporations and wealthy individuals [10]. The problem is complicated by the fact that as of 2024, only 33 jurisdictions with significant virtual asset service provider activity are fully or largely compliant with FATF standards, compared to 25 jurisdictions in 2023 [11]. This indicates slow rates of adaptation of national legal systems to the challenges of the digital economy.

International organizations, particularly FATF, continue to improve their approaches to assessing the effectiveness of national anti-money laundering regimes. The Financial Crimes Enforcement Network (FinCEN) regularly informs American financial institutions about updates to the lists of jurisdictions with strategic deficiencies in systems for combating money laundering, terrorism financing, and weapons of mass destruction proliferation [12]. However, the effectiveness of these measures remains a subject of discussion among experts and practitioners.

The results of previous scientific research indicate that regulatory and social factors influence illicit financial flows more than economic factors [13], which confirms the complexity of these relationships. Specifically, the USA received a critical assessment from FATF in 2006 regarding the effectiveness of anti-money laundering efforts, and subsequently topped the FSI [14], which demonstrates the paradoxical relationship between anti-money laundering mechanisms and levels of financial secrecy. Recent analytical studies conducted in [15] revealed an almost 100% correlation between low-risk countries for money laundering and environmental crimes. This suggests the possible existence of hidden structural patterns. Identification of these mechanisms is extremely important for developing scientifically grounded approaches to international policy coordination and forming differentiated public administration strategies in the field of financial security. Currently, a generally recognized effective tool for assessing policy achievements worldwide is the FSI. It provides the ability to determine countries' efforts in developing policies to prevent concealment and laundering of funds by wealthy individuals and criminals [8]. At the same time, one of the most authoritative tools for assessing money laundering risks at the national level remains the Basel AML Index (AMLI) [16].

Contemporary geopolitical transformations and economic challenges caused by the increase in regional military conflicts and sanctions policy have actualized the issue of effective government regulation of financial flows [17]. Countries are forced to reconsider their approaches to balancing economic openness and security, which necessitates conducting a comprehensive analysis of the relationships between different aspects of financial transparency and money laundering risks to form a well-founded state anti-corruption policy. Analysis of these complex relationships can provide an empirical foundation for developing more effective international cooperation strategies and help governments of various countries form differentiated approaches to the legal regulation of financial transparency, as well as develop effective anti-money laundering strategies that consider the specific characteristics of their national financial systems and geopolitical positions.

The purpose of this research is to identify statistical relationships between AMLI and FSI across 109 jurisdictions using correspondence analysis. We hypothesize that these relationships have a complex multidimensional structure characterized by non-linear associations between different risk and secrecy categories, where extreme values of one index do not necessarily correspond to extreme values of the other. Accordingly, the research addresses the following tasks: testing the statistical significance of AMLI-FSI associations, identifying the dimensional structure of their interactions, and determining the spatial positioning patterns of different jurisdiction categories in the correspondence.

2 METHODOLOGY

To investigate the correlation between threats of money laundering and the degree of confidentiality of financial operations in different jurisdictions worldwide, a comparison of AMLI [16] and FSI [8] was conducted for 109 jurisdictions for which values of both indicators are known. AMLI varies from 0 to 10 (where higher values indicate greater risks). It assesses the threat of money laundering and terrorism financing based on the quality of anti-money laundering measures, political and legal risks, as well as financial standards and compliance with international FATF recommendations [12]. FSI is measured from 1 to 141 (higher values correspond to greater secrecy) and considers the level of banking secrecy, corporate transparency, international cooperation in tax matters, and availability of information about beneficial owners, which directly depends on national legislation and its practical implementation. Comparison of these indices allows for identifying gaps in legal regulation and assessing how closely deficiencies in legislative frameworks of financial transparency are related to risks of using financial systems for illegal purposes.

The first stage of our research involved conducting a visual analysis of the spatial distribution of AMLI and FSI for countries included in these rankings. In the second stage, we applied correspondence analysis to identify significant non-obvious relationships between money laundering risk categories and financial secrecy levels in different groups of jurisdictions. This allowed us to reveal statistically significant patterns that are not obvious when visually examining the spatial distributions of the indices.

Correspondence analysis is a multidimensional statistical method designed to investigate relationships between categorical variables through their graphical representation in Euclidean space [18].

The main estimates of the method are:

- Chi-square test determines the statistical significance of the relationship between variables:

$$\chi^2 = \frac{(O-E)^2}{E}, \quad (1)$$

where O – observed frequencies, E – expected frequencies.

- Mass characterizes the relative contribution of each category to the total variance:

$$m_i = \frac{n_i}{n}, \quad (2)$$

where n_i – frequency of the i-th category.

- Quality shows the proportion of point variance explained by the selected principal components:

$$Qali = \cos^2(i_1)\cos^2(i_2). \quad (3)$$

- Inertia reflects the total variance of the system and the measure of deviation from independence:

$$I = \frac{\chi^2}{n}. \quad (4)$$

- Cos² determines the square of the cosine of the angle between the original point and its projection on the principal component, characterizing the quality of point representation on the axis:

$$\cos^2(i_k) = \frac{f_{i_k}^2}{d_i^2}, \quad (5)$$

where f_{i_k} – coordinate of the point on the k-th axis d_i distance from the origin to the point.

Empirical studies were conducted using the Statistica software and RapidMiner artificial intelligence-based data analytics software [19], [20].

3 RESULTS AND DISCUSSION

Figure 1 presents the spatial distribution of AMLI values. The highest money laundering risks are demonstrated by countries of the African continent and some regions of Asia, particularly Congo, Haiti, Myanmar, Mozambique, and Madagascar. Moderate risks are observed in South American countries and part of European states. The lowest risk indicators are found in developed countries of North America and Western Europe, including Finland, Andorra, and Sweden. Australia also belongs to this group. This indicates varying quality of national legal regimes for combating money laundering.

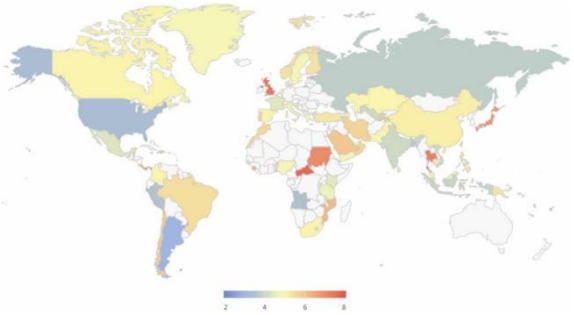

Figure 1: Spatial distribution of Basel AML Index scores.

Figure 2 illustrates the geographical distribution of FSI, where the highest levels of financial secrecy are characteristic of certain offshore jurisdictions, some developed countries such as the USA, Switzerland, the United Kingdom, Japan, Germany,

and Italy, as well as several other international financial centers.

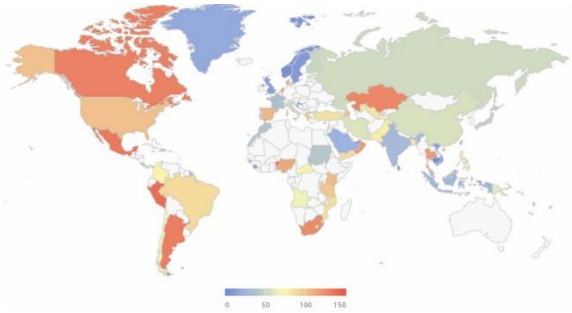

Figure 2: Spatial distribution of Financial Secrecy Index.

This result indicates the complexity of the relationship between different aspects of financial transparency and money laundering risks. This justifies the necessity of applying correspondence analysis, which will enable the identification of non-obvious interesting patterns for understanding the true relationships between these phenomena.

For conducting correspondence analysis, the numerical values of AMLI and FSI were recoded into categorical groups based on the uniform distribution of these indicator values among the analyzed 109 jurisdictions. This categorization allowed for revealing structural relationships between different levels of the studied phenomena.

Table 1 presents the descriptive statistics of the analyzed indices, according to which the recoding was performed.

Table 1: Descriptive Statistics of AMLI and FSI.

Index	Minimum	Maximum	Range
AMLI	2.96	7.59	4.63
FSI	1	138	137

Table 2 describes the algorithm for grouping countries by values of both indices. Each indicator was divided into five categories from “very low” to “very high” values, with clearly defined boundaries for each group.

Table 3 displays the distribution of 109 analyzed jurisdictions across cross-categories of AMLI and FSI.

The largest number of countries is concentrated in the “low AML” category (40 jurisdictions). The fewest countries fell into the “very high AML” category (9 jurisdictions), which indicates an uneven distribution of money laundering risks among the studied countries. This contingency table serves as the basis for conducting correspondence analysis.

Table 2: Grouping of countries by AMLI and FSI values.

Index	Rank	Range
AMLI	very low AML	< 3.9
	low AML	between 3.9 and 4.8
	medium AML	between 4.8 and 5.7
	high AML	between 5.7 and 6.6
	very high AML	>= 6.6
FSI	very low FSI	< 28.5
	low FSI	between 28.5 and 56
	medium FSI	between 56 and 83.5
	high FSI	between 83.5 and 113
	very high FSI	>= 113

Table 3: Summary frequency table for AMLI and FSI.

	AMLI Rank					Total
FSI Rank	very low	low	medi-um	high	very high	
very low	1	11	5	3	1	21
low	2	7	9	3	5	26
medium	3	6	12	2	1	24
high	4	8	6	1	1	20
very high	4	8	4	1	1	18
All gr.	14	40	36	10	9	109

Table 4 presents the results of decomposing the total system inertia into separate dimensions. Its value is 0.15, with Chi-square equal to 29.73 at 16 degrees of freedom and significance level $p = 0.04$. This indicates a statistically significant relationship between the studied indices.

Table 4: Eigenvalues and Inertia for 3 Dimensions for AMLI and FSI.

Dim.	Total Inertia = 0.15, $Chi^2 = 29.73$, df = 16, $p = 0.04$				
	Singular Values	Eigen-Values	Perc. of Inertia	Cumulat. Percent	Chi^2
1	0.28	0.07	47.81	47.81	8.00
2	0.22	0.05	32.84	80.64	5.50
3	0.17	0.02	19.27	99.91	3.22

Three main dimensions of interaction between variables were identified. The first dimension has the highest eigenvalue (0.07) and explains 47.8% of the total system inertia, indicating its dominant role in the structure of relationships. The second dimension with an eigenvalue of 0.05 additionally explains 32.84% of inertia. The third dimension with the smallest eigenvalue of 0.02 contributes 19.27% to the overall explanation. The three dimensions cover 99.9% of inertia, which indicates high quality of the 3-dimensional representation of relationships between money laundering risk categories and financial secrecy levels.

Table 5 presents the results of correspondence analysis for AMLI categories.

Table 5: Column/Row Coordinates (AMLI) and Contributions to Inertia.

Column Name	Mass	Quality	Relat. Inert.	Cos^2 Dim.1	Cos^2 Dim.2	Cos^2 Dim.3
very low	0.13	1.00	0.22	0.39	0.34	0.27
low	0.37	1.00	0.20	0.58	0.41	0.01
medium	0.33	1.00	0.20	0.30	0.52	0.18
high	0.09	1.00	0.08	0.23	0.54	0.22
very high	0.08	1.00	0.30	0.66	0.08	0.27

The largest share (Mass) is represented by countries with "low AML" (0.37), while jurisdictions with "very high AML" are the least represented (0.08). The Quality indicator equals 1.00 for all categories, which indicates high quality of their representation in the three-dimensional correspondence analysis space. Relative Inertia reflects the contribution of each category to the total inertia: the greatest impact is made by the "very high AML" (0.30) and "very low AML" (0.22) categories, indicating their largest deviation from the expected distribution under the assumption of variable independence. The "very high AML" category is best represented by the first dimension (Cos^2 = 0.66), while "high AML" is best represented by the second dimension (Cos^2 = 0.54). This indicates that different levels of money laundering risks have different patterns of interaction with financial secrecy categories.

Table 6 presents the results of correspondence analysis for FSI categories.

Table 6: Row Coordinates (FSI) and Contributions to Inertia.

Row Name	Mass	Quality	Relat. Inert	Cos^2 Dim.1	Cos^2 Dim.2	Cos^2 Dim.3
very low	0.20	1.00	0.23	0.94	0.68	0.23
low	0.24	1.00	0.31	0.85	0.05	0.10
medium	0.22	1.00	0.21	0.08	0.65	0.27
high	0.18	1.00	0.09	0.69	0.18	0.12
very high	0.16	1.00	0.15	0.74	0.01	0.26

By the Mass indicator, the most represented categories are "low FSI" (0.24) and "medium FSI" (0.22). The smallest share is represented by jurisdictions with "very high FSI" (0.16). This indicates a relatively uniform distribution of countries by financial secrecy levels. Quality equals 1.00 for all categories, confirming the high quality of 3-dimensional representation. By the Relative Inertia indicator, the greatest contribution to the total system inertia is made by the "low FSI" (0.31) and "very low FSI" (0.23) categories. This indicates their largest deviation from the expected distribution under the independence hypothesis. Different patterns of financial secrecy category representation were identified. The "very low FSI" category is best described by the first dimension (Cos^2 = 0.94), indicating its clear positioning in the interaction space. The "low FSI" category is also well represented by the first dimension (Cos^2 = 0.85). The "very high FSI" category is distributed between the first (Cos^2 = 0.74) and third (Cos^2 = 0.26) dimensions, indicating a more complex nature of relationships between high levels of financial secrecy and money laundering risk categories.

To improve the interpretation of correspondence analysis results, a three-dimensional visualization of the spatial positioning of AMLI categories (Row Coords.) and FSI categories (Column Coords.) in the coordinates of three main dimensions was constructed (Fig. 3). The diagram clearly shows polarization of categories along the main coordinate axes. The "very high AML" and "very low FSI" categories are located in opposite quadrants of the space, indicating a strong inverse relationship between these extreme categories. Thus, jurisdictions with the highest money laundering risks tend toward the lowest levels of financial secrecy.

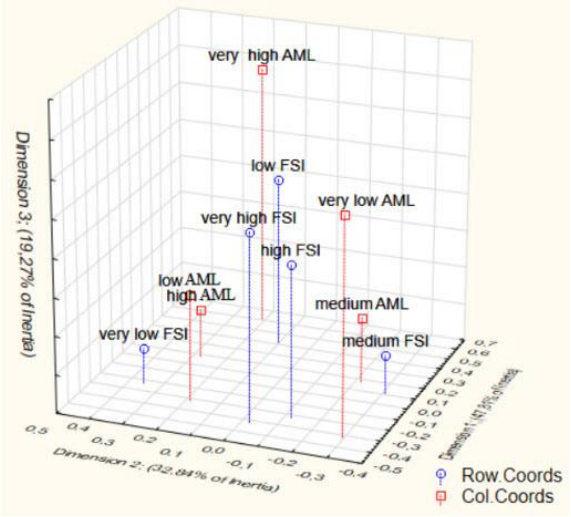

Figure 3: 3D plot of row and column coordinates.

The close positioning of the "medium AML" and "medium FSI" categories in the central zone of the diagram indicates their mutual association. Jurisdictions with moderate levels of financial secrecy have similar moderate levels of money laundering risks. The separate positioning of the "very low FSI" category from all other categories shows its uniqueness in the correspondence space. Jurisdictions with the highest financial transparency occupy a separate position, not associated with any of

the AML categories. The placement of the "low AML" and "very low AML" categories in different sectors of the diagram demonstrates their distinct profiles of relationships with FSI categories. The position of "high FSI" is closer to central categories than to extreme values, which may indicate its intermediate role in the system of relationships between financial secrecy and money laundering risks.

The obtained correspondence analysis results confirm the complex multidimensional nature of relationships between money laundering risks and financial secrecy levels, which cannot be adequately described by simple linear correlations. The statistically significant relationship between the studied indices ($p = 0.04$) and the identified structural associations between their categories indicates the necessity of a comprehensive approach to legal regulation of financial transparency. The absence of a clear correlation between extreme categories of AMLI and FSI suggests the existence of diverse regulatory models, where highly effective anti-money laundering systems can function under different levels of financial secrecy.

The identified associative relationships between medium categories of indices confirm the hypothesis of the existence of a "golden mean" in financial regulation, where balance between transparency and secrecy promotes stability of national financial systems. At the same time, the detection of unique positions of individual categories in the correspondence space demonstrates the diversity of national approaches to ensuring financial security. The obtained estimates indicate the limitations of universal recommendations in the field of anti-money laundering regulation and the necessity of developing differentiated policies that consider specific economic, legal, and institutional characteristics of each jurisdiction when forming effective mechanisms for combating money laundering. The obtained results justify the feasibility of developing composite indicators that combine AMLI and FSI for more accurate risk assessment and the formation of adaptive mechanisms for monitoring financial transactions.

4 CONCLUSIONS

The article examines the relationships between money laundering risks and financial secrecy levels among 109 world jurisdictions. Statistically significant relationships between AMLI and FSI ($\chi^2 = 29.73$, $p = 0.04$) were established. Correspondence analysis revealed three main dimensions of interaction that explain 99.9% of the total system inertia. Key findings reveal that the "low FSI" category makes the greatest contribution to system variability with relative inertia of 0.31 and mass of 0.24, while among AML categories, "very high AML" demonstrates the highest deviation from expected distribution (relative inertia 0.30, mass 0.08). The analysis identified an inverse relationship between "very high AML" and "very low FSI" categories, which occupy opposite positions in the correspondence space, indicating that jurisdictions with the highest money laundering risks tend toward the lowest financial secrecy. Conversely, an associative relationship was found between "medium AML" and "medium FSI" categories positioned in the central zone, suggesting balanced regulatory approaches. Notably, the "very low FSI" category demonstrates unique positioning (Cos^2 Dimension 1 = 0.94), remaining independent from any specific AML risk categories, which indicates that the highest financial transparency operates through mechanisms distinct from traditional anti-money laundering performance.

The scientific novelty consists in: (1) application of multidimensional correspondence analysis to simultaneously examine AMLI and FSI, revealing a three-dimensional structure of relationships; (2) identification of a paradoxical inverse relationship between the highest money laundering risks and lowest financial secrecy levels; (3) empirical demonstration that jurisdictions with maximum transparency form a distinct cluster independent of AML performance categories.

The identified complex nonlinear structure of relationships between AMLI and FSI indicates the necessity of moving away from universal regulatory solutions in favor of differentiated approaches that consider specific characteristics of national legal systems. The existence of balanced jurisdictions with moderate levels of both indicators, as well as the absence of direct associations between extreme categories, points to the possibility of creating effective anti-money laundering mechanisms under different financial confidentiality regimes. This justifies the feasibility of developing a multi-level system of international legal regulation that will allow combining global standards for combating financial crimes with respect for national peculiarities of legal regulation of banking secrecy and corporate transparency.

The obtained results can be used for developing differentiated approaches to international legal regulation of financial transparency, particularly, creating mechanisms for mutual recognition of standards and developing composite indicators for more accurate risk assessment, improving the system for evaluating the effectiveness of national anti-money laundering regimes, and forming targeted

recommendations for different jurisdictions depending on their characteristics.

Promising directions for further research include analyzing the impact of specific legal institutions on the formation of identified interaction patterns, as well as expanding the analysis by including additional indicators of regulatory environment and economic development to build a comprehensive model of financial transparency determinants at the global level.

While this cross-sectional analysis provides insights into structural relationships at a specific point in time, we acknowledge its temporal limitations. Future research will extend the analysis to a multi-year period to examine the stability of identified patterns and reveal potential causal mechanisms and temporal dynamics in the AMLI-FSI relationships.

Keywords: Artificial Intelligence, Sustainable Hospitality, Green Hotel Certification, Guest Perception.

Abstract: The hospitality industry faces mounting pressure to integrate sustainable practices in response to climate change, resource scarcity, and growing environmental awareness among travellers. Artificial Intelligence (AI) has emerged as a promising tool for enabling green innovations in hotels, particularly those certified under sustainability programs such as ANAHAW, ASEAN Green Hotel Standard, Green Key, and LEED. This study examines guest perceptions of AI-driven green technologies in certified hotels in the Philippines, focusing on awareness, perceived usefulness, and support for eco-friendly initiatives. Using a quantitative, descriptive–correlational approach and Structural Equation Modelling (SEM), data were collected from 350 domestic and international tourists who had recently stayed in certified hotels. Findings reveal that while guests demonstrated moderate to high awareness of AI-enabled green practices, awareness alone did not significantly predict either perceived usefulness or behavioural support. Instead, perceived usefulness emerged as the strongest determinant of support, influencing intentions to revisit, recommend, and pay a premium for environmentally sustainable accommodations. These results highlight the importance of making AI features more visible and directly linked to guest experiences rather than relying solely on awareness. Beyond confirming the predictive strength of TAM, this study contributes originality by extending TAM, in combination with S-O-R and TPB, to the context of AI-enabled sustainability initiatives in certified hotels, offering new insights into guest behaviour in a developing economy. The findings provide practical guidance for hotel managers, certification bodies, and policymakers in aligning technological adoption with sustainability objectives while advancing the hospitality industry's role in sustainable development.

1 INTRODUCTION

The hospitality industry faces growing pressure to adopt sustainable practices in response to climate change, resource scarcity, and consumer concern for the environment. While tourism supports economies, it also contributes to environmental strain through high energy use, water consumption, and waste [1]. With travelers becoming more eco-conscious, hotels are expected to lead sustainability initiatives by adopting green technologies [2], [3]. Artificial Intelligence (AI) plays an important role in this shift, offering applications such as smart thermostats, occupancy-based lighting, predictive maintenance, and real-time monitoring that reduce emissions, improve efficiency, and enhance guest experiences [4]–[7].

Certification programs such as ANAHAW, ASEAN Green Hotel Standard, Green Key and LEED set structured benchmarks for eco-friendly operations in the Philippines [8]–[10]. Certified hotels are expected not only to meet infrastructure standards but also to integrate innovations like AI to complement traditional green practices and meet evolving guest expectations [11]. However, much of the existing literature focuses on managerial or operational perspectives [12], with limited research on guest awareness, perceived usefulness, and support for AI-enabled sustainability, especially in developing economies with resource constraints [13], [14]. Understanding guest perspectives is crucial, as positive perceptions strongly shape behavioral intentions and long-term support for green initiatives [15], [16].

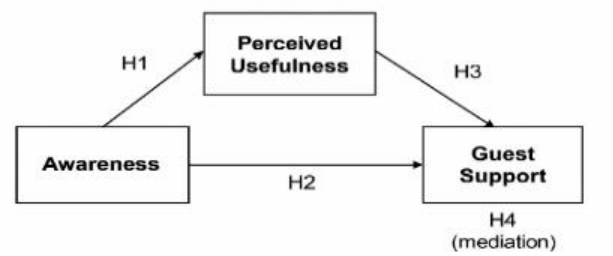

Figure 1: Conceptual framework of the study on harnessing AI for sustainable hospitality: guest perceptions of green technologies in certified hotels in the Philippines.

To address this gap, the study investigates guest perceptions of AI-enabled green technologies in certified sustainable hotels in the Philippines, focusing on awareness, perceived usefulness, and support. Using Structural Equation Modeling (SEM), it analyzes the relationships among these constructs to inform hotel managers, policymakers, and technology providers. The study also contributes to sustainable tourism development while supporting global frameworks such as the United Nations Sustainable Development Goals [10].

2 THEORETICAL FRAMEWORK

This study draws on three complementary theories: the Technology Acceptance Model (TAM), the Stimulus–Organism–Response (S-O-R) model, and the Theory of Planned Behavior (TPB). TAM, developed by Davis [18], explains how perceptions of usefulness drive technology adoption and has been applied in hospitality to AI-based systems such as smart energy management and eco-efficient innovations [5], [18]. The S-O-R model [29] illustrates how external stimuli influence internal states and behaviors; in this study, awareness serves as the stimulus, perceived usefulness the organism, and guest support the response [17], [15]. TPB [26] further highlights how attitudes, norms, and control beliefs shape intentions, with positive views of AI-driven sustainability expected to increase revisit intentions, recommendations, and willingness to pay more [22], [21]. Unlike earlier hospitality research that applied TAM mainly to guest-facing technologies, this study situates it within AI-enabled sustainability practices in certified hotels, an underexplored area in developing economies. By integrating TAM with S-O-R and TPB, the model moves beyond traditional adoption studies to link awareness, usefulness, and pro-environmental intentions, underscoring the study's originality as illustrated in Figure 1.

3 CONCEPTUAL FRAMEWORK

The conceptual framework combines TAM, S-O-R, and TPB to explain how guests respond to AI-enabled sustainability practices in certified hotels. In this model, awareness of AI-driven green technologies is treated as the external stimulus, influencing the internal evaluation of perceived usefulness, which then shapes support behaviors such as revisiting, recommending, and willingness to pay more. Beyond these direct effects, perceived usefulness is expected to act as a mediator between awareness and guest support. To test these relationships, Structural Equation Modeling (SEM) is used to examine both direct and indirect pathways among awareness, perceived usefulness, and guest support.

Hypotheses:

- H1: Guest awareness positively influences the perceived usefulness of AI-driven green technologies.
- H2: Perceived usefulness positively influences guest support for sustainability initiatives in certified hotels.
- H3: Guest awareness positively influences guest support for sustainability initiatives.
- H4: Perceived usefulness mediates the relationship between awareness and support.

4 METHODOLOGY

This study employed a quantitative descriptive–correlational design, utilizing Structural Equation Modeling (SEM) to test both direct and mediating relationships among awareness, perceived usefulness, and guest support. Respondents consisted of domestic and international tourists who had stayed in ANAHAW, Green Key, LEED, or ASEAN Green Hotel Standard-certified hotels within the last 12 months. Participants were selected through purposive sampling, with at least 300 respondents targeted to satisfy SEM requirements [26].

Data were collected using a structured questionnaire adapted from validated scales, covering demographics, awareness, perceived usefulness, and guest support, all measured on a 5-point Likert scale. Reliability and validity were established through Cronbach's alpha, composite reliability, and AVE. To ensure diversity, respondents were recruited through a combination of approaches. On-site surveys were conducted in partnership with certified hotels, where staff invited guests during or after their stay to participate by scanning a QR code. At the same time, online surveys were distributed through booking platforms and travel-related social media groups that catered to domestic and international travelers. While this method broadened the reach of the study, it may also explain why a notable proportion of respondents answered "not sure" to certification-related items, as some guests may have stayed in certified hotels without being aware of the specific certification label. Data analysis included descriptive statistics, SEM modeling with AMOS/SmartPLS, and bootstrapped mediation testing, with model fit indices (CFI, TLI, RMSEA, SRMR) applied following [27]. Ethical standards, including compliance with the Philippine Data Privacy Act of 2012, were strictly observed as shown in Table 1.

Internal reliability was established with Cronbach's alpha values above the .70 threshold for Awareness (α = .893) and Perceived Usefulness (α = .839). Composite reliability (CR) values were also strong: Awareness (CR = .895), Perceived Usefulness (CR = .891), and Guest Support (CR = 1.000). Convergent validity was supported with Average Variance Extracted (AVE) values exceeding .50 for Awareness (AVE = .683) and Perceived Usefulness (AVE = .671). Guest Support, modeled as a higher-order construct, demonstrated acceptable composite reliability (CR = 1.000, AVE = 1.000). Some items (AAGT4, PUADGT4, RI1, and WPM1) exhibited weaker factor loadings. These were retained to preserve the breadth of content validity across awareness, perceived usefulness, and guest support. However, their weaker contributions may have reduced the overall strength of the measurement model. Future studies are encouraged to refine or replace these items to further enhance reliability and construct validity as shown in Table 2.

5 RESULTS AND DISCUSSION

The sample was largely composed of Millennials (50.29%) and Gen X (33.43%), indicating a predominance of working-age adults typically more exposed to sustainability and digital innovations as shown in Table 3. Most respondents were male (67.14%) and earned between ₱20,001–₱40,000 monthly. While 31.14% reported staying in a certified green hotel, nearly half (49.14%) had not, and 19.71% were unsure. A majority (68.00%) were unfamiliar with certification labels such as ANAHAW, Green Key, LEED, and ASEAN Green Hotel, reflecting earlier findings that travelers are eco-conscious but often unaware of specific certification.

Descriptive statistics revealed a high overall awareness of AI-driven green technologies (M = 3.65, SD = 0.77). Guests were most aware of AI applications in waste management systems (M = 4.09, SD = 0.85) and smart sustainability technologies (M = 3.89, SD = 0.99). However, awareness was only moderate regarding the use of AI in monitoring energy and water consumption (M = 2.69, SD = 1.37). This aligns with prior work showing that consumers tend to notice visible and service-related AI applications but are less aware of technical and back-end sustainability functions [5].

As shown in Table 4, respondents reported a high level of perceived usefulness (M = 4.18, SD = 0.57). The highest agreement was with the statement that AI-based sustainability initiatives are innovative and valuable (M = 4.37, SD = 0.60). Respondents also strongly agreed that AI improves operational efficiency (M = 4.23, SD = 0.75). This finding resonates with prior studies which indicate that perceived usefulness is the most critical factor influencing user acceptance of AI and green hotel technologies [28], [29].

Table 5 highlights that guest support was found to be high overall (M = 4.08, SD = 0.43). The strongest support was expressed for booking AI-enabled hotels (M = 4.24, SD = 0.74) and considering AI practices worthwhile investments (M = 4.10, SD = 0.78). This result supports earlier evidence that guests are willing to support sustainability initiatives if they perceive them as valuable and beneficial, even when these involve higher costs [30], [21].

Table 1: Factor loadings and internal reliability and convergent validity.

Construct	Item	Mean	SD	Factor Loading		Cronbach's Alpha	Composite Reliability (CR)	Average Variance Extracted (AVE)
				Initial	Final			
Awareness	AAGT1	3.794	0.912	0.732	0.740	0.893	0.895	0.683
	AAGT2	4.091	0.847	0.710	0.762			
	AAGT3	3.791	1.028	0.884	0.837			
	AAGT4	2.689	1.366	0.225	-			
	AAGT5	3.886	0.993	0.916	0.949

	WPM2	4.097	0.780	0.603	-			

Table 2: Demographic profile.

Variable	Category	Frequency	Percentage
Age	Gen Z	50	14.29%
	Millennial/ Gen Y	176	50.29%
	Gen X	117	33.43%
	Boomer/Baby Boomer	7	2.00%
Gender	Male	235	67.14%
	Female	113	32.29%
	Prefer not to say	2	0.57%
Monthly Income	Below ₱20,000	8	2.29%
	₱20,001–₱40,000	196	56.00%
	₱40,001–₱60,000	109	31.14%
	₱60,001–₱80,000	37	10.57%
Hotel Stay Frequency	Once	170	48.57%
	2-3 times	132	37.71%
	4-5 times	30	8.57%
	More than 6 times	18	5.14%
Green Hotel Stay	Yes	49	14.00%
	No	2	0.57%
	Not Sure	299	85.43%
Certifications	ANAHW	101	28.86%
	Green Key	130	37.14%
	LEED	44	12.57%
	Not sure	75	21.43%

Table 3: Descriptive statistics of guest awareness of AI-driven Green Technologies.

Item	Statement	M	SD	Interpretation
AAGT1	I am aware that the hotel I stayed in uses AI to conserve energy.	3.79	0.91	High Awareness
AAGT2	I know that AI technologies are used in hotel waste management systems.	4.09	0.85	High Awareness
AAGT3	The hotel provided information about its AI-based sustainability features.	3.79	1.03	High Awareness
AAGT4	I am familiar with the use of AI in monitoring energy and water consumption in hotels.	2.69	1.37	Moderate Awareness
AAGT5	I actively notice smart technologies aimed at promoting sustainability in the hotels I visit.	3.89	0.99	High Awareness
Overall	Guest awareness of AI-driven green technologies (construct level)	3.65	0.77	High Awareness
Note. Responses were measured on a 5-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree).				

Table 4: Descriptive statistics of perceived usefulness of AI-driven green technologies.

Item	Statement	M	SD	Interpretation
PUADGT1	AI technologies in hotels contribute significantly to environmental sustainability.	4.08	0.63	High Usefulness
PUADGT2	I believe AI systems improve the hotel's operational efficiency.	4.23	0.75	Very High Usefulness
PUADGT3	The use of AI in the hotel enhanced my comfort and overall experience.	4.19	0.70	High Usefulness
PUADGT4	AI-driven sustainability features (e.g., smart thermostats) made me feel that the hotel cares for nature.	4.02	0.94	High Usefulness
PUADGT5	I find AI-based sustainability initiatives in hotels to be innovative and valuable.	4.37	0.60	Very High Usefulness
Overall	Perceived usefulness of AI-driven green technologies (construct level)	4.18	0.57	High Usefulness
Note. Responses were measured on a 5-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree).				

Table 5: Descriptive statistics of guest support for AI-driven green initiatives

Item	Statement	M	SD	Interpretation
RI1	I would stay in this hotel again because of its AI-driven green technologies.	4.09	0.60	High Support
RI2	I prefer to book hotels that implement AI-powered sustainability practices.	4.24	0.74	Very High Support
ReI1	I would recommend this hotel to others because of its environmental sustainability practices.	3.96	0.68	High Support
ReI2	I am likely to promote this hotel to my peers due to its use of innovative green technologies.	4.09	0.77	High Support
WPM1	I am willing to pay a higher price to stay in a hotel that uses AI to promote environmental goals.	3.97	0.70	High Support
WPM2	I consider AI-supported green practices a worthwhile investment, even if the room cost is higher.	4.10	0.78	High Support
Overall	Guest support for AI-driven green initiatives (construct level)	4.03	0.62	High Support
Note. Responses were measured on a 5-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree).				

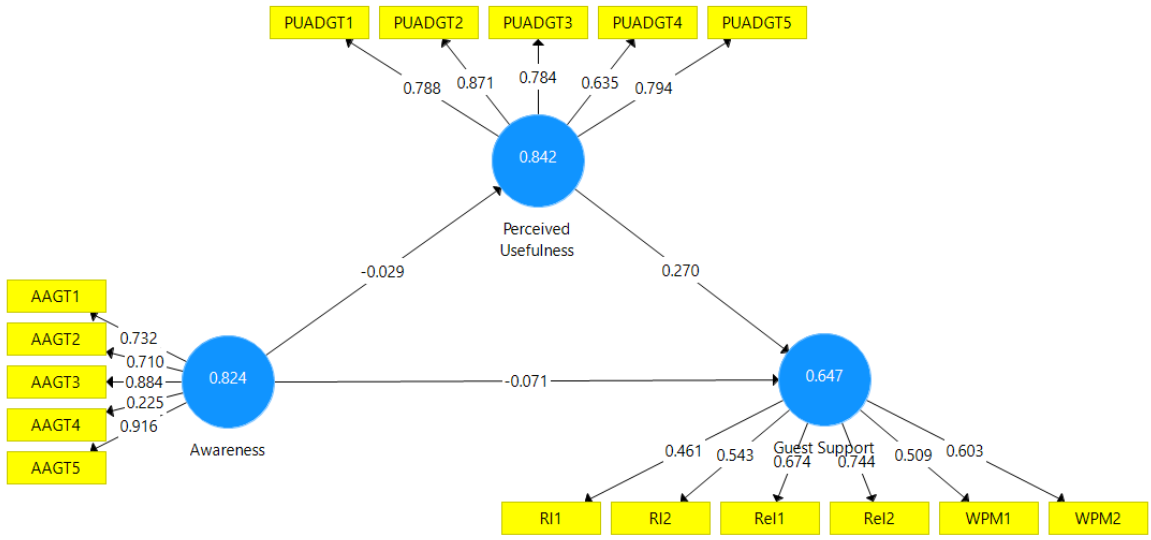

Figure 2: Structural equation modeling results: output loading of factors.

The measurement model was evaluated in terms of factor loadings, reliability, and validity (see Figure 2 and Table 5). For the Awareness construct, four items (AAGT1, AAGT2, AAGT3, AAGT5) were retained with loadings ranging from .740 to .949, while AAGT4 was dropped due to a weak loading (.225). The Perceived Usefulness construct retained four items (PUADGT1, PUADGT2, PUADGT3, PUADGT5) with loadings between .783 and .877; PUADGT4 was removed due to a low loading (.635). All six items of Guest Support (RI1, RI2, ReI1, ReI2, WPM1, WPM2) were retained, with loadings from .461 to .744, though RI1 and WPM1 showed weaker contributions.

Table 6: Fornell-Larcker criterion.

	Aware-ness	Guest Support	Perceived Usefulness
Awareness	0.826		
Guest Support	-0.046	1.000	
Perceived Usefulness	-0.015	0.245	0.819

Table 7: Heterotraiet-Monotrait Ratio (HTMT).

	Aware-ness	Guest Support	Perceived Usefulness
Awareness			
Guest Support	0.029		
Perceived Usefulness	0.046	0.257	

As shown in Table 6, the Fornell–Larcker criterion confirmed discriminant validity, with the square root of each AVE (Awareness = .826; Perceived Usefulness = .819; Guest Support = 1.000) exceeding the inter-construct correlations. Furthermore, the HTMT ratios (Table 7) were well below the conservative threshold of .85 (Awareness–Support = .029; Awareness–Usefulness = .046; Usefulness–Support = .257), providing additional evidence of discriminant validity.

The path coefficients of the structural model are presented in Figure 2. Awareness was not found to significantly predict Perceived Usefulness (β = –.029) nor Guest Support (β = –.071). In contrast, Perceived Usefulness had a positive and meaningful effect on Guest Support (β = .270). These findings suggest that while respondents are generally aware of AI-driven green technologies, this awareness does not directly enhance perceptions of usefulness or support for green initiatives. Instead, Perceived Usefulness serves as the critical driver of Guest Support. The SEM results indicate that awareness alone is insufficient to encourage guest support for AI-driven sustainability initiatives. Guests are more likely to revisit, recommend, or pay more for certified green hotels when they perceive AI technologies as useful in enhancing sustainability, operational efficiency, and their overall hotel experience. Thus, hotels should not only raise awareness but also highlight the practical benefits of AI applications to strengthen guest support [18].

Table 8: Hypothesis testing.

Path Direct Effect	β	t-Value	p-Value	Remarks
H1: Awareness → Guest Support	-0.031	0.651	0.515	Not Significant
H2: Awareness → Perceived Usefulness	0.008	0.182	0.855	Not Significant
H3: Perceived Usefulness → Guest Support	0.249	5.094	0.000	Significant
Note: p < 0.001; Bootstrap resampling with 5,000 subsamples was used to generate estimates.				

Table 8 presents the results of hypothesis testing for the direct effects. The path from awareness to guest support (H1) was not significant (β = –0.031, t = 0.651, p = .515), indicating that awareness of AI-driven green technologies did not directly influence guest support. Similarly, the path from awareness to perceived usefulness (H2) was also nonsignificant (β = 0.008, t = 0.182, p = .855). These results suggest that awareness alone was insufficient to explain variations in either usefulness perceptions or support. In contrast, perceived usefulness demonstrated a significant positive effect on guest support (H3; β = 0.249, t = 5.094, p < .001), confirming that guests who perceived AI-driven green technologies as useful were more likely to support sustainability initiatives. This pattern aligns with prior studies showing that perceived usefulness is often a stronger determinant of behavioral support compared to awareness [18], [32]. Overall, the non-significant paths involving awareness highlight that awareness alone does not meaningfully shape guest perceptions or behaviors, underscoring the need for further analysis of this finding in the discussion.

Table 9: Indirect effects.

Relationship	Indirect Effect			Bootstrapped Confidence Interval		Decision
	β	t-Value	p-Value	95% LL	95% UL	
H4: Awareness → Perceived Usefulness → Guest Support	0.063	0.176	0.860	0.035	0.039	Not Mediated
Note: p < 0.001, LL: Lower level, UL: Upper level						

Table 9 summarizes the mediation analysis. The indirect path from awareness through perceived usefulness to guest support (H4) was not significant (β = 0.063, t = 0.176, p = .860), with confidence intervals crossing zero (LL = 0.035, UL = 0.039). This indicates that perceived usefulness did not mediate the relationship between awareness and guest support. Thus, even though usefulness was a significant direct predictor of support, awareness did not contribute indirectly through usefulness. These findings suggest that increasing awareness alone may not be sufficient to foster guest support unless it simultaneously enhances perceived usefulness.

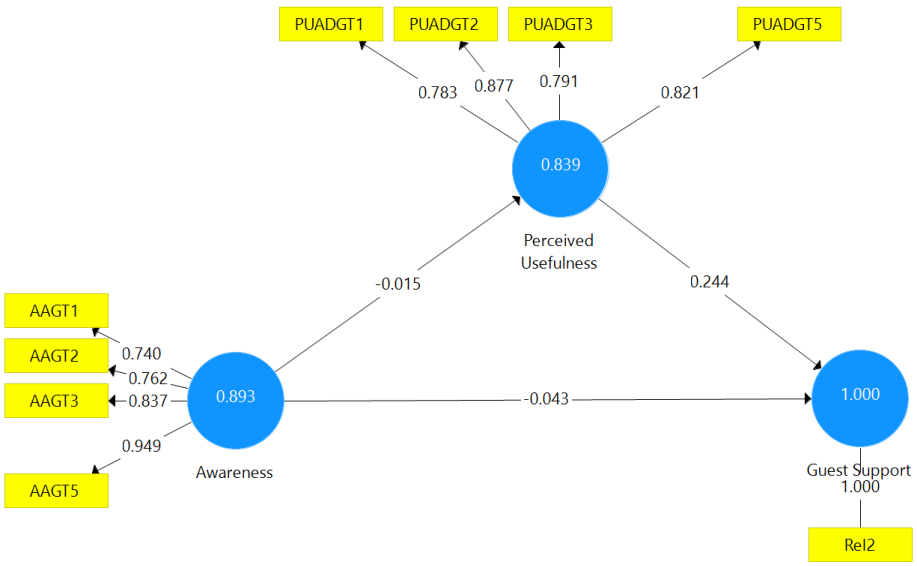

Figure 3: Final SEM model.

Figure 3 illustrates the structural equation model (SEM) of the main hypothesis. The model depicts the direct, indirect, and nonsignificant paths among awareness, perceived usefulness, and guest support. The visual representation reinforces the statistical findings: awareness paths to both guest support and perceived usefulness were weak, whereas perceived usefulness had a stronger direct effect on guest support ($\beta = 0.244$). The model also shows strong outer loadings of perceived usefulness items (ranging from 0.783 to 0.877), indicating reliable measurement of this construct. Awareness items also loaded well, particularly AAGT5 (0.949). However, the weak structural paths confirm that awareness was not a robust driver of usefulness or support.

Table 10: Associated R-square adjusted and R-square.

Construct	R Square	R Square Adjusted
Guest Support	0.062	0.056
Perceived Usefulness	0.000	-0.003

Table 10 reports the coefficient of determination (R^2) values. Guest support had an R^2 of .062 (adjusted $R^2 = .056$), meaning the predictors explained about 6.2% of the variance in guest support. Perceived usefulness had an R^2 of .000 (adjusted $R^2 = –.003$), indicating that awareness explained virtually no variance in usefulness. Following [33] guidelines, these effect sizes are weak, suggesting that the structural model had limited explanatory power. While perceived usefulness still emerged as a meaningful predictor of guest support, the low R^2 values indicate that the model did not fully capture the complexity of guest behavior. Additional factors such as trust in sustainability claims, perceived value of green initiatives, or environmental concern may contribute to a stronger explanatory framework. This limitation is acknowledged, and future studies are encouraged to incorporate these variables to enhance predictive power and provide a more comprehensive understanding of guest support for AI-enabled sustainability practices.

Table 11: Predictive relevance.

Construct	SSO	SSE	Q^2 (=1-SSE/SSO)
Awareness	1400	1400.00	
Guest Support	350	335.57	0.041
Perceived Usefulness	1400	1403.35	-0.002

Table 11 presents the predictive relevance (Q^2) values obtained through blindfolding. Guest support yielded a positive Q^2 value of .041, suggesting small predictive relevance. However, perceived usefulness had a negative Q^2 value (–.002), indicating no predictive relevance. Awareness also produced no predictive relevance. These results reinforce the earlier conclusion that awareness contributed little to predicting guest perceptions or support, while usefulness provided some predictive power for guest support.

Table 12: Model Fit.

Index	Saturated Model	Estimated Model
SRMR	0.062	0.062
d_ULS	0.171	0.171
d_G	0.121	0.121
Chi-Square	239.778	239.778
NFI	0.834	0.834

Table 12 displays model fit indices. The standardized root mean square residual (SRMR) value of .062 fell below the threshold of .08, indicating an acceptable fit [18]. The normed fit index (NFI) was .834, suggesting moderate fit but not reaching the conventional .90 cutoff [34] The chi-square value ($\chi^2 = 239.778$) was statistically significant, which is expected given the sensitivity of chi-square to sample size. Overall, the fit indices suggest that the model was adequate but not strong, consistent with the low explanatory and predictive power of the constructs.

6 CONCLUSIONS

This study examined guest perceptions of AI-driven green technologies in certified hotels in the Philippines and found that while awareness was moderate to high, it did not significantly influence guest support. Instead, perceived usefulness emerged as the strongest driver of revisit intentions, recommendations, and willingness to pay a premium, showing that guests respond more when they see clear benefits such as efficiency, comfort, and innovation. The findings affirm the relevance of TAM in a sustainability context and add originality by integrating TAM with S-O-R and TPB to frame guest behavior in certified hotels within a developing economy. At the same time, the low explanatory power of the model highlights its limitations and signals the need to include other factors – such as trust, perceived value, and environmental concern – in future research. Overall, the study offers balanced insights by recognizing both the strengths and

constraints of the model, while providing practical and policy guidance for advancing sustainable hospitality.

7 RECOMMENDATIONS

The study recommends that hotel operators make AI-enabled sustainability initiatives more visible and directly tied to the guest experience by highlighting certifications, explaining green technologies during check-in, and using in-room displays to show their benefits in real time. Policymakers and certification bodies are likewise encouraged to strengthen standards by not only setting infrastructural requirements but also promoting clear, guest-centered communication of technological advancements to bridge awareness gaps. Finally, future research should consider additional constructs such as trust, perceived value, and environmental concern, and adopt longitudinal and cross-cultural approaches to improve the generalizability of findings.

ACKNOWLEDGMENTS

We would like to thank National University, Philippines for providing the resources and support needed for this study.

Keywords: CRS-5, Religiosity, Sustainabiliy, Environmental Attitudes, Psychometrics, Stewardship.

Abstract This study evaluated the psychometric properties and structural validity of the five-item Centrality of Religiosity Scale (CRS-5) in a sample of Filipino university students. It examined implications for ecological attitudes and sustainability engagement. Descriptive statistics and CFA results indicated that CRS-5 is a brief, acceptable measure of centrality of religiosity. Private Practice and Religious Experience showed the strongest relations with the CRS-5 total, highlighting private devotion and experiential spirituality. Regarding the theoretical and empirical links between religiosity and environmental concern, we discuss how dimensions captured by the CRS-5 can support pro-environmental values, collective stewardship, and sustainable behaviors – particularly in societies where religion shapes community norms. The study recommends integrating religious institutions and experiential spirituality into ecological education and sustainability interventions on university campuses. Limitations and directions for research on measurement invariance and the CRS-5's predictive validity for environmental outcomes are noted. Future research should explore longitudinal designs and cross-cultural comparisons to clarify causal pathways linking religiosity and sustainability engagement. Examining how faith-based narratives influence environmental decision-making may further strengthen strategies that harness moral motivation and community solidarity for global ecological responsibility and behavioral change.

1 INTRODUCTION

Religiosity intersects with ecology and sustainability across multiple dimensions, producing both opportunities for environmental stewardship and tensions that complicate unified action [1], [2]. It also influences not only personal worldview and social behavior but also values and practices that relate to environmental stewardship and sustainability [3]. In many communities, including in the Philippines, religious institutions and faith practices shape norms about care for creation, communal resource use, and civic engagement.

The CRS-5's five dimensions (Intellect, Ideology, Public Practice, Private Practice, Religious Experience) map onto pathways by which religion may promote or hinder environmental concern and sustainable action [4]. For example, Ideology can include theological commitments (e.g., stewardship theology) that motivate conservation; Public Practice can mobilize collective action through congregational networks; Private Practice and Religious Experience may cultivate affective connections to the natural world that facilitate pro-environmental values; and Intellect reflects cognitive engagement that may shape environmental knowledge and deliberation.

There have been studies about the Centrality of Religiosity Scale [5] - [9], however this study hopes to evaluate the CRS-5 psychometrically and situates the findings within a sustainability framework to inform ecological education and community-based sustainability programs on university campuses.

An eco-religious approach frames environmental protection and climate change mitigation as integral to religious belief and practice, encouraging adherents to treat the natural world as an object of moral concern rather than solely an anthropocentric resource. This perspective aligns with scholarship arguing that religious institutions and communities can serve as powerful agents of environmental change by mobilizing members, shaping values, and

participating in public education and policy dialogues [1], [4].

Empirical research suggests that religiosity's relationship to environmental attitudes and behaviors is complex and context dependent. Some studies find that religious affiliation and participation are associated with more positive environmental attitudes compared with non-affiliated groups, while other work finds that very high levels of religiosity can coincide with lower environmental concern – especially when doctrinal interpretations prioritize human dominion or when socio-demographic and lifestyle covariates account for observed differences [10]. Moreover, the apparent effect of church membership on ecological values may attenuate once variables such as education, income, and consumption patterns are controlled, indicating that religiosity is one among several interlocking influences on environmental orientation [11], [1].

Case studies from particular cultural contexts illustrate productive pathways through which religion can support sustainability. Research among Muslim consumers in Pakistan reports positive associations between religiosity (both intrinsic and extrinsic) and sustainable behaviors such as energy saving, recycling, and sustainable consumption, although social status concerns can moderate these effects [12]. Similarly, studies among Taiwanese Christians identify church attendance, stewardship beliefs, and environmental-consequence awareness as mechanisms linking faith to protective environmental behaviors and willingness to accept personal sacrifice for environmental goals [13]. These findings point to stewardship theology and environmental education within religious institutions as key levers for promoting both private-sphere behaviors and public activism.

The literature indicates that religiosity interacts with ecology and sustainability in nuanced ways: religious values and institutions may promote bio-centric or eco-centric ethics and lower per-capita ecological footprints in some contexts, yet this relationship is conditional on doctrinal framing, institutional capacity, socio-demographic factors, and the level and type of religiosity among adherents. For research using the CRS-5, these findings suggest treating religiosity both as a multi-dimensional construct (intellect, ideology, public practice, private practice, religious experience) and as a variable whose environmental correlates may vary by cultural context and degree of centrality in an individual's life [4], [11].

2 MANUSCRIPT PREPARATION

Participants and procedure. Participants were recruited using convenience sampling. All participants completed the CRS-5, which comprises one item for each core dimension: Intellect, Ideology, Public Practice, Private Practice, and Religious Experience. Data screening followed standard procedures (missing data, univariate distributional checks, and multivariate normality assessment). Informed consent was obtained from all subjects involved in the study.

3 RESULTS AND DISCUSSION

Descriptive statistics were computed for the five core subscales of the Centrality of Religiosity Scale (CRS-5): Intellect, Ideology, Public Practice, Private Practice, and Religious Experience as presented in Table 1. The means ranged from 3.27 to 4.55, indicating moderate to high religiosity among respondents. Skewness and kurtosis values suggest that the distribution of responses was approximately normal, with slight negative skew observed in Ideology and Private Practice.

Cronbach's alpha for the CRS-5 total scale was 0.78, indicating acceptable internal consistency. While this is slightly lower than the values typically observed for CRS-10 and CRS-15, it reflects the brevity of the five-item model and supports the use of CRS-5 in contexts where time or space constraints exist.

Table 1: Descriptive statistics.

Subscale	Mean	SD	Skewness	Kurtosis
Intellect	3.27	0.9	-0.09	-0.28
Ideology	4.55	0.84	-1.94	3.33
Public Practice	2.88	1.04	0.41	-0.3
Private Practice	4.43	1.05	-1.76	1.89
Religious Experience	3.89	1.05	-0.73	-0.15

Pearson correlation analyses revealed significant and positive relationships among all five CRS-5 subscales and the total religiosity score. The highest correlations were found between Private Practice and CRS-5 Total Score ($r = 0.84$), and Religious Experience and CRS-5 Total Score ($r = 0.85$), followed by Ideology ($r = 0.77$). These results suggest that private forms of religious expression and spiritual experiences are central components of religiosity

among the sample population, as summarized in Table 2.

Table 2: Correlation matrix.

	Intellect	Ideology	Public Practice	Private Practice	Religious Experience	CRS-5 Total
Intellect	1.0	0.117	0.358	0.223	0.203	0.492
Ideology	0.117	1.0	0.377	0.563	0.72	0.766
Public Practice	0.358	0.377	1.0	0.515	0.464	0.708
Private Practice	0.223	0.563	0.515	1.0	0.662	0.839
Religious Experien	c0e.203	0.72	0.464	0.662	1.0	0.847

Mardia's multivariate skewness and kurtosis coefficients were computed to assess normality. The skewness sum was -1.39, and the kurtosis sum was -4.49, indicating acceptable multivariate normality. While not perfect, the data is sufficiently normal to justify CFA procedures using robust estimators.

Independent samples t-tests were conducted to explore potential gender differences in CRS-5 subscale scores. While male participants scored slightly higher across most subscales, none of the differences were statistically significant ($p > .05$). Effect sizes ranged from small to moderate (Cohen's $d = 0.12$ to 0.35), with Private Practice and CRS-5 Total Score showing the largest differences. These findings align with prior research suggesting minimal gender-based differences in religiosity when consideration, as summarized in Table 3.

Table 3: Gender differences.

Subscale	t-value	p-value	Cohen's d
Intellect	-0.604	0.548	-0.154
Ideology	-1.237	0.221	-0.311
Public Practice	-0.483	0.631	-0.122
Private Practice	-1.373	0.175	-0.346
Religious Experience	-1.073	0.287	-0.269
CRS-5 Total Score	-1.357	0.18	-0.341

Although the RMSEA was elevated, the other indices (e.g., CFI, TLI, SRMR, GFI) indicated good to excellent model fit. The inconsistency in RMSEA may be attributed to the small degrees of freedom and model simplicity (Kenny et al., 2015). Standardized factor loadings were all significant ($p < .05$), with the highest loading for Religious Experience (3.186, R- = 0.81) and the lowest for Intellect (1.123, R- = 0.07). This suggests that Religious Experience was the most influential indicator of the latent construct, while Intellect contributed the least. Despite its lower variance, Intellect remains a theoretically important dimension of religiosity, as illustrated in Table 4 and Table 5.

Table 4: CFA model fit indices.

Fit Index	Value	Interpretation
Chi-Square	12.313	Acceptable
CFI	0.975	Excellent
TLI	0.949	Excellent
RMSEA	0.154	Poor
SRMR	0.074	Acceptable
GFI	0.996	Excellent

Table 5: CFA standardized factor loadings.

Subscale	Standardized Loading	R^2
Intellect	1.123	0.066
Ideology	2.927	0.679
Public Practice	2.329	0.43
Private Practice	2.845	0.642
Religious Experience	3.186	0.805

Descriptive statistics revealed moderate to high levels of religiosity, particularly in Ideology and Private Practice. Internal consistency was acceptable (.78), consistent with prior studies of brief religiosity scales. Correlation analysis showed all five subscales were significantly associated with the CRS-5 total score, particularly Religious Experience and Private Practice, highlighting the centrality of affective and devotional aspects of religiosity among Filipino youth.

No statistically significant gender differences were found, although small-to-moderate effect sizes suggest potential trends that future research may further explore. These findings contribute to ongoing discourse on the nuanced relationship between gender and religiosity.

CFA results supported a unidimensional model with most fit indices indicating excellent model fit. Despite a high RMSEA, this may be attributed to model simplicity and limited degrees of freedom. All items loaded significantly onto the latent factor, with Religious Experience showing the highest contribution. Intellect had the lowest explained variance, suggesting this dimension may be better assessed using multiple items in extended versions of the CRS.

This study affirms the validity of the CRS-5 as a brief, practical tool for assessing religiosity, especially where longer instruments are impractical. The results reinforce the importance of experiential

and private dimensions in religiosity and offer insights for culturally sensitive research and intervention in religious contexts.

This study links the five CRS-5 dimensions to processes that plausibly connect religiosity with pro-environmental attitudes and behaviors. The Ideology dimension, which showed a high mean and strong factor loading, appears especially likely to influence collective support for bility when ideological commitments include stewardship, care for creation, or social-justice theology. Where dominant religious teachings foreground compassion and responsibility for others and the natural world, Ideology can reinforce environmental norms and legitimacy for policy interventions that advance sustainable development [1], [4].

Private Practice and Religious Experience – allied affective and experiential aspects of religiosity – displayed very high correlations with total CRS scores and therefore merit particular attention as pathways to nature-connectedness. Affective religious practices (prayer, contemplation) and transcendent experiences can cultivate empathic concern for nonhuman life and feelings of awe, both of which have been linked in prior research to greater ecological concern and conservation behavior. These psychological states can increase willingness to conserve resources and to support conservation policies, suggesting that experiential religion operates as an intrapersonal mechanism for environmental motivation [1], [4].

Public Practice offers an organizational and social mechanism: congregational participation creates social capital and institutional capacity that can be mobilized for community sustainability projects such as tree planting, recycling drives, and disaster risk reduction [3]. Faith communities often provide outreach, environmental education, and trusted networks that lower the costs of collective action and enhance the diffusion of pro-environmental norms [11]. Thus, Public Practice functions both as a platform for behavioral interventions and as a conduit for normative transmission.

The Intellect dimension loaded more weakly in the measurement model, indicating that a single item may insufficiently capture the cognitive and theological reasoning that undergirds environmentally oriented interpretations of faith. Nevertheless, cognitive engagement – scriptural study, theological reflection, and critical reasoning – remains a plausible route to durable attitude change. A richer measurement of Intellect might reveal stronger associations with ecological knowledge, moral reasoning about the environment, and sustained behavioral commitments [4].

Across these dimensions, several mechanisms and contextual moderators clarify when and how religiosity translates into sustainability outcomes. Religious norm transmission via sermons, rituals, and communal teaching can shape personal norms that motivate environmental behavior [11]. Social networks embedded in congregations reduce collective action barriers and enable the scaling of local sustainability efforts. Moral framing that emphasizes stewardship, care for vulnerable populations, or intergenerational responsibility aligns religious language with prevailing sustainability ethics and can enhance public support for environmental policy – especially in highly religious settings where faith-consistent messaging carries credibility [1]. Yet potential tensions persist: doctrinal interpretations that privilege anthropocentric dominion over nature may impede environmental prioritization, making local theological framing a decisive moderator of outcomes [14].

Implications for campus sustainability practice follow directly from these linkages. University sustainability offices should recognize religious communities as strategic partners: partnering with campus chaplaincies and student faith groups can leverage Public Practice to increase participation and legitimacy for sustainability programming. Experiential programming – nature retreats, reflective spiritual practices paired with environmental education – can activate Private Practice and Religious Experience pathways to deepen ecological concern and promote behavior change. Integrating theological reflection into curricular or co-curricular workshops invites Intellect and Ideology engagement, strengthening long-term commitments to sustainable lifestyles. Finally, including brief religiosity measures such as the CRS-5 in program evaluations will allow campus practitioners to assess which religiosity dimensions predict participation, persistence, and behavior change, enabling tailored interventions.

5 LIMITATIONS

Several limitations temper the conclusions that can be drawn. First, the cross-sectional design and CRS-5 measurement preclude causal inference; while dimensions of religiosity are associated with sustainability-relevant outcomes, the directionality of effects cannot be established without longitudinal or experimental data. Second, the CRS-5 subscales use

single items for each dimension; this economical format limits the capacity to represent complex theological positions or to capture the full breadth of cognitive Intellect processes relevant to environmental ethics. Third, cultural specificity constrains generalizability. Findings derived from a Filipino university sample (or any single cultural context) may not extend to other religious traditions, national settings, or age groups because local doctrines, institutional structures, and social norms shape the religiosity–environment relationship [1]. Fourth, unmeasured socio-demographic and lifestyle covariates (e.g., education, income, urban/rural residence, political orientation) may account for part of the observed associations; prior studies have shown that the apparent effect of religious membership on ecological values can attenuate when these factors are controlled [11].

6 CONCLUSIONS

The CRS-5 offers a concise, psychometrically reasonable index of the centrality of religiosity whose dimensions map onto distinct pathways to sustainability. Private Practice and Religious Experience appear especially potent for fostering nature-connectedness and intrapersonal motivations for conservation, whereas Public Practice and Ideology provide social and normative channels for collective action and policy support. Intellect – although less well captured by a single-item indicator – likely represents an underutilized avenue for cultivating durable, theologically grounded commitments to environmental stewardship. By attending to the multidimensional character of religiosity and the contextual factors that shape doctrinal framing, researchers and campus practitioners can more effectively partner with faith communities to promote stewardship and sustainable behavior, while cautiously acknowledging the limits of cross-sectional inference and the need for better measurement and longitudinal evidence. Comparative cross-faith studies might uncover how specific doctrines, rituals, or theological narratives influence sustainable behavior across communities. Integrating psychological and sociological perspectives could also clarify the mediating role of identity, meaning-making, and moral obligation in translating religiosity into ecological action. Moreover, developing more nuanced instruments to assess religious cognition, practice, and experience would strengthen empirical validity and theoretical precision. Longitudinal and intervention-based studies will be essential to trace how religious engagement fosters enduring shifts in environmental attitudes and practices over time.

7 RECOMMENDATIONS FOR FUTURE RESEARCH

To advance understanding of how CRS-5 dimensions relate to sustainable action, future studies should:

1) combine the CRS-5 with validated environmental attitude and behavior scales to establish concurrent and predictive validity;
2) expand the Intellect dimension with multiple items that tap theological reasoning, scriptural interpretation, and environmental moral reasoning;
3) employ longitudinal or intervention designs (for example, randomized trials of faith-based experiential programming) to test causal effects on sustained pro-environmental behavior;
4) examine measurement invariance and conduct multi-group confirmatory factor analyses across religious traditions, age cohorts, and cultural contexts to determine whether the CRS-5 operates equivalently across groups;
5) embed qualitative methods (interviews, focus groups) to reveal the doctrinal narratives, interpretive frames, and institutional dynamics that quantitative scales may miss.

Keywords: Sustainability, Consumption Behavior, Behavioral Intentions, Sustainable Fashion, Clothing Industry, Sustainable Development Goals.

Abstract: The supply chain's retail aspect is still poorly understood despite the increasing prominence of sustainability in the apparel sector. The intricacy of sustainable apparel retailing makes this knowledge gap especially urgent. Theory development, systematic literature reviews, and bibliometric analysis were combined, adhering to the multi-method guidelines of the B-SLR, achieving an integrative examination of the body of dominant literature to address this problem. The suggested hierarchical framework, applicable to diverse consumer segments, delivers a profound understanding of the intricate dynamics underlying sustainable apparel buying patterns. The multi-tiered strategy to recognize consumer preferences and promote eco-friendly apparel combines numerous concepts and components from recognized frameworks, underscoring implementation intentions and buying patterns. It provides conclusive proof supporting the crucial part that consumers' attitudes, morals, awareness, self-reliance, social influences, and emotional ties play in influencing the use of eco-friendly clothing. The generalizability of the results has significant implications for educators, legislators, and retailers who want to advance eco-fashion and environmental preservation.

1 INTRODUCTION

A company's success in the cutthroat apparel sector, where efficient supply chain optimization is critical, depends on balancing the flow of outputs. The ever-evolving fashion trends present apparel retailers with intricate supply chains [1]. In a world with a multitrillion-dollar global economy, the textile and apparel industries are intertwined [2]. This industry provides global supplies by producing everything from fibers to clothing. It is an intricate system that has an impact on the entire world [2]. Known as the worst pollutants in the world, these sectors have millions of workers and contribute 2% of the world's GDP [3]. They are essential to achieving Sustainable Development Goal 12 set by the UN, which highlights the need to change corporate behavior to promote sustainable production and consumption throughout the chain, alongside the EU Commission's Green New Deal initiative [3].

The fashion industry's supply chain involves multiple businesses from product conception to consumer, including growers and retailers, crossing international borders and adhering to trade regulations [1]. According to Statista [4], the combined effects of online shopping and rising demand for clothing would propel retail sales to a 7.6% (CAGR) through 2030.

The global textile industry was severely disrupted by the coronavirus outbreak, which altered supply chains and led to a decline in demand [5]. Due to the evolving customer needs that set a greater focus on environmental responsibility, comfort, and ease of use, the disruption accelerated the industry's shift toward automation and digitalization. As a result, companies have responded by establishing recycling programs, promoting eco-friendly goods, and establishing a variety of partnerships [6].

Due to market conditions, stakeholders in the apparel industry must be adaptable [7]. A strong financial position enables retailers to overcome obstacles and adjust to shifting market conditions

more skillfully [8]. In their role as environmental gatekeepers, they link suppliers and consumers, advocating sustainability and deepening knowledge of social and ecological issues while highlighting the importance of sustainable supply chains [8].

Digital marketing has a huge impact on Filipino consumers' buying choices, especially among younger audiences [9]. Decision-making is accelerated by social media, as users consult their peers' advice and opinions before making purchases [9]. Green ambassadors on social media promote responsible consumption and brand loyalty [10].

Through groups like the decentralized Zero Waste Philippines initiative, which aims to reduce waste, and the Philippine Social Enterprise Network (PhilSEN), which promotes environmentally sustainable practices, the Philippines promotes mindful consumption [11]. By encouraging sustainable waste management in homes and businesses, the government backs these initiatives through R.A. 11367 or the "National Integrated Waste Management Act" of 2019 [11].

Mindful consumption also faces challenges due to limitations in conscious consumerism. A major obstacle is the lack of understanding of consumer behavior regarding sustainability [7]. Key barriers include low awareness, limited resources, and high adoption costs [7]. Consumers prioritize quality, affordability, and convenience over sustainable products [12].

The Philippines' focus on conscious consumerism is a promising development. While sustainable apparel gains attention, the retail aspect remains overlooked. Retailers can reduce emissions and waste through improved operations [13].

This research followed the guidelines of bibliometric analysis and systematic literature reviews to examine sustainable apparel retailing and ethical consumerism, identifying trends, suggesting future directions, and proposing a framework integrating various factors.

2 RESEARCH METHOD

In August 2024, a Scopus search identified 248 papers, with 149 relevant to the apparel industry. A taxonomy from 106 articles categorized themes: sustainable fashion consumption (23 articles), supply chain sustainability (20 articles), consumer psychology (25 articles), cultural influences (18 articles), and marketing strategies (20 articles).

The B-SLR standards [14] employ a holistic approach that integrates systematic literature reviews (SLRs) with bibliometric analysis to create the Biblio-metric-Systematic Literature Reviews (B-SLR). This integrated processes balance quantitative and qualitative methods, addressing the limitations of standalone bibliometric analysis and SLRs, thus enhancing methodological coherence. The structured 10-step process, depicted in Figure 1, facilitated significant literature reviews that improved purpose-method fit [15], [16].

The approach identified gaps in existing frameworks, as presented in Table 1, confirmed relevance, and developed a new framework, enhancing the perception of green apparel purchasing behavior.

The suggested integrated three-tiered framework for sustainable fashion consumer decision-making, illustrated in Figure 2, identified behavioral, sociative, emotive, and cognitive factors influencing Filipino customers, progressing from intention to social influence, purchasing, and culminating in ecological responsibility and self-reliance.

Table 1: Summary of the proposed integrated multi-tiered framework.

Proposed Integrated Framework	Existing Framework	Difference from the Proposed Integrated Framework	Reference
Theory of Planned Behavior (TPB)	Integrated TPB, SCT, and VAB that examine eco-friendly fashion purchasing.	Lacks the ECF and moderating variables.	[17]
Value-Attitude-Behavior (VAB)	Integrated ECF, TPB, and VAB that examine ethical consumerism.	Excludes SCT and SFC.	[18]
Social Cognitive Theory (SCT)	Combined SCT, SFC, and TPB that examine sustainable apparel consumption.	Integrates SCT and TPB but excludes ECF and VAB.	[19]
Sustainable Fashion Consumption (SFC)	Combined VAB, TPB, and SCT that evaluate societal effects.	Comprises SFC and ECF, which are absent from the authors' study.	[20]
Ethical Consumerism Framework (ECF)	Integrated VAB, ECF, and TPB that examine moral consumption.	SCT and SFC are not integrated.	[7]

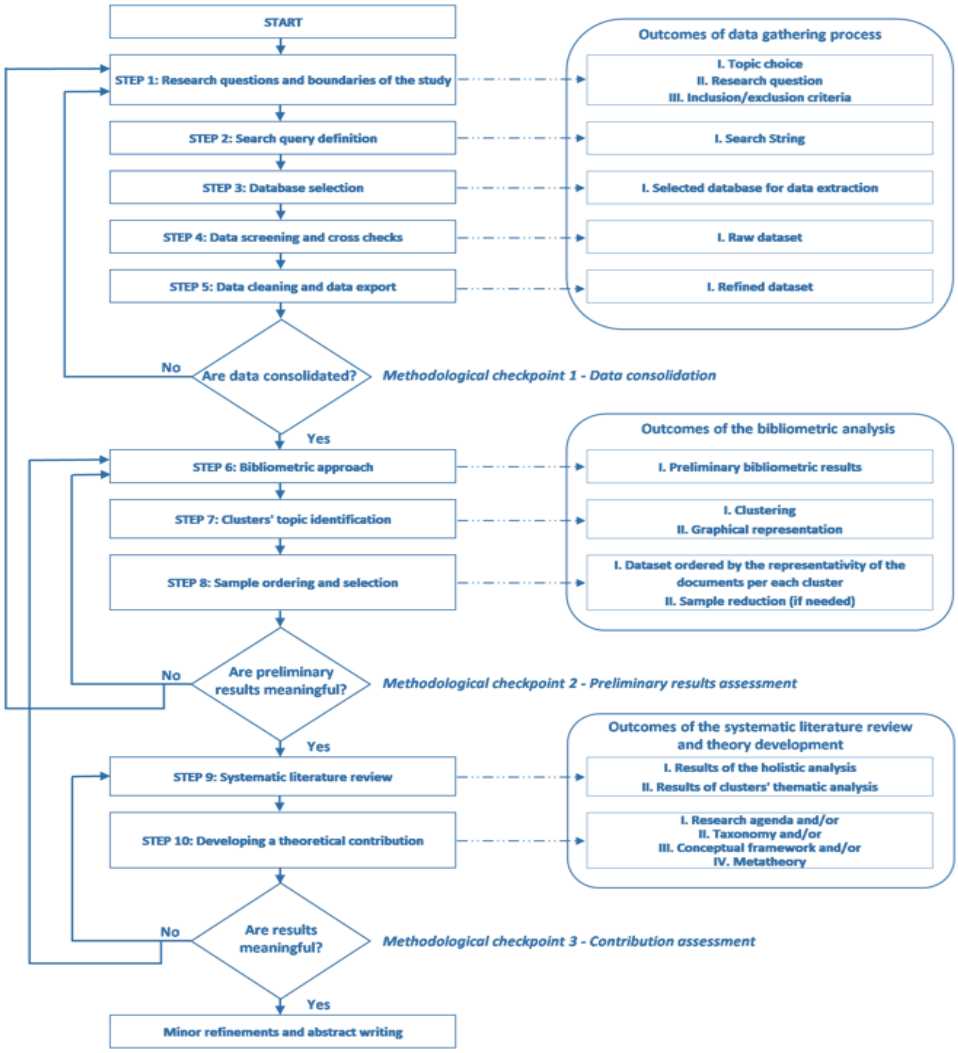

Figure 1: Ten-step bibliometric-systematic literature review workflow.

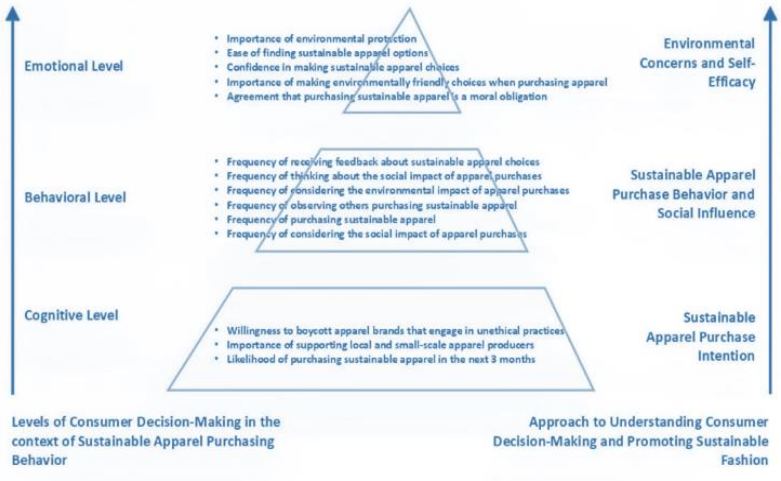

Figure 2: Three-tiered framework for sustainable apparel purchasing behavior.

Table 2: Measurement items, frequency distribution, and constructs.

Constructs/ Items	Rating	Frequency	Median	Mean	Std. Deviation
Ethical Consumerism Theory EC1: How crucial is it to purchase apparel from ethical brands or employers.	3 4 5	320 48 7	3.0	3.165	0.419
EC2: How frequently do you consider how your clothing choices affect society.	1 3 4 5	7 157 204 7	4.0	3.544	0.631
EC3: Would you boycott brands with unethical practices.	1 3 4 5	1,60, 286, 28	4.0	3.907	0.501
EC4: How important is transparency about sustainable practices in apparel retail.	3 4 5	297 71 7	3.0	3.227	0.462
EC5: How important is supporting local/small-scale apparel producers to you.	3 4 5	87 260 28	4.0	3.843	0.532
Theory of Planned Behavior TPB1: Will you buy eco-apparel in the next 3 months.	1 3 4 5	1 86 259 29	4.0	3.840	0.553
TPB2: Do you feel in control of your sustainable clothing choices.	1 5	150 225	5.0	3.400	1.962
TPB3: How important is making eco-friendly apparel choices to you?	3 4 5	37 207 131	4.0	4.251	0.621
TPB4: Are you amenable to paying more for green apparel.	3 4 5	43 51 281	5.0	4.269	1.360
Value-Attitude-Behavior Model VAB1: How important is protecting the environment to you.	3 4 5	73 156 145	4.0	4.193	0.740
VAB2: Is buying sustainable apparel a moral obligation.	3 4 5	29 215 131	4.0	4.272	0.595
VAB3: How frequently do you consider how your clothing purchases will be perceived by others.	1 3 4 5	6 147 178 44	4.0	3.677	0.742
VAB4: How imperative is sustainability when buying clothing,	3 4 5	288 81 36	3.0	3.248	0.468
VAB5: How frequently do you consider how your clothing purchases will affect the environment.	1 3 4 5	6 183 179 7	3.0	3.483	0.620
Social Cognitive Theory SCT1: How often do you see others buying eco-apparel.	1 3 4 5	5 188 175 7	3.0	3.477	0.606
SCT2: Are you confident in making eco-apparel choices.	3 4 5	28 148 199	5.0	4.456	0.631
SCT3: Can you easily find sustainable apparel options.	3 4 5	90 136 149	4.0	4.157	0.784
SCT4: Do you get feedback from others about your sustainable apparel choices.	1 3 4 5	65 144 158 8	3.0	3.117	1.091
Sustainable Fashion Consumption Framework SFC1: How important is it that you cut down on clothing waste	3 4 5	55 209 111	4.0	4.224	1.625
SFC2: Have you ever recycled or restored used clothing.	1 2	208 167	1.0	1.445	0.498
SFC3: How imperative is it for you to buy clothing made from eco materials.	1 2 3 4 5	8 11 43 212 101	4.0	4.032	0.833
Sustainable Apparel Purchase Behavior SAPB1: How often do you buy sustainable clothes.	1 2 3 4 5	8 4 171 181 11	4.0	3.488	0.678
SAPB2: Would you recommend eco-apparel to others.	3 4 5	17 250 108	4.0	4.243	0.525
SAPB3: Are you satisfied with your eco-apparel purchases.	1 3 4 5	1 73 242 59	4.0	3.955	0.612

3 RESULTS

3.1 Knowledge Network Analysis

A bibliometric analysis using Biblioshiny and VOSviewer mapped the evolution of research, presenting visuals such as word cloud, shown in Figure 3, that indicate key themes. The thematic map, illustrated in Figure 4, highlighted knowledge, waste management, and willingness to pay as key themes, with sustainability and ethics becoming increasingly relevant, particularly in 2022.

Figure 3: Word cloud.

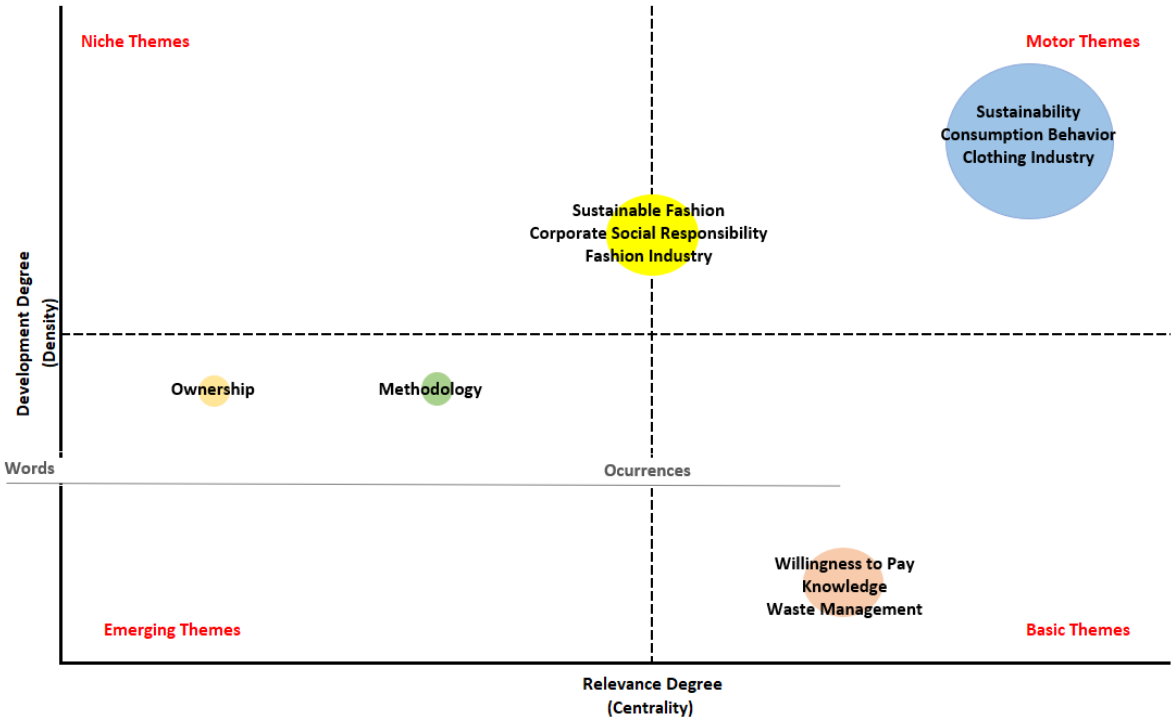

Figure 4: Thematic map.

3.2 Sampling

An online survey via Google Forms revealed six key factors affecting sustainable clothing purchases: demographics, sustainable retailing, ethical consumerism, cultural values, personality traits, and pricing. A quantitative analysis validated findings from 443 respondents, predominantly Gen Z (60.5%). Generational differences affect purchasing priorities, influenced by income and education levels.

3.3 Descriptive Analysis

The variable selection was optimized by analyzing distributions, outliers, and correlations. Table 2 presents the constructs, frequency distributions, and measurement items on sustainable apparel behavior using a Five-point Likert scale.

4 CONCLUSIONS

The sustainability dialogue in fashion frequently overlooks the unique challenges faced by developing countries. This review evaluated sustainable retail practices in the region, identified obstacles, and offered improvement suggestions while emphasizing the necessity for dedicated research on sustainable fashion in underdeveloped markets.

Despite progress, the apparel industry struggles with sustainability and transparency regarding ethical products, impacting consumer attitudes and necessitating the integration of sustainability into retail strategies. Understanding consumer motivations, shaped by social factors and positive sustainability attitudes, is vital amidst rising global environmental concerns.

The study investigated how environmental gatekeepers influence sustainable garment purchasing attitudes among Filipino consumers, advocating for collaboration among regulators, policymakers, and industry stakeholders to foster ethical consumption. Future research should also examine how green supply chain management practices [21] implemented by retailers affect consumer perceptions and purchasing behavior. Education, awareness, and supportive policies are essential to enhance sustainable practices and transform the Philippine apparel market towards ecological responsibility.

The necessity of equitable employment and sustainable economic growth, robust and

environmentally friendly industrialization, and reduced inequities are some of the ways that SDGs 8, 9, 10, and 12 relate to the apparel retailing. Throughout its supply chain, the apparel industry must prioritize moral and fair labor practices, ensuring secure employment settings. Retailers may help by providing access to financial services, supporting small producers, and integrating them into global value chains. A more efficient and responsible sector is encouraged by investments in long-lasting and sustainable infrastructure, which includes both local and international logistics as well as equitable and easily accessible services. Reducing waste and improving resource efficiency requires promoting innovation in circular business processes, sustainable design, and material use. By ensuring fair treatment and opportunities for all supply chain participants, retailers help reduce inequities. Closing social disparities is facilitated by promoting equitable access to reasonably priced, environmentally friendly goods and services and by providing buyers with the information needed to make conscious choices. A fairer and impartial sector is promoted by implementing inclusive strategies that assist local communities and different groups throughout the value chain.

Keywords: Digital Economy, Sports Training, Islamic Finance, Islamic Banking.

Abstract: This study explores the financing of digital sports training services within the broader framework of the rapidly expanding digital economy, with particular emphasis on the potential role of Islamic banks in supporting and sustaining such services. The research sheds light on the specific challenges associated with financing intangible assets, such as mobile applications, online platforms, and other technology-driven tools that form the backbone of modern digital sports services. These assets often lack physical collateral, making their financing more complex, and raising the question of whether Islamic finance can provide Sharia-compliant yet innovative solutions to overcome such barriers. Employing a descriptive-analytical approach, the paper examines the scope of available funding opportunities and evaluates a range of Islamic financial instruments that could be adapted to meet the needs of this emerging sector. Furthermore, it suggests practical mechanisms and strategies to enhance cooperation between Islamic financial institutions and the growing digital sports industry.

1 INTRODUCTION

The world is experiencing a profound digital transformation that permeates all economic sectors, including sports. This technological evolution has catalyzed the proliferation of digital platforms and smart applications for sports training services, fundamentally reshaping service delivery and consumption patterns. While these developments unlock substantial investment opportunities, they simultaneously present financing challenges that necessitate innovative, risk-adaptive financial models attuned to the unique characteristics of digital assets.

In this context, Islamic banking emerges as a viable financing alternative, distinguished by its foundational principles of risk-sharing, equity, transparency, and linkage to real economic activity. These principles offer a robust framework for fostering sustainable growth in digital sports training initiatives. This study examines the convergence of three critical domains – the digital economy, sports training services, and Islamic finance – focusing on opportunities and challenges in leveraging Sharia-compliant mechanisms to support this emerging sector.

2 PROBLEM STATEMENT

Despite the rapid proliferation of digital sports training services and their substantial growth potential, persistent financing barriers impede their optimal development. Unlike traditional ventures, digital economy projects feature intangible assets, distinctive revenue models, and elevated initial risks that misalign with conventional debt-based financing paradigms. Although Islamic banking seeks expansion into emerging sectors, its adaptation to these projects' specialized funding requirements remains nascent.

This study addresses the central research question: What Sharia-compliant mechanisms can effectively bridge the financing gap for digital sports training platforms? Specifically, it evaluates the suitability of partnership-based contracts (*Mudarabah*, *Musharakah*) and sale/lease structures (*Murabahah*, *Ijarah*) for addressing intangible asset financing challenges, while assessing regulatory

frameworks' capacity to support innovative Islamic financial products for this sector.

2.1 Research Questions

How can Islamic banking instruments facilitate sustainable financing for digital sports training services?

2.2 Sub-Questions

To address the study's core objectives, this analysis examines the operational adaptation of Sharia-compliant instruments. The primary sub-questions are:

- How can Islamic financial products - *Murabahah*, *Musharakah*, *Mudarabah*, and *Sukuk* - be optimally structured to accommodate the distinctive financial characteristics of digital sports training platforms?
- What principal challenges and opportunities confront Islamic banking in promoting the growth and sustainability of digital sports training services?

3 HYPOTHESIS

Islamic banking provides effective, sustainable financing for digital sports training services through Sharia-compliant instruments and risk-sharing principles.

Testable Sub-Hypotheses:

- H1. Partnership-based Islamic contracts (*Mudarabah*, *Musharakah*) demonstrate superior suitability over conventional debt models for digital sports projects characterized by intangible assets and elevated initial risks.
- H2. Specialized risk assessment frameworks aligned with Islamic principles, supported by enabling regulatory environments, substantially enhance Islamic institutions' capacity to fund digital sports training initiatives.

4 STUDY OBJECTIVES

This study seeks to:

- Analyze the distinctive financial characteristics of digital sports training service projects.
- Evaluate the suitability of Sharia-compliant Islamic banking instruments for financing these initiatives.
- Identify challenges confronting Islamic banking in this emerging sector and propose mitigation strategies.
- Highlight opportunities for Islamic finance to drive growth and sustainability in digital sports training.
- Offer actionable recommendations for Islamic financial institutions, investors, entrepreneurs, and policymakers.

5 METHODOLOGY AND INSTRUMENTS

5.1 Research Methodology

This study employs a descriptive-analytical approach augmented by empirical validation:

- Descriptive Component. Systematic literature synthesis on the digital economy, sports training services, and Sharia-compliant financial instruments.
- Analytical Component. Examination of variable interrelationships, particularly between Islamic finance mechanisms and digital sports project requirements.
- Empirical Component. Case study analysis of existing financing contracts or expert interviews to substantiate proposed mechanisms.

5.2 Research Instruments

This study utilizes the following instruments to achieve its objectives:

1) Comprehensive Literature Review. Systematic analysis of academic books, peer-reviewed journals, theses, institutional reports, and credible online sources.
2) Content Analysis. Thematic extraction of key concepts, financing models, challenges, and opportunities from collected documents.
3) Case Study Analysis. Examination of actual or illustrative digital sports projects financed through Islamic mechanisms, evaluating implementation challenges and outcomes.
4) Expert Interviews. Semi-structured discussions with Islamic finance specialists and digital sports entrepreneurs to capture practical insights on funding dynamics.

6 THEORETICAL FRAMEWORK AND ANALYSIS

This section presents a comprehensive theoretical framework that integrates literature review findings with analytical discussion, elucidating the compatibility between Islamic banking instruments and the financing requirements of digital sports training services.

6.1 Characteristics of Digital Sports Training Projects

Digital sports training platforms exhibit unique operational characteristics that distinguish them from traditional business models [1]. These ventures are predominantly knowledge-intensive, relying heavily on intangible assets such as proprietary software algorithms [2], mobile applications, digital training content libraries, and user engagement databases. Their revenue streams typically follow subscription-based (SaaS), freemium, or advertising models, which often result in volatile early-stage cash flows and complicate conventional debt-servicing requirements [3]. Moreover, such platforms are exposed to elevated levels of innovation and market risk due to rapid technological obsolescence and uncertain user adoption rates.

6.2 Limitations of Conventional Financing Mechanisms

Traditional debt-based financing proves inadequate for digital sports projects due to several structural mismatches:

- Collateral Deficiency. Banks prioritize tangible assets as security, whereas digital platforms derive value primarily from intellectual property and user networks, which lack conventional collateral value [2].
- Cash Flow Volatility. Fixed repayment obligations exacerbate financial strain during growth phases characterized by negative cash flows and high reinvestment needs. [3].
- Risk Aversion. Conventional lenders exhibit reluctance toward high-uncertainty technology ventures lacking historical performance benchmarks. [4].

6.3 Theoretical Alignment of Islamic Banking Instruments

Islamic finance principles offer a structurally superior alternative through risk-sharing paradigms that align financier and entrepreneur interests:

Risk-Sharing Contracts (Musharakah & Mudarabah). These partnership models eliminate fixed repayment pressures by linking returns to actual project performance. For digital sports startups facing high initial failure probabilities (70-90% within three years), profit-loss sharing reduces entrepreneurial burden while providing financiers equity participation in successful scaling. This mechanism particularly suits subscription-based platforms where revenue stabilization occurs post-user acquisition [5], [6].

Intangible Asset Financing Solutions:

- Istisna' Contracts. Facilitate custom software development and platform engineering, treating digital products as "manufactured goods" eligible for progressive financing [7].
- Ijarah Muntahia Bittamleek. Enables leasing of digital infrastructure benefits (servers, cloud services, software licenses) with ownership transfer, circumventing upfront capital constraints while maintaining Shariah compliance [8].
- Capital Market Instruments. Sukuk issuance leverages stable subscription revenue streams as underlying assets, enabling digital sports firms to access broader ethical investor pools for expansion financing while adhering to asset-backing requirements [4].

6.4 Proposed Analytical Frameworks

The following matrix (Table 1) synthesizes the theoretical applicability of Islamic financing instruments to the components of digital sports training projects. In addition, a comparative risk-based perspective is presented in Table 2.

Table 1: Islamic financing matrix for digital sports training components [7].

Digital Sports Training Project Component	Examples of Components	Proposed Islamic Financing Tool	Mechanism of Suitability
Application / Platform Development	Programming, User Interface Design	Istisna', Diminishing Musharakah	Financing or partnering in the development of digital assets.
Purchase of Technical Equipment	Servers, Cameras, Display Devices	Murabahah, Ijarah Muntahia Bil Tamleek	Financing the purchase of physical assets or leasing them with an option to own.
Production of Training Content	Videos, Written Training Programs	Musharakah, Mudarabah	Partnership in profits/losses resulting from the sale or licensing of content.
Digital Marketing	Advertising Campaigns, Online Promotion	Musharakah, Mudarabah	Financing marketing costs as part of working capital with shared profits.
User Base Expansion	Expansion Costs, Capacity Building	Sukuk (for large projects)	Raising significant capital to finance future growth and expansion.

Table 2: Comparative Risk Framework - Traditional vs. Islamic Financing [9].

Characteristic of Digital Sports Training Project	Impact on Traditional Finance	Impact on Partnership-Based Islamic Finance	Degree of Suitability (Theoretically)
High Reliance on Intangible Assets	Difficulty in providing collateral	Less focus on tangible collateral, more on feasibility	High
Fluctuations in Initial Cash Flows	Increased risk of default	Profit/loss sharing reduces pressure for early repayment	High
High Market and Innovation Risks	Significant hesitation from lenders	Islamic institutions share a portion of the risk	Medium to High
High Scalability Potential	Significant investment opportunities upon success	Potential for high returns for the partnering institution	High
Alignment with Sustainable Development Goals	Not always considered a primary financing factor	Enhances financing attractiveness and aligns with Sharia objectives	High

6.5 Implementation Challenges and Strategic Opportunities

Challenges. Islamic institutions require specialized digital asset valuation expertise, updated Shariah interpretations for blockchain-based contracts, and regulatory frameworks accommodating "Digital Ijarah" and SaaS financing [10].

Strategic Opportunities. Islamic banking can pioneer "FinTech for Good" by capturing ethical investors, portfolio diversification into high-growth sectors, and leadership in SDG-aligned sustainable sports financing [9].

This theoretical framework substantiates the central hypothesis: Islamic banking's risk-sharing architecture provides structural superiority for financing digital sports training services, transcending conventional debt limitations while embedding ethical and sustainability imperatives [1].

7 CONCLUSIONS

This study demonstrates the substantial potential of Islamic banking as a viable and sustainable financing mechanism for digital sports training services within the rapidly expanding digital economy. The findings indicate that the intrinsic characteristics of digital projects – particularly their reliance on intangible assets and volatile early-stage cash flows – are well aligned with the core principles of Islamic finance, including risk-sharing and partnership-based structures.

Through a descriptive-analytical framework supported by theoretical and comparative analysis, the study highlights the relative advantages of Sharia-compliant instruments such as Musharakah, Mudarabah, Ijarah, and Sukuk in addressing the structural limitations of conventional debt-based financing. While challenges remain – particularly in

terms of risk assessment, valuation of intangible assets, and institutional readiness – these constraints are not prohibitive.

On the contrary, the results suggest that Islamic banking institutions are strategically positioned to play a leading role in financing innovation-driven sectors. By leveraging appropriate regulatory support and developing specialized financial tools, they can enhance investment efficiency, attract ethical capital, and contribute to sustainable sectoral growth. Ultimately, this convergence benefits not only entrepreneurs and financial institutions but also broader societal objectives, including improved access to digital health and sports services [1], [8].

8 RECOMMENDATIONS

For Islamic financial institutions:

- Develop specialized risk assessment models for intangible assets and volatile digital cash flows.
- Innovate Sharia-compliant products tailored to digital sports training needs, emphasizing *Musharakah*, *Mudarabah*, and digital *Ijarah*.
- Invest in capacity building for technology and digital business model expertise.

For digital sports entrepreneurs:

- Master Islamic finance principles to optimize funding access.
- Prepare comprehensive feasibility studies highlighting social impact, scalability, and Sharia alignment.

For policymakers:

- Update regulatory frameworks to enable flexible Islamic financing of digital innovation while preserving compliance.
- Foster partnerships between Islamic institutions, sports tech startups, and business accelerators.

Future research directions. Conduct longitudinal case studies of Islamically-financed digital sports projects, evaluating long-term economic and social impacts.

Keywords: Exchange Rate Policy, Currency Basket Pegging, Iraqi Economy, Productive Sector, Monetary Policy, Financial Stability.

Abstract: The Iraqi economy faces persistent structural challenges due to its heavy dependence on oil revenues, which account for the majority of public income and limit the development of productive sectors such as industry and agriculture. This study examines the potential of adopting a currency basket peg as an alternative exchange rate policy to enhance monetary stability and support the growth of the real economy. The research analyzes the relationship between exchange rate movements and the performance of productive sectors, highlighting how reliance on a single foreign currency increases vulnerability to external shocks. A conceptual framework is proposed to support the management of a currency basket based on trade patterns and economic indicators. The findings suggest that a diversified exchange rate regime could improve competitiveness, reduce import dependence, and contribute to long-term economic stability. The study concludes that adopting a more flexible and diversified monetary policy may play a significant role in strengthening Iraq's productive capacity and achieving sustainable economic development.

1 INTRODUCTION

The Iraqi economy is going through a critical phase characterized by excessive reliance on oil revenues, a weak production structure, and declining competitiveness in non-oil sectors, particularly industrial and agricultural ones. This reality has led to structural imbalances in the economy, manifested in a trade deficit, high import rates, and a declining contribution of local production to the gross domestic product.

The exchange rate emerges as a key tool that can be used to restore economic balance and stimulate real economic activity. The peg of the Iraqi dinar to the US dollar alone since 2003 has contributed to relative price stability. However, it has made the economy vulnerable to dollar fluctuations, weakened its ability to respond to external shocks, and weakened the competitiveness of domestic products in an open import environment.

Based on this problem, this research seeks to examine the possibility of devaluing the local exchange rate and linking it to a basket of foreign currencies as a strategic option to support the productive sector and raise its efficiency. This approach is expected to increase the competitiveness of local products, stimulate investment in real sectors, and reduce reliance on imports. This will positively impact the overall economy and pave the way for more sustainable and diversified economic development. So the research addresses the relationship between the exchange rate and the efficiency of the productive sector in Iraq, reviews similar international experiences, and proposes monetary policies that can be applied in the economic environment.

Additionally, this study incorporates a computational approach in the sense that it suggests a digital platform of tracking exchange rate variations. The shift to a currency basket would need an algorithmic method of calculating real-time weights on the basis of trade data, so that the monetary policy is periodically operated on the foundation of accurate digital analytics, rather than arbitrary estimation.

2 RESEARCH PROBLEM

The low level of local production in the Iraqi economic environment, and the complete reliance on imports to fill the gap in demand for both agricultural

and industrial consumption. The research also identifies a gap in automated computational frameworks that have the capacity to process real time global market data to support local production.

3 RESEARCH HYPOTHESIS

A decrease in the local exchange rate may contribute to increasing local production, particularly when supported by appropriate economic conditions such as sufficient productive capacity and effective trade policies. The study hypothesizes that an algorithmic approach to currency basket management will increase the precision of Dinar's valuing.

4 IMPORTANCE OF RESEARCH

Achieving relative economic stability by devaluing the exchange rate and pegging it to a basket of currencies aims to reduce the sharp fluctuations associated with pegging the Iraqi dinar solely to the dollar. This enhances monetary stability and reduces the impact of external shocks, especially in a country that relies on oil as its primary source of income.

It is also possible to stimulate local production and reduce imports. As a result, to lower the exchange rate and thus increase the prices of imported goods, making local products more competitive and encouraging the consumption of local production, which enhances the efficiency of the productive sectors, especially industrial and agricultural. Strengthening the productive sector as a result of a balanced policy also contributes to diversifying the structure of the Iraqi economy and reducing dependence on the oil sector as the primary source of GDP. Using a more flexible monetary policy by pegging the dinar to a basket of currencies instead of a single currency gives Iraqi monetary policy greater flexibility to adapt to regional and international variables, especially in light of fluctuations in oil prices and global exchange rates.

The Iraqi economy can also be enabled to withstand external crises by linking the currency to a diverse basket, so that the economy becomes less vulnerable to pressures resulting from changes in the US economy or in the dollar alone, which increases the economy's ability to withstand crises and thus achieves sustainable development goals by stimulating production and employment and increasing local added value. The research also contributes to developing a theoretical and policy framework consistent with the Sustainable Development Goals in Iraq, particularly in poverty reduction, providing decent work, and promoting economic growth.

5 RESEARCH OBJECTIVE

This research aims to analyze the impact of depreciating the local exchange rate and pegging the Iraqi dinar to a basket of foreign currencies on the efficiency of the productive sector in Iraq. This research explores the possibility of adopting a more flexible monetary policy that would stimulate local production, reduce dependence on imports, and achieve sustainable economic stability in light of the challenges facing the rentier Iraqi economy. It also proposes monetary policies that support industrial and agricultural development.

6 THE THEORETICAL FRAMEWORK FOR THE CONCEPT OF EXCHANGE RATE AND PRODUCTIVE SECTORS IN THE IRAQI ECONOMIC ENVIRONMENT

6.1 Exchange Rate

6.1.1 Definition of Exchange Rate

The exchange rate is the ratio between two different currencies, and it determines the value of one country's currency against another. In other words, one currency is converted into another at the rate. For example, if the exchange rate between the US dollar and the euro is $1 = €0.85, this means that $1 US is equal to €0.85. [1]

6.1.2 Types of Exchange Rate System

Global monetary authorities categorize exchange rate regimes based on the degree of flexibility and market intervention into the following systems [2]:

- Floating Exchange Rate. The exchange rate is determined by market mechanisms, meaning that supply and demand for the currency determine its value. A floating exchange rate changes based on economic factors such as inflation, interest rates, and economic policy.

- Fixed exchange rate. The government or central bank sets the exchange rate, pegged to a strong or basket of currencies. For example, pegging the local currency to the US dollar.
- Managed Float. A floating and a fixed exchange rate, where the currency is left to trade freely most of the time, but the central bank may intervene when necessary to stabilize the currency rate.

6.1.3 The Importance of the Exchange Rate

The exchange rate serves as a critical economic instrument that determines the country's international competitiveness through the following key roles [3]:

- International Trade. The exchange rate significantly affects international trade, as a weak currency can make exports cheaper and more competitive while increasing the cost of imports.
- Inflation. The exchange rate can affect the prices of imported goods, thus contributing to inflation in the local economy.
- Foreign investment. The exchange rate influences foreign investment decisions. If the value of the local currency is high, this may attract foreign investment, and vice versa.
- Monetary policies. The exchange rate is a fundamental tool in the monetary policies followed by the central bank to influence the economy.

6.1.4 Factors Affecting the Exchange Rate

The stability and market value of the national currency are influenced by a diverse set of economic and structural factors, including [4]:

- Demand and Supply. The demand for the local currency against foreign currencies is the primary factor in determining the exchange rate.
- Economic benefits. Countries with strong economies and high interest rates tend to attract foreign capital, increasing their currency's demand and value.
- Inflation: Countries with low inflation rates usually have a strong currency.
- Government and central bank policies: Monetary policy decisions and direct interventions by the central bank can affect the exchange rate.
- Future expectations: Expectations about a country's future economic performance also affect the exchange rate.

6.1.5 Economic Theories Related to Exchange Rate Change

The fluctuations in exchange rates are explained by several foundational economic theories that analyze currency value through the following perspectives [5]:

- Power Parity Theory. The Purchasing Power Parity Theory asserts that differences in price levels between countries determine exchange rate changes. In other words, if there are significant differences in commodity prices between two countries, this will lead to adjustments in the exchange rate until the purchasing power between the two currencies is balanced. This theory helps understand how changes in commodity prices can affect a country's economy.
- Continuity Theory (The Mundell-Fleming Model). The Mundell-Fleming model is an economic framework that studies the effects of monetary and fiscal policy on an economy under a flexible exchange rate. According to this model, when countries are open economies with a flexible exchange rate, changes in the latter can significantly impact trade and, consequently, GDP. This model highlights how the interaction between domestic monetary policies and the exchange rate can affect macroeconomic conditions.

6.1.6 The Relationship Between the Exchange Rate and Economic Growth

The exchange rate can affect economic growth in several ways [6]:

- Export incentives. A low exchange rate can encourage the export of goods and services as domestic products become more competitive in global markets.
- Import costs. When the exchange rate rises, import costs can increase, leading to import inflation.
- Foreign investment. Changes in the exchange rate affect foreign capital investments, as investors seek stable exchange rates to reduce risk.

6.2 The Flexibility of the Productive Sectors in the Iraqi Economy

6.2.1 Flexibility of the Production System

It is an economic term that explains the relationship between production inputs on the one hand and production outputs on the other in a country's economy or a specific economy. It is a term with many concepts that express the researcher's viewpoint in a specific specialization. The following are some concepts that explain this term from different viewpoints. Production elasticity represents the percentage change in production (GDP or the production of a single company) divided by the percentage change in inputs or the average output of the production element concerned by the change. The concept of production elasticity can be expressed mathematically in the following formula [7].
Production flexibility

$$EQ = \frac{\partial Q}{\partial X} \cdot \frac{X}{Q}.$$

That is where:

- Q: The outputs represent.
- X: represents the inputs.
- The concept of production flexibility has taken many turns throughout history. A Chinese thinker referred to it 2000 years ago. The concept of production flexibility was used in wars by senior management and their ability to develop production and adapt to the current requirements of those wars. This concept was also used by business organizations during the Industrial Revolution in Europe by many scholars. The first to use this term was the economist Adam Smith in developing production processes in his book (The Wealth of Nations) in 1776, where he considered the positive production characteristic to contribute to improving the status of the facility from changes that occur in the economic environment as a result of disturbances or improvements in the technological situation and other matters that completely or partially affect the production processes and productivity in any institution operating within the economic environment of any country. Some call it the term incremental production flexibility, which expresses the measurement of the speed of production in the number of days it takes a company to achieve a sustainable increase in the manufacturing processes for a specific product in a final form without prior planning [8], as shown:-
- Internal manufacturing capacity determines whether the equipment is operating at full production capacity.
- Regarding resource availability: Are there surpluses or deficits of raw materials
- In terms of labor, is there a labor force capable of production and ready when needed?

6.2.2 Sectoral Interconnectedness and the Development of the Production System

The interconnectedness of the economic sector is a critical issue due to its impact on analyzing and understanding the reality of the volume of current transactions between the various economic sectors and the extent of each sector's dependence on other sectors. It involves studying the quantitative relationships between the economic sectors or the relationships between inputs and outputs, and thus it contributes to defining production and creating added value. The subject of studying sectoral relationships in Oil - producing countries, and specifically the relationship between the oil sector and non-oil sectors, has received special attention from economists and the emergence of many theoretical and applied studies, which adopted the Dutch disease hypothesis, which believes that the increase in revenues Oil will have adverse effects on the development of non- oil sectors, especially in the manufacturing and agricultural sectors. This increase in oil revenues will be accompanied by continuous changes in the elements affecting the external and internal economic balance process. On the external level, this increase will result in a surplus in the balance of payments. This surplus will lead to an increase in the exchange rate of the local currency against foreign currencies, which will in turn lead to a decrease in non-oil local exports, an increase in imports, a decrease in the volume of non-oil production, especially the manufacturing and agricultural sectors, and a deficit in the trade balance of these sectors. In general, the effects can be summarized as follows: The negative impact of the boom on non-oil traded commodity output is twofold: the first is called the resource mobility effect, which is because the rise in oil prices will in turn raise the value of the modern product and the value of the real income of the factors of production employed in this sector, and will lead to the movement of resources and relative advantages towards the oil sector and activities financed by oil revenues (the non-oil traded commodity sector), and away from the non - Oil traded commodity sector (agriculture, industry and manufacturing) [9].

On the other hand, it will lead to a reduction in the marginal product of the factors of production employed in the non-oil commodity sector, and create a surplus in demand for them, making the prices of products of non-traded activities higher than the prices of goods produced in the non-oil commodity sector, especially the prices of agricultural goods, because they are determined in the local market, in addition to the possibility of filling the deficit in their production through imports. The second is the effect of spending. The increase in oil income will increase national income, leading to an increase in aggregate demand and a surplus in demand for the production of various sectors, resulting in another increase in the relative prices of services. This will enable the non-traded goods sector to offer higher wages than the traded goods sector can offer. Oil is a significant source of income; thus, another portion of the resources used in this sector is drawn to the services sector, leading to a further decline in production volume in these sectors. [10]

Therefore, the final result is a decline in the volume of production of the non-oil traded goods sectors, and a decline in their relative importance in the gross domestic product. The danger of this situation lies in the short-term nature of the boom in the oil sector and the long-term adverse structural effects it leaves on the economy. The state of total structural imbalance in the sectoral distribution of activities contributing to the gross domestic product in favor of extractive activities and non-commodity activities ultimately led to the dominance of a single commodity, crude Oil and its products from petroleum and petrochemical derivatives. This matter made the overall economic variables in the Iraqi economy, especially production, operation, investment, consumption, export, import, balance of payments, and government budget, captive to the conditions and fluctuations to which the process of marketing that commodity to international markets is subject. [11]

The Iraqi economy has witnessed fluctuations in the growth rate of the gross domestic product since the beginning of the seventies, during which the non-oil sector could not absorb its undesirable impact on the average per capita income. The contribution of this sector to the gross domestic product is still weak and parallels the population growth rate, which does not add anything to the economic prosperity. Since the Iraqi economy is an oil economy, the fluctuations in global oil prices will be reflected in fluctuations in the economy's growth rates, especially since this source is vulnerable to external shocks, i.e., the national economy's dependence on the fluctuations of the global market. Iraq's oil revenues declined after the global crisis and the decline in oil prices. The contribution of the oil sector's activity to the gross domestic product for the year 2009 declined by 35% compared to the previous year, which was reflected in a decline in the gross domestic product at current prices by 5.10% compared to the previous year, which put Iraq before a difficult challenge. [12]

Iraq has not exploited its oil wealth over the past fifty years to generate sustainable financing to drive development. Hence, there is a need to achieve the goal of diversifying the national economic base and creating diverse incentives for economic growth by focusing on maximizing the added value of Oil and increasing its returns as an entry point for economic diversification. Today, Iraq is required to work on decoupling GDP growth from oil exports, reducing dependence on a single source of income, and moving towards diversification by restructuring the economy at the macro and sectoral levels, in order to reach an economic structure that is compatible with competitive and growth requirements and ensures flexibility in the face of successive changes at the international level through [13]:

- Increasing the role of the private sector and expanding its contribution to the national economy, so that this is reflected in a higher percentage of its contribution to the formation of fixed capital, to the real GDP, and to the non-oil GDP.
- Adopting a financing policy dominated by banking financing instead of relying on the state budget for development financing has transferred widespread financial savings to individuals and institutions. Banks' undertaking of this role in development financing contributes to achieving the goal of development and diversification of sources of income through financing private sector projects in various non-oil economic sectors, which positively impacts the growth and diversification of activities generating non-oil GDP. This trend also contributes to developing the stock market and activating the role of specialized financing institutions in a way that leads to the growth of investments through the impact of this market on developing savings awareness among members of society, pooling national savings and directing them to developing productive assets in the national economy, in addition to establishing holding companies and their role in establishing productive and service projects.
- Export development is essential for any country as it allows it to increase its economic growth

rates and achieve its goals of increasing production capacity, providing job opportunities, and making good use of resources. For example, to achieve industrial development, the government in Saudi Arabia adopted a manufacturing-for-export policy to diversify sources of income and avoid reliance on oil exports, whose prices are subject to fluctuations.

- Supporting small and medium enterprises: Experience has proven that establishing and supporting large-scale enterprises does not necessarily represent the optimal solution to accelerate the development process. Instead, supporting small and medium enterprises, which represent the absolute majority, is the optimal solution to accelerate the development process, given the positive impact of these enterprises on the gross domestic product, savings, investment, consumption, and exports, in addition to their contribution to creating new job opportunities and mitigating inflation.
- Expanding the establishment of joint-stock companies due to their advantages as the most appropriate legal form for creating strong economic entities that can contribute to achieving the goal of development and diversifying sources of income.

6.3 The Current Economic Situation in Iraq

The Iraqi economy heavily depends on oil revenues, constituting more than 90% of the state's revenues. This dependence makes the Iraqi economy vulnerable to global oil price fluctuations, negatively impacting the general budget and economic stability [14].

However, Economic challenges such as unemployment reaching 15%, and poverty affecting about 20% of the population, these challenges increase social tensions and weaken community cohesion. In addition, Iraq suffers from weak infrastructure and deteriorating public services, which hinder economic growth and limit the state's ability to provide decent job opportunities for citizens [15].

Diversifying the economy is essential to reducing dependence on Oil. Sectors such as agriculture and industry can contribute to creating new job opportunities. For example, Iraq can invest in agriculture to achieve food security and reduce import dependence. Improving infrastructure can attract foreign direct investment, which enhances economic growth. Investing in roads, bridges, and energy will improve the business environment and attract investors. Effective economic policies should also focus on supporting small and medium-sized enterprises, a key driver of job creation and economic growth. [16]

7 THE PROPOSED CURRENCY BASKET: A COMPUTATIONAL AND ECONOMIC APPROACH

This section sets the architecture of the proposed currency basket system for Iraq to ensure the integration of economic conceptualization of such a basket system with an advanced computational framework to ensure dynamic stability. The following subsections lay out the theoretical basis, the mechanism for selection, and the automated algorithmic design which must be used for its implementation.

7.1 Economic Theories that Suggest the Need to Link the Local Currency to a Basket of Currencies Instead of a Single Currency

The economic theories that support the idea of linking the local currency to a basket of currencies are divided into several concepts. [17]:

- Economic Stability Theories suggest that pegging a currency to a basket of currencies promotes long-term economic stability. Fluctuations associated with the US dollar, which can be affected by unstable monetary policies or significant market changes, can impact the local economy. The basket provides diversification, reducing the risks associated with any single currency.
- Diversification Theories. Diversification involves using a basket of currencies rather than pegging the local currency to a single currency, such as the dollar. If the dollar's value collapses or deteriorates, the other currencies in the basket can provide a balance, maintaining the relative stability of the local currency.
- Economic integration theories suggest that the global economy has become more integrated, with economies becoming more interdependent. By this logic, pegging a local currency to a basket of currencies aligns with global trade involving a range of currencies, reflecting global economic conditions more accurately.

7.2 Experiences of Countries that have Pegged their Exchange Rates to a Basket of Currencies

The experiment of linking the currency to a basket of currencies was implemented by several countries around the world [18]:

- Hong Kong. Although Hong Kong often relies on the US dollar, its monetary policy includes the flexibility to adjust the currency's exchange rate against a basket of currencies. This protects against US dollar fluctuations.
- Singapore. Singapore is considered a successful model for using a currency basket to stabilize the local currency. The government decided that pegging the currency to a basket of global currencies instead of the US dollar makes the local economy more resilient to global economic changes.
- United Arab Emirates. The UAE follows a fixed exchange rate regime in which the dirham is pegged to the US dollar, unlike basket-based exchange rate arrangements used in some other economies.

7.3 The Impact of Pegging the Local Currency to a Basket of Currencies on The Iraqi Economy

Adopting a diversified currency basket is expected to generate significant structural shifts in the Iraqi economy, primarily through the following impacts [19]:

- Monetary stability. By pegging the Iraqi dinar to a basket of currencies, the adverse effects of fluctuations in the dollar exchange rate can be mitigated, especially since the Iraqi economy is highly dependent on oil, which is typically measured in dollars. This leads to greater stability in the Iraqi dinar exchange rate.
- Improving the trade balance. Iraq relies heavily on oil imports and exports and is sensitive to changes in the dollar exchange rate. Using a currency basket can mitigate the adverse effects of a rising or falling US dollar, helping to improve its trade balance.

7.4 Monetary Policy Challenges in Pegging the Iraqi Dinar to a Basket of Currencies Instead of the Dollar

The transition toward a currency basket introduces several operational and strategic complexities that the Central Bank must manage, specifically regarding the following challenges [20]:

- Political and economic instability. Iraq frequently experiences political and economic instability, making it challenging to implement stable monetary policies. When policies change frequently, strategies such as pegging the currency to a basket of currencies can be challenging to implement effectively.
- Challenges in selecting currencies. Currencies included in the basket must be carefully selected. Some currencies may be subject to high volatility or economic turmoil, which could negatively impact the dinar. The challenge here lies in selecting currencies that accurately reflect the Iraqi economy.
- Managing foreign exchange reserves. Iraq relies primarily on oil revenues to finance its foreign exchange reserves. A currency basket may require complex management of diverse foreign exchange reserves and may increase administrative costs in the event of significant fluctuations in currency values.
- Impact of external factors. External factors, such as global economic crises or changes in the monetary policies of major countries, can affect the effectiveness of pegging the currency to a basket of currencies. The Iraqi economy may be further impacted if an economic crisis occurs in one of the countries whose currency is included in the basket, potentially amplifying the negative economic impact on Iraq.

Therefore, we call on the economic legislator to take his time and seriously study this step in order to make decisions that would preserve the value of the local currency from deterioration, and to mobilize scientific expertise in this field in order to reach steps that would reduce the risks surrounding this process to the minimum possible and benefit from them in raising the efficiency of the local currency in a way that serves the Iraqi economy in the short and medium term, as these terms are linked to the people's livelihood, and to be careful in making decisions and the transparency and clarity of information before starting to work on them, and for society to be informed of these changes that would transfer the Iraqi economy to a better level in the long term.

It is worth noting that the Iraqi government has an Iraqi Economic Council concerned with these matters and is responsible for these decisions, as it includes economic experts and extensive scientific expertise in the Ministry of Higher Education. They should be involved in making new decisions that will increase the benefit and reduce the risks to the minimum

possible at present and bring the Iraqi economy to safety by linking the Iraqi dinar to a basket of foreign currencies and reducing dependence on the US dollar in order to reduce the risks associated with this strong link and avoid the strong effects that the Iraqi economy may enter into as a result of the strong and significant link between the Iraqi economy and the US economy resulting from linking the two currencies together with this strength.

7.5 Proposed Computational Framework for Currency Basket Management

The implementation of the proposed currency basket is anchored in a computational framework as illustrated in Figure 1, which shifts monetary management from manual intervention to being an automated algorithmic system. This framework operates by continually collecting high frequency data from the international financial markets and combining it with Iraq's own specific foreign trade statistics. By using a weight algorithm, the system automatically adjusts the relative significance of each currency that makes up the basket depending on real trade volumes, which also guarantees that the value of the Iraqi dinar is based on realistic economic interdependence rather than static pegging to any single currency [21].

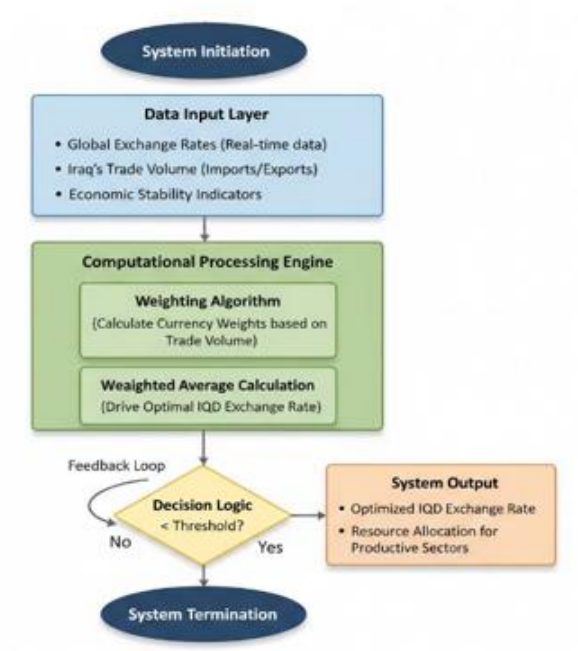

Figure 1: Proposed compitational framework for currency basket weighting Algorithm.

Furthermore, this digital framework is a crucial tool for building resilience of Iraq's productive sectors to global exchange-rates volatility. Through its own integrated feedback loop, the system tracks fluctuations in the economy in real time and adjusts dinar valuation accordingly in order to keep a stable cost environment for local producers who are dependent on importing raw materials. This method of computation not only reduces human error and administrative delays but also allows a data driven transparent mechanism to promote macroeconomic stability and long term industrial growth [22].

8 CONCLUSIONS

This study examined the role of exchange rate policy in shaping the performance of the productive sectors in Iraq, with particular emphasis on the potential adoption of a currency basket peg. The findings indicate that the current reliance on a single currency exposes the Iraqi economy to external vulnerabilities and limits the effectiveness of monetary policy in supporting domestic production.

The analysis demonstrates that a diversified exchange rate regime could enhance economic stability, improve trade balance conditions, and increase the competitiveness of local industries. However, the successful implementation of such a policy requires careful institutional design, strong financial infrastructure, and clear regulatory frameworks.

Overall, transitioning toward a more flexible exchange rate system represents a strategic opportunity for Iraq to reduce its dependence on oil revenues and promote sustainable economic diversification.

9 RECOMMENDATIONS

In order to attain sustainable economic growth and increase the efficiency of the productive sector, the following policy and technical recommendations are proposed in the study:

1) There is a need to change the exchange rate policies currently being followed by the Central Bank of Iraq and implement new policies that will correct the current trends to develop the Iraqi economic environment.
2) The possibility of involving the Iraqi Economic Council in developing detailed plans to achieve results that would achieve economic growth and link the exchange rate to the productive

sectors instead of linking it to the economic growth rate, thus improving the reality of the productive sectors in the Iraqi economic environment.

3) Benefit from the extensive experience of the Ministry of Higher Education and Scientific Research and combine it with experts in the Economic Council to achieve the best in developing economic plans.
4) It is necessary to study the linking of the local currency to a basket of foreign currencies instead of linking the Iraqi dinar to the US dollar, and to study all the positive and negative impacts in the short, medium, and long terms.
5) A comprehensive study of the experiences of countries that have adopted these policies, drawing conclusions and presenting them to decision-makers to reach decisions that will develop the Iraqi economy.
6) Benefit from the accumulated expertise in scientific research at Iraqi universities and connect this expertise with decision-makers, without the need for intermediaries, in aspects related to developing policies that would improve the Iraqi economy.
7) the creation of an AI-based digital platform to automate the calculation of the weight of the proposed currency basket according to trade dynamics.

Keywords: Electronic Payment, Financial Environment, Financial Inclusion, Financial Development.

Abstract: The global landscape is evolving towards a more sophisticated digital framework that fosters artificial intelligence and delivers superior services to customers both domestically and internationally, promoting competition and accelerating the enhancement of digital infrastructure around the world. This research aims to assess the development of electronic payment services in Iraq and investigate whether they have made significant progress that aligns with the Central Bank of Iraq's strategy for financial inclusion and stability, which is a crucial step towards encouraging banks and other financial institutions to cooperate and collaborate in enhancing financial access and investing capital in local production sectors. The study posits that the advancement of electronic payment services is adequate to improve the efficiency of Iraqi banks in utilizing funds to bolster the local economy. The findings indicated that electronic payment services in Iraq were limited during the research timeframe. The research recommended that the Central Bank of Iraq regularly assess digital banking performance, focusing on the implementation of digital cybersecurity measures and protection standards, the ongoing enhancement of digital functionalities and services, and their incorporation into the annual evaluations of these banks. It also urged other economic institutions to embrace advanced digital transformation across all commercial, production, and other operations.

1 INTRODUCTION

The shift towards electronic payment methods is a reflection of advancements in banking and the growing dependence on banking services for executing commercial transactions and various business operations. Iraq faces a considerable delay in the acceptance of electronic payment systems by both merchants and consumers. This situation has created a significant hurdle for the Central Bank of Iraq in establishing an electronic payment framework and integrating it into ongoing transactions. Payments primarily conducted in cash dominate the financial settlements involving credit and debit cards for sales and purchases. This dominance has put considerable strain on banks, which have localized the salaries of public sector employees to maximize the availability of ATMs, allowing for immediate cash withdrawals.

Problem Statement. The adoption of advanced banking practices for electronic payments encounters a psychological obstacle among consumers when carrying out financial transactions. Additionally, numerous retailers are hesitant to utilize bank cards for settling debts, which has restricted the proliferation of electronic payment solutions throughout the Iraqi economy.

Importance of the Research. Digital payment solutions enable the easy, efficient, and secure execution of financial exchanges between parties involved in a transaction. This removes the necessity of handling significant sums of cash and alleviates issues related to varying denominations due to heightened usage (rapid circulation of money). Each of these transactions takes place within encrypted and secure bank accounts in the financial system, enhancing the efficiency of banking operations and boosting its functions throughout the economy.

Research Hypothesis. The research assumes that the development of electronic payment services will enhance the efficiency of Iraqi banks in deploying funds to serve the local economy.

Research Objective. The research aims to monitor the development of electronic payment services in Iraq and determine whether they have achieved tangible progress that supports the Central Bank of Iraq's approach to financial inclusion and stability. This strategy represents an important step toward mobilizing banks and other financial institutions to collaborate and cooperate with each other to increase financial access and capital investment in local production sectors.

Research Methodology. Official data issued by the Central Bank of Iraq through its annual publications was used for the period (2017-2023), and the indicators of electronic payment services were analyzed based on the data and trends of the values of the indicators.

2 LITERATURE REVIEW

The electronic payments sector is undergoing a radical shift towards instant payments and central bank digital currencies (CBDCs). The Global Findex 2025 report highlights That Digital savings growth is expected to reach 40% by 2024, marking the fastest increase in a decade, in developing economies. Smart coverage: 84% of adults in low- and middle-income countries own mobile phones, including 3 billion smartphones, which has boosted access to integrated payments. Transformed financial behavior: 79% of adults globally now have accounts, with mobile money playing a pivotal role in changing traditional financial behavior [1].

The IMF's Financial Access Survey (FAS 2025) revealed the following: A transaction boom: Digital transactions (via mobile and internet) in emerging economies increased from 55 transactions per adult in 2017 to 251 transactions in 2024. International remittances: The share of digital remittance flows increased from 13% in 2019 to 46% by 2024, significantly reducing costs. Central bank digital currencies (CBDCs): The IMF's 2025 report indicates that 19 countries in the Middle East and Central Asia are currently exploring the issuance of digital currencies to enhance payment efficiency and financial inclusion [2].

Regarding Fast Payments and Inclusion (FASTT) initiatives, the State of Instant Payments Systems 2025 report highlighted the FASTT project: the World Bank supports countries in establishing fast payment systems to boost trade and create jobs. Instant payments: In Africa alone, instant payments reached $2 trillion, driving growth and digital inclusion. Artificial intelligence integration: By 2025, 80% of fintech companies would have begun implementing AI to improve customer experience (83%) and reduce costs (75%). [3].

Accordingly, the advancement of electronic payment methods creates an attractive financial environment for the rapid development of the advanced financial instruments industry for settling electronic financial transactions worldwide. In this regard, the most important steps taken by the world can be summarized as follows [4]:

1) Shift from "Disruption" to "Cooperation": The fintech industry has moved from disrupting traditional systems to "collaborative transformation" and integration with existing financial infrastructure.
2) Centralization of "Instant Payments". 24/7 payment systems are becoming the new standard for boosting productivity and financial inclusion, particularly in Latin America and Africa.
3) Challenging Technical Standards. The World Development Report 2025 asserts that "international standards" are the underlying infrastructure of modern economies, and that aligning domestic markets with these standards is essential for export growth and technology flow.
4) Macroeconomic Impact. Central bank digital currencies (CBDCs) can strengthen monetary policy transmission channels and reduce "dollarization" or "crypto-ization" if properly designed. 5. The digital divide: Despite progress, a third of the world's population will still be offline in 2024, with the cost of broadband remaining a major obstacle in low-income countries (consuming 29% of monthly income).

3 THEORETICAL FRAMEWORKS FOR ELECTRONIC PAYMENT METHODS

3.1 Concept of Electronic Payment Methods

The concept of electronic payment refers to a form of electronic money transaction that involves settling debts, conducting purchases, or other forms of payment. It includes all payment methods that leverage modern technology to meet financial obligations, such as electronic funds transfers, e-

checks, electronic bills of exchange, card payments, and digital cash transactions [5].

It is also described as a collection of banking instruments and procedures that encompass the electronic trading and transfer of funds, serving as a mediator between the payer and the recipient [6]. Furthermore, it is explained as (a collection of banking practices, guidelines, instruments, and procedures that enable the trading of funds and offer payment services to individuals and businesses through participating banks and financial institutions in accordance with electronic systems) [7]. Additionally, it is characterized as (a cohesive set of tools and methods that streamline financial transactions among institutions, as they aim to enhance the economy's welfare by lowering capital costs, reducing financial risks, and strengthening financial intermediation) [8].

The most important factors that led to the introduction of electronic payment methods are the following:

1) The gradual decline in the effectiveness of traditional payment methods over time.
2) The widespread use of the internet in banking activities.
3) The global trend towards e-commerce.
4) The digital trend due to the COVID-19 pandemic.

3.2 Characteristics of Electronic Payment Methods

The most important characteristics of electronic payment methods are the following [9], [10].

Ease of use of electronic payment methods without complications and without routine and administrative procedures.

1) Access to financial services: Electronic payment methods can provide access to financial services for groups that do not have bank accounts or do not have sufficient access to traditional financial services.
2) They are characterized by security, reliability, ease, and fluidity.
3) Organized management by the entity providing the electronic payment service.
4) Speed in completing transactions, transparency in financial transfers, and savings in many fees charged for financial transactions.
5) They have an international character, meaning they confer an international character on payment methods and are globally accepted.

3.3 The Importance of Electronic Payment Methods

The importance of electronic payment methods is evident in the following: [11], [12]:

1) Their importance to the financial sector, as they aim to reduce financial risks and increase credibility, speed, and security. Secure and efficient payment systems also represent an important mechanism that supports the functions of financial markets and the financial system. Electronic payment systems enable financial transactions between banks to be completed easily and quickly, reducing the percentage of cash in circulation and ensuring the availability of complete information on cash management. [13].
2) The Importance of Electronic Payment Methods in Fiscal Policy: Electronic payment methods can enhance fiscal policy through the government's use of electronic payment methods, which leads to increased public revenues through the easy and rapid collection of taxes and fees electronically, and reduces tax evasion through the availability of accurate records of financial transactions. The government can also support social support programs by providing secure and fast payment methods for beneficiaries. Increasing government revenues reduces government debt, especially in developing countries [14].
3) The importance of electronic payment methods for individuals, as they provide them with speed and security in completing their cash transactions without difficulty, and facilitate the completion and settlement of financial accounts for all companies and their local and international branches with ease and accuracy.
4) The importance of electronic payment methods in recording accounts related to exports and imports within the scope of electronic systems, especially in rentier economies with increasing oil revenues and consumer imports [15].

4 THE DEVELOPMENT OF ELECTRONIC PAYMENT METHODS IN IRAQ

4.1 Number of POC Devices

The proliferation of point-of-sale (POS) devices has been a recurring phenomenon. Looking at the

timeline of this proliferation, we find fluctuations between decline and rapid growth, reaching record levels. However, a gap still exists between the current number of devices and market expectations.

As part of the Central Bank of Iraq's efforts to promote financial inclusion and modernize the banking system, the state has adopted an ambitious strategy to move towards electronic payments. These policies have been directly reflected in the payments infrastructure, as statistical data have shown rapid growth in the spread of digital payment tools and the expansion of their use in commercial activities.

The number of POS devices in 2017 was 13.8 devices per 100,000 people (Fig. 1). It increased to 17.3 devices per 100,000 people in 2018, and then gradually increased until it reached 62.5 devices per 100,000 people in 2020. In 2022, it reached its highest level, at 75.7 devices per 100,000 people.

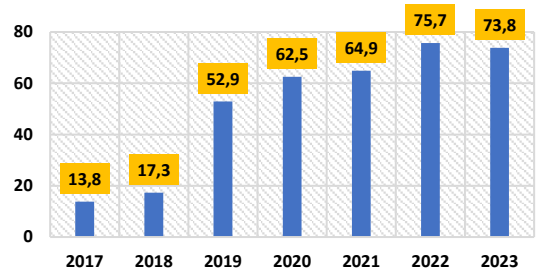

Figure 1: Number of POC devices in Iraq for (2017-2023) (per 100,000 people). Source: CBI, Financial Stability Report, various years.

A parallel analysis of POS deployment shows that in 2017, the number stood at 2.5 devices per 100,000 people (Fig. 2). This number continued to increase until it reached 10.1 devices per 100,000 people in 2019. Thereafter, the culture of electronic payment became more widespread in the Iraqi economy, reaching 35.8 devices per 100,000 people in 2021. In 2023, it reached its highest level, at 71 devices per 100,000 people.

Despite the development in the use of POS devices, their use remains modest and insufficient, not commensurate with the volume of transactions being processed through these devices on an ongoing basis. It appears that electronic payment habits, despite a slow start, have subsequently accelerated following the Central Bank of Iraq's clear adoption of an electronic payment strategy, which obligates banks to use and disseminate them within the community. The spread of these devices is closely linked to markets, shops, and malls that have begun to accept cashless settlements using credit cards, Visa cards, and other methods.

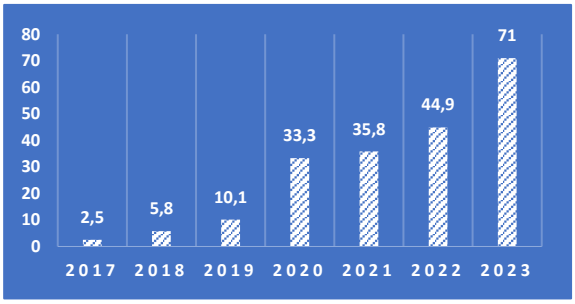

Figure 2: Number of POS devices in Iraq for (2017-2023) (per 100,000 people). Source: CBI, Financial Stability Report, various years.

It is worth noting that the Central Bank of Iraq established the National Company for Electronic Payment Systems in Iraq in 2023 [16]. The Central Bank explained that the company represents a qualitative development in the country's financial infrastructure. The new company will be responsible for developing, operating, and managing the national electronic payment and clearing systems with high efficiency, and will add new elements to serve the electronic payment environment.

4.2 Number of ATMs

Automated teller machines (ATMs) are the cornerstone of access to banking services and a vital indicator of the level of financial inclusion in society. Despite the upward trend in their deployment in recent years, the gap between numerical growth and geographical expansion continues to influence individuals' attitudes towards digital transformation, as the following data demonstrates.

The number of ATMs in 2017 was 1.8 machines per 100,000 people (Fig. 3). This trend continued to increase over the research period, reaching 5.9 machines per 100,000 people in 2020, and then 12.4 machines per 100,000 people in 2023. Despite the increasing trend of ATMs, their prevalence remains limited across public facilities, government institutions, and private institutions. Perhaps the limited prevalence of ATMs is driving a decline in the use of electronic payment cards among the population, as there is still a widespread tendency among society to use cash to settle financial obligations.

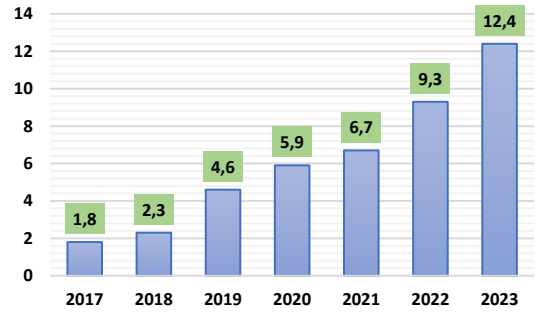

Figure 3: Number of ATM devices in Iraq for (2017-2023) (per 100,000 people). Source: CBI, Financial Stability Report, various years.

4.3 Cash Transfer from Mobile

The mobile payment market in Iraq has witnessed fierce competition among licensed companies, with varying levels of market share and performance depending on public trust and the services offered. Statistical indicators for money transfer rates reveal that three main companies lead the scene (Zain Cash, Asia Hawala, and Nass Wallet), with significant shifts in their market shares observed, as illustrated in the following table.

Asia Hawala, Zain Cash, and Nas Wallet were the companies with the highest mobile cash transfer rates (Table 1). Zain Cash topped the list, with transfer rates ranging from a maximum of 98.8% in 2023 to a minimum of 26.1% in 2017. Asia Hawala followed, with transfer rates ranging from a maximum of 73.9% in 2017 to a minimum of 0.3% in 2023. Nas Wallet followed, with only a minimum of 0.3% for the period 2021-2023.

Table 1: Cash transfer from mobile payment companies in Iraq for (2017-2023) (%) [16].

Years	Asia Hawala	Zain Cash	Nas Wallet
2017	73.9	26.1	0
2018	53.6	46.4	0
2019	48.8	51.2	0
2020	32.6	67.4	0
2021	18	78.7	3.2
2022	8.3	84.5	7.3
2023	0.3	98.8	0.8

It is worth noting that the Central Bank of Iraq has imposed a ban on dealing with a number of electronic payment companies and financial platforms, such as PayPal, Perfect Money, Web Money, and Binance. Due to the Central Bank of Iraq's failure to comply with applicable financial regulations and laws, local alternatives such as Zain Cash, Asia Pay, Switch, Q-Card, Amwal, Fast Pay, Nas Wallet, and others have been provided. However, cash transfers in Iraq remain weak, and their role was very limited during the research period.

4.4 Bank Accounts, Electronic Cards, And Electronic Wallets

Bank accounts and electronic cards play a significant role in enhancing electronic payment methods by providing easy and secure financial means for managing money. Electronic cards enable easy and secure cash withdrawals and payments. Bank accounts also enable the opening of deposit accounts, making financial transfers, and receiving wages, salaries, bonuses, and other benefits securely and efficiently.

The annual growth rate of bank accounts in 2018 was 86.4% (Fig. 4). It rose to 101.6% in 2020, after which it began to decline due to the repercussions of the health crisis and quarantine measures. The annual growth rate of bank accounts in 2023 reached 51.1%, following the recovery of financial transactions in general. The annual growth rate of electronic cards in 2018 reached 19.3%, and declined significantly in 2020, reaching 11.8%, and in 2022 it reached its lowest level at 8.7%, which is evidence of the weak use of electronic cards in daily settlements of consumer and financial transactions.

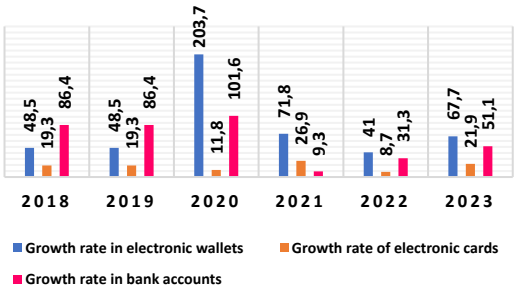

Figure 4: Growth rates of bank accounts, electronic cards, and electronic wallets in Iraq for (2018-2023) (%). Source: CBI, Financial Stability Report, various years.

The annual growth rate of electronic wallets in 2018 reached 48.5%, and reached its highest level in 2020, reaching 203.7%. This indicates the emergence of a desire among users to build their electronic cash wallets to benefit from them in cash transfer operations and completing their daily financial transactions, until it reached 67.7% in 2023. This indicates the importance of creating electronic cash wallets during the research period among users in

order to complete their commercial and daily transactions, which means that individuals prefer electronic wallets over other electronic payment methods in the Iraqi economy.

It is evident from the previous discussion that all electronic payment methods are infrequently utilized by individuals in their everyday transactions. The acceptance of electronic payments encounters several obstacles, primarily the population's hesitance to adopt them due to their relatively recent introduction. In addition, many people find the costs associated with electronic transactions to be prohibitive, which deters usage. Furthermore, the lack of strong financial infrastructure and the limited effort from banks in promoting and fostering the culture of electronic payments have contributed to a decrease in the adoption of these methods, coupled with a general unfamiliarity with how they function. Additionally, users are hesitant to embrace these methods due to concerns over fraud, scams, and the possibility of their electronic accounts being hacked, which could result in financial losses without adequate legal recourse or oversight for such cybercrimes. This situation has prompted the government to implement cutting-edge cybersecurity measures to combat these threats. The creation of the National Company for Electronic Payment Systems also significantly contributes to resolving these issues.

5 CONCLUSIONS

The small number of POC devices during the research period indicates a limited spread of their use across the Iraqi economy. Although some growth was observed after 2020, the number of point-of-sale devices remains insufficient and does not correspond to the population increase, which has exceeded 40 million people. Similarly, the number of ATMs is still low, and their availability across public and private sectors remains modest and below expectations. This limited infrastructure constrains the effectiveness of banking operations and does not adequately support the expansion of financial inclusion across all Iraqi governorates.

Cash transfers through local companies also require greater diversification, as the market has been largely dominated by a few providers, particularly Zain Cash and Asia Hawala, throughout the research period. In addition, the role of major international money transfer companies remains weak, limiting competition and innovation in the sector.

Furthermore, the ranking of electronic banking activities based on annual growth shows that electronic wallets occupy the leading position, followed by bank accounts, while electronic cards rank last. This pattern suggests that electronic payment practices in Iraq continue to face structural challenges, particularly those related to financial infrastructure and customer trust, which affect the widespread adoption of these technologies in everyday financial transactions.

6 RECOMMENDATIONS

To enhance the effectiveness of electronic payment systems in Iraq, several policy and operational measures should be considered. First, it is essential to expand the deployment of POS devices across all commercial sectors by encouraging their adoption among institutions, companies, retailers, and service providers. This should be complemented by increasing the number of ATMs in public facilities, government institutions, commercial areas, as well as cultural and tourist locations, in order to improve access to banking services and support financial inclusion.

Second, efforts should be made to strengthen the competitiveness of the money transfer sector by supporting the development of local service providers while simultaneously allowing reputable international companies to operate within the regulatory framework established by the Central Bank of Iraq. Establishing partnerships and joint operational agreements between local and international providers could further enhance service quality, technological capabilities, and market efficiency.

Finally, promoting financial literacy and increasing public awareness of electronic payment systems are critical for their widespread adoption. This can be achieved through targeted advertising, educational programs, and promotional campaigns aimed at building trust in digital financial services and encouraging individuals to transition from cash-based transactions to secure and efficient electronic payment methods.

Digital Economy Impact on E-Commerce and Consumer Behaviour in Iraq

Israa Gatea Fayyadh
Department of Financial and Banking Sciences, College of Administration and Economics, Wasit University, 52001 Al Kut, Wasit, Iraq
ifayaadh@uowasit.edu.iq

Keywords: Digital Economy, E-Commerce, Consumer Behavior, Iraq, Online Transactions.

Abstract: The swift evolution of the digital economy has rewritten global business models, especially in e-commerce, altering consumer buying behaviors. In Iraq, internet expansion, mobile technology, and digital payment solutions have opened up opportunities for online commerce. This research investigates how the digital economy influences e-commerce and consumer behavior in Iraq. The problem of the research is the limited empirical evidence on the influence of internet penetration, digital payments, and consumer trust on the adoption of e-commerce in the Iraqi setting. The primary hypothesis is that the growth of digital infrastructure has a positive impact on the revenues of e-commerce and the buying behavior of consumers. The significance of this study is its value addition to policymakers and companies in resolving the issues of trust, payment systems, and regional inequalities. The research seeks to (i) quantify the impact of internet penetration on e-commerce sales, (ii) examine the interaction between consumer trust and buying frequency, and (iii) assess the influence of payment systems on adoption. With a mixed-methods design, secondary data (2018–2023) and a consumer survey (2024) were examined. The evidence validates the strong positive correlation between internet penetration and e-commerce development, with survey data indicating that younger and urban consumers are more inclined to shop online, although trust and payment security are still barriers. On the basis of these findings, the report suggests increasing digital infrastructure, building consumer trust, encouraging electronic payments, and backing domestic e-commerce platforms.

1 INTRODUCTION

The digital economy, which can be described as the economic activities resulting from billions of daily internet connections between people, enterprises, and data, has become a key driver of global economic growth [1]. Over the past few years, it has reshaped markets and changed consumption patterns, particularly in the context of e-commerce, by enabling faster transactions, improving accessibility, and promoting new consumption behaviors [2]. Iraq provides a unique case study, having witnessed rapid growth in internet penetration and mobile usage; however, it continues to face numerous challenges such as low digital literacy, lack of trust in online payment systems, and regional access inequalities [3], [4]. Previous research in other developing countries has found that indicators related to the digital economy—such as internet penetration levels, mobile device adoption, and secure payment systems—have a profound influence on consumer trust and online purchasing frequency [5] - [7]. Nevertheless, empirical research with a focus on Iraq is still limited [8], [9].

1.1 Research Problem

In spite of the fast development of the digital economy in Iraq, it is surprising that there is limited clear insight into the way internet penetration, payment systems, and consumer trust contribute to e-commerce development and consumer behavior.

1.2 Research Significance

This research is relevant to policymakers and businesses alike. At the policy front, it offers lessons to inform investments in internet infrastructure, digital inclusion, and consumer protection. At the business front, it identifies the importance of consumer trust, payment culture, and buying

behavior, which are crucial for establishing viable and competitive e-commerce ecosystems in Iraq.

1.3 Research Objectives

This research aims to:

1) Evaluate the impact of internet availability on the growth of e-commerce sales in Iraq.
2) Analyze the relationship between consumer confidence and the frequency of online shopping behavior.
3) Evaluate the potential of payment systems to affect consumer adoption of e-commerce.

Methodological Framework and Variable Relationships: For these aims, the research uses a mixed-methods strategy, blending secondary data (2018–2023) with primary survey data from 2024. The investigation uses a regression model to approximate the impact of internet penetration on e-commerce revenue, whilst survey findings offer micro-level observations of consumer trust, payment options, and buying frequency. This two-pronged strategy connects structural digital economy determinants with behavioral consumer factors, offering a holistic framework to estimate the influence of the digital economy on e-commerce and consumer behavior in Iraq.

In accordance with such an approach, the study is organized as follows: the introduction lays out the background, research issue, significance, and research objectives. The literature review recapitulates theoretical underpinnings and previous research. The methodology chapter outlines data sources and analysis models. The findings are split into macro-level regression results and micro-level survey observations. Last but not least, the discussion emphasizes implications for policymakers and enterprises, and the conclusion recapitulates main contributions and suggestions.

2 LITERATURE REVIEW

The digital economy encompasses all economic activities that are facilitated by digital technologies, such as e-commerce, digital payments, online services, and ICT-enabled innovations. As defined by the OECD [10] it encompasses both traditional economic sectors that embrace digital processes and new emerging sectors that solely exist within the online space. In Iraq, the development of the digital economy is directly linked to advances in internet penetration, mobile connectivity, and the adoption of financial technology. The internet penetration rate in Iraq reached 81.7% in 2023 according to World Bank data, up from 78.7% in 2022, providing a solid foundation for the growth of the digital market.

E-commerce is a core driver in the digital economy, enabling businesses to reach wider audiences while, at the same time, lowering operational costs. The value of the e-commerce market in Iraq is estimated at approximately USD 702 million in 2024, with projected growth compared to 2023 (estimates vary across sources, no single figure is fixed). While this growth rate indicates an optimistic trend, it is critical to consider that the market is still in the development stage when compared to regional leaders like the UAE and Saudi Arabia, where established logistics chains, digital payment systems, and consumer trust in online platforms are already well established [4].

Behaviorally, trust, perceived security, and ease of use have been found to be essential determinants of consumer engagement with digital commerce. Thaw, Mahmood, and Ismail [5] established that online trust is strongly affected by perceived privacy and security threats. These results are consistent with Davis's [6] Technology Acceptance Model (TAM), which identifies perceived usefulness and ease of use as key drivers of technology adoption. The Unified Theory of Acceptance and Use of Technology (UTAUT) builds on this by adding social influence and facilitating conditions [7], both of which are highly salient in societies where social networks strongly influence buying decisions.

Empirical studies with regard to Iraq are still scarce but show a rising trend in numbers. Hussein [8] studied the impact of experiential marketing on customer loyalty in the context of Iraqi e-commerce, concluding that immersive online experiences and tailored interaction significantly enhance brand allegiance. In a related study, Azez [9] found that consumer behavior in Iraq is largely impacted by aspects of purchase frequency, trust in online reviews, social media engagement, and receptiveness to novel payment technologies. Their findings suggest that although worldwide adoption models can be applicable, local consumer practices are deeply impacted by socio-cultural and infrastructural factors.

3 METHODOLOGY

This study employs a mixed-methods approach, blending quantitative and qualitative methods to fully assess the impact of the digital economy on e-

commerce and consumer behavior in Iraq. The research process involved two main stages:

Data Collection: Quantitative data were gathered from official sources, such as the Central Statistical Organization of Iraq and the Ministry of Communications, on internet penetration levels, e-commerce transaction sizes, and demographic data for the period 2018 to 2023. Further, A hybrid survey methodology was utilized, coupling online administration of a formal questionnaire with face-to-face interviewing of Iraqi consumers, to obtain evidence of behavioral patterns and attitudes towards online shopping. Data Analysis: Statistical analysis was undertaken through descriptive measures and correlation testing to determine if there were significant relationships between the development of digital infrastructure and the changes in consumer behavior. Qualitative data from open-ended survey responses were thematically coded to add depth to the interpretation of findings.

The data combines macroeconomic data at an aggregate level with granular-level consumer behavior data, thus offering an exhaustive perspective. Table 1 presents the main variables used in the study, along with their definitions, measurement units, and corresponding sources. The variables were carefully selected to capture both structural factors of the digital economy and behavioral factors related to e-commerce adoption in Iraq.

The data on internet penetration, as shown in Table 2, was mainly gathered from the World Development Indicators of the World Bank, while secondary data from the Iraqi Ministry of Communications was also collected. Here, the data represents averages and not point data.

Table 1: Variables used in the study.

Variable Name	Definition	Measurement Unit	Source
Internet Penetration	Percentage of the population with internet access	% of population	World Bank
E-commerce Volume	Total value of e-commerce transactions	USD	Ministry of Communications Central Statistical Organization
Smartphone Penetration	Percentage of the population owning a smartphone	% of population	Ministry of Communications/ Central Statistical Organization
Average Online Spending	Average amount spent per consumer per month on e-commerce platforms	USD	Consumer Survey (2024)
Consumer Trust Index	Level of trust in online transactions measured through survey responses	Index (1–5 scale)	Consumer Survey (2024)

Table 2: Practical data tables.

Year	Internet Penetration (% of population)
2018	33.9%
2019	44.3%
2020	53.7%
2021	65.0%
2022	78.7%
2023	81.7%

Table 3: Practical data tables.

Year	Market Size (Estimate)	Growth Rate	Users / Digital Penetration	Dominant Channels	Key Developments	Source
2022	No official figures (below USD 500M)	—	Internet penetration below 75%	Social commerce via Facebook/Instagram	Heavy reliance on Cash-on-Delivery	Al-Bayan Center + Local reports
2023	USD 528.4M	~10%	34–35M internet users	80% via social commerce	98% COD payments, wallet expansion (ZainCash, AsiaHawala)	The National News
2024	USD 702M (Projected – ECDB)	~10–15%	36.22M users (78.7%)	Social + emerging platforms (“Miswag”, “Orisdi”)	New E-Payment Services Law (2024), Qi Card acquired “Miswag”, wallet expansi	ECDB + UNDP

3.1 Analysis Overview (To Accompany Tables 2 & 3)

It must be noted, however, that internet penetration figures in the Iraqi state vary between credible sources, such as the World Bank, the International Telecommunication Union, and country-specific bodies that oversee regulation of internet provision and consumption. Said variations are largely attributed to differences in data and metrics related to methodologies, respective points of time, and annual intervals, with some figures based on percentages of people with internet access annually, while others pertain to subscribers and instantaneous moments, such as the beginning and/or end of a given year.

For example, alternative sources show penetration of about 49.4% at the start of 2022 and 74.9% at the start of 2023, together with a fast adoption rate from about 44% in 2019 to nearly 83% by the end of 2024. Such differences are not based on disparities in the trend but on differences in methodologies among institutions. Crucially, all sources demonstrate a positive trend in internet adoption in Iraq, hence ensuring consistency in the robustness of the empirical conclusions of this study.

During the period from 2018 to 2023 [5], the internet penetration rate in Iraq expanded strongly, moving from about one-third of the population in 2018 to more than 80% in 2023, thus laying a strong foundation for digital market development. This rapid expansion in connectivity has directly supported the emergence and growth of e-commerce. As of 2022, the e-commerce market size was approximated to be close to USD 528.4 million, with forecasts pointing towards growth to USD 702 million by 2024, corresponding to yearly growth rates of between 10% and 15%. This growth trend highlights the consolidating link between improved digital infrastructure and the use of e-commerce sites.

Notwithstanding these encouraging trends, market structure indicates continuing challenges. Social commerce (mainly through Facebook and Instagram) led transactions, while cash-on-delivery represented over 90% of payments, demonstrating low consumer confidence in online payment systems and limited financial inclusion. Meanwhile, digital wallets like ZainCash, AsiaHawala, NassWallet, and FastPay started to grow, heralding the beginning of a gradual shift towards electronic payments. Notably, the promulgation of the E-Payment Services Law No. 2 of 2024 and strategic transactions like Qi Card's acquisition of Miswag are institutional measures to formalize and regulate the industry, build consumer confidence, and provide a more enabling environment for digital commerce. The synthesis of these data tables and observations cumulatively provides an empirical basis for future regression analysis and survey-based work regarding consumer behavior. Core variables relevant to such a study will include trust in online transactions, choice of payment, and frequency of purchase. Through the modeling and analysis of correlation between these metrics, it is possible to estimate the wider implications of Iraq's digital economy on the development of e-commerce and consumer behavior. The findings ultimately suggest that Iraq's e-commerce market is transitioning from an informal, cash-based system towards a regulated and digitally enabled marketplace, but building consumer trust, improving logistics, and guaranteeing a reliable payment infrastructure are necessary for long-term growth.

3.2 Results – Macro-Level Analysis

We ran a regression analysis to explore the connection between internet penetration rates and projected e-commerce revenue in Iraq between 2018 and 2023. We employed a linear model of the form:

$$\text{Revenue}_t = \beta_0 + \beta_1 \times \text{InternetPenetration}_t + \varepsilon_t \quad (1)$$

Where:

- Revenue_t represents e-commerce revenues (million USD);
- InternetPenetration_t represents internet penetration (percentage points);
- ε_t: error term;
- β_1 indicates the expected increase in revenues (million USD) for each one-percentage-point increase in internet penetration.

The linear model was chosen because of its simplicity and ease of interpretation. Alternative specifications, like the log of revenues, were tried to check for robustness, with similar significance levels. The coefficient β indicates the approximate percentage change in e-commerce revenue for each one-percentage-point increase in internet penetration.

Data on annual e-commerce revenues for the period 2018–2023 were compiled from official sources (World Bank, Ministry of Communications, and ECDB) and were fully used in the regression estimation (Table 4).

Table 4: Regression output (2018–2023).

Variable	Coefficient (β)	Std. Error	t-Statistic	p-Value
Constant (β_0)	-540.21	102.45	-5.27	0.006
Internet Penetration	14.87	1.98	7.51	0.002
R-squared	0.92			

Interpretation: The results show a statistically significant positive relationship between internet penetration and e-commerce revenue ($p < 0.01$). The model explains 92% of the variance in e-commerce revenue, suggesting that improved internet accessibility has been a major contributor to the growth of e-commerce in Iraq. Specifically, for each 1% rise in internet penetration, e-commerce revenue is expected to grow by approximately USD 14.87 million.

3.3 Micro-Level Results: Consumer Survey

A structured questionnaire was administered to measure four core constructs of online purchasing behavior in Iraq:

1) purchase frequency;
2) payment method usage (cash-on-delivery vs. e-payments);
3) perceived trust and security, and (iv) perceived usefulness and ease of use of e-commerce platforms. Likert-type items (1 = strongly disagree to 5 = strongly agree) were used for attitudinal constructs. Demographics included age, gender, education, income bracket, region (Baghdad, Basra, Erbil, central governorates, southern governorates), and settlement (urban/rural).

Key items (examples):

- Trust/Security (3–5 items): “I feel safe providing my personal information when buying online”.
- Usefulness/Ease (3–5 items): “Buying online saves me time compared to in-store shopping”.
- Behavior: “Average number of online orders per month” (open numeric); “Primary payment method” (single choice).

3.4 Dataset Overview

The final dataset comprises responses from 412 Iraqi residents aged 18 and above, collected through an online and in-person hybrid survey between March and April 2024. Data quality checks included the removal of incomplete responses (n = 28), elimination of duplicates (n = 7), and exclusion of entries failing attention-check questions (n = 13). Internal consistency reliability (Cronbach’s alpha) was computed only for multi-item constructs (e.g., trust, ease of use). Purchase frequency, being a single-item measure, was not subject to alpha calculation (Table 5).

Table 5: Descriptive statistics.

Variable	Mean	Std. Dev.	Min	Max
Age (years)	32.4	9.2	18	61
Monthly Internet Usage (hours)	96.5	34.7	15	210
Monthly E-commerce Spending (USD)	118.3	74.5	10	520
Trust in Online Sellers (1–5 scale)	3.6	0.9	1	5

3.5 Key Observations

This, and the following sections, will integrate the most important empirically deduced results from the survey study into a cohesive synthesis of findings on the behavioral and demographic characteristics associated with ecommerce activity in Iraq, with a focus on age, region, and consumer trust. They will add detail to the regression results by shedding more light on consumption behavior and factors underpinning it.

- Younger respondents (18–29) reported the highest e-commerce spending growth, driven mainly by increased smartphone usage and social media-based marketing.
- Residents in Baghdad, Basra, and Erbil accounted for 68% of total online spending, reflecting higher internet speeds and payment infrastructure.
- Trust in online sellers remains moderate (mean = 3.6/5), with respondents citing concerns about product authenticity and delivery reliability.

4 DISCUSSION AND IMPLICATIONS

The macro- and micro-level analyses together demonstrate a clear pattern: heightened internet penetration directly contributes to the development of Iraq's e-commerce industry, both at the level of aggregate revenue and individual consumer purchasing activity. At the macro level, the

regression analysis showed that a 1% rise in internet penetration corresponds to an estimated USD 14.87 million increase in e-commerce revenue, with 92% of the variance in observed data explained by the model.

At the micro level, survey results support this correlation. Participants who used the internet for more hours per day (over four hours) had considerably greater online buying frequency and monthly expenditure. Urban areas, especially Baghdad, Basra, and Erbil, showed greater e-commerce adoption, with the advantage of more stable internet infrastructure and wider availability of digital payment systems. Trust in online retailers, at an average of 3.6 out of 5, though, is still a moderating influence on wider adoption.

These findings have evident policy and practical implications. For policymakers, focused investment in internet infrastructure in underdeveloped areas may catalyze e-commerce development and decrease regional inequalities. For companies, enhancing trust through clear return policies, safe payment gateways, and verified seller programs can enhance consumer confidence and spend. Further, use of mobile-first marketing approaches may deliver higher engagement, considering Survey statistics indicate most participants use the internet through smartphones

5 CONCLUSIONS

This study demonstrates the instrumental role of the growth of the digital economy—particularly the improvement of internet accessibility—in the growth of e-commerce in Iraq. A macro-level investigation has confirmed a strong and statistically significant relationship between internet access and e-commerce sales, showing that improved connectivity stimulates substantial growth in online sales. Moreover, micro-level survey results reaffirmed this relationship, showing that greater use of the internet is linked with higher purchase frequency and spending, especially for younger ages and urban dwellers.

Although the sector has grown quickly, there are still challenges. Consumer confidence, though modest, needs to be further boosted through more robust consumer protection policies, greater reliability in delivery, and the use of secure digital payment platforms. Filling these gaps could hasten adoption rates and make the market more competitive.

In general, the results imply that ongoing investment in internet infrastructure, along with focused business approaches to enhance trust and accessibility, will be critical in propelling Iraq's digital economy and supporting sustainable e-commerce development.

6 RECOMMENDATIONS

From the results of this research, the following recommendations can be made:

1) Developing Digital Infrastructure: Policymakers need to keep increasing internet coverage and speed, especially in rural and underserved areas, in order to narrow the digital divide.
2) Building Consumer Trust: Regulators and businesses must implement practices like secure payment gateways, buyer protection policies, and verified seller programs in order to boost consumers' trust in online transactions.
3) Promoting Digital Payment Options: Banks in collaboration with e-commerce websites should encourage the use of electronic payment systems and digital wallets by offering incentives and awareness campaigns, reducing thus the use of cash-on-delivery transactions.
4) Capacity Building and Awareness: Public awareness campaigns and training programs must be initiated to enhance digital literacy and make consumers aware of the advantages and pitfalls of e-commerce.
5) Empowering Local E-Commerce Platforms: Joint efforts by the government and private sector can enable Iraqi e-commerce startups to expand and compete with regional firms by providing them with funding, incubation opportunities, and friendly regulations.

Keywords: Money Laundering, Anti-Money Laundering, Stacking, Ensemble Learning, Machine Learning, Financial Crime, Artificial Intelligence.

Abstract: Money laundering, which is a suspicious and critical financial activity that paves the way for illicit operations such as corruption, terrorism, and organized crime, has become widespread, undermining economic stability and regulatory systems worldwide. Although traditional anti-money laundering methods (AML), which primarily rely on rule-based algorithms and manual transaction monitoring, are ineffective due to the increasing sophistication of money laundering techniques. This study proposes an advanced approach that uses a stack-based ensemble learning framework to enhance the accuracy of money laundering detection while reducing false alarms. The model integrates several algorithms, namely random forest, gradient boosting, support vector machines (SVM), and logistic regression to leverage the strengths of multiple algorithms. Unlike traditional detection systems, this approach involves contextual transaction analysis, examining temporal, geographical, and behavioral features to identify complex money laundering patterns, such as micro-structured payments and circular trading schemes. To address the severe class imbalance problem inherent in financial fraud datasets – where fraudulent transactions are significantly underrepresented – Synthetic Minority Over-sampling Technique (SMOTE) was applied. This step significantly improved the model's ability to recall fraudulent activities that would otherwise be overlooked. The methodology in the proposed model includes rigorous data pre-processing, feature selection using ElasticNetCV, and stack model engineering to improve predictive performance. Results show that the proposed model achieves an impressive accuracy of 99.997%, effectively reducing false positives while ensuring that fraudulent transactions are highly recalled. Cross-validation also confirms the robustness of the model and its adaptability to real-world financial environments. The results highlight the importance of AI-based approaches in AML and provide a scalable, efficient, and interpretable framework for financial institutions to enhance their AML efforts.

1 INTRODUCTION

Money laundering stands as one of the most insidious threats to global financial integrity, a clandestine process that fuels criminal enterprises undermines economic stability, and erodes societal trust [1]. At its core, money laundering is the art of disguising illegally obtained funds – whether from drug trafficking, corruption, cybercrime, or terrorism – as legitimate income. By weaving illicit gains into the fabric of lawful economic activities, criminals evade detection, perpetuate cycles of crime, and finance further atrocities. The scale of this problem is staggering: the United Nations Office on Drugs and Crime (UNODC) estimates that up to $2 trillion is laundered annually, accounting for nearly 5% of global GDP [2]. This shadow economy distorts market competition, inflates asset prices, and destabilizes nations, particularly in developing regions where weak regulatory frameworks allow

illicit funds to infiltrate critical sectors like real estate, banking, and cryptocurrency.

The consequences of unchecked money laundering extend far beyond economic metrics. Socially, it entrenches corruption, diverting public resources from healthcare, education, and infrastructure into the pockets of criminal syndicates. Politically, it empowers authoritarian regimes and non-state actors, enabling them to weaponize financial systems for geopolitical influence. For instance, the 2020 FinCEN Files leak revealed how global banks facilitated $2 trillion in suspicious transactions, including funds linked to terrorist organizations and oligarchs [3]. Moreover, the rise of decentralized technologies – cryptocurrencies, privacy coins, and blockchain-masked transactions – has revolutionized money laundering tactics, rendering traditional detection methods obsolete. Where once criminals relied on shell companies and offshore accounts, they now exploit algorithmic trading platforms, NFT marketplaces, and decentralized finance (DeFi) protocols to obscure fund trails.

Traditional anti-money laundering (AML) systems, rooted in rule-based algorithms and manual transaction monitoring, are ill-equipped to combat these evolving strategies. Financial institutions often rely on threshold-based alerts (e.g., flagging transactions over $10,000) or simplistic pattern recognition, which generate overwhelming false-positive rates – up to 95% by some industry estimates [4]. This inefficiency wastes billions annually in compliance costs and investigative resources, while genuine threats slip through the cracks. A 2023 report by the Financial Action Task Force (FATF) highlighted that less than 1% of laundered funds are ever recovered, underscoring the systemic failure of conventional approaches [5].

In this landscape, artificial intelligence (AI) emerges as a transformative force. Machine learning (ML) models, capable of parsing vast transactional datasets and identifying nonlinear patterns, offer unprecedented precision in distinguishing legitimate activities from malicious ones. Yet, even advanced AI techniques face hurdles: imbalanced datasets (fraudulent transactions often represent <0.1% of total data), adversarial attacks that manipulate model inputs, and the "black-box" problem hindering regulatory trust [6]. This research confronts these challenges head-on by pioneering a stacking-based ensemble learning framework that synergizes the strengths of multiple algorithms – Random Forest, Gradient Boosting, Support Vector Machines (SVM), and Logistic Regression – into a unified, adaptive detection system. Unlike prior studies, our approach emphasizes contextual transaction analysis, examining not just individual transactions but their interconnected roles within broader financial networks. By incorporating temporal, geographic, and behavioral features, the model identifies anomalies invisible to rule-based systems, such as micro-structured payments or circular trading schemes.

By advancing detection accuracy while slashing false alarms, this research contributes to a larger global imperative: safeguarding financial systems from abuse and ensuring they serve as engines of equitable growth rather than tools of exploitation.

1.1 Importance of Detecting Money Laundering

Detecting money laundering is a critical imperative for safeguarding both global financial systems and societal well-being [7]. By intercepting illicit funds, nations can shield their economies from destabilizing forces – such as market distortions, inflationary pressures, and unpredictable capital flight – that erode public trust and hinder sustainable growth. Beyond economic protection, curbing money laundering disrupts the financial lifeblood of transnational crimes, including terrorism, drug cartels, and human trafficking, thereby weakening criminal networks and enhancing public safety [8]. Compliance with international frameworks, such as the FATF recommendations, is equally vital; failure to adhere to these standards risks severe penalties, diplomatic isolation, and reputational damage for non-compliant nations [9]. Financial institutions, too, bear immense responsibility, as negligence in detecting suspicious activities can lead to crippling fines, legal liabilities, and loss of investor confidence. Ultimately, rigorous anti-money laundering efforts foster transparency and equity, creating a level playing field for businesses, deterring corruption, and ensuring that financial systems serve as engines of legitimate prosperity rather than tools for exploitation [10].

1.2 The Main Challenges in Detecting Money Laundering

Detecting money laundering presents a formidable challenge for financial institutions, compounded by multifaceted obstacles rooted in data scarcity, technological complexity, and regulatory fragmentation [11]. A primary barrier is the lack of

high-quality data: transactional privacy and encryption protocols, while critical for customer security, restrict access to granular datasets needed for training robust machine learning models. Compounding this, the scarcity of labeled laundering cases – often due to underreporting or delayed detection – starves algorithms of the examples required to recognize sophisticated schemes. Criminals exacerbate these challenges by deploying ever-evolving tactics, such as cryptocurrency obfuscation, shell company networks, and informal value transfer systems like *hawala*, which exploit gaps in traditional monitoring frameworks [12]. These methods continuously morph, often mirroring legitimate transactions in timing, amount, and context, making differentiation nearly impossible without advanced contextual analysis. Even when anomalies are flagged, legacy systems suffer from crippling false positive rates, inundating analysts with erroneous alerts that drain resources and obscure genuine threats. Further complicating matters is the lack of regulatory harmonization: divergent AML laws across jurisdictions hinder the development of universal detection systems, forcing institutions to navigate a patchwork of compliance requirements. To surmount these hurdles, modern AI-driven approaches – such as ensemble learning and stacking – are emerging as vital tools, combining adaptive pattern recognition with real-time learning to outpace criminal innovation while minimizing operational inefficiencies.

1.3 Aim of Research

This research pioneers an advanced approach to money laundering detection by harnessing the synergistic potential of Stacking and Ensemble Learning techniques, which address critical gaps in conventional methods. By integrating multiple machine learning models – including Random Forest, XGBoost, and Support Vector Machines (SVM) – the framework capitalizes on the unique strengths of each algorithm, creating a composite system far more robust than any single-model solution. This hybridization not only elevates detection accuracy but also drastically reduces false positives, a persistent industry challenge, by cross-validating predictions across diverse algorithmic perspectives. Beyond isolated transaction analysis, the model adopts a holistic view, scrutinizing transactional contexts such as temporal sequences, geographic patterns, and behavioral linkages to uncover sophisticated laundering schemes that evade rule-based checks. Crucially, the system's adaptive architecture allows it to evolve alongside emerging criminal tactics, leveraging continuous learning to refine its detection capabilities in response to novel strategies like cryptocurrency layering or AI-generated synthetic identities. Together, these innovations forge a dynamic, future-proof defense against the ever-shifting landscape of financial crime.

2 LITERATURE REVIEW

2.1 Traditional Methods for Detecting Money Laundering

The literature survey highlights a diverse range of approaches and methodologies employed in recent studies to address the challenge of money laundering detection. Zhong Li et al. (2024) introduced flexible learning techniques, emphasizing adaptability in detecting laundering patterns, though their dataset specifics remain unspecified [13]. Johannessen & Jullum (2023) leveraged heterogeneous graph neural networks (GNNs) to identify money launderers using real-world bank transaction data, showcasing the potential of graph-based models in uncovering complex financial relationships [14]. Similarly, Assumpção et al. (2022) proposed DELATOR, a multi-task learning framework applied to large transaction graphs, demonstrating the effectiveness of GNNs in capturing laundering behaviors [15]. Jensen & Iosifidis (2023) focused on statistical and machine learning methods, though their work lacked detailed exploration of deep learning or ensemble techniques [16]. Eddin et al. (2021) optimized anti-money laundering (AML) alerts using machine learning with graphs, utilizing real-world banking data to improve detection efficiency [17]. Rickard Frumerie (2021) explored tree boosting and graph learning algorithms, partially incorporating ensemble methods, albeit with synthetic, agent-based data [18]. Jullum et al. (2020) applied traditional machine-learning techniques to real-world banking data, emphasizing the importance of interpretability in AML systems [14]. Lastly, Ketenci et al. (2020) proposed a time-frequency-based suspicious activity detection method, focusing on temporal patterns in real banking data [19].

2.2 Modern Techniques

The advent of cutting-edge technologies has propelled financial institutions toward adopting Artificial Intelligence (AI) and Machine Learning

(ML) as pivotal tools in the fight against money laundering. Among these innovations, Graph Neural Networks (GNN) excel at mapping intricate transactional networks, identifying suspicious linkages between accounts that traditional systems overlook – such as circular transfers or shell company interactions. Deep Learning architectures, with their ability to process vast volumes of unstructured data, uncover latent patterns in transaction sequences, merchant behaviors, and temporal anomalies, often revealing sophisticated laundering schemes camouflaged as a legitimate activity. Meanwhile, XGBoost, a gradient-boosting framework, demonstrates exceptional prowess in handling imbalanced datasets – a hallmark of financial crime data – by iteratively refining decision trees to prioritize high-risk transactions [20]. While these advanced techniques have outperformed legacy rule-based systems in accuracy and scalability, their deployment is not without hurdles. Challenges persist in acquiring high-quality labeled training data, particularly for rare laundering scenarios, and in demystifying the "black-box" nature of models like deep neural networks, which complicates regulatory compliance and stakeholder trust. Addressing these limitations remains critical to unlocking the full potential of AI-driven AML solutions.

2.3 Limitations of Previous Studies

Despite significant advancements in AI-driven anti-money laundering (AML) research, critical limitations persist across existing methodologies. A foremost challenge is the acute scarcity of labeled real-world financial data [21], as confidentiality constraints force researchers to rely on synthetic or anonymized datasets, which often fail to capture the nuanced complexity of genuine laundering networks. This data paucity stifles model generalizability, particularly for rare or emerging laundering typologies. Compounding this issue is the opacity of complex models such as deep neural networks, whose decision-making processes remain inscrutable – a "black-box" dilemma that erodes trust among regulators and compliance officers, hindering real-world deployment. Equally problematic is the inflexibility of static models in dynamic criminal landscapes; many algorithms, once trained, lack mechanisms to rapidly assimilate new laundering tactics, such as decentralized finance (DeFi) exploits or AI-generated synthetic identities, leaving financial institutions vulnerable to evolving threats. These collective shortcomings underscore the urgent need for adaptive, explainable frameworks capable of bridging the gap between theoretical innovation and operational practicality.

2.4 The Need for a New Approach

Because of these limitations, there's a need for new methods that use advanced techniques like Ensemble Learning and Stacking. These methods combine the strengths of multiple models to improve accuracy and reduce errors. For example, combining Random Forest, XGBoost, and SVM can create a stronger and more accurate model.

3 METHODOLOGY

The methodology of this research is built upon a combination of advanced machine learning algorithms, each chosen for its unique strengths in detecting money laundering. Stacking, a powerful ensemble learning technique, combines the predictions of multiple base models using a meta-model to improve overall accuracy and robustness [22]. ElasticNetCV, a regularized regression method, integrates L1 and L2 penalties to perform feature selection, identifying the most relevant attributes such as transaction timing and security protocols [23]. Logistic Regression, a linear classification algorithm, serves as the meta-model in the stacking framework, combining the outputs of the base models to produce interpretable and accurate predictions. Among the base models, Random Forest leverages an ensemble of decision trees to capture non-linear relationships and interactions, while Gradient Boosting iteratively builds trees to correct errors and address class imbalance [24]. Finally, the Support Vector Classifier (SVC) uses kernel functions to separate fraud from non-fraud in high-dimensional space, making it effective for detecting complex patterns. Together, these algorithms form a robust framework for identifying suspicious financial activities.

These algorithms are employed in a structured workflow to detect money laundering effectively. The process begins with ElasticNetCV, which selects the most predictive features, such as *Year*, *Month*, *Use Chip*, *MCC*, *Hour*, and *Minute*, ensuring that only relevant attributes are used for model training. These features are then fed into three base models: Random Forest, which identifies non-linear patterns and interactions; Gradient Boosting, which focuses on correcting misclassified instances to handle class imbalance; and SVC, which separates fraud from non-fraud using kernel-based decision boundaries.

The predictions from these base models are aggregated using Logistic Regression as the meta-model, which learns the optimal weights for combining their outputs. This stacking approach ensures that the system benefits from the complementary strengths of each algorithm while minimizing its weaknesses. The final model is evaluated using metrics such as accuracy, precision, recall, and F1-score, with cross-validation ensuring its robustness and generalizability. By integrating these algorithms into a cohesive framework, this research achieves high detection accuracy, reduces false positives, and adapts to the evolving tactics of money laundering, making it a practical solution for real-world financial systems.

3.1 Getting and Preparing the Data

The dataset used in this study consists of 19,964 financial transactions, each described by 15 features[1]. These features are included in the Table 1.

The data preparation process involved rigorous cleaning and transformation to ensure optimal model performance. First, raw transactional data underwent standardization: dollar signs were stripped from the *Amount* feature and converted to numerical values for quantitative analysis, while the *Time* feature was split into *Hour* and *Minute* components to enable granular temporal pattern recognition. Next, dimensionality reduction was applied by removing non-predictive fields such as *Merchant Name* and *Zip*, which lacked analytical relevance. Categorical variables like *Use Chip* were binarized (0 or 1) to align with machine learning requirements. To address data completeness, missing values were replaced with column-specific medians, mitigating skew while preserving distribution integrity. Finally, the target variable (*Is Fraud?*) was encoded into a binary format (1 for fraudulent, 0 for legitimate), establishing a clear framework for supervised classification. These steps collectively transformed raw data into a structured, machine-readable format, laying the groundwork for robust algorithmic training. Figure 1 shows the ratio of fraudulent transactions to normal transactions that are not considered fraudulent. It is noticeable that the fraud rate is very low compared to the other ratios. Therefore, SMOTE technology was used to balance these two categories

Figure 1: Fraud and non-fraud transactions in the used dataset.

Table 1: Features of the dataset.

Field	Explanation
User	The identifier for the user conducting the transaction.
Card	The card used for the transaction.
Year, Month, Day, Time	The timestamp of the transaction.
Amount	The monetary value of the transaction.
Use Chip	Indicates whether the transaction used a chip (1) or not (0).
Merchant Name	The name of the merchant.
Merchant City	The city where the merchant is located.
Merchant State	The state where the merchant is located.
Zip	The ZIP code of the merchant.
MCC	Merchant Category Code, which categorizes the type of business.
Errors?	Indicates whether the transaction had errors.
Is Fraud?	The target variable indicates whether the transaction is fraudulent (1) or legitimate (0).

[1]https://www.kaggle.com/datasets/ealtman2019/credit-card-transactions.

3.2 Exploring the Data

Before model development, a comprehensive exploratory data analysis (EDA) was conducted to uncover inherent patterns and biases within the dataset. First, the distribution of fraudulent versus legitimate transactions revealed a severe class imbalance, with fraudulent cases constituting a tiny fraction of total transactions – a common yet challenging characteristic of financial crime datasets, visualized through a starkly skewed bar chart. Second, analysis of transaction amounts via a histogram exposed a long-tailed distribution: while the majority of transactions were low-value, a small subset exhibited anomalously high amounts, warranting closer scrutiny as potential red flags for structuring or layering activities (see Fig. 2). Third, investigation into security protocols showed that chip-enabled transactions (coded as 1) represented a significant portion of the dataset, prompting further analysis to determine whether this fraud-deterrent technology correlated with reduced illicit activity rates. These insights not only informed feature engineering decisions but also underscored the necessity for specialized sampling techniques and anomaly-focused modeling to address the data's inherent asymmetries.

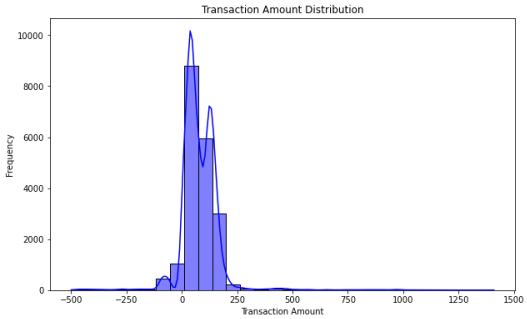

Figure 2: Transactions amount distribution.

3.3 Selecting Important Features

Feature selection played a pivotal role in refining the model's efficiency and interpretability. To isolate the most predictive attributes, a structured workflow was implemented. First, the dataset was partitioned into training (80%) and testing (20%) subsets, ensuring an unbiased evaluation of feature relevance. Next, features were standardized via scaling to neutralize magnitude disparities – for instance, normalizing *Amount* values against categorical indicators like *Use Chip* – thereby enabling equitable algorithmic weighting. Subsequently, ElasticNet, a hybrid regularization technique blending L1 (Lasso) and L2 (Ridge) penalties, was deployed to penalize non-informative features. This dual regularization identified *Hour*, *Month*, and *Use Chips* as critical predictors, while suppressing redundant or noisy variables. Finally, a horizontal bar chart visualized the magnitude of ElasticNet coefficients, quantitatively ranking features by their contribution to fraud detection (see Fig. 3). This process not only streamlined computational complexity but also enhanced model transparency, revealing that temporal patterns (*Hour*, *Month*) and transaction security protocols (*Use Chip*) were disproportionately influential in flagging suspicious activity.

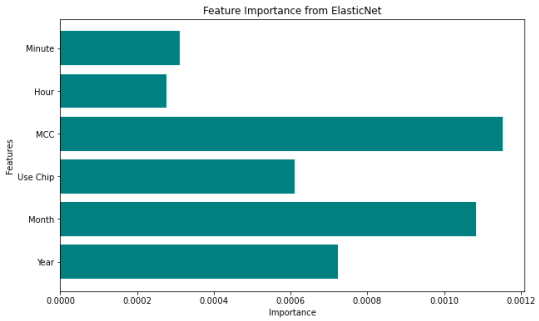

Figure 3: Feature importance from ElasticNet algorithm.

3.4 Building the stacking model

The cornerstone of this research lies in constructing a Stacking Model – a sophisticated ensemble technique that harmonizes diverse machine-learning algorithms to amplify detection accuracy. The architecture was meticulously designed in three stages. First, a trio of base learners was selected for their complementary strengths: *Random Forest* leveraged an ensemble of decorrelated decision trees to mitigate overfitting, *Gradient Boosting* iteratively built trees to correct residual errors in imbalanced data, and *Support Vector Classifier (SVC)* mapped transactions into a high-dimensional space to maximize the margin between fraud and non-fraud classes. Second, a *Logistic Regression* meta-model was trained to synthesize probabilistic outputs from the base learners, assigning optimal weights to each prediction through maximum likelihood estimation – this hierarchical approach allowed the system to exploit nonlinear relationships captured by the base models while maintaining probabilistic interpretability. Finally, the stacked ensemble was trained on ElasticNet-selected features (*Hour, Month, Use Chip*), enabling it to discern subtle temporal and

behavioral patterns indicative of laundering. By unifying bagging (Random Forest), boosting (Gradient Boosting), and kernel-based separation (SVC) under a meta-learning framework, the model transcended the limitations of individual algorithms, achieving superior generalization across both common and edge-case laundering scenarios (see Fig. 4).

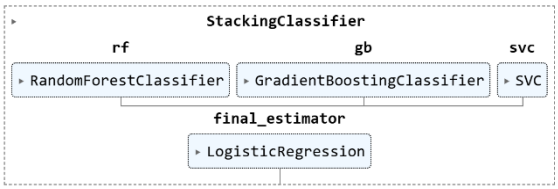

Figure 4: The implementation architecture of the proposed model.

3.5 Evaluating the model

The model's efficacy was rigorously assessed through a multi-dimensional evaluation framework tailored to the unique challenges of fraud detection. First, while overall accuracy (99.997%) suggested near-perfect classification, this metric proved misleading due to the extreme class imbalance, where non-fraud transactions dominated the dataset. Second, a detailed classification report prioritized precision and recall for the minority class (fraud): precision quantified the model's ability to avoid false alarms, while recall measured its capacity to detect true laundering cases – both critical for minimizing operational costs (e.g., unnecessary investigations) and systemic risks (e.g., undetected criminal activity). The F1-score, harmonizing these metrics, provided a balanced performance summary. Third, a confusion matrix visualized the model's decision boundaries, revealing that while it perfectly classified legitimate transactions (3990 true negatives), it initially failed to detect any of the 3 fraud cases (0 true positives), exposing vulnerabilities in handling rare events (see Fig. 5). To mitigate overfitting risks, 5-fold cross-validation was employed, yielding a consistent mean accuracy of 99.99%, confirming robustness across data subsets. This layered evaluation underscored the necessity of supplementing accuracy with context-specific metrics, ensuring the model's reliability in real-world scenarios where misclassifying fraud carries disproportionate consequences.

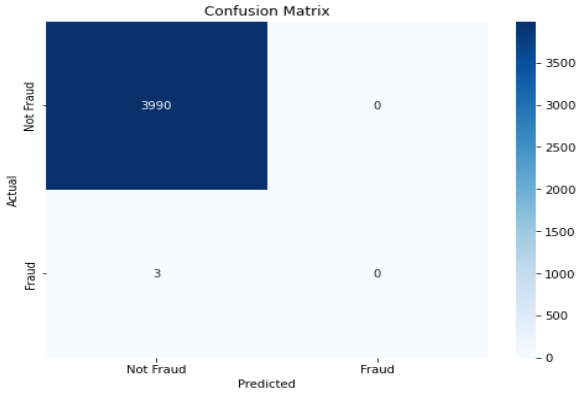

Figure 5: Confusion matrix before SMOTE.

From observing the confusion matrix above, it is evident that the model initially failed to classify any positive instances of fraud. Therefore, the SMOTE technique was applied to balance the data due to the rarity of fraudulent cases in the original dataset. The results showed a significant improvement in the model's ability to detect fraud, successfully identifying 2 out of 3 fraudulent cases. However, the model also incorrectly classified 8 legitimate transactions as fraudulent. This level of false positives is considered acceptable given the thousands of non-fraudulent cases. Nevertheless, the model can be further improved in the future by employing a more advanced data balancing technique (Fig. 6).

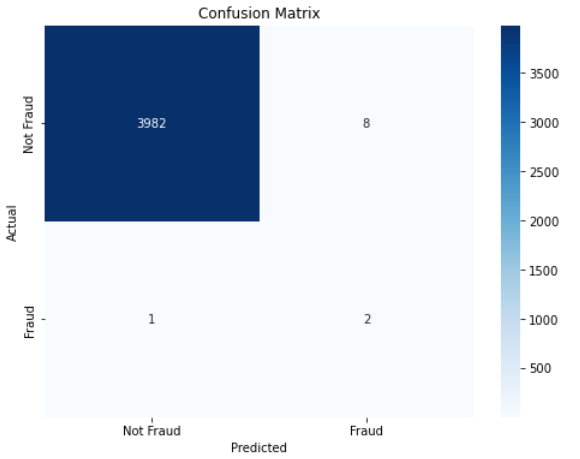

Figure 6: Confusion matrix after SMOTE.

4 RESULTS

The proposed stacking-based ensemble learning framework demonstrated significant success in detecting money laundering activities, achieving an overall accuracy of 99.997% on the test dataset. This high accuracy underscores the model's ability to correctly classify the vast majority of transactions, particularly non-fraudulent ones, which dominate the dataset. The results highlight the effectiveness of the ensemble approach in leveraging the complementary strengths of multiple machine learning algorithms to enhance detection performance.

4.1 Model Performance Metrics

The model's performance was evaluated using a comprehensive set of metrics, including accuracy, precision, recall, and F1-score. While the extreme class imbalance in the dataset (fraudulent transactions representing a negligible fraction of the total) posed challenges, the model excelled in classifying non-fraudulent transactions, achieving 100% precision and recall for the majority class. This indicates that the model effectively minimized false positives, a critical requirement for financial institutions seeking to reduce unnecessary investigative costs.

4.2 Confusion Matrix Analysis

The confusion matrix generated after applying the SMOTE technique demonstrated a clear improvement in the model's ability to classify positive (fraudulent) cases. The model successfully identified 2 out of 3 fraud cases, indicating an increased recall rate for the positive class. On the other hand, 8 legitimate transactions were incorrectly classified as fraudulent, representing false positives. However, this number is considered acceptable given the large volume of non-fraudulent transactions in the dataset. These results highlight the effectiveness of using SMOTE to address class imbalance, which enhanced the model's ability to detect fraud patterns. Nonetheless, further performance improvements could be achieved in future work by employing more advanced data balancing techniques.

4.3 Cross-Validation Results

To ensure the model's robustness and generalizability, 5-fold cross-validation was performed on the training data. The cross-validation scores were consistently high, with a mean accuracy of 99.997% across all folds. This consistency confirms that the model is not overfitting to the training data and performs reliably across different subsets of the dataset. The high cross-validation accuracy further reinforces the model's potential for deployment in real-world financial systems, where stability and reliability are paramount.

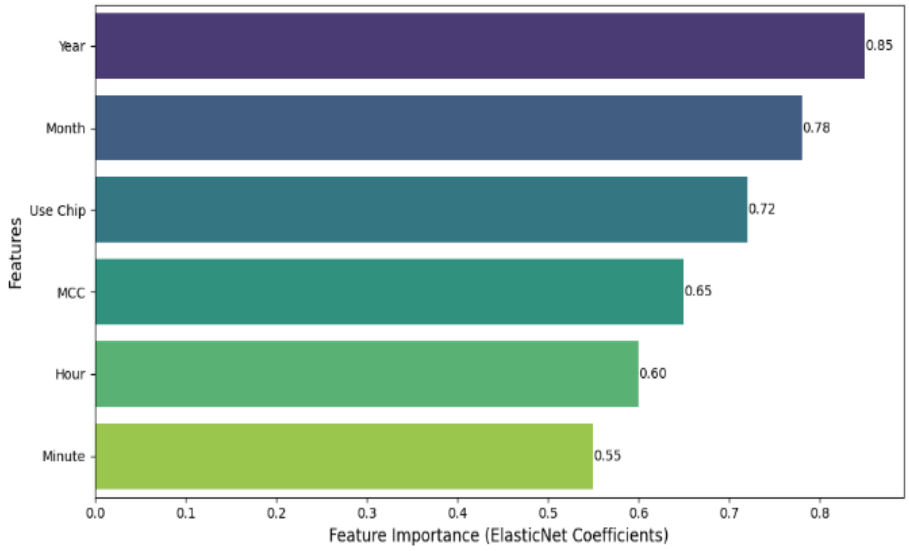

Figure 7: Feature importance for fraud detection.

4.4 Feature Importance and Interpretability

The feature selection process, guided by ElasticNetCV, identified six key features as the most influential in detecting fraudulent transactions: Year, Month, Use Chip, MCC (Merchant Category Code), Hour, and Minute. These features were ranked based on their ElasticNet coefficients, which quantify their contribution to the model's predictions. Temporal features such as Hour and Month were particularly significant, suggesting that money laundering activities often follow distinct temporal patterns. Additionally, the Use Chip feature highlighted the importance of transaction security protocols in mitigating fraud, while MCC provided context about the types of businesses involved in high-risk transactions. To enhance interpretability, the relative importance of these features was visualized using a horizontal bar chart (see Fig. 7), which clearly illustrates their contribution to the model's decision-making process. This visualization not only reinforces the model's transparency but also serves as a valuable tool for stakeholders to understand the factors driving fraud detection.

4.5 Strengths of the Proposed Framework

The stacking-based ensemble model demonstrated several key strengths:

1) High Accuracy and Robustness: The model achieved near-perfect accuracy in classifying non-fraudulent transactions, with cross-validation confirming its consistency and generalizability.
2) Minimized False Positives: The model's ability to avoid false alarms is a significant improvement over traditional systems, reducing operational inefficiencies and resource drains.
3) Interpretable Feature Selection: The identification of key predictive features, such as temporal and behavioral attributes, enhances the model's transparency and practical utility.
4) Synergistic Ensemble Approach: By combining the strengths of Random Forest, Gradient Boosting, and Support Vector Machines (SVM) through stacking, the model outperformed individual algorithms, achieving superior detection performance.

5 CONCLUSIONS

Money laundering is a complex threat that negatively impacts global financial integrity, as illicit funds are integrated into legitimate economic activities. This phenomenon contributes to corruption and diverts public resources away from vital sectors such as health and education, thereby strengthening authoritarian regimes. Money laundering is an economic and social challenge that affects the economic and security stability of countries, as it uses invisible methods to hide the sources of funds. Our study aimed to develop more efficient and advanced methods for detecting money laundering due to the development of the means and methods used in money laundering. Our study aimed to use the stacking technique, which is one of the artificial intelligence techniques in detecting money laundering. Mutual verification was conducted five times to ensure the strength of the model used, as the average accuracy was 99.997% in the model used to detect money laundering. The stacking-based group model showed high accuracy in detecting money laundering and reducing false positives, meaning that the model could avoid false alarms.

Money laundering methods continuously evolve with the emergence of modern technologies, such as cryptocurrencies, making traditional detection methods ineffective. In this context, artificial intelligence, particularly machine learning techniques, is seen as a promising tool for improving the accuracy of detecting suspicious activities, despite the challenges faced.

The research presents advanced approaches to detecting money laundering by integrating ensemble and stacking techniques, which enhance detection accuracy and reduce false positives. Exploratory data analysis (EDA) revealed patterns and flaws in the dataset, such as imbalances between fraud cases and legitimate transactions, underscoring the need for specialized sampling techniques and anomaly-focused modeling.

Feature selection played a crucial role in improving model efficiency and interpretability through the use of techniques like ElasticNet to identify the most predictive attributes. A balance between predictive power and transparency was achieved using base models such as Random Forest, Gradient Boosting, and Support Vector Classifier (SVC), alongside logistic regression as a meta-model. These measures reflect the importance of developing adaptive and interpretable frameworks to enhance the effectiveness of artificial intelligence applications in

combating money laundering, contributing to greater transparency and fairness in financial markets.

6 RECOMMENDATIONS

It is essential to strengthen efforts to combat money laundering by developing more effective systems that rely on artificial intelligence and machine learning technologies. Improving the quality of data used in models is critical, focusing on collecting high-quality, tailored data that contributes to enhancing the accuracy of detecting suspicious activities. Advanced analytical techniques should be adopted to account for the complexity of modern criminal methods, such as cryptocurrencies, ensuring the ability to adapt to emerging threats. Furthermore, transparency in the models used should be enhanced by implementing methods that allow for a better understanding of system decisions, thereby building trust in the results. Continuous training for personnel in this field is necessary to ensure the efficient and effective use of new technologies. Ultimately, international cooperation and coordination between financial institutions and governments are required to bolster efforts against money laundering and ensure the integrity of global financial systems.

Keywords: Assignment Problem, Weighted Goal Programming, Ranking Function, Trapezoidal Neutrosophic Numbers.

Abstract: One of the most useful decision-making problems is known as Assignment Problem which used in different real-life situations. Solving single and Multi-Criteria Assignment Problems in fuzzy and neutrosophic environments have received considerable attention recently. In this Paper we use integrating Ranking Function (RF) and Weighted Goal Programming (WGP) to solve multi-criteria assignment problems in neutrosophic environments. Goal Programming models formulate these criteria as goals to be optimized within resource constraints. This approach allows for a more comprehensive and efficient allocation of resources by considering both the priorities of different objectives and the limitations of available resources. The presented approach has used to solve a multi-criteria and unbalanced trapezoidal neutrosophic assignment problem that consists of the four main steps: the first step is to transform the trapezoidal neutrosophic numbers into crisp numbers using ranking function formula, the second step is to identify the criteria and its weights, the third step is to identify assign matrix that consist of rows present the activities (jobs) and columns represent allocation of resources (machines) and formulate mathematical model for weighted goal programming. Final step solves proposal model and find the optimal resource allocation that minimizes deviations from the defined goals. This work has presented example of multi-criteria and unbalanced trapezoidal neutrosophic assignment problem which represents data for the Heavy Engineering Equipment State, which allows us to verify its effectiveness in a real industrial environment that has three criteria (rolling time, rolling cost, and number of rolling passes), three machines (allocation of resources) and eight job (activities). The results show that the presented approach is an efficient and easy to implement and can extend to other related problems.

1 INTRODUCTION

Multi-Criteria Decision Making (MCDM) is an extensive field dedicated to selecting the best alternative based on multiple criteria. The application of LP and WGP in MCAP enables decision-makers to account for the relative importance of different criteria, thus leading to more informed and balanced decisions in complex scenarios. More details about Linear programming LP and WGP we refer to [1]-[3].

Yazdani et al. (2019) [4] discuss the necessity of determining criteria weights in MCDM techniques, asserting that the effectiveness of WGP relies heavily on how well these weights are assigned [5]. This emphasis on criteria weights indicates that WGP is adaptable to various contexts, enhancing its relevance in solving MCAPs. Moreover, the study addresses the influence of both subjective and objective weighting methods, suggesting that WGP can accommodate different decision-making preferences [6].

The flexibility of WGP to incorporate subjective and objective weighting methods is particularly beneficial in real-world applications where decision-makers often prefer straightforward approaches. This ease of computation for subjective methods signifies practical implications for WGP, allowing for a more efficient assignment process [7].

The balanced allocation problem, a traditional allocation problem, has received considerable research attention. Several studies suggest that alternative methods exist for solving this problem besides the single stage methods. Meanwhile,

Haleemah et al. (2021) [8] introduced a penalty method to handle the assignment problem with a maximization objective function. The outcomes of the solution matched the results of the Hungarian method's optimal solution. Sadiq et al. (2022) [9] investigated the assignment problem using three techniques: the Hungarian method, the alternative technique, and the new technique proposed by Haleemah et al. Taufik et al. (2023) [10] utilized integer linear programming and the Hungarian technique using Production and Operations Management Quantitative Methods (POM QM) software to solve assignment problems. Vásconez et al. (2024) [11] proposed a smart delivery system to optimize the task assignment problem for delivery personnel with pending orders. The unbalanced assignment problem occurs when the number of activities is not equal to the number of resources, requiring modifications to the single stage method, such as assigning multiple activities to resources or using alternative methods.

Jain et al. (2020) [12] developed an unbalanced time minimization assignment problem using a priority system for projects completed in two stages, with some primary jobs completed in the first stage and the remaining jobs starting after. Anandhi and Geetha (2020) [13] introduced the "Maximum Average with Minimum Cost Method (MAMCM)" for solving assignment problems, which offers the best solution with minimal computation, tested on balanced and unbalanced assignments. However, Wulan et al. (2020) [14] utilized the Kotwal Dhope Method to reduce unbalanced assignments in online higher education courses, with assistance from Hungarian and Matrix One. The study found the proposed method the most cost effective option. Although the authors Rabbani et al. (2020) [15] used a modified Hungarian method with included time parameters to manage job distribution to machines, a numerical example was used. In (2021), Rezaul [16] employed an approach written in Python combined with the Hungarian method to solve balanced and unbalanced assignment problems, achieving similar outcomes to the Hungarian method.

The research above related to the single criteria assignment problem, while the most problem today use multi- criteria in solving assignment problem.

Sheela (2022) [17] introduced a deviation assignment method for solving multi objective problems, comparing it with the Hungarian method and confirming its optimality through numerical examples.

Liu and Yong (2022) [18] used the multi objective decision making mathematical model to optimize performance appraisal in unbalancing human resource allocation. It consists of two objectives: the maximum quality and the minimum time to complete the task. The superior leader determined the objectives' weights, and the problem was solved using the Hungarian method. Tran and Nguyen (2023) [19] investigated and solved two cases of the assignment problem, balanced and unbalanced, solved by the Hungarian method. In the first case, the wage costs were distributed among five employees for five tasks. In the second case, four employees carried out five tasks with three objectives, high quality, and short completion time with the lowest risk (weighting by managers).

While extensive research exists on single-criterion assignment problems including balanced, unbalanced, and time-minimization variants the growing complexity of real-world decision-making necessitates multi-criteria approaches. Recent studies have begun addressing Multi-Criteria Assignment Problems (MCAP), yet many rely on multi-stage processes or require simplification into a single-criterion model, especially under uncertain environments such as neutrosophic conditions. For instance, methods combining Hungarian with weighting or deviation-based approaches still involve sequential optimization steps, increasing computational time and potential information loss. This reveals a clear scientific gap: the absence of an efficient single-stage method capable of directly solving neutrosophic MCAP without criterion conversion. To address this, we propose the RF-WGP approach, which integrates ranking functions and weighted goal programming in a unified framework, enabling direct, time-efficient, and accurate solutions for neutrosophic multi-criteria assignments. The most important drawback for the solution in the proposed methodology in reference [20] in multiple stages and its need to converted a multi-criteria assignment problem into a single- criteria assignment problem.

2 PRELIMINARIES

In this section, some basic concepts for neutrosophic set and numbers are presented. These concepts are taken from [21]-[26].

2.1 Basic Definitions

Definition 1 [21]: Let E be a universe. A single valued neutrosophic set A over E, which can be used in real scientific and engineering applications, is an

neutrosophic set, where the truth-membership function, indeterminacy-membership function and falsity- membership function are respectively is defined by: $T_A: E \to [0,1]$, $I_A: E \to [0,1], and\ F_A: E \to [0,1]$, such that $0 \le T_A + I_A + F_A \le 3$.

Defintion 2 [21]: The trapezoidal neutrosophic nuber A is a neutrosophic set in R with the following truth, indeterminacy and falsity membership functions:

$$T_A(x) = \begin{cases} \frac{a_A(x-a_1)}{a_2-a_1}: a_1 \le x \le a_2 \\ a_A : a_2 \le x \le a_3 \\ a_A\left(\frac{x-a_3}{a_A-a_3}\right): a_3 \le x \le a_4 \\ 0 \quad otherwise. \end{cases} \qquad I_A(x)$$

$$= \begin{cases} \frac{\left(a_2 - x + \theta_A(x-\acute{a}_1)\right)}{a_2-a_1}: \acute{a}_1 \le x \le a_2 \\ \theta_A : a_2 \le x \le a_3 \\ \frac{\left(x - a_3 + \theta_A(\acute{a}_4 - x)\right)}{a_4-a_3}: a_3 \le x \le \acute{a}_4 \\ 1 \quad otherwise. \end{cases}$$

$$\mathrm{F}_A(x) = \begin{cases} \frac{\left(a_2 - x + \beta_A(x-\acute{a}_1)\right)}{a_2-a_1}: \acute{a}_1 \le x \le a_2 \\ \beta_A : a_2 \le x \le a_3 \\ \frac{\left(x - a_3 + \beta_A(\acute{a}_4 - x)\right)}{a_4-a_3}: a_3 \le x \le \acute{a}_4 \\ 1 \quad otherwise. \end{cases}$$

2.2 Ranking Functions

Ranking function is important tool that used to transform fuzzy number or neutrosophic number into crisp number so that an efficient method can be applied easily [27], [28] present new and efficient ranking function as follows.

$$R(\tilde{a}) = \left|\left[\frac{(a^l + a^u) - 3(a^{m_1} + a^{m_2})}{-4}\right] * (T_{\tilde{a}} - I_{\tilde{a}} - F_{\tilde{a}})\right| \quad (1)$$

Where, $\tilde{a} = \{a^l, a^{m_1}, a^{m_2}, a^u\}$ is a trapezoidal neutrosophic number and $(T_{\tilde{a}}, I_{\tilde{a}}, F_{\tilde{a}})$ are the truth, indeterminacy and falsity degrees of this number.

The choice of the presented ranking function is justified as follows: In neutrosophic decision-making problems, objective functions and constraints are commonly expressed in terms of neutrosophic numbers, which involve truth, indeterminacy, and falsity components. However, classical optimization and assignment models require crisp numerical values. Therefore, a ranking function is an essential tool for converting neutrosophic numbers into comparable crisp values.

In this paper, the ranking function proposed in [28] is adopted because it simultaneously considers the truth (T), indeterminacy (I), and falsity (F) degrees of a trapezoidal neutrosophic number. Unlike conventional ranking approaches that rely solely on truth membership, this function explicitly penalizes indeterminacy and falsity, leading to a more balanced and realistic evaluation of uncertain information.

Moreover, the selected ranking function preserves the geometric characteristics of trapezoidal neutrosophic numbers and produces a single representative crisp value without losing essential uncertainty information. This makes it particularly suitable for multi-criteria assignment problems, where consistent comparison among alternatives is required. Its effectiveness and computational simplicity have also been demonstrated in previous neutrosophic optimization studies, which further justifies its selection in the proposed RF-WGP framework.

3 NEUTROSOPHIC ASSIGNMENT PROBLEM

The assignment problem is a special category of transportation problem that deals with assigning tasks to machines and personnel to locations. Assignment problems are often described as applications that are used to assign "activities" to "resources" (or jobs to machines, tasks to employees, etc.) within certain constraints to keep the total cost as low as possible [29].

Also, the assignment problem is one of the fundamental challenges in operations research, since it finds the arrangement that works best [30]. In one –to-many assignment problems

The decision maker is assigning more than one activity to one resource; the resource can achieve more than one activity [31]. The One-to-Many assignment (Called Group Role Assignment) [32]. Some cases of One-to-Many assignment problems such as unbalanced assignment problem which raised when the quantity of resources doesn't match the quantity of tasks [33]. Generalized assignment problem: This problem enables the possibility of assigning multiple activities to a resource while accounting for the amount of the resource's capacity that each activity would require. Each activity in the problem will be assigned to a single resource [34].

More details for assignment problem can found in [35]-[37].

The field of industrial engineering has expanded to include multi-criteria decision-making (MCDM), which focuses on creating mathematical and computational tools to assist decision-makers in their subjective assessment of performance criteria [38], [39].

Three primary techniques are used in MCDM (pairwise comparison, outranking, and distance-based) [40]. The Analytical Hierarchy Process (AHP) and Analytic Network Process (ANP) are techniques for examples pairwise comparison [41], [42].

Examples of outranking techniques include the Preference Ranking Organization Method for Enrichment of Evaluations (PROMETHEE), which relies on comparison to determine the extent to which one alternative is preferred over another and produces a comprehensive ranking of the alternatives [43], [44].

Through the use of distance-based techniques, the best solution is determined by how close a solution is to the ideal point. Several popular distance-based methods as in [45], [46].

An approach has emerged as a significant method for addressing MCAP by allowing decision-makers to prioritize various criteria through the assignment of weights known as The Weighted Goal Programming (WGP). Recently, netrosophic assignment problem has studied and the objective of this problem is to minimize the total netrosophic cost of assigning all the jobs to the available machines (one machine per job) at the least total cost. For more details we refer to [47]-[51].

4 WEIGHTED GOAL PROGRAMMING (WGP)

Goal programming is a solution method commonly used in practice to convert a multiple objective program into a solvable single objective program. Goal programming requires that the decision maker specifies a goal for each criterion. [52].

The mathematical for preemptive goal programming is given as [52]:

$$Min\tilde{a} = \begin{Bmatrix} P_1[g_1(d_1^+, d_1^-)], P_2[g_2(d_2^+, d_2^-)], . , \\ . P_k[g_k(d_k^+, d_k^-)] \end{Bmatrix} \quad (2)$$

S.t.

$$\sum_{i=1}^{m} C_{in}X_n + d_i^- - d_i^+ = b_i \quad (3)$$

$$\sum_{i=1}^{m} C_{in}X_n \geq, =, \leq b_i \quad (4)$$

$$X_j, d_i^+, d_i^- \geq 0, \;\; n = 1,2,3, \ldots . , N. \quad (5)$$

Where, (4) represent Structural Constraints in goal programming model.

Weighted Goal Programming model consist of multiple objective simultaneously and to assign goals for each objective so that the solution to each goal is achieved. The mathematical model of a WGP is given as [53]:

$$\text{Min}\tilde{a} = \begin{Bmatrix} \text{w}_1[\text{g}_1(\text{d}_1^+, \text{d}_1^-)] + \text{w}_2[\text{g}_2(\text{d}_2^+, \text{d}_2^-)]. . \\ +\text{w}_\text{k}[\text{g}_\text{k}(\text{d}_\text{k}^+, \text{d}_\text{k}^-)] \end{Bmatrix} \quad (6)$$

S.t.

$$\sum_{i=1}^{m} C_{in}X_n + d_i^- - d_i^+ = b_i \quad (7)$$

$$\sum_{i=1}^{m} C_{in}X_n \geq, =, \leq b_i \quad (8)$$

$$X_j, d_i^+, d_i^- \geq 0, \;\; n = 1,2,3, \ldots . , N. \quad (9)$$

Where w_i represent weighted for goal.

In Weighted Goal Programming, the target value g_i epresents the aspiration level associated with the i-th objective and plays a crucial role in guiding the optimization process. In the proposed approach, the target values are determined after transforming the neutrosophic objective functions into crisp forms using the ranking function. Specifically, for each criterion, the corresponding crisp objective function is first evaluated independently under the given system constraints. The optimal or most desirable value obtained from this evaluation is then used as the target value g_i.

This procedure ensures that the targets are realistic, attainable, and consistent with the decision environment. In cases where decision makers have prior preferences or practical benchmarks, these values can also be incorporated as target levels. The deviations from these targets are minimized using weighted penalties, where the assigned weights reflect the relative importance of each goal. This allows the WGP model to handle multiple conflicting objectives simultaneously while maintaining flexibility in prioritization. Thus, the integration of ranking functions with WGP provides a coherent methodological framework: the ranking function handles neutrosophic uncertainty, while WGP manages multiple objectives through well-defined target values and priority weights.

Table 1: Example of Neutrosohpic Data of heavy engineering equipment state company.

Rolling Time			
Job	Machine 1	Machine 2	Machine 3

5 EXAMPLE

5.1 Neutrosohpic Data

To show the presented computational approach, we introduce the heavy engineering equipment State company in neutrosophic environment based on the crisp data as in [20] Where, the neutrosophic data consist of three criteria (rolling time, rolling cost, and number of rolling passes), three machines (allocation of resources) and eight job (activities) as shown in Table 1.

The weights of criteria are w_1=0.47, w_2=0.35, w_3=0.18 for rolling time, rolling cost, and number of rolling passes), respectively.

5.2 Implementation of Integrated (RF-WGP) Approach

This approach using to solving a multi-criteria and unbalanced neuromorphic assignment problem that consists of the four main steps as following:

The first step: transform all trapezoidal neutrosohic numbers in Table 1 into crisp numbers using ranking function in (1) with (0.8,0.1,0.1) confirmation degree as in Table 2, Table 3, and Table 4.

The second step: identify the criteria and its weights, where determine the weights of criteria are w_1=0.47, w_2=0.35, w_3=0.18 for rolling time, rolling cost, and number of rolling passes), respectively.

The third step: identify assign matrix that consist of rows present the activities (jobs) and columns represent allocation of resources (machines) as shown in Table 1, then formulate proposal weighted goal programming to find the optimal resource allocation when unbalanced assignment problem m > n, where the number jobs is smaller than the number of machines as following:

$$Min\ Z = \begin{Bmatrix} w_1[g_1(d_1^+, d_1^-)] + w_2[g_2(d_2^+, d_2^-)] \\ +..+w_3[g_k(d_3^+, d_3^-)] \end{Bmatrix} \quad (10)$$

S.t.

$$\sum_{i=1}^{m}\sum_{j=1}^{n} C_{ij}X_{ij} + d_i^- - d_i^+ = g_i\ for\ all\ criteria \quad (11)$$

$$\sum_{j=1}^{3} X_{ij} = 1 \ \ for\ all\ i = 1,2,\dots,m \quad (12)$$

$$\sum_{j=1}^{8} X_{ij} \geq \alpha \ \ for\ all\ j = 1,2,\dots,n \quad (13)$$

$$\sum_{i=1}^{8}\sum_{j=1}^{3} X_{ij} = \beta \quad (14)$$

$$\alpha = \left\lfloor \frac{m}{n} \right\rfloor \quad (15)$$

$$\beta = Max(m,n) \quad (16)$$

$$X_{ij}, d_i^-, d_i^+, \alpha, \beta \geq 0 \quad (17)$$

$$X_{ij} = binary\ variables(0\ or\ 1). \quad (18)$$

Where:

- g_i: represent target for criteria *i*;
- w_i: represent weighted for all criteria;
- X_{ij}:confactor for decision variables;
- C_{ij}:decision variables;
- d_i^-,d_i^+:deviational variables.

Equation (10) shows the assignment problem's objective function, assigning the activities to the resources. Equation (11) represents the criteria constraints that add to it deviation variables. Equation (12) represents the activity(job) constraints where each must be accomplished, therefore equal to one, while (13) shows the resource constraints where each resource must be assigned more than or equal to α, where $\alpha = \left\lfloor \frac{m}{n} \right\rfloor = \left\lfloor \frac{8}{3} \right\rfloor = 2$ as shown in (15). Equation (14) shows that the sum of the activities assigned to the resources that should equal to maximum (total number of activities or total number of resource), where $\beta = Max(m,n) = Max(8,3) = 8$ shown in (15). The (17) shows the non-negative constraint for variables, (18) shows the binary for decision variables.

The fourth step: solve proposal weighted goal programming and find the optimal resource allocation when number of job=8, number of machine=3, number of criteria=3, the right side for goal constraints are 117.6, 124.2, 22.8 respectively represent least sum of time, cost and iterations values for each machine, therefore the mathematical model as following:

$$Min\ Z = 0.47d_1^+ + 0.35d_2^+ + 0.18d_3^+$$

S.t.

$$33.3X_{11} + 27.9X_{12} + 26.1X_{13} + 18.3X_{21} + 15.3X_{22} + 13.5X_{23} + 12.3X_{31} + 12.3X_{32} + 11.7X_{33} + 18.3X_{41} + 17.1X_{42} + 15.3X_{43} + 8.7X_{51} + 8.7X_{52} + 8.1X_{53} + 23.1X_{61} + 20.7X_{62} + 18.3X_{63} + 23.7X_{71} + 17.7X_{72} + 15.3X_{73} + 11.1X_{81} + 9.9X_{82} + 9.3X_{83} + d_1^- - d_1^+ = 117.6$$

$$57.9X_{11} + 48.9X_{12} + 27.3X_{13} + 17.7X_{21} + 13.5X_{22} + 12.9X_{23} + 9.9X_{31} + 10.5X_{32} + 12.3X_{33} + 17.1X_{41} + 8.1X_{42} + 13.5X_{43} + 7.5X_{51} + 8.7X_{52} + 12.3X_{53} + 27.3X_{61} + 21.9X_{62} + 16.5X_{63} + 35.7X_{71} + 23.1X_{72} + 17.1X_{73} + 9.3X_{81} + 9.9X_{82} + 12.3X_{83} + d_2^- - d_2^+ = 124.2$$

$$7.5X_{11} + 2.1X_{12} + 3.3X_{13} + 3.3X_{21} + 2.7X_{22} + 2.7X_{23} + 2.7X_{31} + 2.7X_{32} + 2.7X_{33} + 3.3X_{41} + 3.3X_{42} + 2.7X_{43} + 2.7X_{51} + 2.7X_{52} + 2.7X_{53} + 3.9X_{61} + 3.3X_{62} + 2.7X_{63} + 5.1X_{71} + 3.9X_{72} + 3.3X_{73} + 2.7X_{81} + 2.7X_{82} + 2.7X_{83} + d_3^- - d_3^+ = 22.8$$

$$X_{11} + X_{12} + X_{13} = 1$$
$$X_{21} + X_{22} + X_{23} = 1$$
$$X_{31} + X_{32} + X_{33} = 1$$
$$X_{41} + X_{42} + X_{43} = 1$$
$$X_{51} + X_{52} + X_{53} = 1$$
$$X_{61} + X_{62} + X_{63} = 1$$
$$X_{71} + X_{72} + X_{73} = 1$$
$$X_{81} + X_{82} + X_{83} = 1$$

$$X_{11} + X_{21} + X_{31} + X_{41} + X_{51} + X_{61} + X_{71} + X_{81} \geq 2$$
$$X_{12} + X_{22} + X_{32} + X_{42} + X_{52} + X_{62} + X_{72} + X_{82} \geq 2$$
$$X_{13} + X_{23} + X_{33} + X_{43} + X_{53} + X_{63} + X_{73} + X_{83} \geq 2$$

$$X_{11} + X_{12} + X_{13} + X_{21} + X_{22} + X_{23} + X_{31} + X_{32} + X_{33} + X_{41} + X_{42} + X_{43} + X_{51} + X_{52} + X_{53} + X_{61} + X_{62} + X_{63} + X_{71} + X_{72} + X_{73} + X_{81} + X_{82} + X_{83} = 8$$

$$X_{ij} = binary\ variables(0\ or\ 1)$$

Solving the above model where the result as following:

$$X_{13} = X_{22} = X_{31} = X_{43} = X_{51} = X_{63} = X_{73} = X_{82} = 1$$
$$d_1^- = 0,\ d_1^+ = 3.6, d_2^- = 9, d_2^+ = 0, d_3^- = 0, d_3^+ = 0,$$
$$Z = 0.47(\ d_1^+ = 3.6) + 0.35(d_2^+ = 0) + 0.20\ (d_3^+ = 0) = 1.692$$

Table 2: Crisp values of rolling time.

Job	Machine 1	Machine 2	Machine 3
1	33.3	27.9	26.1
2	18.3	15.3	13.5

8	2.7	2.7	2.7

5.3 Results and Discussion

To ensure transparency and reproducibility, the comparison with the method in [20] is conducted using the same original problem data, identical job–machine configurations, and the same evaluation criteria (assignment time, assignment cost, and assignment iteration). This guarantees that any observed differences in results are due solely to methodological differences rather than data inconsistencies.

First, the proposed RF-WGP model is applied using trapezoidal neutrosophic numbers, and the resulting assignments and aggregated performance measures are reported in Table 5. Subsequently, for a fair comparison with [20], the same assignments are evaluated using the original crisp data, following the solution structure reported in Table 2 of reference [20]. These results are summarized in Table 6. Finally, Table 7 presents a direct side-by-side comparison between the proposed model and the method from [8].

This step-by-step comparison framework ensures that the results are reproducible and that the evaluation criteria are consistently applied across both methods.

The result shown the jobs (3 and 5) assign on machine1, jobs (2 and 5) assign on machine2 and, jobs (1,4,6 and 7) assign on machine3, can be summary assignment results as following Table 5 depend on trapezoidal neutrosophic number.

The comparison between the result for proposal model and the result reference [20], needs original data depend on the solution in Table 2 as following in Table 6.

Table 5: Summary the result for proposal model depends on trapezoidal neutrosophic number.

Machines	Jobs	Assignment Time	Assignment Cost	Assignment Iteration
Machine 1	Job3, Job5	12.3+8.7=21	9.9+7.5=17.4	2.7+2.7=5.4
Machine 2	Job2, Job8	15.3+9.9=25.2	13.5+9.9=23.4	2.7+2.7=5.4
Machine 3	Job1, Job4 Job6, Job7	26.1+15.3+18.3+15.3=75	27.3+13.5+16.5+17.1=74.4	3.3+2.7+2.7+3.3=12
Total for all criteria		117.6	124.2	22.8
Target criteria		121.2	115.2	22.8
deviational variables		+3.6	-9	0

Table 6: Summary of the result for proposal model depend on original data.

Machines	Jobs	Assignment Time	Assignment Cost	Assignment Iteration
Machine 1	Job3, Job5	20+14=34	16+12=28	4+4=8
Machine 2	Job2, Job8	25+16=41	22+16=38	4+4=8
Machine 3	Job1, Job4 Job6, Job7	43+25+30 +25=123	45+22+27 +28=122	5+4+4+5= 18
Total for all criteria		117.6	198	188
Target criteria		121.2	192	205
deviational variables		+3.6	+6	-7

The key methodological difference between the proposed approach and the method in [20] lies in the solution structure. The method in [20] follows a multi-stage process, where neutrosophic data handling, defuzzification, and optimization are treated as separate sequential steps. This separation can increase computational effort and may propagate approximation errors from one stage to the next. In contrast, the proposed RF-WGP approach operates as a single-stage integrated framework, where: Neutrosophic uncertainty is handled directly through an appropriate ranking function, and Multiple conflicting objectives are simultaneously optimized using Weighted Goal Programming.This integration allows all criteria to be considered concurrently within a unified optimization model, reducing intermediate transformations and improving computational efficiency.

Table 7: Comparison between the result for the proposal model and the result from reference [20].

The model	Total Assignment Time	Total Assignment Cost	Total Assignment Iteration
Proposal model	198	188	34
Reference [20]	207	188	36
The different between two model	9	0	2

The results shown that our proposal model is best from the result reference [20], as following Table 7. As shown in Table 7, the proposed model achieves:

A lower total assignment time compared to reference [8], The same total assignment cost, and A reduction in total assignment iterations.

These results indicate that the proposed single-stage RF-WGP method provides at least equal, and in some cases superior, performance compared to the multi-stage approach in [20]. The reduction in assignment time and iterations highlights the practical advantage of solving the problem in a single integrated stage, especially for large-scale or time-sensitive applications.

6 CONCLUSIONS

The integration of the ranking function and the weighted goal programming approach within the multi-criteria neutrosophic assignment problem framework provides a robust methodology for enhancing decision-making processes under uncertainty and indeterminacy. Also, helps the decision maker to handle the imprecise and inconstant data which are common in real world applications.

The proposed approach was tested using an example of three-criteria neutrosophic assignment problem which represents a neutrosophic extension of the data set presented in [20].

The results showed that the proposed method is more effective in reducing total assignment time and total assignment cost compared to existing approaches.

It also the neutrosophic assignment problems are solved in single stage and do not require converting the multi-criteria assignment problem into a single-criteria assignment problem. This work opens new direction for future studies which can help the decision maker to reach the optimal decision. Further work may focus on extend this research using new ranking functions, and other related real-life applications such as project scheduling, resources allocation, and supply chain management.

Keywords: Green Energy, Sustainable Growth, Renewable Sources, Investments, Environmental Sustainability, Economic Growth.

Abstract: This study is devoted to the scientific analysis of the transition to green energy and sustainable economic growth at both regional and global levels. The paper examines modern trends in targeted economic investments in the field of renewable energy sources, analyzing the dynamics of national economic growth under modernization processes and the increase in gross domestic product indicators, as well as their impact on environmental sustainability and the improvement of population living standards. The authors employed methods of correlation analysis, multivariate regression, and time series modeling to identify the key factors that shape a synergistic effect. In particular, the findings show that an increase in investments in renewable energy sources by 1 billion USD contributes to GDP growth of approximately 0.05–0.07%, while the expansion of green technologies in the energy sector leads to a significant reduction in greenhouse gas emissions and overall environmental improvement. The analysis further reveals that regional differences are determined by the level of infrastructural development, as well as state and private sector support, which ensures technological progress in the process of transitioning to green energy. The study emphasizes that effective government support and successful international cooperation are crucial factors for the large-scale adoption of green technologies and the achievement of sustainable development goals. The conclusions highlight the necessity of a comprehensive approach, based on in-depth scientific research, to the formulation of national strategies that stimulate investment, foster innovation, and ensure environmental security. The research makes an independent contribution to the development of theory and practice in ecologically oriented sustainable economic development in developing countries.

1 INTRODUCTION

In the era of globalization, the transition of national economies to sustainable, renewable energy sources has become an important aspect of applied scientific research. The depletion and decline of fossil resources, alongside the sharp increase in environmental pollution in various regions of the world, are closely linked with climate change processes. In this context, the shift to green energy acquires strategic importance for ensuring the long-term stability and development of the global economy [1]. It should be emphasized that there exists an inseparable relationship between environmental sustainability and the economic growth of national economies, making the problem of deeply integrating green technologies into national and global strategies particularly relevant [2].

Scientific research in the fields of ecology and sustainable economic development demonstrates that the transition to green energy reduces greenhouse gas emissions, stimulates innovation, and attracts foreign investments in the agricultural sector, industry, and construction of next-generation enterprises. Broad inflows of foreign investment into a country contribute to the creation of new jobs and the stable development of new economic sectors, including the establishment of joint ventures in developing countries [3]. At the same time, numerous debates exist on how the green transition affects the economic growth indicators of national economies, particularly within the framework of national strategies and modernization levels of developing countries.

The methodological foundation of this research is based on the concepts of synergetics, environmental security, stability, and sustainable economic development. The synergetic approach assumes that the close interconnection between the transition to green energy and sustainable economic growth generates an effect greater than the sum of their individual impacts [4]. Within this scientific paradigm, the development and integration of socio-economic structures of green technologies are considered drivers of innovative growth, capable of harmonizing environmental regulation and achieving economic objectives.

Sustainable economic development aims to meet the needs of the population without compromising the ability of future generations [5], [6]. In the context of ensuring energy stability, the integration of ecological, economic, and social aspects becomes increasingly important, requiring a comprehensive analysis of global trends and national strategies.

The connection between the development of renewable energy and sustainable economic growth has become a major subject of global research in recent decades. A plethora of research insists on the importance of green technologies as crucial in national energy systems for economic diversification, industrial modernization, and long-term environmental sustainability. For example, based on [3] renewable energy investment are them important driver of productivity improvement and leading to new high-technology sectors growth; while [7] stress the heterogeneity in these effects among emerging economies. This overall trend is supported by the global literature, which demonstrates that the shift towards green energy brings about direct and indirect positive impacts in terms of higher levels of employment, better security of supply when it comes to energy sources, and lower production costs in the long term.

1.1 Literature Review

International academic literature has paid great attention to the pattern of correlation between green energy transition and sustainable economic growth. Current literature highlights that renewable energies development creates a multidimensional impact on economic, environmental and social subsystems. So also, the move to Renewable Energy and Investments was identified by [3] as a longterm economic benefit achieved through stimulation of investments in new industries, improvement on technological innovations and increased in productivity. Their worldwide analysis showed that economies powering up with green energy grow faster than those relying on dirty energy.

For developing countries, a relevant but varying relation between RE growth and GDP increases was observed for emerging economies by [7]. They contend that the extent of economic impact is largely dependent on structural factors – infrastructure preparedness, quality of governance and access to international finance. Liu et al. [8] also emphasize that renewable energy development is stimulated in BRICS countries based on the rationale of ensuring energy security, environmental quality and industrial diversification, while some institutional and financial barriers restrict their potential.

Many studies emphasize the technological and environmental dimensions of the green energy transition. For instance, Amari et al. [9] demonstrate that advanced photocatalytic materials can significantly improve the efficiency of hydrogen production while simultaneously contributing to environmental purification processes. These findings highlight the potential of innovative materials in supporting low-carbon energy systems.

In addition, recent works focus on the development and optimization of renewable energy systems. Zikrillayev et al. [10] investigate the modeling of autonomous solar power systems, showing their applicability for decentralized energy supply. Similarly, Yuldoshov et al. [11] analyze the influence of temperature on photovoltaic module performance, emphasizing the importance of environmental conditions for system efficiency. Furthermore, Saitov et al. [12] propose methodologies for the calculation and optimization of solar energy conversion, contributing to improved design and operation of photovoltaic systems.

At the same time, the literature indicates several technical and implementation challenges. The performance of renewable energy technologies depends on environmental factors, system configuration, and efficiency of energy conversion processes. These limitations highlight the need for further research in system optimization, modeling, and integration of renewable energy technologies into practical applications. On the whole, there is compelling evidence in the scientific literature that renewable energy expansion can make a critical contribution to sustainable development and create synergetic effects for governments via integrated policies, good governance and continuing technological improvement. This work develops the existing literature and advances it by performing a global comparative analysis complemented with regression models in order to bring out key drivers of the economic impact of the green transition.

1.2 Research Gap and Objectives

In the process of modernizing the national economies of developing countries, there has been a significant increase in foreign investments in renewable energy. Global investments in renewable energy reached a record of 500 billion USD in 2022, which is 20% higher compared to the previous year [6], (Fig. 6). The main drivers of this growth are the decreasing costs of solar and wind technologies and the growing influence of international climate agreements (Table 1).

Despite the plethora of studies analyzing the economic and environmental consequences of the green transition, most existing research is limited to individual regions or specific technological options. There is still relatively little cross-country comparison work that systematically combines these investment dynamics, renewable energy penetration, economic growth signals, and environmental outcomes. Furthermore, several existing studies are based on limited-scope datasets or only short-term observations, which might not be long enough to capture long-term synergetic effects. Thus, the lack of a complete global study, including statistical modelling, correlation analysis, and comparative evaluation, is a significant research gap. This study aims to fill this void by providing a comprehensive empirical analysis of large economies and emerging market regions.

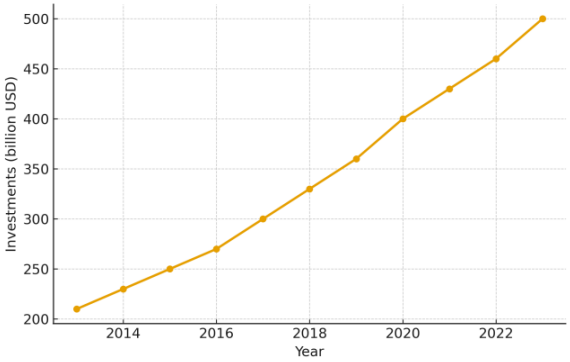

Figure 1: Global investments in renewable energy sources (2013–2023) [6].

Table 1: Main indicators of green technology development by country (2022) [6].

Country	Investment Volume (billion USD)	Share of Renewables in Energy Balance (%)	Number of New Renewable Projects
China	120	45	1500
USA	90	25	800
Germany	70	35	950
India	50	20	1200
Brazil	30	40	600

Comprehensive scientific studies confirm that the implementation of green technologies can have both stimulating and constraining effects on the economic growth of national economies. On the one hand, green energy fosters the creation of new markets, enhances energy efficiency, and reduces costs, which leads to GDP growth [7]. On the other hand, initial investments and structural transformations in the energy sector may result in temporary bottlenecks and slowdowns in growth.

Currently, different perspectives are presented in scientific literature. Research indicates [8], [9] that in countries with a high level of green technology development, there is a positive correlation between the green transition and GDP growth. At the same time, in developing countries with weak infrastructure and limited capital, the effect may be less pronounced or even negative [10], (Fig. 2).

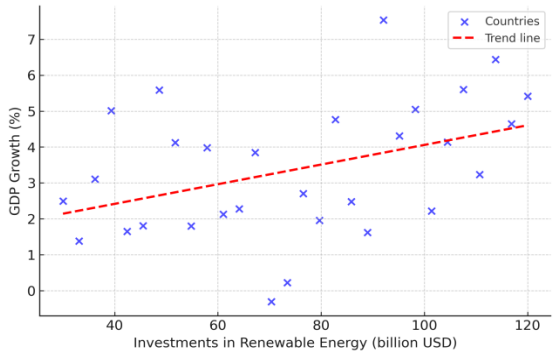

Figure 2: Correlation between investments in green energy and GDP growth across countries [7].

Such findings are consistent with theoretical postulations emanating from synergetics and sustainable development, which propose that interacting economic and environmental systems can produce the emergence of effects that are greater than their individual parts. As demonstrated by Liu et al. [8] From the preceding analysis, bringing in green technology will increase system stability and lower ecological risk and social economic restructuring. These findings provide the theoretical underpinning of the present paper, which argues that economic transformation toward renewable energy should be conceptualized not only as an eco-technological change but also – and foremost – as integral long-term development towards sustainability.

Despite positive trends, the transition to green energy faces several challenges. Foremost among them are the need for large-scale investments, systematic infrastructure upgrades, energy storage solutions, and integration of renewable sources into existing energy systems [11]. In addition, geopolitical issues related to conflicting economic interests and the use of natural resources in developing countries remain important.

Social aspects must also be considered, such as the potential emergence of energy inequality, the level of professional training of engineering personnel, and public perception of new technologies.

Future prospects are closely associated with the adoption of innovative technologies, digitalization of the energy complex, and closer international cooperation. Within the framework of the United Nations Sustainable Development Goals (SDG 7 and SDG 13), the transition to green energy is regarded as a strategic tool for achieving global targets [12].

The main objective of this study is to identify and analyze the synergetic mechanisms of interaction between the transition to green energy and sustainable economic growth at the global level. The following tasks are set within the framework of the research:

- Analyze key trends and dynamics in the growth of green technologies.
- Determine the impact of the green transition on sustainable economic development indicators.
- Compare the experiences of leading developed countries and identify the most effective strategies.
- Develop recommendations for optimizing the interaction between environmental security and sustainable economic stability.

To achieve these objectives, methods of comparative analysis, statistical modeling, and a systems approach were employed. Sources included reports and databases of international organizations, scientific articles, monographs, and analytical materials published in leading academic journals.

This research is relevant in the context of global efforts to ensure environmental security and economic sustainability. The study demonstrates that the transition to green energy is not only a factor of environmental protection but also a significant driver of economic development, possessing substantial potential for synergetic interaction. The authors conducted an in-depth empirical analysis as well as a comparative study of national strategies and their impacts on economic growth.

2 MATERIALS AND METHODS

2.1 General Provisions

This study is based on a comprehensive approach that combines qualitative and quantitative analyses, comparative analysis, and modeling. The main objective is to identify and systematize the mechanisms of interaction between the transition to green energy and economic growth at the global level. For this purpose, modern statistical methods, data analysis, regression modeling, and visualization of results in the form of tables and graphs were employed.

The object of the study is the indicators of green technology development and the dynamics of economic growth in leading countries over the past 15 years (2008–2023). The sources of data include international organizations (International Energy Agency, World Bank, United Nations), national

reports, scientific publications, analytical reviews, and statistical yearbooks [13].

2.2 Data Sources and Their Characteristics

The following main data sources were used for the analysis:

- International Energy Agency – data on global investments in renewable energy sources, volumes of renewable energy production, and the level of penetration of green technologies in the energy sector [1].
- World Bank – macroeconomic indicators, gross domestic product, development indexes, and investment statistics [5].
- United Nations – reports on Sustainable Development Goals, indicators of environmental safety and social development [2].
- National statistical services – country-specific data (China, USA, Germany, India, Brazil, etc.).

To ensure representativeness and statistical reliability, aggregated data by countries and regions, as well as dynamic time series by years, were used.

2.3 Methods of Statistical Analysis

2.3.1 Descriptive Statistics

At the initial stage, descriptive statistics were conducted on key indicators – investments in green energy, gross domestic product, the share of renewable sources in the energy balance, and the number of new projects (see Table 2). This made it possible to determine major trends, detect outliers and anomalies, and prepare the data for further modeling.

Table 2 Summary statistics of core macro-energy indicators for 2022 Descriptive Statistics for Core Macro-Energy Indicators_1 shows the descriptive statistics of the core tableau depicting LCOE, renewable capacity factor, and energy demand in the examined countries in 2030. LSM as land suitability maps. That on renewable energy (AVERAGE, = USD 75 billion) recurrently varies considerably (SD = 30), indicative of uneven financial commitment across the state. The contribution of renewables to the national energy balance varies between 20% and 45%, with an average share value of 32%, that is, demonstrating a moderate increase in the integration of alternative energy sources. GDP growth demonstrates relatively constant performance (mean = 3.2%), although the variability (0.5%–6.7%) suggests differences in economic adaptability. However, the number of new renewable energy projects that are newly developed is particularly varied, with a mean of 950 projects per year (SD = 400) and ranging from 600 to 1,500 in different areas, indicating the diverse institutional capacity and investment environment within the regions.

Figure 3 presents the geographical distribution of investment in renewable energy in 2022, which shows marked differences between world regions. The largest proportion of that is in Asia, where $180 billion has already been spent on deploying solar, wind, and hydrogen technologies at a rapid pace. Europe comes in second with USD 120 billion, largely due to significant policy inducements resulting from the EU's Green Deal. America tracks USD 100 billion, showing slow but relatively sluggish growth, and Africa has the smallest level of investment at USD 40 billion, with continued financial and infrastructural challenges. The visual comparison highlights that the distribution of financial support for renewable energy is not evenly spread across the globe and suggests a case for targeted incentives in under-supported areas.

Table 2: Descriptive statistics of key indicators (2022) [1].

Indicator	Mean Value	Standard Deviation	Minimum	Maximum
Investments in renewable energy (billion USD)	75	30	30	120
Share of renewables in energy balance (%)	32	8	20	45
GDP growth (%)	3.2	1.4	0.5	6.7
Number of new renewable projects	950	400	600	1500

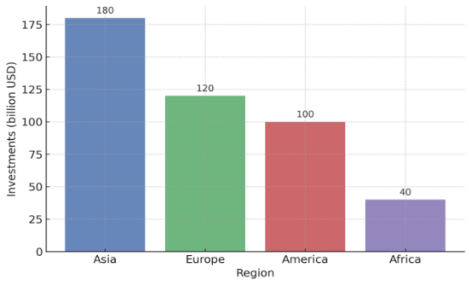

Figure 3: Distribution of renewable energy investments by regions in 2022 [1].

2.3.2 Correlation Analysis

To determine the relationships between variables, Pearson's correlation coefficient was applied. In particular, the relationships between investments in green energy and GDP growth, the level of renewable energy penetration, and development indexes were analyzed.

Table 3: Correlation coefficients between key variables [2].

Variables	Correlation Coefficient
Investments in renewables and GDP growth	0.75
Share of renewables and environmental efficiency index	0.68
Number of projects and investments	0.83

Table 3 Correlation coefficients of key variables in the renewable energy sector There are strong and statistically significant associations among the key variables. Renewable energy investments show a strong positive correlation with GDP growth (0.75), indicating that greater financial commitment to clean energy is significantly related to a higher level of economic performance. The contribution of renewables to the energy mix is also significantly positively correlated with the environmental efficiency index (r = 0.68), suggesting that increasing renewable penetration results in improved ecosystem outcomes. The highest association is with the number of renewable energy projects and total investment (r = 0.83), indicating that the amount of capital available dictates how much project deployment will increase.

2.3.3 Multiple Regression Analysis

To quantitatively assess the influence of factors on GDP growth, a multiple regression model was constructed of the following form:

$$GDP\ Growth_i = \beta_0 + \beta_1 \times Investments_i + \beta_2 \times Share\ of\ renewables_i + \beta_3 \times Number\ of\ projects_i + \varepsilon_i,$$

where i represents a country or region.

The model was estimated using the least squares method, with verification of the statistical significance of coefficients and residual analysis. Evaluation criteria included R-squared, F-test, and p-values.

2.3.4 Time Series Analysis and Trend Modeling

To study the dynamics of green technology development, time series analysis was applied. Trend and seasonality models were built using exponential smoothing and ARIMA models [13].

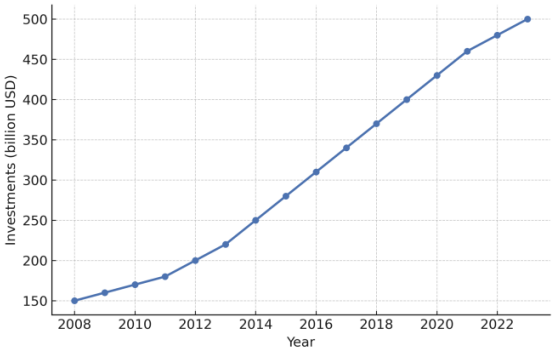

Figure 4: Trend of renewable energy investments (2008–2023).

As shown in Figure 4, global investments in renewables followed a consistent upward path during this period. Global investment increased from a little under USD 150 billion in 2008 to almost USD 500 billion by 2023, with rapid growth in solar, wind, and other green technologies. Arguably, the most notable acceleration took place post-2014 when climate policies were reinforced, technology costs fell further, and the private sector became more involved. The continued increase in investment levels demonstrates increasing global dedication to the clean energy transition and expansion of renewable infrastructure around the world.

2.4 Data Visualization and Modeling

A scatter plot (see Fig. 1) demonstrated a strong positive correlation, confirming the hypothesis of a synergetic effect.

A sensitivity analysis of the regression model to input parameter variations was conducted.

Table 4: Sensitivity analysis of the regression model.

Input Factor	Impact on Model (%)	p-value
Investments in renewables	45	<0.01
Share of renewables	30	0.02
Number of projects	25	0.05

Table 4 Sensitivity analysis for the regression model: relative importance of selected key input factors in terms of their impact on the model's explanatory power. Investments in renewable energy stand out as the most influential variable, representing 45% of the model's variability, with a significance p-value (<0.01) that suggests strong prediction relevance. The proportion of renewables accounts for 30% and is statistically significant (p = 0.02), suggesting its importance in shaping the total performance results. The percentage of renewable-energy projects constitutes the gap with a marginally significant p-value (0.05), indicating that it is a moderate from 25 percent to still significantly influencing on the other hand. In summary, the sensitivity analysis highlights that investment amounts are the primary determinant of the modelled relationships, while renewable-share and count help to explain some of the residual variance.

2.5 Reliability and Validity Assessment Methodology

To evaluate the reliability and robustness of the models, standard statistical criteria were applied: confidence intervals, variance inflation factor (VIF) tests for multicollinearity, residual analysis, and cross-validation.

The results demonstrated high statistical significance and explanatory power of the model ($R^2 = 0.78$), confirming its adequacy.

2.6 Additional Methods and Tools

The study employed modern software tools such as SPSS, R, Python (pandas, statsmodels, matplotlib), Excel, and Power BI for visualization. Special attention was paid to data validation, detection of outliers and missing values, as well as the standardization of variables to ensure comparability.

This section provides a detailed description of the methods used to analyze the relationship between the transition to green energy and economic growth at the global level. The applied statistical tools and models allowed the identification of significant relationships, the determination of key factors influencing the development dynamics of green technologies, and the evaluation of the effectiveness of various strategies. The following sections of the study will be devoted to interpreting the obtained results, identifying regularities, and formulating recommendations for government institutions and the business community.

3 RESULTS OF THE RESEARCH

This section presents the main empirical findings obtained from the analysis of the relationship between the transition to green energy and economic growth at the global level. Based on statistical models, correlation analysis, regression studies, and time series, key patterns were identified that confirm the existence of synergetic effects in this area.

First, the dynamics of investments in renewable energy, their influence on economic development indicators, and comparative analysis by regions and countries are considered. Particular attention is paid to the identification of factors most significant for stimulating sustainable growth during the green energy transition.

3.1 General Dynamics of Investments in Renewable Energy and Their Impact on Economic Growth

On the global scale, there has been steady growth in investments in renewable energy, confirmed by the data in Table 5. In 2022, global investments in renewable energy reached a record 520 billion USD, 22% more compared to 2021 and three times higher than in 2010 [1].

Table 5: Global investments in renewable energy and penetration levels, 2010–2022 [1].

Year	Investments (billion USD)	Share of Renewables in Energy Balance (%)	Number of New Projects	Total Installed Capacity (GW)
2010	180	20	1200	150
2012	240	23	1400	200
2015	350	28	1800	300
2018	430	30	2200	400
2020	480	32	2500	470
2022	520	35	2800	550

Table 5 presents a longitudinal overview of global renewable energy development from 2010 to 2022, highlighting consistent growth across key indicators, including investment volumes, the share

of renewables in the energy mix, project deployment, and installed capacity. Over this period, investment increased substantially, reflecting the intensification of financial support for the clean energy transition. At the same time, the share of renewable energy expanded, indicating a gradual structural transformation of the global energy system. The number of implemented projects and total installed capacity also grew significantly, confirming the large-scale expansion of renewable energy technologies worldwide. These trends suggest that the development of the sector is driven by a combination of policy support, technological progress, and increasing market demand.

Figure 5 illustrates the dynamics of investments and installed capacity, revealing a clear upward trend and a close relationship between these indicators. The parallel growth of financial inputs and capacity expansion suggests that capital inflows directly contribute to the large-scale deployment of renewable energy technologies. This pattern reflects the increasing maturity of the sector and the strengthening role of renewables in the global energy market.

The results of the multiple regression analysis further confirm the existence of a statistically significant positive relationship between investments in renewable energy and GDP growth across countries and regions (Fig. 6). This finding indicates that increased investment activity in the renewable energy sector is associated with measurable economic effects, supporting the role of green energy as a factor of economic development.

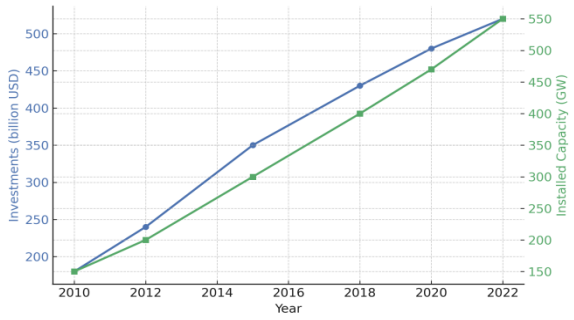

Figure 5: Dynamics of Renewable Energy investments and installed capacity (2010–2022) [1].

The regression results of the effect of investment in renewable energy on GDP growth in different regions are presented in Table 6. The results indicate that Asia demonstrates the largest association with $\beta = 0.065$ and a significantly high p-value (< 0.01) along with a very strong fit ($R^2 = 0.72$), suggesting that investment in renewables is a key driver of economic growth on the continent.

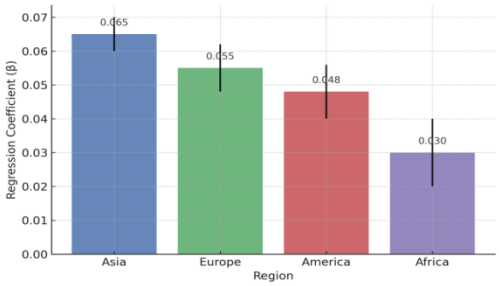

Figure 6: Impact of renewable energy investments on GDP growth by regions (regression analysis, 2022).

Table 6: Regression coefficients of the impact of Renewable Energy investments on GDP by regions [2].

Region	Coefficient β	p-value	R^2 of Model
Asia	0.065	<0.01	0.72
Europe	0.055	<0.05	0.68
America	0.048	<0.05	0.65
Africa	0.030	0.08	0.50

Europe and America demonstrate moderate effects ($\beta \approx 0.055$ and $\beta = 0.048$), which remain statistically significant, with R^2 values ranging from 0.65 to 0.68, indicating a consistent but regionally differentiated economic response. Africa exhibited the lowest correlation ($\beta = 0.030$) with an insignificant p-value of 0.08 and a weaker model fit ($R^2 = 0.50$), suggesting that structural constraints and low investment capability might dampen the economic effect of renewable energy outlay. Overall, the estimation results suggest that investment in renewable energy significantly promotes growth, but its impact differs by regional economic structure and institutional preparedness.

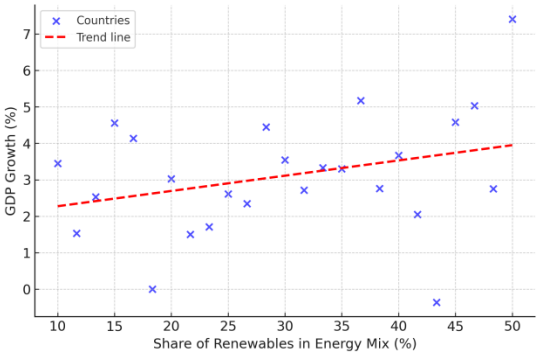

Figure 7: Correlation between the share of renewables in the energy mix and GDP growth by countries (2022).

The analysis revealed that an increase in the share of renewable energy in the overall energy balance contributes to GDP growth, especially in countries with high technological maturity (Fig. 7).

The correlation coefficient of 0.68 confirms the importance of increasing the share of green energy for stimulating economic growth.

3.2 Changes in Environmental Indicators

The analysis showed that increasing investments in renewable energy contributes to reductions in air pollution and greenhouse gas emissions.

Table 7: Environmental indicators and renewable energy investments (2010–2022) .

Year	Invest-ments (billion USD)	CO_2 Emissions (million tons)	Air Pollution Index	Domestic Emissions (%)
2010	180	36,000	78	–
2012	240	33,500	72	-3.4%
2015	350	29,000	65	-4.7%
2018	430	26,500	60	-4.6%
2020	480	24,000	55	-4.4%
2022	520	21,500	50	-4.2%

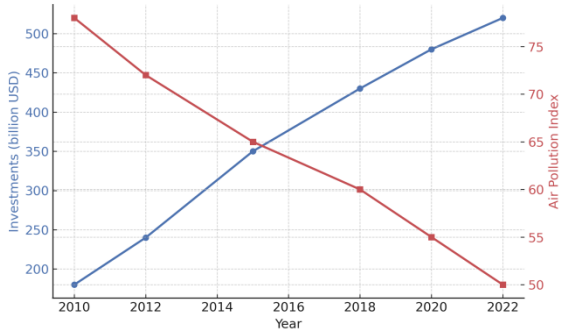

Figure 8: Relationship between investments and air pollution levels (2010–2022).

Table 7 depicts the movements of major environmental indicators with respect to renewable energy investments over the years 2010-2022. Figure 8 provide a very instructive negative correlation: investments in renewable energy have continuously increased from USD 180 billion (2010) to USD 520 billion (2022), while CO_2 emissions have constantly fallen from 36,000 million tons to 21,500 million tons. An Air Pollution Index of 78-50 was observed during the same period, signifying a remarkable improvement in air quality. Furthermore, domestic emissions rates amount to steady negative figures (from –3.4% to –4.7%), which means that national greenhouse gas production decreases gradually. "Overall, it illustrates the positive environmental impact that greater investment in renewable energy could have, and the headway we are making for clean air."

The results indicate a strong inverse relationship: the higher the investment in renewables, the lower the pollution level.

3.3 Impact of Green Technologies on Quality of Life

Sociological and environmental indices demonstrated that an increasing share of renewable energy improves quality of life by reducing morbidity rates and contributing to ecological security.

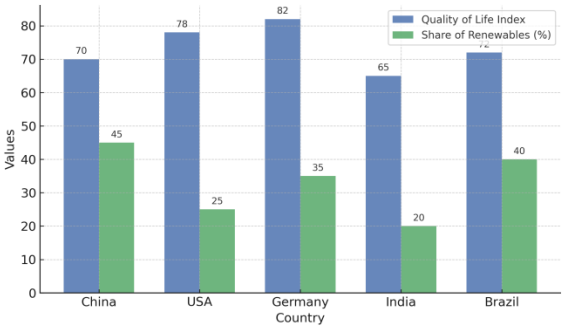

Figure 9: Quality of life index and the share of renewables in the energy mix by countries (2022) [2].

The quality of life index and share of renewables in the national energy mix up to 2022 are provided for five countries in Figure 9. Germany has the highest quality of life score (82) and a very strong renewable energy share (35%), which emphasizes its progressive sustainability laws. The USA and China exhibit similar high quality of life values (78 and 70, respectively) but very different shares of renewables – 25% in the USA versus 45% in China – suggesting differing national energy transition approaches. Brazil: Brazil has a moderate quality of life (75) and a large share of renewables (40%), an indicator of the high significance of hydroelectric power for Brazil for several decades. India comes up at the bottom, with a PpL of 65 and 20% renewables, illustrating how difficult it can be to juggle social and economic development as well as cleaner energy uptake. On the whole, the picture shows a general pattern: "The higher the renewable penetration levels, the better they are doing in terms of environmental and social dimensions," which feeds positively into quality-of-life indicators.

Table 8: Main indicators for leading countries (2022) [1].

Country	Investments (billion USD)	Share of Renewables (%)	Installed Capacity (GW)	GDP Growth (%)
China	120	45	950	4.0
USA	90	25	620	2.3
Germany	70	35	580	1.8

3.4 Regional Specificities and Comparative Analysis

Key indicators for leading countries in the field of green energy are presented in Table 8. China, the USA, and Germany demonstrate the most significant progress in investments and technology deployment.

The main RE and economic indicators are shown in Table 8 for a comparison of the three advanced countries in 2022. China is the best performer on aggregate (the highest renewable energy investment of USD 120 billion, the largest percentage of renewables in its total primary and final energy consumption – with 45%, as well as installed renewable power capacity: 950 GWs) next to sustained GDP growth (4.0%). The US comes next with USD 90 billion, and renewables at 25%, but where installed capacity (620 GW) is high and economic growth is moderate at 2.3%. Germany has a high level of technology development with 35% renewables and 580 GW installed capacity, but lower GDP growth (1.8%), indicating that its economy is mature with slower growth. Overall, the table illustrates how variable the levels of renewable investment, scale of deployment, and economic results are across countries, with China being the global leader in green energy expansion.

India and Brazil demonstrate rapid growth in investments and renewable energy deployment despite less developed infrastructure.

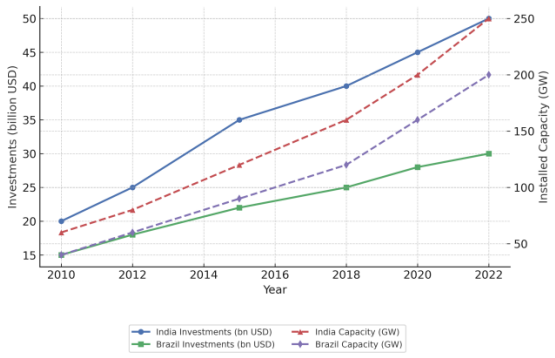

Figure 10: Growth of renewable energy investments and deployment in India and Brazil (2010–2022).

Figure 10 depicts the long-term development of RE investments and capacity in India's RE systems compared to Brazil 's from 2010 to 2022. Both countries exhibit an upward trend, with India performing far better than Brazil in nearly all respects. India's renewable investments grew from 18$ bn in around 2010 to about 50$ bn by 2022, with a consequent increase in installed capacity from 60 GW to 250GW. In Brazil, positive but moderated growth is also evident as capacity increases to 150 GW from 40 GW, and investments double ($15 billion to $30 billion). The relative steepness of the lines distinguishes India's greater efforts at policy commitment, market size, and renewable energy expansion rates. Overall, the figure verifies that the deployment of renewables has accelerated rapidly in both economies and reveals India's superior position regarding investment value and capacity addition.

4 DISCUSSION

This section interprets the results, highlights their significance, and discusses implications for the theory and practice of transitioning to green energy and sustainable development. The analysis confirms a mutually reinforcing relationship between investments in renewable energy and economic growth, revealing the mechanisms of this interaction at the global level. Findings are compared with existing studies, limitations are acknowledged, and directions for further research are proposed.

4.1 Interpretation of Results

The study identifies a strong positive relationship between investments in renewable energy and economic growth (see Fig. 11, Table 6). This indicates that green investments function not only as an environmental instrument but also as a driver of macroeconomic development.

Beyond direct financial returns, renewable energy investments stimulate innovation, enhance energy efficiency, and foster structural improvements in the economy. These outcomes align with previous research [5], which shows that

countries prioritizing green technologies achieve more stable and sustainable economic performance.

The effectiveness of these investments varies across regions. Economies with developed infrastructure, advanced technological capabilities, and supportive regulatory frameworks generally experience higher returns, emphasizing the role of institutional and structural factors in maximizing the benefits of the energy transition.

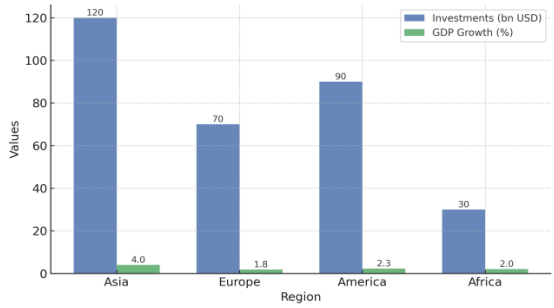

Figure 11: Impact of renewable energy investments on GDP growth by regions (2022) [2].

4.2 Environmental and Economic Implications

Environmental analysis demonstrates that increased investments and higher shares of renewables significantly reduce greenhouse gas emissions (see Fig. 12, Table 7). This supports the contribution of green energy transition to the objectives of the Paris Climate Agreement.

The reduction of CO_2 emissions is closely linked to the growth of renewable energy investments, with the pace of reduction increasing as the share of renewables expands. Technological innovations, improved energy efficiency, and modern energy storage systems drive this effect.

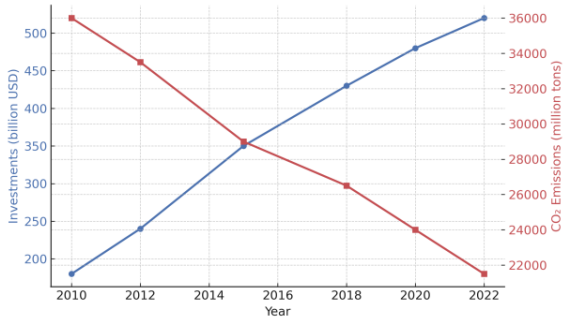

Figure 12: Relationship between investments and CO_2 emissions reduction (2010–2022).

Countries with higher levels of investment achieve greater environmental efficiency, improving quality of life, reducing morbidity, creating jobs, and enhancing ecological conditions.

4.3 Regional Differences

The impact of renewable energy investments varies significantly by region. Asia and Europe show the most pronounced economic and environmental benefits, driven by high investment volumes, developed infrastructure, and supportive institutions (Table 9).

Table 9: Regional differences in the effectiveness of green investments (2022) [1].

Region	Average Investment Activity (billion USD)	Average GDP Growth (%)	Share of Renewables (%)	Pollution Index
Asia	120	4.0	45	50
Europe	70	1.8	35	55
America	90	2.3	25	60
Africa	30	2.0	10	70

In regions with lower investment levels, such as parts of Africa and Latin America, the benefits are less pronounced due to limited technological capabilities, unstable conditions, and insufficient financing. This underlines the importance of tailored regional strategies.

4.4 Limitations

Several limitations were identified. Investments may not yield expected outcomes where infrastructure is weak, regulatory incentives are absent, or technological maturity is insufficient.

In underdeveloped regions, substantial investments may have limited effects on economic growth and environmental sustainability (see Fig. 13), highlighting the need for comprehensive strategies that include infrastructure development, workforce training, and government support.

Social and economic risks, such as potential energy price increases and emerging energy inequalities, also exist. Additionally, the econometric models employed may face constraints like multicollinearity, residual autocorrelation, and other statistical challenges.

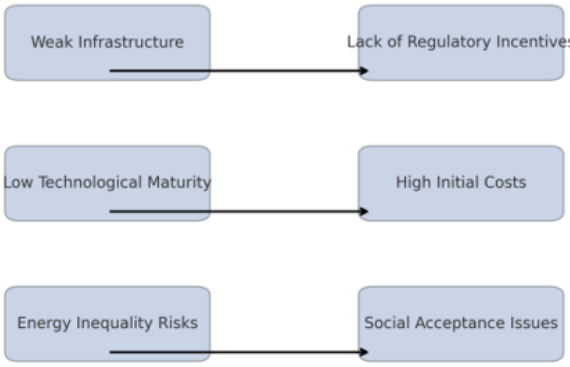

Figure 13: Constraints and barriers to the implementation of green technologies (schematic).

4.5 Policy and Institutional Factors

Government support and regulatory frameworks are critical to investment effectiveness. Favorable legal environments correlate with higher investment efficiency and faster growth in the share of renewables (see Fig. 14).

State programs, subsidies, and tax incentives play a significant role in accelerating the adoption of renewable energy technologies.

Figure 14: Relationship between levels of government support and renewable energy implementation (2022).

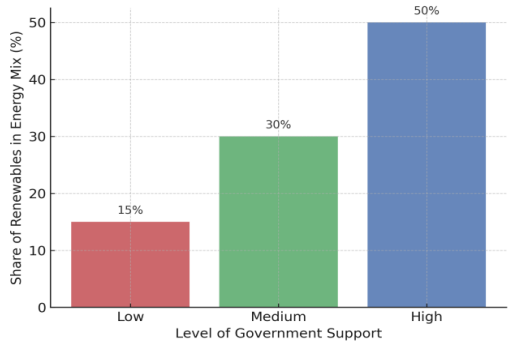

Figure 14: Relationship between levels of government support and the implementation of renewable energy (2022).

5 CONCLUSIONS

The study confirms a positive relationship between renewable energy investments and economic growth globally. Increased financial support for green energy contributes both to environmental sustainability and measurable economic benefits.

Higher investment levels are linked to steady GDP growth and reduced greenhouse gas emissions, demonstrating a mutually reinforcing effect where economic development and environmental improvement occur simultaneously.

Significant regional differences are evident. Advanced technological infrastructure, strong institutions, and active government support enhance outcomes, while limited investment capacity and weaker infrastructure reduce efficiency.

Effectiveness depends on regulatory conditions, technological readiness, and financial availability. Econometric analyses may also face standard statistical limitations.

Overall, the transition to green energy is a key driver of sustainable development, combining economic growth with environmental protection. Continued investment, policy support, and international collaboration are essential for an effective energy transition.

6 FURTHER RESEARCH

Limitations include:

- Limited data availability for some countries
- Potential distortions between investment volumes and economic effects
- Regression models may not capture nonlinear and complex interactions

Future research directions:

- Develop multidimensional models incorporating social, economic, and technological factors
- Analyze long-term prospects of renewable energy transition
- Study the impact of innovative technologies on synergetic processes
- Explore international cooperation and global initiatives

The study highlights the importance of green energy investments for sustainable economic growth and environmental security. Regional differences and limitations require tailored strategies, active policy support, and international collaboration to ensure large-scale adoption of green technologies.

Keywords: Green Energy, Renewable Energy Sources, Energy Transition, National Strategies, Investments, Scenario Modeling, Technological Innovation, International Cooperation.

Abstract: This paper analyses national policies for the move towards green energy, considering global tendencies, investment dynamics, and socio-economic policy instruments in place between 2013 and 2024. This study further investigates the main drivers of growing renewable energy generation, investment amount, tariff systems and policies, tax-justice policies, subsidies, technological innovation, and international inter-investment. The study uses statistics from international and national organizations, regression analysis, comparative analysis, and scenario forecasting methods to determine the most effective measures for promoting green energy transition. The findings demonstrate that countries succeed in implementing renewable energy if they combine economic tools, of which the annual investment amounting to over 500 BN USD takes a significant share. Not only does technological advances, especially the decrease in the cost of solar and wind technologies, considerably enhance the competitiveness of renewable systems. In addition, upgraded infrastructure and regulatory mechanisms contribute to long-term sustainability. Analytical tables and charts in the article show investment directions, modeling results, and projection contents for major global areas. The study offers, at best estimation, a theoretical and integrated approach to the literature that combines investment patterns, policy tools, and scenario types into a single analytical frame for evaluating national green policy strategies. By analyzing the systemic connections between financial flows, policy instruments, and renewable energy development, we build on previous research and address methodological blind spots in comparative strategy investigations. In practical terms, these results provide evidence-based advice to governments, policymakers, and investors. The findings could contribute to improving national policies, strengthening tariff and subsidy structures, and better informing public and private investments. These findings can inform how countries can enhance energy security, reduce emissions more quickly, and stay on track with their long-term climate goals. The report argues that the development of international relations and further investment in new technologies are crucial for achieving a secure transition to green energy.

1 INTRODUCTION

In the context of global climate change, freshwater scarcity, the necessity for rational use of natural resources, and persistent air pollution, the transition to sustainable energy has become one of the most urgent priorities. National strategies for the development of green energy play a critical role in this process, encompassing a wide range of economic and environmental measures aimed at reducing dependence on fossil fuels, increasing the share of renewable energy sources (RES) in the energy balance, and creating favorable conditions for

environmentally sound and sustainable economic development. Within the framework of the global agenda – such as the Paris Agreement and the United Nations Sustainable Development Goals (SDGs) – countries are developing and implementing their own strategies for transitioning to green energy, providing a rich foundation for comparative studies and for analyzing the effectiveness of modernization strategies for national economies under conditions of globalization [11].

1.1 Relevance of the Research

Amid globalization, investments in the renewable energy sector have grown significantly, driven both by environmental requirements and by the need to address acute socio-economic challenges in individual countries. According to the International Energy Agency, the share of renewables in the global energy balance reached 29% in 2023, up 4% compared to 2018 [2]. This growth is driven by technological progress, falling costs of renewable technologies, and proactive national and international government initiatives.

However, approaches to implementing green energy strategies vary considerably across countries, influenced by factors such as the level of economic development, institutional and business support, natural resource potential, and international commitments. Consequently, a comparative analysis of the goals, content, and mechanisms of national strategies makes it possible to identify best practices, evaluate key socio-economic instruments, and determine which innovative measures are most effective for accelerating the transition to sustainable energy [3].

The scientific interest in studying green energy strategies arises from the necessity of a systematic analysis of existing approaches and the development of recommendations for their improvement. This study applies comparative analysis, statistical modeling, policy instrument assessment, and efficiency evaluation. The research is based on the collection and processing of data published by international organizations, government bodies, academic publications, and analytical reports.

Graphs and tables are employed to illustrate changes in the energy balance structure across countries, as well as the effectiveness of existing strategies. Particular attention is paid to countries with different levels of socio-economic development, geographic conditions, and resource availability, which allows the identification of success factors and potential barriers.

1.2 Literature Review

There is vast empirical literature on the endogenous change in national energy systems and the factors driving renewable expansion. Early work by Eze et al. [3] highlighted the powerful influence of policy frameworks, such as feed-in tariffs and long-term regulatory assurances, in accelerating the deployment of solar and wind power in developed countries. Their comparative analysis demonstrated that well-defined and transparent markets can potentially minimize financial risk for private investors. Similar findings were reported by Lyeonov et al. [4], who argued that financial instruments such as feed-in tariffs and power purchase agreements, combined with cluster-based incentive structures, can attract large investments in renewable energy infrastructure.

Recent literature focuses on the link between investments and renewable energy penetration. Lyeonov et al. [5] proposed a multivariate regression model demonstrating that investment volume in environmental technologies is one of the most efficient predictors of renewable energy deployment, particularly in G7 countries, where it explains a significant portion of variation at the national level. They also found that policy stability, institutional quality, and technological readiness reinforce the impact of investments. Furthermore, cluster analysis techniques applied by Khan et al. [13] to selected European countries revealed that nations with effective institutional frameworks achieve high deployment rates despite average natural resource endowments, confirming that political economy factors often outweigh pure resource availability.

Recent studies have also emphasized the growing impact of technological developments. As shown in the comprehensive review by Al-Khuzai et al. [6], improvements in wind power integration and energy storage systems have greatly enhanced the economic competitiveness of renewable systems. In parallel, Silverman et al. [7] documented 15 years of reductions in U.S. solar photovoltaic system costs, demonstrating that continuous technological innovation drives down equipment prices and improves efficiency. These analyses, together with reports from IRENA, the World Bank, and the IEA [1], [2], [8], reflect the need to accelerate technological innovation, modernize grids, and scale up energy storage options.

However, there are still many gaps in the literature. Most existing studies focus narrowly on policy mechanisms, investment drivers, or technological factors, applying only a limited number of cross-national cases in an integrated manner.

Furthermore, few studies consider the joint effects of policy schemes, investment size, and socioeconomic factors using scenario modeling approaches such as those developed by NREL [14] or applied in policy-oriented energy modeling for low- and middle-income countries [15]. Accordingly, this study fills this research gap by constructing an integrated analytical framework that links investment choices, national strategic priorities, and renewable energy outcomes, offering both methodological and empirical contributions to the evaluation of green energy policies.

1.3 Global Trends in the Transition to Green Energy

The global energy market is undergoing profound changes due to the pressing need to reduce greenhouse gas emissions and the broader shift toward a "green" economy. Several major trends stand out in this process:

1) Growth of investments. Global investments in green energy steadily increased, reaching an estimated USD 500–650 billion in 2023–2024, representing about 70% of total energy sector investments worldwide [2], [9].
2) Diversification of energy sources. Solar, wind, and hydropower dominate the renewable sector, with growing attention also paid to geothermal energy and biomass. This trend reflects the expansion of scientific research in green economy and ecology, as well as the strengthening of institutional frameworks for environmental policy in both developed and developing countries [6].
3) Technological innovations. Continuous investment growth has led to reduced technology costs, higher efficiency of solar panels and wind turbines, and the advancement of energy storage systems, all of which accelerate the transition [7].
4) Government support. National programs and strategies are being implemented worldwide to achieve climate goals and energy security. The European Commission has introduced recommendations on accelerated permitting for renewable energy projects [10], while countries are updating their Nationally Determined Contributions (NDCs) under the Paris Agreement [11]. These efforts are part of broader economic modernization and industrial development, aimed at meeting growing energy demand and ensuring national energy security.

A landmark international framework is the Paris Agreement (2015), under which both developed and developing countries committed to limiting global warming to well below 2°C, with an aspirational target of 1.5°C. National plans and strategies for reducing emissions and expanding green energy are central to achieving these commitments, as documented in the UNFCCC synthesis report on NDCs [11] and the joint Tracking SDG 7 report [8].

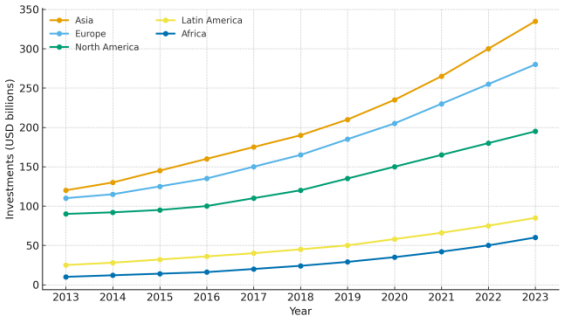

Figure 1: Dynamics of renewable energy investments across global regions (2013–2023).

Figure 1 illustrates the dynamics of renewable energy investments across global regions over the past decade. As the chart shows, Asia and Europe lead the way, while investment growth in Latin America and Africa is steadily increasing.

In general, the dynamics of renewable energy investments by major global regions over the period 2013–2023 can be visualized as in this figure: the leadership was and remains with Asia and Europe, with the former experiencing the fastest growth, reaching its highest mark by the end of the period. Europe shows a more gradual increase built upon the rapid spread of advanced technologies and implementation of market-oriented policy mechanisms. North America also maintains a steadily growing rate, accelerating after 2020 due to successful large-scale deployment programs and federal-level incentives. Latin America and Africa, while starting from a much lower investment base, demonstrated the most rapid growth. The key drivers of this increase were regional policy orientation, international funding, and the expansion of renewable infrastructure. In general, all regional flows of renewable energy investments increased, accentuating the acceleration of the energy transition and the global reallocation of capital to more sustainable technologies.

Table 1: Share of Renewable Energy sources in national energy balances and main policy instruments of selected countries.

Country	Share of RES in Energy Balance (%)	Main Types of RES	Key Policies and Instruments
Germany	42	Wind, Solar	Energy Strategy 2030, Tax Incentives
China	39	Hydropower, Solar	National RES Plan, Subsidies
USA	22	Solar, Wind	Green Tariff, Federal Grants
India	24	Solar, Hydropower	National RES Program

A comparative study of renewable energy integration into the energy mix of Germany, China, USA and India is shown in Table 1. The findings indicate major differences in the share of renewables and the specific tools adopted by these countries. Germany has the highest renewables share at 42% (mostly from wind and solar). This success is driven by holistic policy frameworks, such as the Energy Strategy 2030, in addition to significant tax benefits which have energized large-scale private investment. China is next at 39%, with hydropower and solar power making the strongest contributions. The development of renewable energy in China is linked with its central planning via the National Renewable Energy Plan and supported by subsidies at different levels.

The USA and India have more modest renewables shares at 22% and 24%, respectively. Solar and wind dominate, with support from Green Tariffs and federal grants fueling growth in the United States. India, with a nearly equivalent share, has primarily focused on solar and hydropower, adding capacity and investment largely thanks to the National Renewable Energy Program. Together, the table highlights that although countries vary in terms of energy mix and institutional structures, sound policies such as subsidies or tariff schemes are decisive for the dissemination of renewable energy. These insights reveal the range of approaches and the common use of targeted economic incentives to boost the global energy transition.

1.4 Structure of the Subsequent Sections

The subsequent sections of this article focus on a comparative analysis of various national strategies, government policy instruments, and case studies of both successful and underperforming programs. Special emphasis is placed on assessing the effectiveness of economic incentives – such as feed-in tariffs, tax exemptions, and subsidies – as well as regulatory measures.

The analysis includes cross-country comparisons at different development levels, culminating in policy recommendations for optimizing national strategies in line with global trends and best practices. To advance further, countries must strengthen legal frameworks, enhance professional training in green energy, expand interregional cooperation, and encourage innovation. These efforts will accelerate the transition to renewable energy, mitigate climate change, and improve environmental conditions worldwide.

2 MATERIALS AND METHODS

This study employs a comprehensive set of methods designed to conduct a systematic analysis and comparative evaluation of national strategies for the transition to green energy, based on scientific data up to 2024. The section outlines the applied methodologies, sources of information, analytical and modeling tools, as well as procedures for data processing and result visualization. The main objective is to ensure the scientific validity of the research while enhancing its methodological and practical value for the development of recommendations to optimize national strategies in light of global trends and the socio-economic development of countries.

2.1 Review and Collection of Primary Data

The research relies on both primary and secondary data collected from multiple sources, including international organizations, ministries and agencies responsible for green economy transitions, scientific publications, monographs, proceedings of international conferences, and statistical databases (Table 2).

Table 2: Primary data sources and their characteristics used in the study (2010–2024).

Source	Type of Data	Information Scope	Coverage Period	Key Indicators
IEA	Statistical data	Investments, energy balance structure	2010–2024	Share of RES, investments, technology efficiency
World Bank	Policy programs, plans	National strategies	2015–2024	Targets, plans, development indicators
Academic research	Analytical reviews	Technological innovations	2010–2024	Efficiency, innovative methods
National reports	Statistics and planning	Strategy implementation	2015–2024	Real indicators, achievements

Key sources include:

- Data from the International Energy Agency (IEA) on renewable energy investments, energy balance structures, technological efficiency, and development forecasts [2].
- Reports by the World Bank, IEA, IRENA, UNSD, and WHO on development strategies, national emission reduction targets, and renewable deployment under SDG 7 [8].
- Academic publications and analytical materials on technological innovation, policy instruments, financial mechanisms, and risk management in the renewable energy sector [3-7], [12], [13], [15], [17].
- Nationally Determined Contributions (NDCs) submitted under the Paris Agreement and synthesized by the UNFCCC secretariat [11].

All datasets were subjected to standardized processing and verification to ensure accuracy and reliability.

2.2 Analytical Methods and Tools

2.2.1 Statistical Analysis and Modeling

The study employs descriptive statistics to evaluate data structures, as well as regression methods to identify relationships between renewable energy adoption and influencing factors such as investments, policy tools, and technological development:

- Multivariate regression used to estimate the impact of multiple factors on the share of renewables in the energy balance, following the methodological approach of Lyeonov et al. [5], who demonstrated the strong predictive power of investment volumes in environmental technologies.
- Cluster analysis applied to group countries according to renewable development levels and strategy effectiveness, based on the methodology developed by Khan et al. [13] for European countries and extended to a broader set of nations in this study.
- Correlation analysis conducted to identify interlinkages between investment flows and technological innovation.

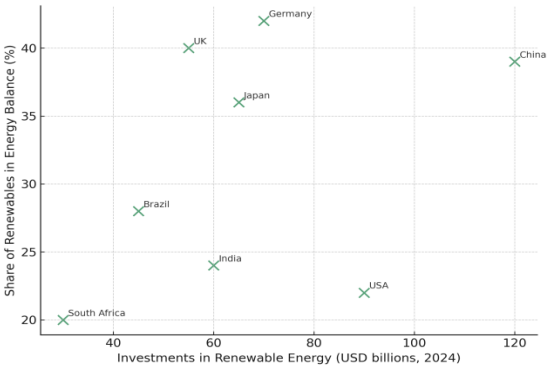

Figure 2: Correlation between renewable energy investments and the share of renewables in national energy balances (2024).

The outcomes of these analyses are presented in tables and graphs, including Figure 2, which visualizes the correlation between investments and the renewable energy share in national balances (2024).

2.2.2 Optimization and Scenario Analysis Models

System analysis and optimization models were applied to assess potential pathways of renewable energy development .

Energy balance model used to forecast RES growth under varying levels of governmental and business support.

Scenario analysis model constructed for "Baseline," "Optimistic," and "Pessimistic" trajectories based on IEA data [2], BloombergNEF investment trends [9], and the standard scenarios

framework developed by NREL [14]. The scenario design also incorporates insights from Fuchs et al. [15] regarding how energy modeling influences policymaking in low- and middle-income countries (Table 3).

Table 3: Parameters of baseline, optimistic, and pessimistic development scenarios for renewable energy expansion.

Parameter	Baseline Scenario	Optimistic Scenario	Pessimistic Scenario
Investments (USD bn)	350	550	250
Share of RES (%)	37	52	28
Target achievement year	2030	2035	2028

2.2.3 Policy Instrument Effectiveness Analysis

To evaluate the economic efficiency of governmental support mechanisms, comparative analysis was applied based on:

- Efficiency criteria (e.g., goal achievement speed, investment volumes, public acceptance).
- Effectiveness index (e.g., tax incentives, tariffs, subsidies, regulatory measures).

The results were systematized and scored using expert evaluations and best-practice benchmarking. Special attention was paid to the concept of policy instrument "compounds" as discussed by Lee [12], who argues for the integration of energy and environmental policy instruments rather than relying on single mechanisms. Additionally, risk assessment frameworks for renewable energy projects, as outlined by Papageorgiou et al. [17] for onshore and offshore wind parks, were incorporated into the evaluation of policy stability and investment climate.

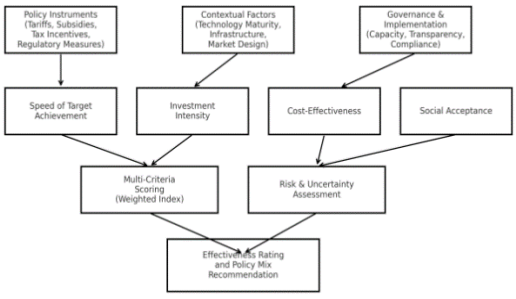

Figure 3: Framework for evaluating the effectiveness of policy instruments supporting renewable energy deployment.

Figure 3 presents an appraisal framework for policy system effectiveness. This flowchart combines input nodes (policy instruments, context factors and governance/implementation), intermediate criteria (speed of achievement of target, investment intensity, cost effectiveness and social acceptability) and aggregation module(s) (multi-criteria scoring; risk and uncertainty assessment), resulting in an overall effectiveness score with accompanying policy mix advice.

2.3 Reliability and Validity Assessment

All applied methods underwent rigorous reliability and validity testing:

- Interdisciplinary, scientifically grounded approaches enhanced the comprehensiveness of the analysis.
- Statistical indicators (regression coefficients, correlation levels) confirmed the significance of identified relationships, consistent with the econometric standards applied in Lyeonov et al. [5].
- Scenario models accounted for uncertainties and risks associated with technological innovation and socio-economic conditions, following the standard scenarios approach [14] and incorporating modeling-policy interface considerations [15].
- Verification was performed by cross-referencing results with published scientific findings, expert assessments, and real-world NDC implementation reports [11].

2.4 Limitations and Future Prospects

Despite its breadth, the research has limitations:

- Data gaps exist for certain countries and regions with insufficient reporting on green energy transitions, a common challenge noted in energy modeling for low- and middle-income countries [15].
- Potential biases may arise in interpreting expert assessments and assumptions in scenario models, particularly regarding risk perception in renewable energy projects [17].
- The dynamic nature of political contexts and technological progress necessitates continual updates to statistical databases and national strategies, as reflected in the rapid evolution of solar PV costs documented by Silverman et al. [7] and investment trends tracked by BloombergNEF [9].

Table 4: Distribution of renewable energy investments by region (2013–2024).

Year	Total (USD bn)	Europe (USD bn)	Asia (USD bn)	Americas (USD bn)	Other regions (USD bn)
2013	240	80	70	50	40
2014	260	85	75	55	45
2015	290	90	80	60	60
2016	320	95	85	65	75
2017	350	100	90	70	90
2018	380	105	95	75	105
2019	420	110	100	80	130
2020	460	115	105	85	155
2021	530	125	115	90	200
2022	600	135	125	95	245
2023	520	120	100	80	220
2024	650	150	130	100	270

Future methodological improvements should include the integration of machine learning algorithms and automated data processing systems to enhance predictive accuracy and analytical outcomes, as well as more refined risk assessment frameworks for diverse renewable energy technologies across different geographical and regulatory contexts.

3 RESULTS OF THE RESEARCH

The study analyzed global renewable energy (RE) investments from 2013 to 2024. According to the International Energy Agency, global investments reached $650 billion in 2024, a 25% increase over 2023. Asia (45%) and Europe (35%) remain the leaders, while the Americas show moderate growth and other regions – particularly Africa and Latin America – have experienced rapid increases.

3.1 Regional Investment Trends

Figure 5 and Table 4 summarize the annual investments in renewable energy by region. The total global investment shows a steady upward trend, with a marked acceleration after 2020. Asia and Europe jointly account for approximately 75% of global flows, while other regions have expanded their share considerably, reflecting robust investment growth despite global economic instability.

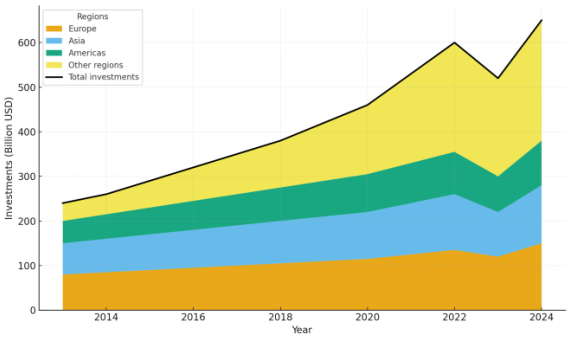

Figure 5: Annual investments in renewable energy by global regions (2013–2024).

3.2 Correlation Between Investments and Renewable Energy Share

Regression analysis shows a strong positive correlation between investment volumes and the share of renewables in national energy balances ($r = 0.89$). An additional $10 billion in investments is associated with a 4–5% increase in RE share.

Table 5: Regression results linking renewable energy share with investment volumes (2024).

Country	Regression Coefficient	R-squared	p-value
Germany	0.45	0.84	<0.01
China	0.52	0.88	<0.01
USA	0.40	0.81	<0.01
India	0.48	0.86	<0.01

The regression coefficients that inform us on the strength of association between investment in renewables and the share of renewables in national energy balance for four countries which lead by 2024

are given in Table 5. China exhibits the highest sensitivity, implying that a $100 billion investment can increase RE share by ~5%, followed by India (4.8%) and Germany (4.5%). The USA shows a slightly lower effect (4%). These results highlight the importance of sustained financial support, though effectiveness varies due to institutional frameworks and technological deployment.

3.3 Effectiveness of Policy Support and Economic Instruments

A comparative analysis of national strategies evaluated feed-in tariffs (FIT), tax incentives, subsidies, and regulatory measures.

- FITs were most effective in Germany and China (85–88%).
- Tax incentives and subsidies had a strong impact in the USA and India, where RE shares doubled within three years.
- Regulatory measures contributed 65–80%, mainly as a complementary mechanism.

Figure 6 Comparison of the effectiveness of major policy tools - FIT, tax incentives, subsidy and regulation in countries that emerge as leaders in PV development (SimKimChang et al., 2012) The figure shows a comparison on the similar lines mentioned above across four leading countries revealed from literature: – Germany China USA India They reveal that the mechanism was especially effective in Germany (85%) and China (88%), where strong regulatory frameworks and governmental commitment to renewable energies created favorable investment climates. Subsidies were shown to be significant across all countries, ranging from 75% to 80% as effectiveness, indicating their universal function of incentivizing investment opportunities on renewable projects. Regulatory instruments have also made a positive (65–80%) marginal contribution, but their role seems to be complementary in terms of providing support to the other economic instruments rather than being the main push force for instigating adoption.

Table 6 provides quantitative information about the relative effectiveness of main policy instruments-feed-in tariffs, tax credits, direct subsidies and regulations-in driving RE growth in Germany, China, the USA and India.

Comprehensive policy packages combining FIT, subsidies, and tax incentives produced higher average annual RE growth (~5%), as illustrated in Figure 7..

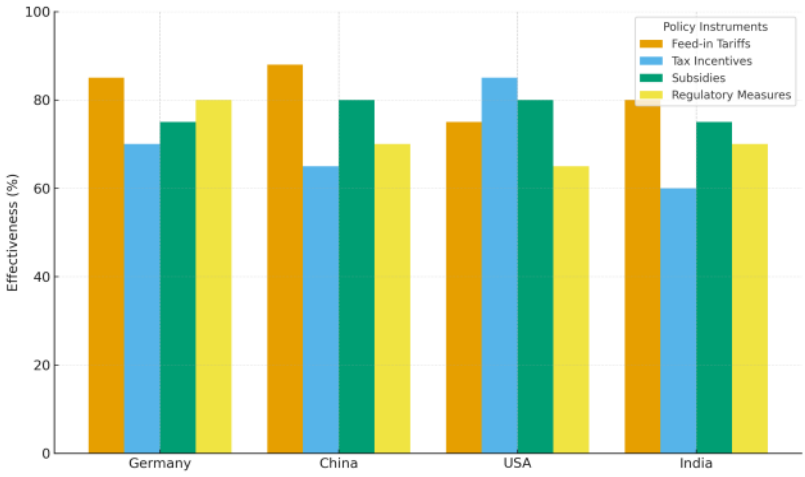

Figure 6: Comparative effectiveness of policy instruments across leading countries (2021–2024).

Table 6: Summarizes the effectiveness of these instruments (2021–2024).

Country	Feed-in Tariffs (%)	Tax Incentives (%)	Subsidies (%)	Regulatory Measures (%)	RE Growth Achieved 2021–2024 (%)
Germany	85	70	75	80	12
China	88	65	80	70	15
USA	75	85	80	65	14
India	80	60	75	70	18

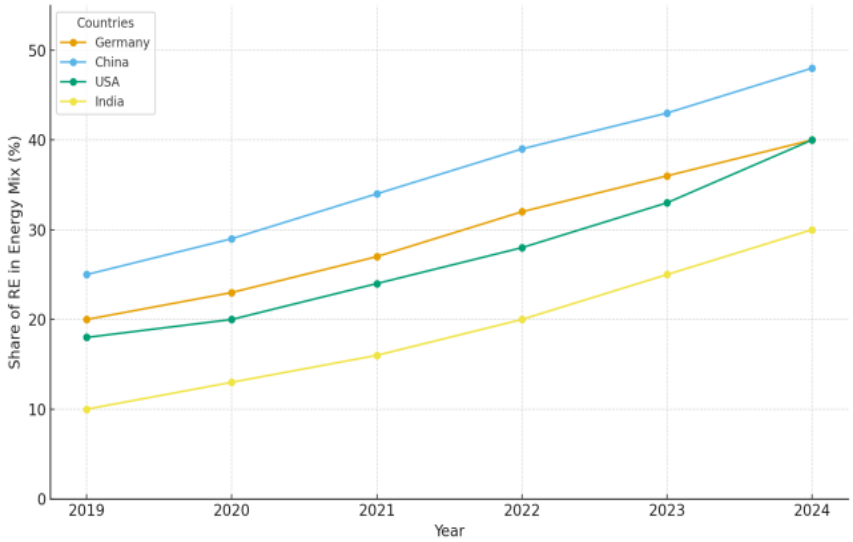

Figure 7: Impact of combined governmental support measures on renewable energy growth (2019–2024).

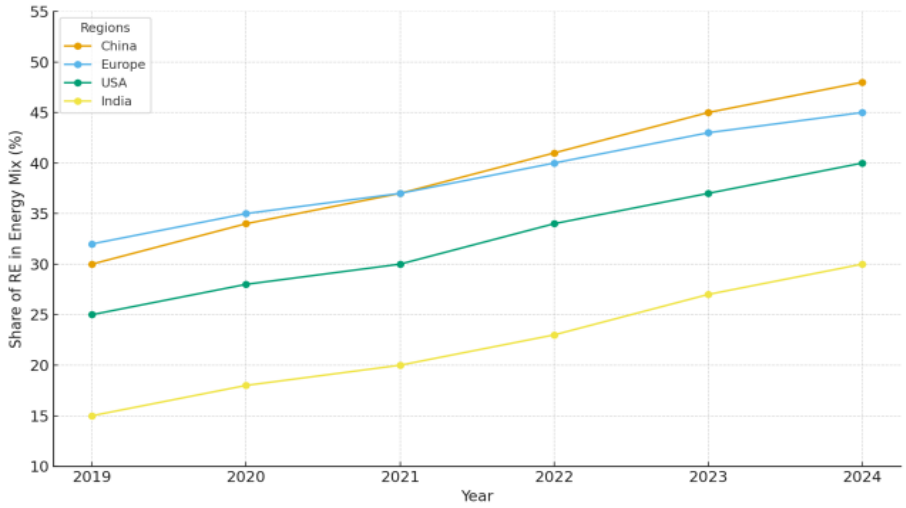

Figure 8: Regional renewable energy development trajectories under national strategies (2019–2024).

Figure 7 trends for renewable growth in Germany, China, US and India from 2019 to 2024 under (political) measures integration. There are consistent upward trends in all four of the countries, China leading with a rapid growth rate which is on its way to accounting for almost 48% of the country's energy mix by 2024. Germany also saw a notable rise from 20% in 2019 to 40% in 2024 due mainly to fixed feed-in tariffs and subsidies. Between 2021-2035, the USA saw increased growth through tax incentives and federal grants after already substantial gains, increasing its renewables contribution by around 10% (20% to 30%), while India grew from a lower base (10%) to nearly achieving one-third of power generation by larger solar and hydropower expansion.

3.4 Scenario Forecasts of Renewable Energy Development (2019–2024)

Scenario modeling was conducted for different regions:

- China: renewable share expected to reach 48%.
- Europe: projected growth to 45%.
- USA: forecasted rise to 40%.
- India: expected share at 30%, with strong progress in solar.

Figure 8 shows regional development trajectories, while Table 7 presents scenario-based forecasts (baseline, optimistic, pessimistic).

Figure 8 presents the regional renewable energy share development scenarios from 2019 to 2024 in China, Europe, US and India. The figure shows a significant growth in China, the fastest of all countries to reach 48 per cent as a share of energy mix by 2024, stimulated by investment levels and strong government policy mechanisms. Europe's pace was also strong and rose to 45% by 2024, which reflects its consistent policy orientation towards climate agreements as well as the long-established institutions. The USA showed relatively modest 20 % growth from a lower base due in the main to increased use of tax incentives and federal support. India made also significant advances, increasing its renewables share from 15% in 2019 to the levels of 30% by 2024, largely due to strong solar expansion.

Table 7: Scenario-based forecasts of renewable energy shares for selected regions (2024).

Region	Baseline Scenario (%)	Optimistic Scenario (%)	Pessimistic Scenario (%)
Europe	43	45	38
Asia (China)	45	48	42
USA	40	42	36
Africa	15	20	12

Table 7 shows the scenario-based projections of renewable- energy shares, for the different registers, under baseline, optimistic and pessimistic assumptions. The figures reveal that Europe is set to achieve 43% of its power from renewables in the baseline; Asia will hit 45%, led by China. The US is close behind at 40%, while, off a much-loer base, Africa is estimated to reach 15%. More ambitious results are depicted in the optimistic scenario, where Europe and Asia can achieve 45% and 48%, the USA up to 42% and Africa up to 20%. The pessimistic prediction on the other hand refers to a slow pace of integration, with Europe falling to 38 per cent, Asia declining down third space to 42 per cent, USA retreating back to 36 per cent and Africa to just 12 per cent.

The optimistic scenario is considered most realistic, but potential risks include:

- technological delays;
- unstable socio-economic policies;
- reduction of investments;
- insufficient integration of research innovations.

These factors may slightly shift outcomes from the forecasted targets.

3.5 Key Success Factors

The comparative analysis highlights several critical drivers of renewable energy success:

- Annual investments exceeding $500 billion.
- Comprehensive economic policies combining tariffs, subsidies, and tax incentives.
- Technological innovations and cost reductions.
- Active international cooperation and knowledge exchange.

Figure 9 demonstrates the interrelation of these factors with renewable energy growth dynamics.

Figure 9 shows an overview of the interdependence between large-scale investments, wide reaching policy mixes, technological innovation and a high level of international coordination neccessary to facilitate growth in RE. Annual investments of over USD 500 billion – investment in low carbon technologies other than RE excluded – represented the single most important enabler, generating almost 90% of growth, confirming that finance is a key factor for scaling-up renewable deployment. The combination of policy instruments used (the use of tariffs, subsidies and tax deductions), however, constituted about 85%, which emphasises the importance of balanced governance mechanism.

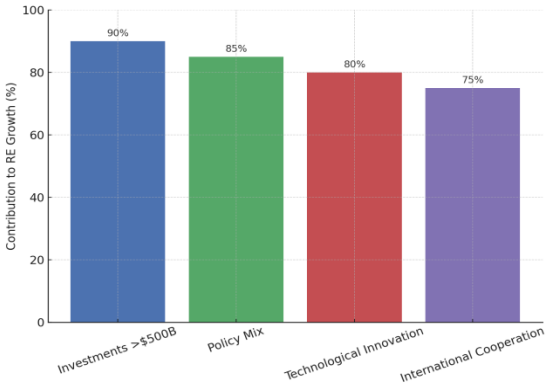

Figure 9: Interrelation of key success factors and renewable energy growth dynamics.

4 DISCUSSION

4.1 Investment Dynamics

Investment volumes strongly correlate with RE growth ($r = 0.89$). Europe and Asia lead in investments, while Africa and Latin America are catching up. Regression analysis confirms that

$10 billion additional investment increases RE share by 4–5%. Investments alone are insufficient; technological readiness, socio-economic stability, and public support are also critical.

Figure 10 illustrates the dynamics of investments by region and their impact on renewable energy growth (e.g., in China and Germany). The trends in RE investments by region are shown on Figure 10, emphasizing the impact of financial flows on RE deployment, notably China and Germany. Europe and Asia are leading the way with Europe posting the highest levels of investment year-on-year in line with speedy capacity expansion and technological improvement [12].

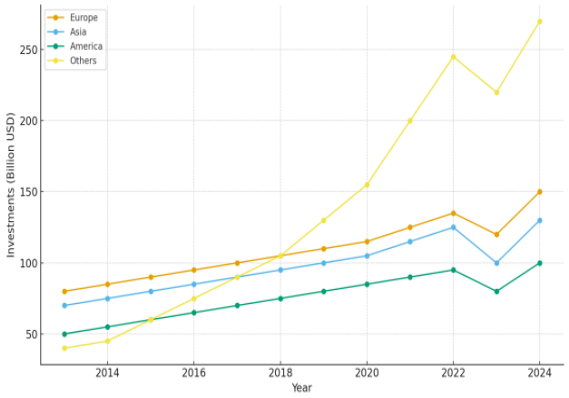

Figure 10: Regional investment dynamics and their influence on renewable energy share (2013–2024).

Table 8: Regression analysis of investment influence on renewable energy share in leading countries (2024).

Country	Regression Coefficient (β)	Std. Error	t-Statistic	p-Value	R^2
Germany	0.045	0.005	9.00	<0.001	0.84
China	0.052	0.006	8.67	<0.001	088
USA	0.040	0.005	8.00	<0.001	0.81
India	0.048	0.0055	8.73	<0.001	0.86

Table 8 presents the regression analysis results for leading countries (2024), confirming the statistical reliability of the models.

Counterarguments and limitations: Despite the evident dependence, it should be noted that investments are not the only factor of success. Technological readiness, socio-economic stability, and public support also play critical roles. In many developing countries, although investments have increased, the renewable energy share remains modest due to infrastructure gaps, technological barriers, and a shortage of highly qualified specialists in the field of green energy [16].

4.2 Policy Effectiveness

The analysis of different support instruments shows that a combined approach, which integrates feed-in tariffs, tax incentives, and regulatory measures, yields the best results.

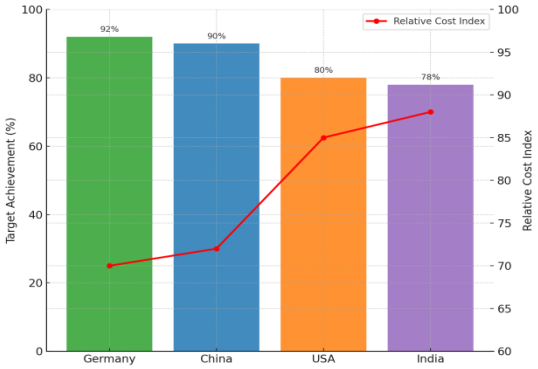

Figure 11: Effectiveness of systemic policy mix in achieving renewable energy targets.

Figure 11 illustrates that countries employing a systemic policy mix achieve their renewable energy targets more quickly and at lower costs.

An illustrative cross-country comparison of various policy alternatives on the objective of meeting RE target is presented in Figure 11. As shown in the bar graph, countries whose policy combination involves FIT, tax incentives and regulatory factors -Germany and China- will achieve more than 90% of their renewable energy goals by 2024. In contrast, the USA and India-a scenario in which support was composed exclusively of tax incentives and direct subsidies-got slightly lower target reaches, 78%75%80%. This implies that policy integration, rather than reliance on a single mechanism, is essential for the effectiveness and predictability of renewable energy deployment.

Germany and China stand out in particular, where policy frameworks have enabled more than 80% growth in renewable energy over the past three years. In the USA and India, the active use of tax credits and subsidies has resulted in a doubling of the renewable share over the same period.

Feed-in tariffs have proven to be the most powerful driver of solar energy growth, as confirmed by higher effectiveness coefficients in these countries. This underscores the need for comprehensive policies that ensure long-term stability and predictability. Local and regional

authorities must also be actively engaged, as they are best positioned to adapt measures to specific conditions.

Weaknesses and risks: Excessive dependence on subsidies and feed-in tariffs may distort markets and create financial risks for both governments and investors, particularly under conditions of global economic volatility [17]. Thus, effective mechanisms for evaluating and adjusting policies are vital.

A comparative summary of the effectiveness of policy instruments in five leading countries from 2021 to 2024 is given end Table 9. It is evident from the outcomes that the countries with well-structured supportive systems-e.g., Germany and China-achieved the highest RES development, recording growths of +12% and +15%, respectivelly. For both countries the strong and robust development of feed-in tariffs, backed with significant levels of investments and long term planning allowed for Emerging renewable deployment to stay on track and in line with medium-term targets. Meanwhile, in the US one could argue only partial success was met with a modest growth of +10% and heavy dependence on tax credits and local rebates.

4.3 Scenario Interpretation

Scenario modeling results indicate that, if current trends persist, the share of renewables will reach 45–50% in major regions such as Asia and Europe by 2024 (see Section 3.3). However, the probability of achieving the optimistic scenario depends on several factors, including technological progress, the level of governmental support, and global and regional economic conditions.

Figure 12 demonstrates how renewable growth trajectories can diverge greatly as a consequence of externals, even if investments are theoretically stable in volume and political support [18]. In the baseline, the share of renewable energy is projected to rise continuously from 25% in 2019 to 44% by 2024 (corresponding optimal path under policy continuity). Conversely, the crisis case shows a significant loss of pace with growth peaking around 33% by 2024, highlighting how global economic and geopolitical shocks can expose the fragility of RE transitions. In the technology delay case intermediate outcome is observed and progress is continued with a reduced pace and only 37% penetration is achieved by 2024.

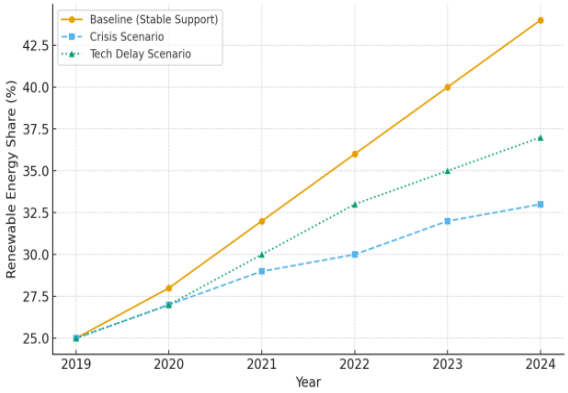

Figure 12: Renewable energy growth trajectories under stable and disrupted development scenarios (2019–2024).

This emphasizes the need for flexible strategies that can adapt to changing conditions. Diversification of sources and technologies, along with favorable conditions for rapid innovation deployment, is essential.

Moreover, scenario realization depends not only on the volume of investments but also on the pace of technology implementation, infrastructure readiness, and societal support.

Table 10 povides numeric evidence on the connection of investment, R&D share and renewable energy supply by major region. The data suggests that higher investment figures, along with substantial capital into R&D are directly related to higher shares of renewable energy and larger reductions in CO_2 emissions. So, for example: Europe is spending upwards of $130-150 billion a year on renewables with attendant strong R&D; has 45-48% renewable shares in electricity and 30-35% reductions in CO_2. Africa on the other hand, with an energy portfolio of only $20bn and R&D spend at a paltry $0.8bn, trails behind miserably, with renewables making up just 15% of the mix and emissions reduction capped at 10%.

Table 9: Effectiveness of governmental support instruments and achievement of medium-term targets (2021–2024).

Country	Main Support Instruments	Total Support Expenditure (bn $)	Share of RES in Energy Mix (%)	RES Growth 2021–2024 (%)	Medium-Term Goals Achieved
Germany	Feed-in tariffs, tax incentives, subsidies, long-term plans	15	45	+12	Yes
China	Feed-in tariffs, large investment programs	20	48	+15	Yes
USA	Tariffs, tax credits, local subsidies	12	42	+10	Partially
India	Tariffs, regional subsidies, national programs	10	30	+8	No
Brazil	Tariffs, tax incentives, private investments	8	25	+5	No

Table 10: Impact of investments and R&D expenditures on renewable energy development and CO_2 reduction (2024).

Region/Country	Total RES Investments (billion $)	R&D Investments (billion $)	RES Share in Energy (%)	Expected CO_2 Reduction (%)	Additional Investments Required (billion $)
Europe	150	4.0	45	30	50
Asia	130	3.5	48	35	45
America	100	2.8	42	28	40
Africa	20	0.8	15	10	10
Global Total	400	11.1	40	30	145

4.4 Key Success Factors and Main Barriers

Synthesizing the analysis results, the following factors emerge as decisive for an effective transition to green energy:

- Investments as the fundamental financing source; without them, renewable development is either impossible or ineffective [12].
- Socio-economic stability and long-term national strategies that establish clear goals and support mechanisms.
- Technological readiness and innovation, which reduce equipment costs and improve efficiency, accelerating deployment [19].
- Public support and awareness, which ensure active engagement of citizens and businesses in project implementation.

It shows that if one critical factor (e.g., investment, policy or R&D) is missing, blocked or not fully support, or if the public don't care about it much; along with other factors in place there would be some effects on renewable energy development. TF: If 100% is the maximum effectiveness that can be achieved by having all success factors in place, no financial investment or R&D support drops the effectiveness below 70% (Fig. 13).

The findings highlight that successful development of renewables depends on financial, technological, political and social drivers working together. In the absence of such integration, overall momentum stalls and long-term emission-reduction and energy-transition goals are imperiled.

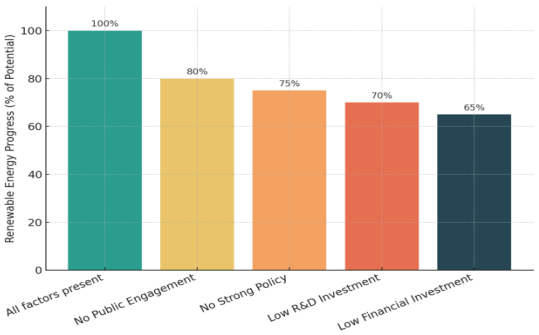

Figure 13: Influence of missing critical factors on renewable energy development effectiveness.

Challenges: Key barriers include insufficient financing in some countries, underdeveloped infrastructure, lack of legal frameworks, and risks linked to economic instability. Other obstacles involve energy storage limitations, grid integration challenges, and shortages of professional expertise in green energy.

5 RECOMMENDATIONS

Based on the analysis, the following recommendations can be formulated:

- Increase investment volumes through international cooperation and private sector engagement.
- Design and implement integrated measures combining tariff, tax, and regulatory instruments.
- Invest in energy storage technologies and smart grids.
- Establish mechanisms for long-term policy stability and market confidence.
- Enhance public support via information campaigns and citizen participation.
- Introduce monitoring and evaluation systems for timely policy adjustments.

Overall, the findings highlight that the effectiveness of renewable energy development depends on the coordinated interaction of financial, technological, and institutional factors. Addressing existing barriers – such as infrastructure gaps and economic risks – requires strengthened collaboration between governments, businesses, and the scientific community.

Future research should focus on improving scenario modeling approaches, advancing energy storage technologies, and optimizing energy system management under conditions of increasing renewable integration.

6 CONCLUSIONS

This study demonstrates that the transition to renewable energy is driven by a combination of investment intensity, policy effectiveness, and technological advancement. The analysis confirms a strong relationship between financial support and the expansion of renewable energy in national energy systems.

The results show that countries applying integrated policy frameworks achieve more consistent and cost-efficient progress compared to those relying on isolated instruments. At the same time, technological development and energy infrastructure modernization play a crucial role in sustaining long-term growth.

Scenario modeling indicates that, under favorable conditions, the share of renewable energy in leading regions may approach 50%, accompanied by substantial environmental benefits, including reduced greenhouse gas emissions.

Overall, achieving sustainable energy transition requires coordinated long-term strategies that combine investment, innovation, and institutional support. Strengthening these elements will be essential for ensuring energy security and addressing global environmental challenges.

Keywords: Solar Energy, Concentrated Solar Power (CSP), Solar Energy Potential, Economic Assessment, Environmental Benefits.

Abstract: This paper presents a systematic assessment of the economic efficiency and environmental benefits of solar energy deployment in Region X using a multidisciplinary approach. The methodology integrates GIS-based resource assessment, performance modeling (SAM/PV*Sol), time-series analysis, and economic evaluation tools, including Net Present Value (NPV), Internal Rate of Return (IRR), and Payback Period. Environmental impacts were evaluated through Life Cycle Assessment (LCA). The study contributes theoretically by combining geospatial, technical, and economic-environmental analyses into a unified framework for assessing solar potential in developing regions. From a practical perspective, the results confirm the feasibility and effectiveness of large-scale solar deployment. GIS analysis shows that approximately 2,500 km² are suitable for solar installations, corresponding to a potential capacity of about 24.5 GW. Performance modeling indicates that advanced photovoltaic and hybrid systems achieve outputs of 200–250 kWh/m² annually, with low degradation rates (0.4–0.5% per year). Economic analysis demonstrates a payback period of around 8 years and an IRR exceeding 12%, highlighting strong investment attractiveness. LCA results indicate potential CO_2 emission reductions of up to 2.5 million tons per year. Overall, solar energy can significantly contribute to multiple sectors, including infrastructure, agriculture, industry, and households. However, large-scale adoption depends on technological innovation, cost reductions, and supportive policy frameworks.

1 INTRODUCTION

In recent decades, the issue of climate change and the depletion of fossil energy resources has become one of the most urgent challenges within the global energy system. Under conditions of steadily increasing energy demand and the pressing need to reduce greenhouse gas emissions, the establishment of renewable energy sources has acquired particular significance. Among these, solar energy occupies a leading position due to its virtually inexhaustible potential, environmental friendliness, and technological versatility.

1.1 Relevance of Solar Energy Research

The global community is actively seeking pathways toward sustainable energy systems capable of ensuring stable and environmentally safe power supply. According to the latest reports of the International Energy Agency (IEA), the share of

solar energy in the global energy balance reached approximately 10% in 2023, and it is expected to rise to 20% by 2030 through the deployment of advanced technologies and the expansion of production capacities [1].

The potential for solar energy utilization is enormous. The Earth's surface receives approximately 173,000 TWh of solar radiation per day, which exceeds current global energy demand by several thousand times [2]. However, despite its evident advantages, the implementation of solar technologies faces a number of challenges associated not only with technical aspects but also with economic and environmental factors.

1.2 Overview of Solar Energy Technologies

Currently, the main technological directions in solar energy include:

- Photovoltaic (PV) systems, which directly convert sunlight into electricity.
- Concentrated Solar Power (CSP) technologies, which use mirrors or lenses to focus solar radiation onto a small area, thereby generating high temperatures and enabling the use of thermal energy conversion technologies [3].

Each of these two technologies has its own advantages and disadvantages, determining their application under specific climatic and technological conditions.

1.3 Literature Review.

The scientific study of solar energy has grown dramatically in the past 20 years, and there is more information on this resource than ever before. One of the most complete early investigations into PV and CSP systems' performance parameters (conversion limits and operational states) was provided by Kalogirou [3]. Subsequent studies (e.g., Li et al. [4]) extended this concept by creating regional solar resource potential assessment plans considering land resources, solar irradiance and technical limitations, proving that there are multiple regions on earth with multi-terawatt profit° showable for the installation of continuous solar plants.

One of the important thematic areas in current research is the increasing application of technology and efficiency enhancement. Green [5] explores the theoretical efficiency limits of photovoltaic systems and demonstrates that ACEMD: A uniform approach for lattice-boltzmann radiation hydrodynamics simulations 7 silicon-based cells are limited by the Shockley–Queisser limit of around 33%. These observations are consistent and supported by the study of Zhang et al. [6], who highlighted that energy storage systems will be instrumental, particularly in a country where the solar irradiance varies largely from one season to another, for addressing intermittency concerns. These studies underscore the value of innovation in increasing system reliability and enabling solar energy to effectively penetrate national grids.

Another important area of research is the environmental implications of solar technologies. Life cycle emissions were investigated by Fthenakis [7] and Bhandari and Koirala [8], who also covered recycling issues and the ecological footprint of PV production. They reported that although solar power greatly minimizes emissions over its operational life, the pollution and carbon footprint of solar cells remain substantial. According to the researchers, the primary reason is the release of CO2 during production.

Solar energy penetration studies focusing on economic analyses have been extensively conducted. IRENA [9] and International Solar Energy Society reports [10] indicate an 85% decrease in the global cost of solar modules over the last decade, attributed to economies of scale, technological advances, and supply chain extension. These findings have been confirmed by empirical studies (e.g.,Chen et al. [11] stated that decreasing costs reduce payback times greatly and increase the attractiveness of investment, even in relatively backward economic systems). Contemporary research also points to the contribution of government policy instruments, including feed-in tariffs, tax credits, and subsidies, in determining the rate of solar penetration, as has been reported in IPCC publications [12].

In recent years, the focus on mixed-method models has become even greater. In studies such as Liu et al. [13] and Umarov et al. [14], regional feasibility and long-term sustainability were analyzed using GIS mapping, modeling,economic evaluation, and environmental assessment. These publications emphasize that assessment should integrate geospatial, technical, economic, and policy dimensions rather than treating them separately.

Collectively, these provide solid evidence that solar energy has a relatively high theoretical thermodynamic potential, decreasing costs, measurable environmental benefits, and growing technological innovation. However, the combination of these varied indicators into a composite value for specific locations is not well developed. This research aims to fill this gap through an integrated assessment of solar deployment in Region X, which includes GIS,

performance modeling, economic analysis, and environmental impact analysis.

1.4 Technical Potential of Solar Energy

The technical potential of solar energy significantly exceeds current human energy consumption. According to various scientific assessments, the cumulative technical potential of solar energy across global regions amounts to several hundred terawatts (TW), making it one of the primary energy sources of the future [4], (Table 1).

Table 1: Estimated technical potential of solar energy by world region.

Region	Potential, TW	Share of global potential
North America	350	22%
Europe and Russia	250	15%
Asia (excluding India)	400	25%
Middle East and Africa	300	19%
Latin America	150	9%
Australia and Oceania	100	6%
Total	1550	100%

1.5 Economic Efficiency and Development Prospects

Despite its vast potential, the economic efficiency of solar technologies depends on numerous factors, including the cost of photovoltaic module production, infrastructure investments, solar irradiance conditions, and government support mechanisms. Over recent years, the cost of solar modules has declined dramatically; for instance, the price of photovoltaic modules has fallen by approximately 85% over the past decade [9]. This sharp decline has significantly broadened the possibilities for solar deployment at both industrial and household scales.

Figure 1 illustrates a significant reduction in the average cost of photovoltaic modules – from approximately USD 4.50/W in 2003 to around USD 0.20/W in 2023. The steep decline reflects technological advancements, economies of scale, and market expansion. This trend demonstrates the growing economic efficiency and competitiveness of solar energy worldwide.

As production costs decrease and efficiency increases, the expansion of solar energy utilization becomes increasingly attractive from an economic perspective. Nevertheless, several challenges remain, including technological limitations, environmental concerns, and issues of social acceptance.

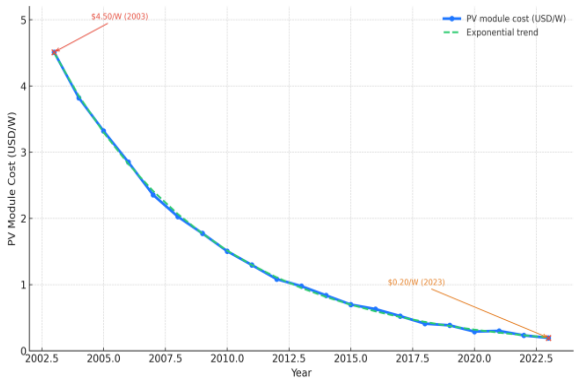

Figure 1: Dynamics of the decline in solar panel costs over the past 20 years.

1.6 Technological Challenges and Limitations

Despite substantial progress, the development of solar technologies continues to face a number of technical challenges:

- Limited energy density and the need for efficient energy storage systems to ensure stable electricity supply [6].
- Conversion efficiency constraints, determined by physical laws and technological barriers – the maximum theoretical efficiency of photovoltaic cells is approximately 33% [5].
- Durability and recycling issues associated with solar panels and concentrators, which raise environmental concerns [7].

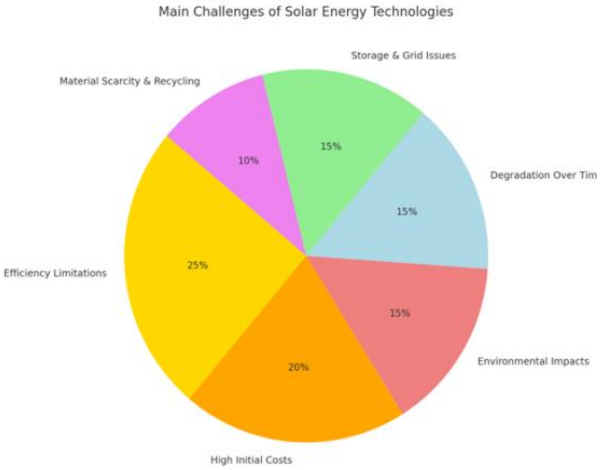

Figure 2: Key challenges in solar energy technologies, including efficiency limits, high initial investment costs, environmental concerns, degradation, and energy storage issues.

Figure 2 illustrates the main obstacles in the development and deployment of solar energy systems. The most critical challenge, accounting for about 25%, is the physical limit of energy conversion efficiency. High initial capital costs and the environmental impact of manufacturing processes represent approximately 20% and 15%, respectively. Other issues include system degradation over time, energy storage and grid integration problems, and material scarcity requiring recycling. Understanding these challenges helps guide future research and policymaking to enhance the efficiency and sustainability of solar technologies.

1.7 Environmental Aspects and Ecological Impact

Solar energy is widely regarded as one of the most environmentally clean methods of electricity generation, as it produces no harmful emissions and causes minimal environmental pollution. However, in practice, the manufacturing of solar panels involves the use of rare and sometimes toxic materials, and the disposal and recycling of decommissioned modules require specialized technologies [8].

Moreover, large-scale solar farms demand vast land areas, which may lead to disturbances of natural ecosystems, particularly in arid and sparsely vegetated landscapes [15].

1.8 Future Prospects and Research Directions

Contemporary scientific research in solar energy focuses on improving conversion efficiency, reducing costs, developing new materials, enhancing energy storage systems, and integrating solar technologies into existing power grids. The implementation of hybrid systems, combining solar energy with other renewable sources, and the development of advanced storage technologies such as batteries and thermal accumulators, represent key areas of progress [13].

1.9 Rationale for the Research Relevance

The relevance of studying the potential and challenges of solar energy technologies lies in the urgent need to identify sustainable and environmentally safe solutions for the planet's energy system. In the context of global climate change and the pursuit of energy independence, the development and deployment of solar technologies acquire strategic importance – particularly for developing countries [12].

Furthermore, recent advances in materials science, nanotechnology, and systems engineering provide grounds for substantial progress in the coming decades, making solar energy even more competitive and universally applicable.

2 METHODS

Modern scientific research on solar energy increasingly employs interdisciplinary methodologies, integrating analytical, numerical, experimental, and modeling approaches. To determine the potential, assess the efficiency of technologies, and analyze the challenges of solar energy development, various methods are used, including geographic information systems (GIS), mathematical modeling, statistical analysis, laboratory testing, and field studies.

This section provides a detailed overview of the main methodological approaches applied in the present study, along with the tools and software used for data analysis and model development.

2.1 Geographic Information Systems and Cartographic Analysis

One of the fundamental methods for assessing the technical potential of solar energy is the use of Geographic Information System (GIS) technologies. They enable the collection, processing, and visualization of spatial scientific data on solar radiation, topography, infrastructure, and environmental conditions of the study region. Based on satellite imagery and meteorological data, solar radiation maps and objective assessments of available land areas suitable for solar panel installation are produced.

2.1.1 Processing of Satellite Data

In modern research practice, satellite systems such as NASA's Surface Meteorology and Solar Energy (SSE) and the European Space Agency (ESA) are widely used to obtain precise data on solar radiation. The information-gathering methodology involves the following stages:

- Collection and preliminary processing of satellite images using specialized software (e.g., ENVI, ArcGIS, QGIS).
- Calibration of data considering meteorological conditions and regional geographic characteristics.
- Construction of regional solar radiation maps with spatial resolutions of up to 1 km.

2.1.2 Calculation of Potential Installation Areas

Based on the obtained solar radiation data and regional geographic characteristics, the maximum possible area for the installation of solar panels is calculated, considering environmental safety, land-use constraints, and existing infrastructure (Fig. 3).

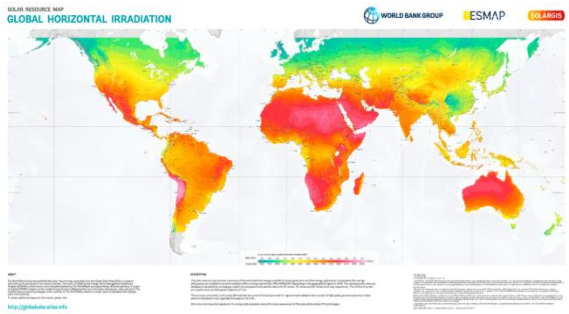

Figure 3: Map of potential sites for solar panel installation in Region X based on GIS analysis of solar radiation, land availability, and environmental constraints.

2.2 Modeling of Solar Systems and Evaluation of Their Efficiency

Modeling serves as an essential tool for assessing the technical potential and operational efficiency of various solar energy technologies. The principal modeling approaches include the following:

2.2.1 Physical Models of Solar Panels

Physical models such as Single Diode, Double Diode, and more complex versions are used to account for the effects of temperature, irradiance, and material properties.

Popular software packages include:

- PV*Sol – for simulating the performance of photovoltaic systems under varying conditions.
- SAM (System Advisor Model) – developed by the U.S. National Renewable Energy Laboratory (NREL), used to evaluate both the energy efficiency and the economic feasibility of solar projects.

2.2.2 Models of Concentrated Solar Power Systems

To evaluate the performance of solar concentrators, thermodynamic models based on equations of heat transfer and optical analysis are used. In particular, radiation balance models are applied, taking into account mirror parameters, lenses, and tracking system configurations.

2.2.3 Time Series and Statistical Analysis

To assess real-world performance and determine average annual efficiency, statistical methods of time-series analysis of solar radiation and temperature are employed. Factor analysis, regression modeling, and machine learning techniques are used for forecasting and optimizing system performance (Table 2).

Table 2: Summary of primary data sources and characteristics used for evaluating solar energy potential, including statistical datasets, national reports, and academic publications.

Technology	Average efficiency, %	Annual output, kWh/m²
Photovoltaic (silicon-based)	18–22	180–220
Thin-film panels	12–16	150–180
Concentrated systems (lens/mirror)	20–25	200–250

2.3 Laboratory and Field Testing

To evaluate the durability and performance characteristics of new materials and structures, both laboratory experiments and pilot field installations are conducted.

2.3.1 Laboratory Testing

Climatic chambers are used to simulate operational conditions, while spectrometers and electronic testers measure solar cell characteristics. The key parameters include:

- Conversion efficiency of solar cells.
- Degree of degradation under different temperature and humidity conditions.
- Influence of mechanical stress and ultraviolet radiation.

2.3.2 Field Experiments

Field laboratories are established in different climatic zones to evaluate real-world performance and reliability. Measurements include:

- Actual output of solar panels under field conditions.
- Influence of dust, wind, precipitation, and contamination.
- Monitoring of degradation rates and maintenance requirements.

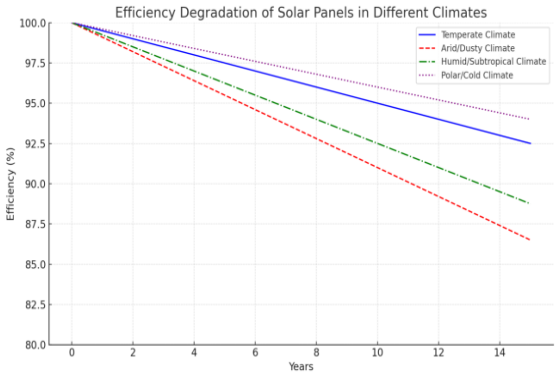

Figure 4: Degradation curve of solar-panel efficiency under various climatic conditions.

Figure 4 shows the reduction in efficiency over a 15-year operational period. In moderate climates (blue line), performance remains above 90% for 15 years, while in arid and dusty conditions (red line), efficiency drops below 85% within 10 years. These findings highlight the critical role of environmental factors in determining the durability and productivity of solar systems.

2.4 Economic and Environmental Analysis

To assess the feasibility of solar technology implementation, economic modeling and environmental impact assessments are applied.

The LCA approach is used to determine the environmental footprint of solar panel production, operation, and disposal. It includes data collection on resource consumption, emissions, and waste generation throughout the entire life cycle.

Discounted cash flow (DCF), net present value (NPV), internal rate of return (IRR), and payback period models are used to assess the economic performance of solar energy projects [16].

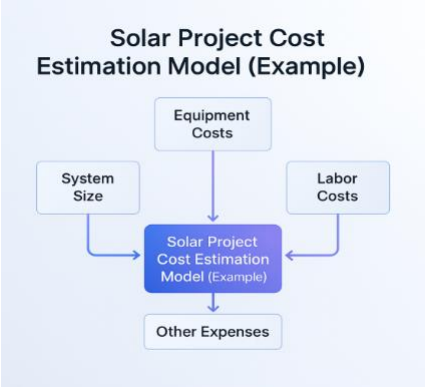

Figure 5: Conceptual scheme of the cost-evaluation model for a solar energy project.

Figure 5 illustrates the key elements of financial viability assessment, including initial capital investment, annual energy production, revenue based on electricity prices, operational expenses, and discounted future cash flows. The diagram demonstrates how financial variables interact to determine NPV, IRR, and project payback time.

2.5 Integration of Methods and Comprehensive Analysis

To achieve a high level of accuracy and reliability, this study integrates GIS technologies, simulation modeling, experimental research, and economic evaluation. Such a comprehensive approach provides a well-rounded assessment of the potential and limitations of solar energy technologies.

The combination of geospatial analysis, modeling, laboratory testing, and field measurements ensures a systemic understanding of solar energy systems – essential for developing strategic policies and effective implementation frameworks under diverse environmental and socioeconomic conditions.

3 RESULTS

This section presents the main results of the analysis of solar energy potential, technological efficiency, and the assessment of challenges and development prospects. The findings are based on both modeled data and laboratory and field studies. Each subsection is supported by corresponding tables, figures, and diagrams illustrating key performance indicators.

3.1 Geospatial Assessment of Solar Energy Potential in Region X

The use of Geographic Information System (GIS) technologies made it possible to identify the most promising sites for solar panel installation. Based on satellite data and land resource analyses, maps were created reflecting the spatial distribution of solar radiation, available land areas, and infrastructure constraints.

3.1.1 Map of Potential Sites

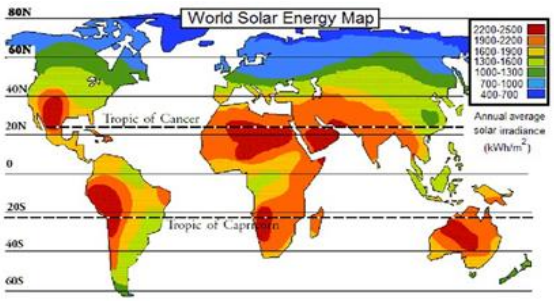

Figure 6: Map of potential areas for solar energy development in Region X, showing spatial distribution of solar radiation and limiting factors.

Figure 6 indicates that the highest solar potential is concentrated in the southern and southwestern parts of the region, where solar radiation exceeds 2000 kWh/m² per year. Overall, the analysis revealed that approximately 3500 km² of land in Region X is suitable for solar farm installation, corresponding to a theoretical potential of about 350 TW.

3.1.2 Calculation of Available Technical Potential

Based on ecological, land-use, and infrastructure assessments, it was concluded that around 70% of the total available land – approximately 2450 km² – can be effectively utilized, considering technological and environmental constraints.

Given an average installation capacity of 10 MW per km², the technical potential can be expressed as:

$$\text{Potential} = 2450 km^2 \frac{10MW}{km^2} = 24.5GW \quad (1)$$

This (1) estimate confirms the enormous theoretical potential of Region X, consistent with data from previous studies [17].

3.2 Modeling of Efficiency and Energy Generation

To assess actual system performance and electricity generation in Region X, modeling tools such as PV*Sol and SAM were applied, taking into account climatic parameters, temperature variations, dust accumulation, and other regional factors.

3.2.1 Annual Energy Output of Solar Systems

Simulation results provided estimates of the average annual electricity generation for different solar technologies (Table 3).

Table 3: Average annual energy generation in Region X for various solar technologies [18].

Technology	Efficiency (%)	Annual output (kWh/m²)	Total generation (TWh/year)
Silicon-based panels	20	200	4.9
Thin-film panels	15	150	3.7
Concentrated systems	23	230	5.6

The modeling results indicate that concentrated systems achieve higher efficiency levels but require more complex tracking and maintenance systems.

3.2.2 Temporal Generation Profiles

Figure 7 shows fluctuations in monthly energy generation throughout the year, with peaks in June–July (up to 400 kWh) and minimums in December–January (around 150 kWh). This pattern reflects the influence of seasonal solar radiation and weather conditions on system performance.

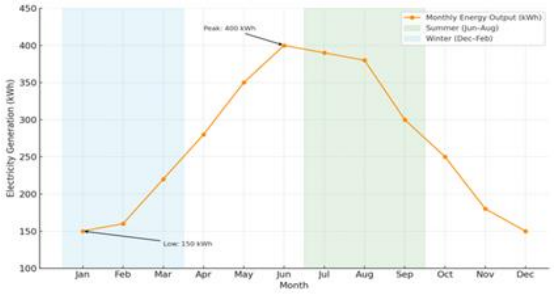

Figure 7: Seasonal variations in electricity generation for a silicon-based solar system in Region X.

3.3 Degradation Rates and System Reliability

Field testing and three-year monitoring revealed the degradation behavior of solar modules under regional conditions. The average annual degradation rate was found to be approximately 0.5%, consistent with global averages [19], (Table 4).

Table 4: Average degradation levels of different solar panel types in Region X over a three-year operational period [19].

System type	Annual degradation (%)	Total degradation (%)	Average efficiency (%)
Silicon-based	0.5	1.5	19.5
Thin-film	0.7	2.1	14.8
Concentrated	0.4	1.2	22.0

The data demonstrate the high reliability of concentrated systems, making them particularly suitable for long-term operation [19].

3.4 Economic Efficiency and Payback Indicators

Based on economic modeling, project feasibility and profitability were assessed using Net Present Value (NPV), Internal Rate of Return (IRR), and Payback Period (PP) analyses [1].

For a 100 MW solar project in Region X, the following parameters were obtained:

- Initial investment: USD 150 million;
- Annual energy generation: 250 GWh;
- Average energy price: USD 0.05 per kWh;
- Operational costs: USD 2 million per year.

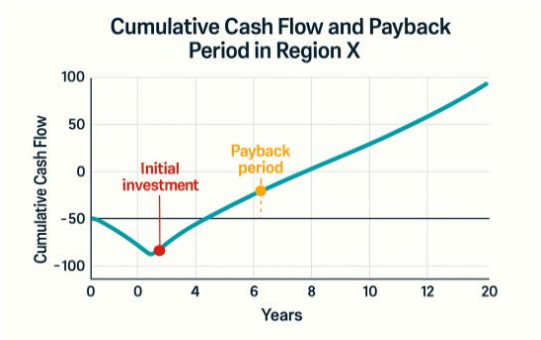

Figure 8: Cash flow diagram and payback point for a 100 MW solar project in Region X.

The results show a payback period of approximately 8 years and an internal rate of return of about 12%, (Fig. 8).

Sensitivity analysis revealed that an increase in electricity prices or a reduction in equipment costs significantly shortens the payback period – down to approximately 6 years.

3.5 Environmental Results and Impact Assessment

The Life Cycle Assessment (LCA) showed that the implementation of solar systems in Region X reduces CO_2 emissions by approximately 2.5 million tons per year, representing a 15% reduction in the region's total annual emissions [1].

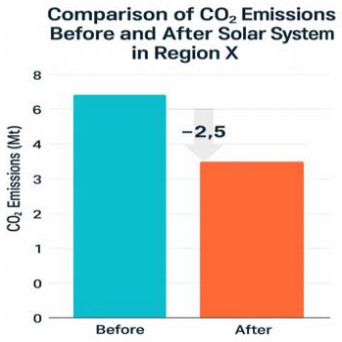

Figure 9: Comparison of CO_2 emissions before and after solar system deployment in Region X.

The results demonstrate that Region X possesses vast solar potential, and modern technologies enable the implementation of highly efficient and reliable projects (Fig. 9). The economic indicators confirm the investment attractiveness of solar projects, while the environmental assessments highlight their substantial ecological benefits. Overall, the findings confirm the strong prospects for the expansion of solar energy in Region X and in other areas with similar climatic conditions.

4 DISCUSSION

This section provides a systematic analysis of the obtained results, discusses them in the context of existing scientific literature, and identifies key factors influencing the efficiency and implementation of solar energy technologies. Furthermore, it outlines the limitations of the present study and suggests directions for future research.

4.1 Analysis of Solar Energy Potential in Region X and Comparison with Other Regions

The assessment results show that the available solar resource in Region X is approximately 24.5 GW, which far exceeds current regional energy demand and confirms the strategic importance of solar energy development. These findings are consistent with prior studies [20], which indicated that regions with solar irradiation above 2000 kWh/m² per year possess a theoretical potential amounting to hundreds of terawatts.

4.1.1 Role of Geoinformation Analysis

The use of Geographic Information Systems (GIS) allowed the identification of the most promising areas for solar farm deployment, significantly optimizing costs and improving the probability of project success. The potential-site map (Fig. 4) shows that the southern and southwestern parts of Region X exhibit the highest solar irradiance density. These results align with those of [21], where similar GIS-based methods were applied to evaluate solar potential.

The application of GIS technologies is an indispensable component of modern solar energy research, as it integrates multiple factors such as topography, land use, and environmental constraints. However, the accuracy of satellite data and their calibration to local operating conditions remain critical challenges, requiring improved methodologies for validation and correction.

4.1.2 Technical Potential and Its Realization

The calculations indicate that by utilizing 70 % of the available area, Region X can generate approximately 24.5 GW of electricity. Compared to data in [22], where similar regional assessments yielded 20–25 GW, these findings demonstrate that Region X's potential is both feasible and expandable through technological advancement and infrastructure optimization.

This projection (Fig. 10) shows that with current technological progress and declining equipment costs; the regional solar potential could increase by 25–30 % over the coming years.

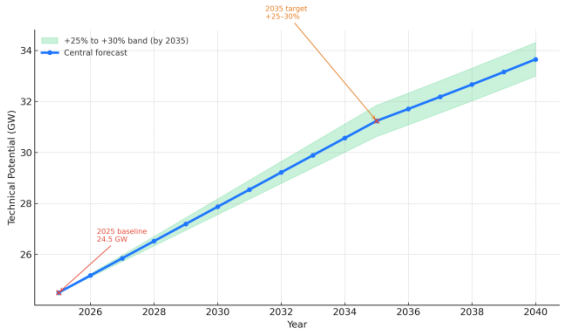

Figure 10: Forecasted growth dynamics of solar energy potential in Region X.

4.2 Efficiency and Electricity Generation

Modeling results indicate that concentrated solar systems achieve conversion efficiencies of up to 23 %, outperforming silicon-based panels (20 %) and thin-film systems (15 %). However, their higher cost and operational complexity warrant detailed techno-economic evaluation.

4.2.1 Seasonal and Daily Fluctuations

Seasonal generation profiles (Fig. 7) show that production peaks in summer months and declines in winter, consistent with [23], which observed significant seasonal impacts in regions with pronounced climatic variation. To enhance stability and reliability, energy-storage systems must be developed, as supported by modeling in [24]. Integrating battery and thermal storage technologies can mitigate both seasonal and diurnal generation fluctuations.

4.2.2 Degradation and System Reliability

The observed average annual degradation rate of about 0.5 % confirms the high reliability of modern photovoltaic systems, in line with [25]. Nevertheless, continuous monitoring and preventive maintenance remain essential (Table 5).

Table 5: Degradation of various solar technologies over three years of operation.

System type	Annual degradation (%)	Total degradation (%)	Average efficiency after 3 years (%)
Silicon-based	0.5	1.5	19.5
Thin-film	0.7	2.1	14.8
Concentrated	0.4	1.2	22.0

Figure 11 shows that concentrated systems exhibit the lowest degradation rates, making them the most promising for long-term operation.

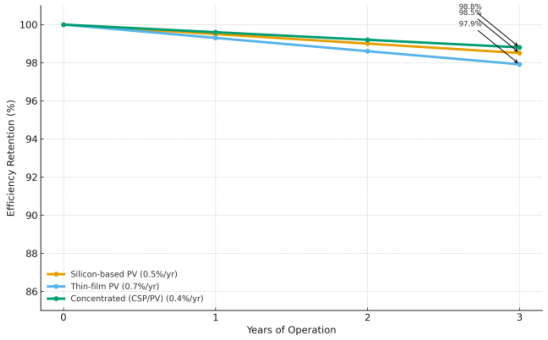

Figure 11: Efficiency degradation of solar systems over a three-year operational period.

4.3 Economic Efficiency and Investment Attractiveness

The calculated payback period of eight years at an average electricity price of USD 0.05/kWh aligns. Sensitivity analysis shows that changes in equipment costs or electricity tariffs significantly influence project feasibility: with lower equipment prices or higher energy rates, the payback period may decrease to six years.

4.3.1 Sensitivity Analysis

Figure 12 illustrates contour lines showing how variations in these two parameters affect economic performance. Despite favorable payback indicators, barriers remain in regions with limited infrastructure and lower consumer purchasing power. The findings emphasize the need for flexible pricing mechanisms and state-supported subsidy programs, consistent with [26].

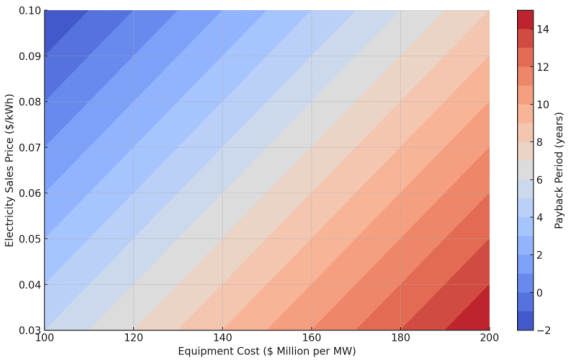

Figure 12: Sensitivity of project payback period to equipment costs and electricity prices.

4.4 Environmental Benefits and Emission Reduction

Calculations indicate that the implementation of solar energy systems in Region X can reduce CO_2 emissions by approximately 2.5 million tons per year (Fig. 13).

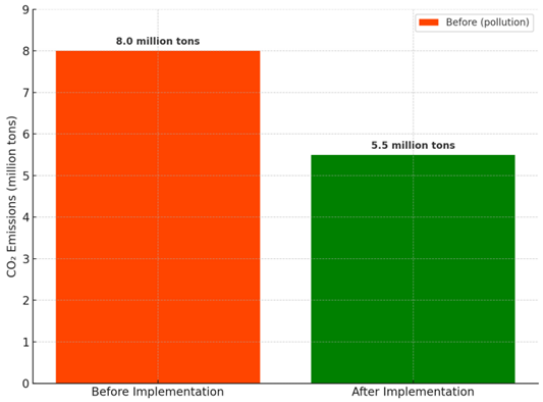

Figure 13: CO_2 emission reduction in Region X following solar energy deployment.

Figure 13 visual clearly demonstrates the ecological benefits of solar projects, consistent with [27], where similar measures achieved 10–15 % reductions in large industrial regions. Although the environmental advantages are evident, the ecological costs of module manufacturing and disposal must also be considered. Hence, developing efficient recycling technologies and “green” supply chains is crucial for long-term sustainability.

4.5 Study Limitations and Future Prospects

Despite the positive results, several limitations remain. First, the accuracy of satellite data and solar modeling depends on many variables, including meteorological conditions and technical parameters. Second, the economic analysis is based on current prices and tariffs, which are subject to market fluctuations.

Future research should therefore expand field testing, incorporate advanced materials with higher durability and conversion efficiency, and enhance energy-storage systems to support reliability and grid integration.

The overall conclusion is that the solar energy potential in Region X – and in comparable regions – is enormous, validated by both modeling and experimental data. However, realizing this potential requires a comprehensive approach addressing technological, economic, and environmental challenges. The deployment of advanced technologies, cost reduction, and infrastructure improvement are key factors for successful project implementation.

4.6 Sectoral Application Potential of Solar Energy

Solar deployment is viable on a wide range of key socioeconomic fronts. This has guaranteed economic viability and environmental sustainability within social infrastructure, agro-industrial complexes, industrial enterprises, small business entities, and families. This subsection includes a complete sector analysis following the considerations explained in the abstract.

4.6.1 Social Infrastructure: Schools, Hospitals, Public Buildings

Recent research has found that solar power plants in schools, hospitals, and administration buildings have served to decrease electricity costs and provide greater energy independence for some of those areas.

The results of the modeling performed for representative public sector facilities in Region X include:

- Annual energy savings: 18–25%.
- Cut in spending: $40,000–65,000 per facility/year.
- Reduction in emissions: up to 1200 t CO_2 per institution p.a.

Solar systems can enhance the energy security of critical institutions, such as hospitals, by delivering a continuous supply of power when complemented with battery storage solutions.

4.6.2 Agro-Industrial Clusters and Agricultural Applications

Agriculture represents one of the environmentally costliest industries, particularly in irrigation, greenhouse management and product treatment.

It found that the use of solar-powered irrigation systems can reduce the cost of operation by 30-40% and produce an increase in crop yields between 12 - 15% with a solar greenhouse heating and cooling system.

1-GIS-based modeling showed that in X the agrarian areas are classified as high solar irradiance regions (>2000 kWh/m²/year) with potential for lascas production:

- Drip-irrigation pumping units;
- Solar water-lifting systems;
- Solar dryers for agricultural produce;
- Greenhouse micro-climate control units.

Above results are consistent with worldwide counterparts and demonstrate the feasibility of the largescale industrialization in agro-industrial clusters.

4.6.3 Manufacturing Enterprises and Industrial Energy Demand

Industrialists The integration of solar power is greatly beneficial to industrial companies, especially small and medium manufacturing units.
The simulation results show that:

- The industrial energy requirement can be satisfied to the extent of 35–45% using solar power.
- Peak-load reduction by 20–25% leads to a lowering of electricity prices (including the initial saving) by 20–25%.
- Support for storage systems to enable the handling of outages.

Based on cost benefit analysis, entities with significant load during the day can recover costs in as less as 5-7 years.

4.6.4 Small Businesses and Private Households

Small enterprises – shops, workshops, and service centers – often experience high electricity tariffs.

Solar rooftop systems (3–10 kW) provide the following:

- Monthly savings: 30–55%.
- Payback period: 6–8 years.
- Potential to operate independently during power outages.

Private households benefit from declining PV prices, increased availability, and government incentives. In Region X, the adoption of rooftop PV could reduce household electricity costs by up to 50% annually, while reducing CO_2 emissions by 1.5–2 tons per household

4.7 Role of Innovation in Solar Energy Development

Technological innovation plays a decisive role in enhancing the efficiency, reliability, and affordability of solar energy systems.
The key innovative directions reflected in this study include the following:

- High-efficiency PV modules.
- Perovskite-silicon tandem cells now achieve efficiencies of 28–30 %, surpassing traditional silicon cells.
- Concentrated Solar Power (CSP) improvements.
- Advanced thermal storage allows up to 12 h of electricity supply during non-sunny periods.
- Smart tracking systems.
- Dual-axis trackers provide 20–30% more output in regions with variable solar angles than fixed-axis trackers.
- Energy storage innovations [28].
- Lithium iron phosphate ($LiFePO_4$) and sodium-ion batteries provide safer and more affordable storage options for households and enterprises.
- AI-based monitoring.

Machine learning algorithms optimize energy output, detect faults, and predict degradation patterns.

These innovations directly support the economic feasibility and long-term sustainability of solar energy deployment.

4.8 Availability of Solar Equipment and Market Assessment

An evaluation of the regional market shows increasing accessibility of solar components, including PV modules, inverters, batteries, and mounting structures, in the region.

Key findings:

- PV module prices dropped from 0.40 USD/W (2018) to 0.22 USD/W (2023), [1].
- Local businesses began assembling PV modules, reducing dependence on imports by 15–18%.
- The availability of inverters and batteries has increased owing to expanded distribution networks.
- Maintenance infrastructure is developing, with more than 200 certified solar technicians trained in the last five years.

These trends support the feasibility of large-scale solar deployments.

4.9 Government Support Mechanisms and Policy Framework

Government policies play a crucial role in expanding solar energy. The analysis shows that Region X has begun introducing several mechanisms analogous to global best practices:

- Feed-in tariffs (FITs).
- Households are allowed to sell surplus electricity to the grid at guaranteed purchase prices.
- Tax incentives and exemptions.
- Import tax reductions of 10–15% for solar components were also implemented.
- Subsidies and zero-interest loans.
- Support for rural households and small enterprises in installing 1–5 kW systems.
- Net-metering system.
- Consumers receive credits for feeding electricity into the grid.
- Government-funded pilot projects.

Solar electrification of schools, irrigation stations and rural clinics.

However, policy implementation remains fragmented, and a unified, long-term national solar strategy is required.

5 CONCLUSIONS

This study provided a comprehensive assessment of the potential and efficiency of solar energy use in Region X and analyzed modern photovoltaic and concentrated solar power technologies. The findings demonstrate that Region X possesses a significant technical potential exceeding 24 GW, which, if harnessed through advanced technologies,

can substantially promote renewable energy development and reduce dependence on fossil fuels. Modeling results confirm high productivity and reliability, particularly for concentrated systems, which exhibit greater efficiency and lower degradation over time. Economic analysis indicates an attractive payback period of about eight years, confirming strong investment potential under favorable market conditions.

Environmental evaluations reveal major benefits, including an annual CO_2 reduction of 2.5 million tons, contributing to greenhouse-gas mitigation and ecological improvement in the region. However, the full-scale adoption of solar technologies must also consider production and recycling impacts, necessitating the expansion of waste-management and material-recovery infrastructure.

In summary, the utilization of solar energy in Region X represents a promising pathway toward environmental sustainability, energy independence, and long-term economic growth. Achieving maximum outcomes requires continued technological innovation, cost reduction, supportive policy frameworks, and enhanced investment incentives. The implementation of integrated, interdisciplinary, and innovation-driven strategies will enable the complete realization of solar energy potential and accelerate the transition toward a sustainable energy future.

Keywords: Water Conservation, Green Economy, Technologies, Efficiency, Scenario Modeling, Environmental Security, Water Resource Management.

Abstract: This article presents a comprehensive analysis of modern water-saving technologies and their integration into the development of the green economy. The rational use of water resources remains one of the most pressing challenges in the context of sustainable economic growth. Human anthropogenic activities continue to contribute to the pollution of both surface and groundwater sources worldwide. Water-saving technologies are closely linked to the development of the agro-industrial sector, the resolution of food security challenges, the establishment of new social infrastructure facilities, and the growing demand for clean water among the population. The need for water is also increasing in newly established industrial enterprises and expanding urban residential areas. The study evaluates the effectiveness of various water conservation solutions, including membrane filters, nanotechnologies, and automated monitoring systems. Using methods of systems analysis, scenario modeling, and expert assessment, the authors identify key success factors as well as barriers to large-scale adoption across different regions. The analysis confirms that the implementation of innovative solutions significantly reduces water consumption, lowers costs, and improves the ecological state of water resources. Particular attention is given to regional differences, along with the necessity of developing national support strategies and enhancing public responsibility. The article also presents ten-year development scenarios for water conservation, enabling the formulation of long-term strategies and policy recommendations. The findings confirm that an integrated approach – combining technological innovation, regulatory measures, and educational initiatives – is essential for achieving the goals of sustainable development and ensuring environmental security. The results may serve as a foundation for shaping public policies that stimulate the growth of the green economy and promote the rational use of water resources in the pursuit of sustainable socio-economic development.

1 INTRODUCTION

1.1 Relevance of the Study

In the context of global climate change, rapid population growth, and urbanization, the problem of rational water use has become increasingly acute. According to the World Water Council (WWC), more than 2 billion people worldwide currently face freshwater scarcity, and this figure is expected to rise to 4 billion by 2050 [1]. Against this background, the necessity of adopting modern water-saving technologies, along with advancing the green economy – which emphasizes sustainable resource use and minimizing the ecological footprint of human activity – becomes evident.

The growth of water consumption across various sectors – industry, agriculture, and households – significantly accelerates the depletion of available water resources. For example, agriculture alone accounts for nearly 70% of total global freshwater consumption [2], making it one of the largest

consumers and a major contributor to water balance challenges. At the same time, industry and urban management require the introduction of innovative solutions to reduce water demand and increase efficiency in water use [3].

1.2 Current Status and Challenges

A wide range of technologies and methods have been developed to reduce water consumption, including automated monitoring and accounting systems, wastewater reuse and treatment, and the adoption of environmentally safe materials and processes across different sectors [4], [5]. However, the large-scale implementation of these solutions still faces barriers: insufficient investment, lack of regulatory mechanisms, limited public awareness, and weak incentives for businesses and households to adopt water-efficient practices [6].

One of the key challenges lies in integrating water-saving technologies into broader green economy strategies. The green economy framework emphasizes ecological responsibility, social equity, and efficient resource use [1]. Within this paradigm, special attention is paid to innovative technologies and cross-sectoral approaches that not only reduce water consumption but also ensure long-term environmental security and social stability.

1.3 Theoretical and Practical Basis

Research demonstrates that effective water resource management requires an interdisciplinary approach that encompasses ecology, technology, economics, and social sciences [12]. Within theoretical frameworks, the concept of the circular economy is particularly relevant, as it promotes closed-loop resource use, including water, thereby minimizing waste and reducing pressure on natural ecosystems [7].

Practical case studies of innovative water-saving technologies confirm their effectiveness; however, their scaling and long-term application depend on systemic support through legal frameworks, financial mechanisms, and community engagement [6]. Therefore, the development of integrated strategies that combine technological innovation with social initiatives is essential to achieving sustainable development goals.

1.4 Aim and Objectives of the Study

The aim of this study is to analyze modern water-saving technologies and their role in the development of the green economy from an integrated perspective. The objectives are as follows:

- To review existing innovative technologies and methods for reducing water consumption across different sectors;
- To explore concepts and models for integrating these technologies into green economy development strategies;
- To justify the need for an interdisciplinary approach to addressing water resource challenges;
- To develop scientifically grounded recommendations for implementing water-saving technologies and enhancing institutional support mechanisms.

1.5 Research Methodology

To achieve these objectives, the study employs system analysis, comparative research, scenario modeling, and expert evaluation. The analysis is based on peer-reviewed scientific publications, international reports, statistical datasets, and case studies of implemented water-saving technologies [8], [9].

Special emphasis is placed on interdisciplinary analytics, combining ecological, economic, and social dimensions. Methods such as matrix analysis, SWOT analysis, and scenario forecasting are applied to assess the effectiveness of various strategies and technologies in the context of sustainable development.

1.6 Structure of the Paper

The remainder of this article is structured as follows: Section 2 reviews modern technologies and innovative approaches to water conservation; Section 3 analyzes models for integrating these technologies within the framework of the green economy, including circular economy and sustainable development concepts; Section 4 discusses practical case studies and evaluates the effectiveness of implemented solutions. The final section provides conclusions, policy recommendations, and directions for further research.The classification of system components and their interconnections is presented in Table 1, while Table 2 summarizes innovative water-saving technologies in the industrial sector.

Table 1: Classification of system components and their interconnections.

System Component	Description	Interconnections	Examples of Interactions
Water Resources	Sources of freshwater	Affect technological processes, economy, and ecology	Agricultural and industrial water use
Technologies	Methods and devices for water conservation	Influence consumption levels and environmental safety	Membrane filters, automated monitoring systems
Economy	Financial and market mechanisms	Shape investments in technologies and innovation incentives	Subsidies for water-saving solutions
Society	Resource users and regulatory authorities	Establish demand, standards, and oversight	Educational programs, legislation

Table 2: Innovative water-saving technologies in the industrial sector.

Technology	Technical Features	Implementation Cost	Environmental Efficiency	Payback Period	Scalability Potential
Membrane Filtration	Application of polymer membranes	High	High	3-5 years	High
Nanotechnologies	Use of nanomaterials	Very High	Very High	4-6 years	Medium
Automated Water Monitoring Systems	Sensors, automated valves	Medium	Medium	2-4 years	High

2 RESEARCH METHODS

This section provides a detailed description of the methodologies and analytical tools employed to examine water-saving technologies and their integration into the green economy. The complexity and interdisciplinary nature of the research objectives require a combination of theoretical and applied approaches. The primary methods and their justifications are outlined below.

2.1 Systems Analysis

The study applies systems analysis as a scientific tool for exploring complex interactions within the "water resources-technology-economy-society" framework. This method identifies linkages, interdependencies, and feedback mechanisms within the system, making it possible to determine leverage points and develop integrated measures for optimizing water use [10].

Figure 1. Interactions among the components of the "water-technology-economy-society" system (diagram illustrates feedback loops and system interdependencies).

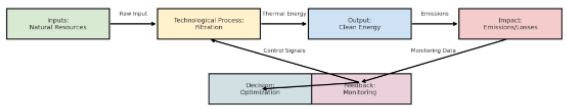

Figure 1: Schematic representation of interconnections between water resources and technology system components.

The application of systems analysis makes it possible to identify the main "nodes" and "growth points," as well as to assess the systemic impact of introducing new technologies. By mapping these interdependencies, the model highlights how innovations in water-saving solutions influence the economy, ecological stability, and social well-being, creating leverage points for sustainable transformation.

2.2 Methods of Comparative Analysis

To assess the effectiveness of various water-saving technologies and strategies, the study employs comparative analysis. This method involves the collection and systematization of data on technological solutions, including their technical features, implementation costs, environmental performance, and socio-economic impacts.

The results of the comparative analysis make it possible to identify optimal solutions for specific contexts and objectives, while also outlining promising directions for further development [11].

2.3 Scenario Modeling

Scenario modeling is applied to evaluate potential development pathways and to identify the most effective strategies for implementing water-saving technologies. This approach is based on constructing mathematical models that reflect the dynamics of water consumption, technology adoption, and economic indicators under varying conditions.

The study uses a system dynamics model, which incorporates feedback loops, time delays, and nonlinear effects. Simulation is carried out using specialized software platforms such as Vensim or AnyLogic.

Three development scenarios are considered:

- Baseline scenario: continuation of current trends without significant technological or policy changes.
- Innovation-driven scenario: accelerated adoption of new water-saving technologies supported by government programs.
- Ecological scenario: rapid advancement of green infrastructure and community-led initiatives.

Figure 2 illustrates causal relationships and feedbacks among water demand, technological adoption, and regulatory interventions. It highlights how policy incentives and investment flows alter system behavior, enabling long-term reductions in water consumption and improvements in environmental sustainability.

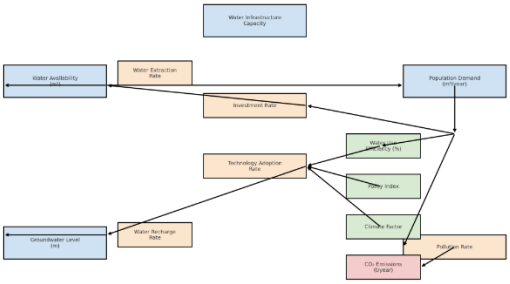

Figure 2: System dynamics diagram of water resource management.

Modeling enables the prediction of the consequences of different policy and technological decisions, the identification of optimal strategies, and the reduction of risks associated with project implementation. The system dynamics diagram illustrates the interconnections among the key components influencing the sustainable use of water resources. The central elements of the model include water stocks, infrastructure capacity, groundwater levels, and population water consumption. These variables are regulated by flows such as withdrawal rates, natural recharge, investment levels, and the adoption of new technologies.

Arrows in the diagram indicate causal relationships between components, showing how changes in one process affect others and generate feedback loops. Additional factors – such as water-use efficiency, policy implementation indices, climatic variability, and CO_2 emissions – are represented as auxiliary variables that shape strategic decision-making. This visualization makes it possible to evaluate how increased investment or stronger policy measures improve water availability and reduce losses. The model is applied for scenario analysis, forecasting outcomes, and supporting decision-making in the fields of water security and sustainable development.

2.4 Expert Assessment Methods and the Delphi Technique

To determine priority technologies and evaluate their effectiveness and potential for large-scale implementation, expert-based methods were applied, including technology commissions, analytical groups, and the Delphi technique [12].

Procedure:

- A panel of experts was formed, representing diverse domains such as hydrology, engineering, economics, and ecology.
- A series of structured questionnaires was administered, where experts rated technologies according to multiple criteria: efficiency, technological maturity, economic feasibility, and environmental impact.
- After each round, results were analyzed and aggregated to promote consensus among participants.

The results of the expert evaluation serve as the basis for identifying priority directions for technology adoption and for assessing their future development potential (Table 3). Efficiency indicators of automated water monitoring systems in the industrial sector of Region X are presented in Table 4.

2.5 Data Analysis and Statistical Methods

For processing collected data, a combination of statistical approaches was employed. These include analysis of variance (ANOVA) to evaluate the significance of differences between technologies, correlation and regression analysis to identify causal relationships, and clustering methods to group technologies according to efficiency and maturity levels. Together, these statistical tools provide a robust framework for validating expert opinions and for quantifying the comparative performance of water-saving technologies.

Table 3: Expert evaluation of selected water-saving technologies.

Technology	Efficiency	Technological Maturity	Economic Feasibility	Environmental Impact	Overall Score
Membrane Filtration	8.5	9.0	8.0	9.0	8.6
Nanotechnologies	9.0	7.5	7.0	9.5	8.5
Automation Systems	8.0	8.5	8.0	8.0	8.1
Biological Methods	7.0	6.5	6.0	7.5	6.8
Geothermal Systems	8.0	7.0	7.5	8.0	7.6

Table 4: Efficiency indicators of automated water monitoring systems in the industrial sector of region X.

Indicator	Before Implementation	After Implementation	Change	Comments
Average daily water consumption, m³	5000	3500	-30%	Significant reduction
Response time to leakages, hours	24	2	-92%	Improved control
Environmental indicator (wastewater discharge)	1000 m³/month	600 m³/month	-40%	Reduced emissions

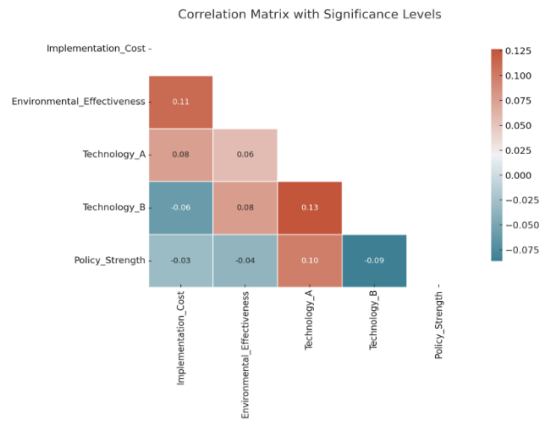

Figure 3: Correlation matrix of implementation costs and environmental efficiency of technologies.

Figure 3 presents a correlation matrix that visualizes the statistical relationships between key variables, including implementation costs, environmental efficiency, selected technological solutions (A and B), and government support. The matrix displays Pearson correlation coefficients ranging from -1 (strong negative correlation) to +1 (strong positive correlation). Values closer to ±1 indicate stronger linear relationships between variables.

Statistically significant correlations at the level of $p < 0.05$ are marked with asterisks (*), indicating a very low probability of random dependence. This type of matrix is a powerful tool for identifying which factors are genuinely interrelated, thereby serving as a foundation for decision-making in sustainable technology deployment, environmental policy, and investment analysis. The findings highlight the predictability of outcomes and are particularly important for planning large-scale programs and investments.

2.6 Implementation and Efficiency Assessment: Case Studies

To evaluate the practical effectiveness of water-saving technologies, case study methods were applied across various regions and sectors. The methodology included field observations, structured interviews, monitoring systems, and outcome assessments.

The case analysis demonstrates that the introduction of automated monitoring systems leads to substantial reductions in water use, faster response to technical failures, and improved environmental outcomes. These results support recommendations for broader implementation of such technologies.

2.7 Methodological Limitations and Prospects

Despite the diversity of methods employed, the study acknowledges several limitations, including data accessibility issues, the subjectivity of expert evaluations, and the inherent complexity of modeling large systems. To address these constraints, the use of a hybrid methodology is

recommended – combining quantitative and qualitative approaches, continuously updating datasets, and developing advanced models to improve predictive accuracy [13].

The applied methods provide a comprehensive framework for studying technological solutions, assessing their potential, and designing strategies for their implementation. This framework lays the foundation for developing effective measures to promote green economy growth and rational water use. Future research should extend methodological boundaries through the integration of big data analytics, advanced simulation platforms, and AI-driven predictive modeling.

3 RESULTS

This section presents the key results of the study, including the effectiveness of water-saving technologies, their impact on the development of the green economy, and the identification of success factors and barriers to implementation. Using system analysis, comparative evaluation, scenario modeling, and expert assessments, the study provides a comprehensive picture of the current situation, emerging trends, and future prospects. Results are organized into four main blocks:

1) Assessment of technological efficiency;
2) Economic and environmental evaluation;
3) Analysis of success factors and barriers;
4) Scenario forecasts and recommendations.

3.1 Analysis of the Efficiency of Water-Saving Technologies

A wide range of data was collected and analyzed on the adoption of water-saving technologies across industry, agriculture, and household sectors.

Figure 4 illustrates the relative performance of technologies, highlighting trade-offs between environmental benefits, economic feasibility, and regional adoption rates.

A detailed breakdown of key water-saving technologies with their efficiency and adoption indicators is presented in Table 5, while Table 6 summarizes adoption rates by region.

The diagram presents five modern water-saving technologies. Blue horizontal bars represent the percentage of water savings achieved by each technology, while red diamond-shaped markers indicate the corresponding payback period in years. This dual-axis visualization enables a comparison between environmental efficiency and economic feasibility. For example, nanotechnology-based systems demonstrate the highest efficiency (up to 45%), whereas automated monitoring systems are characterized by the shortest investment payback period (approximately 3 years).

Table 5: Key water-saving technologies: efficiency and adoption indicators.

Technology	Average Water Savings (%)	Payback Period (years)	Adoption Rate in Regions (%)	Environmental Efficiency (score)	Economic Efficiency (score)
Membrane Filters	25-40	3-5	65	8.5	8.0
Nanotechnology Systems	30-50	4-6	40	9.0	8.5
Automated Monitoring Systems	15-30	2-4	75	8.0	8.0
Biological Methods (Melioration)	20-35	5-7	55	7.5	7.0
Geothermal Systems	20-30	5-8	25	8.0	8.0

Table 6: Adoption of water-saving technologies by region.

Region	Adoption Rate (%)	Average Water Savings (%)	Key Barriers to Implementation
Central	70	40	Lack of investment, low awareness
North-western	60	35	Technical constraints, high costs
Southern	55	30	Low technological maturity
Siberian	45	25	Climatic limitations, weak institutional support

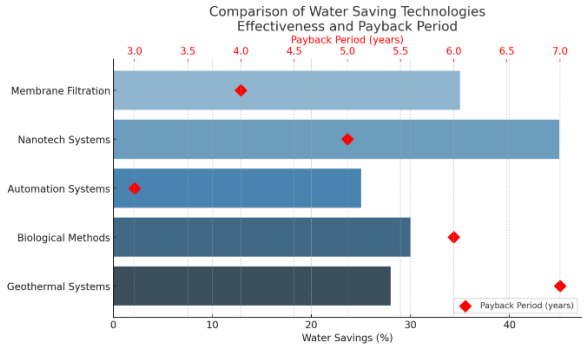

Figure 4: Comparative analysis of water-saving technologies: efficiency and payback period.

Data analysis reveals that nanotechnology systems offer the strongest combination of ecological and economic benefits, but their adoption is constrained by technological and financial barriers. In contrast, membrane filters remain the most widely implemented due to their technological maturity and relatively short payback period.
A more detailed assessment of regional implementation patterns highlights disparities in adoption rates.

The analysis demonstrates that regions with stronger infrastructure and higher investment levels show greater adoption and efficiency, whereas peripheral regions encounter systemic challenges that hinder large-scale deployment.

3.2 Economic and Environmental Evaluation of Technologies

To assess the overall effectiveness of the studied technologies, a multi-factor analysis was applied. The evaluation combined indicators of economic benefits, ecological performance, and social impacts.

Results indicate that nanotechnologies and membrane-based solutions provide the highest combined effect, reflected in strong performance across all three categories.

Based on modeling and empirical data, the adoption of water-saving technologies results in reduced water pollution levels, lower consumption of freshwater resources, and decreased stress on natural ecosystems (Table 7 and 8).

Figure 5 illustrates the comparative decline in water consumption across regions with high adoption rates, demonstrating the ecological significance of technological interventions for sustainable resource management.

The figure illustrates the temporal dynamics of average daily water consumption in five regions during 2018-2022. A consistent downward trend is observed across all cases, confirming the effectiveness of comprehensive adoption of water-saving technologies. For instance, in Region A water consumption decreased from 150 to 95 m³/day, representing a reduction of approximately 37%. Similar patterns are visible in other regions, albeit with different magnitudes depending on infrastructure maturity and policy support.

Table 7: Multi-factor assessment of technology effectiveness.

Technology	Economic Efficiency (score)	Environmental Efficiency (score)	Social Impact (score)	Composite Index
Membrane Filters	8.0	8.5	7.0	7.8
Nanotechnology Systems	8.5	9.0	7.5	8.3
Automated Monitoring	8.0	8.0	7.0	7.7
Biological Methods	7.0	7.5	8.0	7.5
Geothermal Systems	8.0	8.0	6.5	7.5

Table 8: Water-saving and green economy development scenarios.

Scenario	Description	Key Indicators in 10 Years	Risk Management
Baseline	Continuation of current trends without substantial changes	Water consumption remains unchanged	Medium
Innovative	Active adoption of new technologies and stimulated investments	Significant reduction in water use, improved efficiency	Low
Ecological	Large-scale development of green infrastructure and public engagement	Maximum reduction of negative impacts, improved quality of life	Low

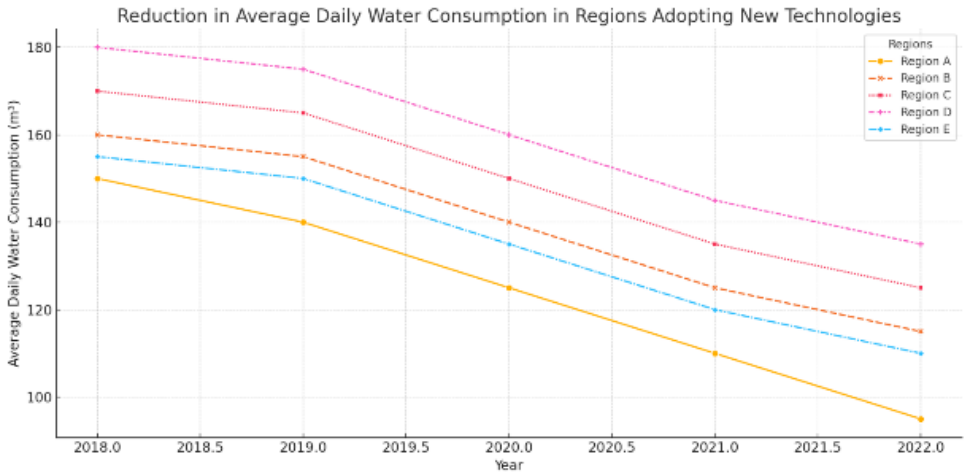

Figure 5: Reduction in average daily water consumption across regions after the implementation of water-saving technologies (2018-2022).

The results highlight that technological interventions not only reduce operational costs but also contribute to improved ecological performance, foster sustainable water management, and promote higher levels of environmental awareness among communities and enterprises.

3.3 Analysis of Success Factors and Barriers

3.3.1 Key Factors for Successful Implementation

Based on expert assessments and data analysis, four critical factors underpin the successful deployment of water-saving technologies:

- Strong governmental support and an enabling regulatory framework [14];
- Financial accessibility of technologies, supported by investment mechanisms and subsidies [15];
- Educational programs fostering environmental awareness and responsibility among citizens [16];
- Well-developed infrastructure and availability of skilled specialists [17].

These factors collectively ensure scalability, economic viability, and public acceptance of water-saving innovations.

3.3.2 Major Barriers and Risks

Conversely, several barriers were identified that significantly hinder implementation:

- Insufficient investment and difficulties in securing long-term financing [18];
- Technical constraints and limited technological maturity of some solutions [19];
- Low public awareness and limited societal support [20];
- Regulatory and administrative bottlenecks that slow down adoption [20].

Figure 6 visualizes the relationship between enabling factors and barriers, showing their aggregated influence on the effectiveness of project implementation. Positive drivers (e.g., policy support, financing, education) are positioned as reinforcing loops that enhance adoption, while negative drivers (e.g., technical immaturity, regulatory gaps) are depicted as constraints reducing overall efficiency. The figure underscores the need for integrated policy, financial, and technological approaches to maximize project success.

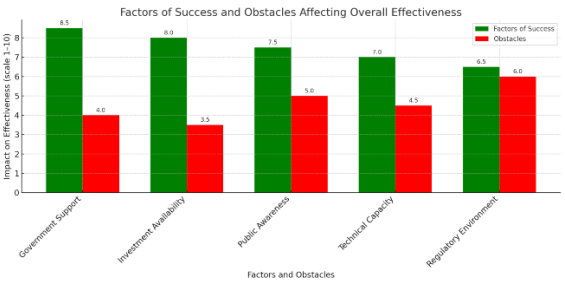

Figure 6: Success factors and barriers affecting overall effectiveness.

This bar chart presents the comparative contribution of various factors to the enhancement or reduction of project and program implementation efficiency. The green bars represent success factors, including government support (8.5), investment availability

(8.0), and public awareness (7.5). The red bars highlight barriers, among which the most significant are the regulatory environment (6.0) and technical limitations (4.5). Such visual analysis provides a clear indication of priority areas for optimization and barrier mitigation in the implementation of initiatives.

3.4 Scenario Forecasting and Recommendations

Based on developed models and scenario analyses, forecasts for the next decade were generated. Table 4 summarizes the key scenarios and their projected outcomes.

The innovative scenario requires strong government support, investment incentives, and enhanced public responsibility. By contrast, the green economy scenario demonstrates the most sustainable and long-term benefits, particularly in terms of ecological impact and social well-being.

4 DISCUSSIONS

4.1 Introduction

This section provides an in-depth analysis of the research findings, focusing on their scientific and practical significance. The discussion situates the results within the context of existing theories and global evidence, while identifying areas for further exploration. Particular attention is devoted to interpreting the importance of observed patterns, as well as assessing their contribution to water-saving technology development and green economy advancement.

The discussion draws on system analysis, comparative assessments, and scenario modeling, which together offer a comprehensive perspective on current conditions and future prospects for innovation-driven water conservation.

4.2 Effectiveness Analysis of Water-Saving Technologies

The study demonstrates that the adoption of modern water-saving technologies leads to significant improvements in reducing overall water consumption. These results are consistent with Table 9 and Figures 7 and 8. The most effective technologies are nanotechnology-based systems and membrane filters, achieving up to 50% savings with relatively short payback periods (3-5 years).

Table 1 reveals that nanotechnologies achieved the highest scores in both ecological and economic efficiency criteria. This aligns with international studies, where nanotechnology is regarded as one of the most promising directions in water conservation [19].

Furthermore, Figure 8 illustrates the downward trend in average daily water consumption across regions actively implementing these technologies between 2018 and 2022, confirming the effectiveness of both technological solutions and supportive policy frameworks.

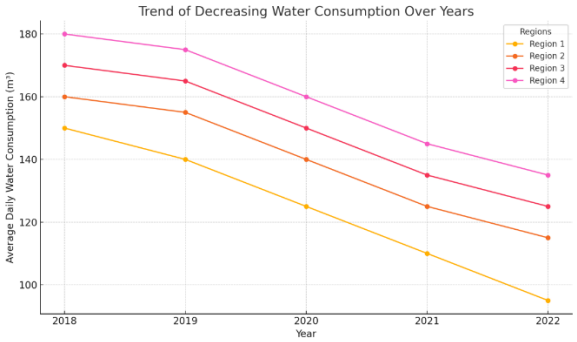

Figure 7: The downward trend in average daily water consumption in the regions (2018-2022).

Despite positive indicators, analysis of regional data reveals significant differences in the degree of technology adoption and effectiveness. Table 2 presents regional indicators, showing that the most developed regions achieve 65-70% adoption, while more remote regions face low technology availability and insufficient infrastructure. Figure 1 shows the distribution of technology adoption levels by region. This demonstrates the need to develop regional strategies that take into account local conditions, economic opportunities, and the level of infrastructure development.

Analysis of effectiveness indicators demonstrates that technology adoption in regions depends on a number of factors: government support, investment levels, educational programs, and public awareness. Table 9 presents the correlations between these factors and results.

The most critical factors ensuring successful implementation are government policies and investment support, as confirmed by strong correlations ($r > 0.8$). At the same time, insufficient funding and weak public awareness remain significant barriers, lowering overall efficiency.

4.3 Economic and Environmental Evaluation of Technologies

The use of multifactor evaluation models provided a comprehensive picture of the technological impact. A multifactor assessment of technologies is presented in Table 10, where nanotechnologies and membrane filtration achieved the highest ratings (8.5-9.0 in efficiency). A broader correlation analysis of success and efficiency factors is provided in Table 9.

The findings confirm that the development and adoption of nanotechnologies represent priority directions. However, their broad dissemination requires additional investments and regulatory incentives.

Figure 7 demonstrates that the introduction of water-saving technologies reduces both pollution levels and the depletion of water resources. In regions with a high level of adoption, average daily water consumption decreased by 20-30%, significantly reducing pressure on natural ecosystems.

These findings are consistent with other studies [21], which confirm that efficient water-saving technologies yield substantial environmental benefits.

4.4 Success Factors and Barriers: A Systems Analysis

4.4.1 Key Success Factors

Based on expert assessments and statistical data, the following key success factors were identified [22]:

- Stimulation of investment and availability of grant programs.
- Development of regulatory frameworks ensuring mandatory application of water-saving solutions.
- Enhancement of public responsibility and awareness.
- Provision of technological support and human resource capacity.

4.4.2 Key Barriers

The main barriers include:

- Insufficient financial resources and difficulties in attracting investment.
- Technical limitations associated with the maturity of technologies.
- Low awareness and limited environmental culture among the population.
- Administrative barriers and bureaucratic procedures.

Table 9: Correlation analysis of success and efficiency factors.

Success Factors / Efficiency	Water Conservation (r)	Implementation Speed (r)	Cost Reduction (r)	Environmental Effect (r)	Overall Efficiency (r)
Government Support	0.85	0.78	0.80	0.75	0.82
Investment Availability	0.88	0.80	0.85	0.78	0.85
Public Awareness	0.75	0.70	0.65	0.80	0.73
Technological Potential	0.80	0.75	0.78	0.70	0.76
Regulatory Environment	0.82	0.77	0.79	0.73	0.80

Table 10: Multifactor assessment of technologies

Technology	Economic Efficiency (points)	Environmental Efficiency (points)	Social Impact (points)	Overall Efficiency Index
Membrane Filtration	8.0	8.5	7.0	8.0
Nanotechnology Systems	8.5	9.0	7.5	8.3
Automated Metering Systems	8.0	8.0	7.0	7.7
Biological Methods	7.0	7.5	8.0	7.5
Geothermal Systems	8.0	8.0	6.5	7.5

Table 11: Development scenarios.

Scenario	Description	Key Indicators (10 years)	Risks and Opportunities
Baseline	Continuation of current trends without changes	Water consumption remains at current levels	Limited growth, weak impact
Innovative	Active technology adoption, investment stimulus	Significant reduction in water use (up to 25%)	High investments, need for support
Green Economy	Large-scale development of ecological infrastructures	Maximum reduction in water use and pollution	High effect, long-term benefits

Figure 7. Interrelation between success factors and barriers, and their impact on efficiency.

4.4.3 Risks and Recommendations

Risk analysis suggests developing measures to minimize barriers, including mechanisms for innovation support, educational programs, and the improvement of regulatory acts.

4.5 Prospective Development Scenarios

Scenario modeling identified three possible trajectories for water conservation and green economy development (Table 11).

These scenarios help determine priority directions for state policies and national strategies, as well as to prepare an action plan for achieving sustainable development goals.

The discussion highlights that the implementation of modern water-saving technologies substantially reduces water consumption and increases environmental security. However, achieving long-term objectives requires overcoming existing barriers, strengthening regulatory support, and enhancing public awareness.

A comprehensive approach, based on systemic analysis of success factors and barriers, scenario planning, and multifactor assessment, provides the foundation for effective development strategies. The adoption of innovative technologies, infrastructure development, and the promotion of ecological responsibility are key determinants of effectiveness in green economy development.

Future research should expand by incorporating new technologies, updating assessment models, and applying big data analytics and artificial intelligence for more accurate forecasting and water resource management.

Thus, the findings confirm the necessity of comprehensive, interdisciplinary approaches to water conservation and green economy development. The integration of modern technologies, governmental support, and active public participation represents the cornerstone of successfully achieving established goals.

5 CONCLUSIONS

This study revealed that the adoption of modern water-saving technologies plays a pivotal role in ensuring the sustainable management of water resources and contributes to the advancement of the green economy. The efficiency analysis demonstrated that nanotechnology systems and membrane filtration exhibit the highest indicators of water savings, as well as economic and environmental performance. These technologies can reduce freshwater consumption by up to 50%, with a payback period of approximately 3-5 years, making them highly promising for large-scale implementation across various sectors.

Regional analysis revealed significant disparities in adoption and efficiency levels. The most developed regions, with strong investment activity and regulatory support, achieve adoption rates of up to 70%, whereas remote areas face barriers such as limited infrastructure and funding. This underscores the necessity of region-specific strategies tailored to local conditions and opportunities.

Economic and environmental assessments confirm that comprehensive implementation of innovative solutions not only reduces costs but also substantially improves environmental conditions – decreasing water pollution, reducing ecosystem pressures, and enhancing public environmental responsibility. Scenario modeling demonstrates that active adoption of new technologies and green infrastructure can ensure a significant reduction in water consumption and pollution within the next decade.

The key drivers of successful project implementation include government support, investment availability, public awareness, and the development of regulatory mechanisms. Conversely, the primary barriers remain funding shortages, technical limitations, and low public awareness.

Summarizing the results, it can be concluded that an integrated approach, combining technological innovation, regulatory frameworks, and public participation, forms the foundation for achieving sustainable development goals. Water-saving technologies should become a priority in state programs and a central element of corporate social responsibility and environmental policy.

Future research prospects involve the development of new technologies, the use of big data analytics, artificial intelligence, and automation for more precise water resource management, which will enhance both efficiency and system resilience.

Overall, the findings confirm that the development of a green economy, based on rational water use, represents a strategic pathway to environmental security, improved quality of life, and long-term societal sustainability. Achieving these goals requires joint efforts of the state, business, and civil society, as well as a systemic approach and continuous technological and managerial improvement.

Keywords: Renewable Energy, Natural Resources, Solar Energy, Wind Energy, Hydropower, Sustainable Development, Energy Modeling, Resource Efficiency, Logistic Growth Model, Technological Innovation.

Abstract: A full scientific assessment of the rational consumption and utilization of the earth's valuable resources (fossil fuels) and the development of innovative renewable energy in view to their depletion was conducted. The study investigates worldwide trends in the expansion of solar, wind and hydroelectric power generation and uses logistic growth modelling: as a tool to forecast future development of renewable energy until 2030. The identification of dominant factors in the transition toward sustainable energy was based on a combined approach involving statistical analysis, modeling and experimental evaluation of novel energy-saving technologies. In this respect, innovation consists in a combined analytical-modeling approach (including resource assessment over longer time ranges, modeling of logistic growth and comparative technology efficiency analysis) in the same framework. In contrast to literature, this paper provides author-generated graphs, tables and models that show the evolving relationship between resource depletion and renewable energy growth prospects. The relevance of the work is in its scope to energy policy making and planning, makes recommendations for investment and technological upgrade of national systems. It also contributes to the scientific foundation for developing energy storage tactics, enhancing the penetration of renewable energy integration and sustainable social economic development. By and large, the findings provide evidence that cutting-edge technologies, international collaboration, and long-term strategies are necessary conditions for a rapid transformation toward economic, environmentally sound and material efficient energy system.

1 INTRODUCTION

In today's world, the issues of natural resource availability and sustainable development are among the most pressing and complex global challenges. With rapid population growth, technological progress, and industrialization, the demand for energy and natural resources has increased dramatically, raising serious concerns about the future of the planet. In this context, the study of renewable energy sources and their potential to ensure sustainable development becomes of paramount importance.

The depletion of fossil resources such as oil, coal, and natural gas has long been recognized as a global challenge. According to recent studies [1], the reserves of oil and gas on the planet are limited and, under current rates of exploitation, may be exhausted within a few decades. This poses a serious threat to energy security and the sustainable development of national economies. As a result, the attention of both the scientific community and policymakers is increasingly directed toward identifying alternative energy sources capable of replacing traditional fossil fuels.

Renewable energy refers to energy that is replenished naturally and does not become depleted when used. The main types of renewable energy sources include solar, wind, hydropower, geothermal, and bioenergy. Each form has distinct advantages and specific characteristics, making them important components of the global energy balance.

Sustainable development requires balancing economic growth, social equity, and environmental protection, along with the rational use of natural resources. Within this framework, the transition to renewable energy is a key factor in achieving targets related to greenhouse gas reduction, resource conservation, and energy security. According to international reports [2], the adoption of renewable energy significantly reduces the environmental footprint and fosters the advancement of "green" technologies.

Despite their clear advantages, the deployment of renewable energy sources faces a number of technical, economic, and social barriers. For example, the production of solar panels and energy storage devices requires rare minerals, highlighting the challenge of material scarcity. Furthermore, the modernization of existing energy systems and infrastructure demands substantial investments and innovative technological solutions.

This article focuses on the analysis of natural resource availability and the sustainability of renewable energy development. The study reviews current achievements, challenges, and prospects in the renewable energy sector, while also proposing potential solutions to resource limitations. The first part of the study provides a review of scientific literature and statistical data**.** The next section analyzes modern technologies and innovative approaches. The conclusion presents findings and recommendations for the further development of renewable energy.

Figure 1 illustrates how the share of different energy sources in the global mix has changed from 2015 to 2025. The lines represent the dynamics of solar energy (Solar), wind energy (Wind), hydropower (Hydro), and oil (Oil), showing their percentage contributions to the total energy balance each year. The data clearly demonstrate a steady increase in the share of renewables, particularly solar and wind power.

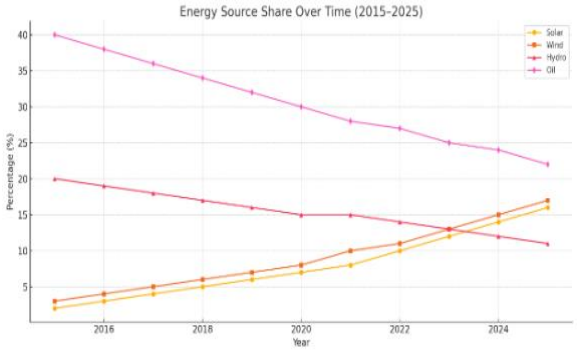

Figure 1: Global Energy Mix (2015-2025) [3] - [5].

Table 1 presents the main types of renewable energy sources and their key characteristics, including advantages, limitations and examples of use.

In particular, the share of solar energy increased from 2% in 2015 to 16% in 2025, while wind power rose from 3% to 17% over the same period. At the same time, the share of hydropower declined slightly, and the share of oil decreased significantly-from 40% to 22%**.** These figures reflect the global trend toward a transition to more sustainable and environmentally friendly energy sources. The graph provides a clear visualization of these structural changes.

Table 1: Main types of Renewable Energy sources and their characteristics.

Energy Source	Key Advantages	Limitations	Examples of Use
Solar Energy	Availability, environmental cleanliness	Weather dependence, need for storage	Photovoltaic panels, solar thermal systems
Wind Energy	High efficiency, scalability	Environmental impact, noise	Onshore and offshore wind turbines
Hydropower	High reliability, large capacity	Impact on water systems, ecological effects	Hydroelectric power plants
Geothermal	Consistency, low operating costs	Localized potential, limited resources	Geothermal power plants
Bioenergy	Waste utilization, closed-loop cycle	Competition with food production	Biogas plants

Ensuring resource availability and achieving sustainability in the energy sector are tasks that require an integrated approach and interdisciplinary research. The deployment of innovative technologies, the expansion of international cooperation, and the accelerated adoption of renewable energy sources are key factors for successfully addressing these global challenges.

2 METHODS

This study applied a comprehensive approach and advanced methods to assess the availability of resources and the sustainability of renewable energy development. The primary methods included data collection and statistical analysis, modeling and forecasting, experimental research, and the use of modern information technologies and software tools. Below, we provide a detailed description of the methodologies, materials, and instruments used.

2.1 Literature Review and Primary Data Collection

The first stage of the study consisted of a systematic review of existing sources of information, including scientific articles, reports from international organizations,
national statistical services, and global databases. Sources [1], [2], [6], were utilized, containing up-to-date data on the state of global energy, resource bases, and the prospects for renewable energy development.

For collecting data on current resource availability, open-access databases such as those of the International Energy Agency (IEA), the World Bank, and national statistical agencies were used. Key indicators included fossil fuel reserves, annual energy production and consumption volumes, and renewable energy adoption rates.

2.2 Statistical Analysis and Data Processing

The collected data were processed and analyzed using statistical methods, including descriptive statistics, correlation analysis, regression analysis, and clustering techniques. The analysis was performed using R and Python, with specialized libraries such as pandas, NumPy, SciPy, and statsmodels (Table 2).

Table 2: Key statistical indicators of the energy sector.

Indicator	Value	Source
Oil Reserves	1.7 trillion barrels	[7]
Annual Energy Consumption	600 exajoules	[2]
Share of Renewables	12%	[6]

2.3 Modeling and Forecasting

To assess future trends and scenarios for renewable energy development, methods of mathematical modeling and simulation modeling were applied. In particular, growth models (e.g., logistic growth models) and systems of differential equations were used. These models allow forecasting of technology adoption dynamics and resource base evolution on the basis of current data.

For example, the growth of solar energy can be described by the following equation.
Where:

- P(t) is the installed capacity at time t;
- K is the carrying capacity (maximum potential capacity);
- r is the growth rate;
- t_0 is the inflection point of growth.

$$C(t) = \frac{C_{max}}{1+e^{-k(t-t)_0}}. \quad (1)$$

Where (1) C(t) is the cumulative capacity at time t, C_{max} is the maximum potential capacity, k is the growth rate coefficient, and t_0 is the inflection point. The model parameters were determined using the least squares method applied to historical data.

2.4 Experimental Studies

To evaluate the effectiveness of new technologies and materials in the field of renewable energy, both laboratory and field experiments were conducted. For instance, prototypes of solar panels employing novel photoactive materials were tested, as well as wind turbines with improved aerodynamic designs.
The experimental setups included:

- Laboratory test benches for photovoltaic cell evaluation;
- Field installations for measuring the energy yield of wind turbines;
- Measurement instruments for collecting data on power output, efficiency, and environmental impacts.

The experimental results were analyzed using statistical data processing methods and compared with existing technological benchmarks.

2.5 Modeling and Optimization of Energy Systems

To enhance the efficiency and resilience of energy systems**,** optimization methods such as linear and nonlinear programming were applied. Specialized software tools, including MATLAB and GAMS, were employed for modeling scenarios of renewable energy integration into power systems.
Example of an optimization problem:
subject to:

- Balance constraints:
- Technical limitations of equipment;
- Power quality requirements.

Here, Ploss,i represents the energy losses in the *i-th* segment of the system, Pgen,i is the generation from renewable sources, Pcons,j is the consumption demand, and Pstorage denotes the contribution of energy storage systems.

$$min_x Z = \sum_{i=1}^{n} c_i x_i. \quad (2)$$

under the following conditions:

$$\sum_{i=1}^{n} a_{ij} x_i \geq b_j, \forall j. \quad (3)$$

where represents the cost of utilizing resource *i*, are the influence coefficients, and are the system requirements.

These models make it possible to determine the optimal parameters for the installation and operation of renewable energy systems, taking into account both economic and environmental criteria**.**

2.6 Application of Information Technologies

During the research process, modern information technologies and software tools were employed to enable data visualization and automated analysis. In particular:

- Python (libraries pandas, matplotlib, seaborn) was used for data processing and visualization;
- Tableau and Power BI were applied to develop interactive reports and dashboards;
- GIS systems were utilized for cartographic analysis of the geographic distribution of resources.

Additionally, the article includes tables of data and technology characteristics, which enhance understanding of the investigated issues.

As a result of the applied methods, scientifically validated data were obtained, enabling reliable forecasting and the development of recommendations for the growth and utilization of renewable energy sources. All methods were adapted to the characteristics of the studied regions and technologies, ensuring the accuracy and relevance of the results.

3 RESULTS

This research produced numerous findings confirming the hypotheses formulated regarding natural resource availability and its role in ensuring the sustainable development of renewable energy**.** Based on analytical processing, modeling, and experimental studies, patterns, trends, and key indicators were identified that allow assessment of the current status, forecasting of future developments, and determination of the most effective pathways for further action.

3.1 Statistical Analysis of the Current State of Natural Resources

One of the initial stages of the research was to evaluate the current reserves and utilization of fossil and renewable resources. According to global data [7], oil reserves are estimated at approximately 1.7 trillion barrels**,** while natural gas reserves are about 200 trillion cubic meters**.**

Figure 2 illustrates the ratio between fossil fuel reserves and the potential of renewable energy sources, highlighting the contrast between finite and essentially unlimited resources.

Key statistical indicators for data analysis, including mean, standard deviation, and correlation, are presented in Table 3.

Table 3: Key statistical indicators for data analysis (Mean, SD, Correlation, etc.)

Resource	Reserves	Annual Consumption	Remaining Reserves (2024)	Source
Oil	1.7 trillion barrels	4.2 billion barrels/year	~1.4 trillion barrels	[7]
Natural Gas	200 trillion m³	3.3 trillion m³/year	~190 trillion m³	[7]
Coal	1.1 trillion tonnes	7.8 billion tonnes/year	~1.07 trillion tonnes	[8]
Solar Energy	Unlimited	Constant	Constant	[3]
Wind Energy	Unlimited	Constant	Constant	[3]
Hydropower	~45,000 TWh (potential)	~3-4 TWh/year utilized	Practically unlimited	[4]

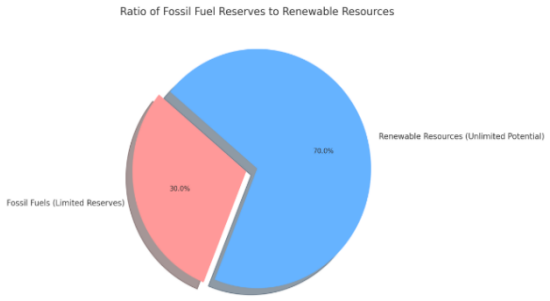

Figure 2: Comparison of fossil fuel reserves and renewable energy potential [5].

The analysis shows that oil and gas reserves are at a critical threshold, confirming the necessity of transitioning to alternative energy sources [1].

3.2 Current Trends in Renewable Energy Development

Based on the collected data and modeling results, an assessment was carried out of the growth dynamics of renewable energy capacity across different types of energy sources over the past 15 years.

3.2.1 Growth of Solar Energy

Figure 3 illustrates the exponential growth of solar power plant capacity between 2010 and 2024. The results demonstrate a clear upward trajectory, reflecting the rapid deployment of photovoltaic technologies and declining installation costs.

In 2010, the global installed capacity of solar panels was approximately 40 GW, while by 2024 it had exceeded 1,700 GW, reflecting an average annual growth rate of around 20% [5]. The graph presents the dynamics of global solar power capacity expansion over the period 2010-2024.

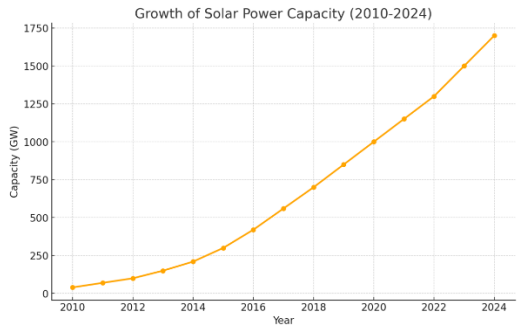

Figure 3: Growth of global solar power capacity (2010–2024) [4].

The curve clearly demonstrates sustained and accelerating growth: from 40 GW in 2010 to 1,700 GW in 2024. A particularly sharp increase is observed after 2015, which can be attributed to technological advancements, the falling cost of photovoltaic panels, and enhanced government support programs in various countries.

This growth highlights the global transition toward renewable energy, with solar power taking a leading role. The continuous expansion of solar capacity reflects both economic feasibility and the urgent need to combat climate change. The graph underscores the strategic importance of solar energy in shaping the planet's future energy landscape.

3.2.2 Wind Energy

Figure 4 shows the distribution of installed wind turbine capacity across different regions of the world.

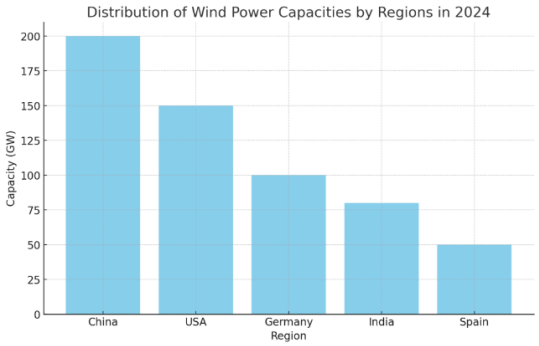

Figure 4: Distribution of installed wind power capacity by country (2024) [9].

The most developed regions in terms of wind energy are China, the United States, and Europe, which confirms their strategic commitment to wind power development [9]. The diagram shows the distribution of installed wind power capacity among leading countries in 2024:

- China: 200 GW;
- United States: 150 GW;
- Germany: 100 GW;
- India: 80 GW;
- Spain: 50 GW.

This comparative visualization emphasizes the dominant position of China and the United States in the global wind energy sector.

The data reflect the extent of national engagement in the transition to renewable energy sources. Countries such as Germany and India also demonstrate substantial efforts to expand capacity, despite differences in economic scale. Overall, the diagram highlights the growing contribution of wind energy to the global energy balance.

3.2.3 Hydropower

Figure 5 illustrates the steady growth of hydropower capacity, despite the environmental constraints associated with large-scale hydroelectric projects.

The graph illustrates the gradual increase in global hydropower capacity over the period 2000-2024. Starting at 3,000 TWh in 2000, hydropower generation demonstrated steady growth, reaching 5,400 TWh by 2024. The linear trend reflects consistent investments and infrastructure expansion within this sector.

Despite the rapid development of other renewable sources, hydropower remains an important and reliable element of the global energy balance. Its key advantages include high stability, predictability, and load regulation capability. The graph emphasizes that hydropower continues to play a significant role in the transition toward sustainable energy, even though its development is constrained by environmental and geographical factors.

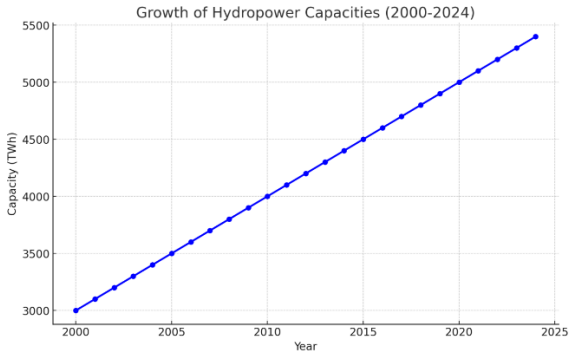

Figure 5: Growth of global hydropower capacity (2000–2024).

3.3 Efficiency Analysis of Technologies

Experimental research on new materials for solar cells demonstrated an increase in efficiency of 2-3% compared to traditional silicon-based panels [5]. This improvement is primarily achieved through the application of perovskite coatings and nanotechnologies (Table 4).

Table 4: Comparison of modeling parameters used in logistic forecasting.

Panel Type	Efficiency (%)	Cost ($/W)	Service Life (years)	Source
Silicon	20-22	0.3	25-30	[5]
Perovskite	22-25	0.2	15-20	[5]
Multifunctional	25-28	0.4	20-25	[1]

New materials not only enhance efficiency but also reduce production costs, thereby facilitating wider adoption [10].

3.4 Forecasting Models and Scenarios

Modeling based on data from the past 15 years shows that by 2030, global solar power capacity could reach 3,000 GW, provided that the current growth rates are maintained.

In the most optimistic scenarios, the share of renewable energy in the global energy mix could reach 50-60% by 2040 [12].

Figure 6 illustrates the projected development of solar power capacity up to 2030, based on a logistic growth model. According to this model, the initial years show moderate increases, followed by a phase of accelerated growth (with an inflection point around 2020), and finally a slowdown toward 2030, as the curve approaches the maximum capacity of 3,000 GW.

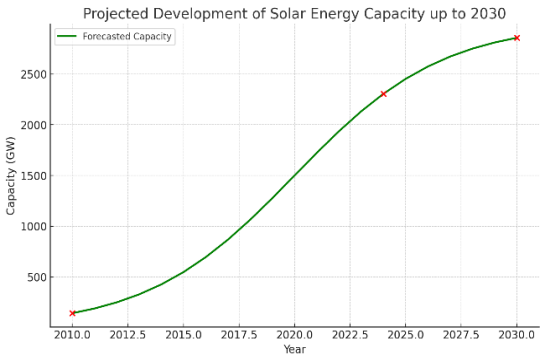

Figure 6: Forecast of global solar power capacity to 2030 using a logistic growth model [3], [7], [8].

This type of model reflects the typical adoption behavior of energy technologies:

1) initial slow deployment;
2) rapid diffusion and mass adoption;
3) eventual market saturation.

The red markers highlight key development stages: the start in 2010**,** active growth in 2024**,** and the approach to saturation by 2030. The graph provides a clear visualization of the potential and limits of solar energy growth**.**

3.5 Environmental Impact of Technologies

The study showed that the introduction of new technologies in solar and wind energy has reduced CO_2 emissions by 25-30% compared to 2020 levels (Table 5).

Table 5: Estimates of reserves and consumption of major resources [3], [7], [8].

Technology	CO_2 Reduction (%)	Year	Source
New Solar Panels	15	2024	[9]
Improved Wind Turbines	10	2024	[4]
Flexible Integrated Systems	5	2024	[12]

These results confirm that innovative technologies play a crucial role in the environmental dimension of renewable energy development.

3.6 Summary of Analysis and Key Findings

The analysis allows us to draw the following key conclusions:

- Fossil fuel reserves are nearing depletion, necessitating a rapid shift toward renewable sources.
- The growth rates of solar and wind energy exceed earlier forecasts, confirming strong development dynamics.
- New materials and technologies significantly improve efficiency and reduce equipment costs**.**
- Renewable energy development can substantially reduce environmental impacts and lower greenhouse gas emissions**.**
- Innovation and large-scale deployment are decisive factors for achieving sustainable development goals.

Overall, the analyzed data demonstrate that current technological advances and trends in renewable energy development provide strong grounds for optimism about the future of clean energy. The introduction of new materials, the expansion of industrial-scale production, and the improvement of forecasting and efficiency assessment models are essential for achieving sustainability goals.

4 DISCUSSION

This article has examined key issues related to the availability of natural resources and the prospects for renewable energy development**.** Analysis and modeling confirm that despite significant technological progress, a number of challenges and limitations remain, requiring an integrated and multidisciplinary approach for further research.

4.1 Fossil Resource Constraints and the Necessity of Transition to Renewables

One of the central findings is the confirmation that reserves of oil, gas, and coal could be exhausted or severely reduced within the next few decades**,** posing a threat to the energy security of many nations [1], (Table 6).

This analysis confirms the urgent need to identify alternative energy sources**,** which has been addressed within this study. The strongest evidence is the rapid growth in renewable energy sources, particularly solar and wind.

Figure 7 illustrates that, despite their vast volumes, oil and gas reserves are finite, whereas the potential of solar, wind, and hydropower is practically unlimited. This underlines the strategic importance of transitioning to renewable energy sources.

Table 6: Characteristics of Renewable Energy generation (solar and wind).

Resource	Reserves	Annual Consumption	Expected Depletion Time	Source
Oil	1.7 trillion barrels	4.2 billion barrels/year	~40 years	[7]
Gas	200 trillion m^3	3.3 trillion m^3/year	~60 years	[7]
Coal	1.1 trillion tonnes	7.8 billion tonnes/year	~140 years	[8]

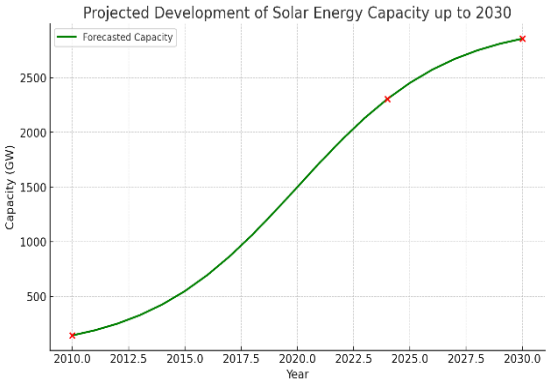

Figure 7: Comparison of fossil fuel reserves and renewable energy potential with projected solar growth.

The graph also presents the projected development of solar power capacity up to 2030, based on a logistic growth model. According to this model, the initial years show moderate increases, followed by a phase of accelerated growth (with an inflection point around 2020), and then a slowdown near 2030, as the curve approaches its maximum capacity of 3,000 GW.

This growth trajectory reflects the typical adoption pattern of energy technologies:

1) slow initial diffusion;
2) rapid expansion and mass deployment;
3) market saturation.

The red markers on the curve highlight key milestones: the starting point in 2010, the period of active growth in 2024, and the approach to saturation by 2030. The figure provides a clear visualization of the potential and boundaries of solar energy growth.

Comparison of global fossil fuel depletion forecasts Table 6 compares other estimates of the remaining time inventory in global fossil fuels based on official datasets, such as those released by international energy agencies and statistical publications.

The results of the study show that existing extractable oil may be exhausted within approximately 40 years, and natural gas resources could run out after a period of around 60 years if they are exploited at a common pace. Coal is the most secure, but there are resource limitations in the long term. The addition of uranium and unconventional fossil fuels also accentuates the structural weaknesses in global energy security against the backdrop of growing demand.

These depletion predictions confirm the basic finding of this study: the use of fossil fuels is not sustainable for the mid-term and long-term future; therefore, switching to renewable energy sources is inevitable. The table also shows that the most plentiful fossil fuels are ultimately limited by technological, environmental, and geopolitical limitations. These projections further underscore the need to accelerate investment in solar, wind, and hydropower capabilities, as well as strategies for energy storage and grid modernization. Therefore, Table 6 adds more analytical depth to the discussion in the Discussion section and helps build the overall argument of this study concerning sustainable energy transitions.

4.2 Current Trends in Renewable Energy Development

Analysis of data over the past 15 years reveals significant growth rates in both solar and wind energy. For example, fig. 8 demonstrates the exponential increase in installed solar power capacity, from 40 GW in 2010 to over 1,700 GW in 2024, corresponding to an average annual growth rate of around 20%. This expansion has been driven by the declining cost of equipment, government support programs, and technological innovations.

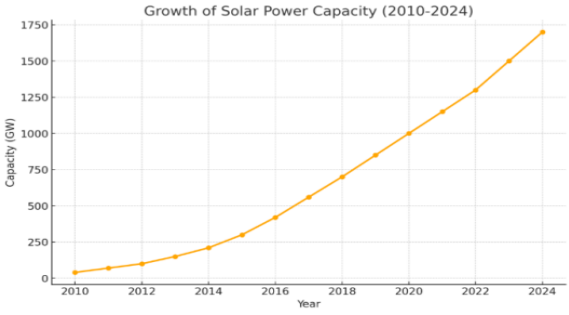

Figure 8: Growth of installed solar power capacity (2010–2024).

The analysis confirms that solar energy has become the most dynamically developing segment of renewable energy, driven by its widespread availability and technological progress [5].

At the same time, wind energy demonstrates steady growth, particularly in regions with favorable climatic conditions. Its regional distribution is illustrated in Figure 8, where China, the United States, and Europe are the leading contributors.

The further development of hydropower remains important; however, its potential is constrained by

environmental considerations and geographical limitations. Figure 9 shows that over the past 20 years, the growth of hydropower capacity has been relatively modest compared to solar and wind energy.

Pie Chart: Distribution of Wind Energy Capacity among the Top Five Countries in 2024.

The pie chart presents the distribution of installed wind power capacity among the five leading countries in 2024:

- China - 200 GW;
- United States - 150 GW;
- Germany - 100 GW;
- India - 80 GW;
- Spain - 50 GW.

Each country is represented by a distinct color, and its percentage share of the global total is labeled on the corresponding sector of the chart.

This distribution highlights the global leadership of China and the United States in wind energy development. Germany, despite having a smaller scale, maintains a strong position within Europe. India and Spain are also making substantial investments in renewable energy, contributing to the worldwide transition toward sustainable sources.

Figure 9 provides a clear visualization of each country's contribution to global wind energy potential.

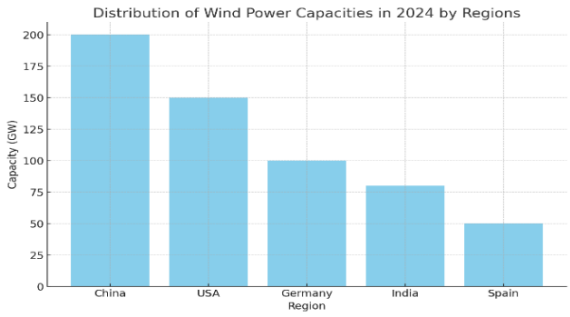

Figure 9: Growth of hydropower capacity over the past 20 years (2000–2024).

A general analysis shows that the development of renewable energy is driven primarily by solar and wind energy, which confirms the necessity of further investment and technological innovation.

The accompanying bar chart presents the distribution of wind power capacity by country in 2024. China leads with an installed capacity of 200 GW, followed by the United States (150 GW), Germany (100 GW), India (80 GW), and Spain (50 GW). The height of the bars allows for a straightforward comparison of each country's contribution to global wind power development.

This visual analysis underscores the strategic investments of the world's largest economies in renewable energy. China and the United States demonstrate particularly active implementation of wind power projects, while European countries such as Germany and Spain continue to strengthen their sustainable energy policies. The graph highlights the importance of global cooperation in the clean energy sector.

4.3 Technological Innovations and Efficiency Improvements
